gmacgrp_mac_address37_high

Register 554 (MAC Address37 High Register)

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address37 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8008A8
i_emac_emac1	0xFF802000	0xFF8028A8

gmacgrp_mac_address44_low

Register 569 (MAC Address44 Low Register)

The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8008E4
i_emac_emac1	0xFF802000	0xFF8028E4
i_emac_emac2	0xFF804000	0xFF8048E4

Offset: 0x8E4

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
addrlo RW 0xFFFFFFFF

gmacgrp_mac_address44_low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	MAC Address44 [31:0] This field contains the lower 32 bits of the 45th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.	RW	0xFFFFFFFF

gmacgrp_mac_address45_high

Register 570 (MAC Address45 High Register)

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address45 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8008E8
i_emac_emac1	0xFF802000	0xFF8028E8
i_emac_emac2	0xFF804000	0xFF8048E8

Offset: 0x8E8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

gmacgrp_mac_address46_high

Register 572 (MAC Address46 High Register)

The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address46 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
31:0	addrlo	MAC Address52 [31:0] This field contains the lower 32 bits of the 53rd 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.	RW	0xFFFFFFFF

gmacgrp_mac_address53_high

Register 586 (MAC Address53 High Register)

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address53 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800928
i_emac_emac1	0xFF802000	0xFF802928
i_emac_emac2	0xFF804000	0xFF804928

Offset: 0x928

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mac_address54_high

Register 588 (MAC Address54 High Register)

The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address54 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

gmacgrp_mac_address62_high

Register 604 (MAC Address62 High Register)

The MAC Address62 High register holds the upper 16 bits of the 63rd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address62 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

gmacgrp_mac_address70_high

Register 620 (MAC Address70 High Register)

The MAC Address70 High register holds the upper 16 bits of the 71st 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address70 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8009B0
i_emac_emac1	0xFF802000	0xFF8029B0
i_emac_emac2	0xFF804000	0xFF8049B0

Offset: 0x9B0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mac_address78_high

Register 636 (MAC Address78 High Register)

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address78 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8009F0
i_emac_emac1	0xFF802000	0xFF8029F0
i_emac_emac2	0xFF804000	0xFF8049F0

Offset: 0x9F0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

31:0	addrlo	MAC Address94 [31:0] This field contains the lower 32 bits of the 95th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.	RW	0xFFFFFFFF

gmacgrp_mac_address95_high

Register 670 (MAC Address95 High Register)

The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address95 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800A78
i_emac_emac1	0xFF802000	0xFF802A78
i_emac_emac2	0xFF804000	0xFF804A78

Offset: 0xA78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mac_address96_high

Register 672 (MAC Address96 High Register)

The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address96 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

gmacgrp_mac_address103_high

Register 686 (MAC Address103 High Register)

The MAC Address103 High register holds the upper 16 bits of the 6-byte 104th MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address103 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800AB8
i_emac_emac1	0xFF802000	0xFF802AB8
i_emac_emac2	0xFF804000	0xFF804AB8

Offset: 0xAB8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Register 701 (MAC Address111 High Register)

The MAC Address111 High register holds the upper 16 bits of the 6-byte 112th MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address111 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800AF8
i_emac_emac1	0xFF802000	0xFF802AF8
i_emac_emac2	0xFF804000	0xFF804AF8

Offset: 0xAF8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mac_address120_high

Register 719 (MAC Address120 High Register)

The MAC Address120 High register holds the upper 16 bits of the 6-byte 121st MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address120 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800B40

gmacgrp_mac_address127_high Fields

Bit	Name	Description	Access	Reset
31	ae	Address Enable When this bit is set, the address filter module uses the 128th MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. Value: Description 0x0: DISABLED 0x1: ENABLED	RW	0x0
30:16	reserved_30_16	Reserved	RO	0x0
15:0	addrhi	MAC Address127 [47:32] This field contains the upper 16 bits (47:32) of the 128th 6-byte MAC address.	RW	0xFFFF

gmacgrp_mac_address127_low

Register 734 (MAC Address127 Low Register)

The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800B7C
i_emac_emac1	0xFF802000	0xFF802B7C
i_emac_emac2	0xFF804000	0xFF804B7C

Offset: 0xB7C

Access: RW

gmacgrp_mac_address127_low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	MAC Address127 [31:0] This field contains the lower 32 bits of the 128th 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.	RW	0xFFFFFFFF

dmagrp_bus_mode

Register 0 (Bus Mode Register)

The Bus Mode register establishes the bus operating modes for the DMA.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801000
i_emac_emac1	0xFF802000	0xFF803000
i_emac_emac2	0xFF804000	0xFF805000

Offset: 0x1000

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dmagrp_bus_mode Fields

Bit	Name	Description	Access	Reset
30:26	reserved_30_26	Reserved	RO	0x0
25	aal	Address Aligned Beats When this bit is set high and the FB bit is equal to 1, the AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
24	eightxpbl	PBLx8 Mode When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
23	usp	Use Seperate PBL When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
22:17	rpbl	Rx DMA PBL This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high. **Value** **Description** 0x1 RXDMAPBL1 0x2 RXDMAPBL2 0x4 RXDMAPBL4 0x8 RXDMAPBL8 0x10 RXDMAPBL6 0x20 RXDMAPBL32	RW	0x1
16	fb	Fixed Burst This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the interface uses only SINGLE, INCR4, INCR8, or INCR16 during start of the normal burst transfers. When reset, the AHB or AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEF). **Value** **Description** 0x0 NONFB 0x1 FB1_4_8_16	RW	0x0
15:14	reserved_15_14	Reserved	RW	0x0

Bit	Name	Description	Access	Reset
13:8	pbl	Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: **1.** Set the PBLx8 mode. **2.** Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set PBLx8 to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified. For different data bus widths and FIFO sizes, the valid PBL range (including x8 mode) is provided in the following list. If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered. **Note:** Note: In the half-duplex mode, the valid PBL range specified in the following list is applicable only for Tx FIFO.	RW	0x1

Bit	Name	Description	Access	Reset

		• 32-Bit Data Bus Width
		  • 128 Bytes FIFO Depth: In the full-duplex mode, the valid PBL range is 16 or less. In the half-duplex mode, the valid PBL range is 8 or less for the 10 or 100 Mbps mode.
		  • 256 Bytes FIFO Depth: In the full-duplex mode and the half-duplex (10 or 100 Mbps) modes, the valid PBL range is 32 or less.
		  • 512 Bytes FIFO Depth: In the full-duplex mode and the half-duplex (10 or 100 Mbps) modes, the valid PBL range is 64 or less.
		  • 1 KB FIFO Depth: In the full-duplex mode, the valid PBL range is 128 or less. In the half-duplex mode, the valid PBL range is 128 or less in the 10 or 100 Mbps mode and 64 or less in the 1000 Mbps mode.
		  • 2 KB and Higher FIFO Depth: All PBL values are supported in the full-duplex mode and half-duplex modes.		

Bit	Name	Description	Access	Reset
7	atds	Alternate Descriptor Size When set, the size of the alternate descriptor increases to 32 bytes (8 DWORDS). This is required when the Advanced Timestamp feature or the IPC Full Offload Engine (Type 2) is enabled in the receiver. The enhanced descriptor is not required if the Advanced Timestamp and IPC Full Checksum Offload (Type 2) features are not enabled. In such cases, you can use the 16 bytes descriptor to save 4 bytes of memory. When reset, the descriptor size reverts back to 4 DWORDs (16 bytes). This bit preserves the backward compatibility for the descriptor size. In versions prior to 3.50a, the descriptor size is 16 bytes for both normal and enhanced descriptor. In version 3.50a, descriptor size is increased to 32 bytes because of the Advanced Timestamp and IPC Full Checksum Offload Engine (Type 2) features. **Value** **Description** 0x0 CLEARRST 0x1 RESET	RW	0x0
6:2	dsl	Descriptor Skip Length This bit specifies the number of Words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, the descriptor table is taken as contiguous by the DMA in Ring mode.	RW	0x0
1	reserved_1	Reserved_1	RW	0x0

Bit	Name	Description	Access	Reset
0	swr	Software Reset When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the DWC_gmac clock domains. Before reprogramming any register of the DWC_gmac, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. Bit 0 of Register 64 (Channel 1 Bus Mode Register) or Register 128 (Channel 2 Bus Mode Register) has no impact on the Software reset function. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion. **Value** **Description** 0x0 CLEARRST 0x1 RESET	RW	0x1

dmagrp_transmit_poll_demand

Register 1 (Transmit Poll Demand Register)

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory. When this register is read, it always returns zero.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801004

Module Instance	Base Address	Register Address
i_emac_emac1	0xFF802000	0xFF803004
i_emac_emac2	0xFF804000	0xFF805004

dmagrp_transmit_poll_demand Fields

Bit	Name	Description	Access	Reset
31:0	tpd	Transmit Poll Demand When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 18 (Current Host Transmit Descriptor Register). If that descriptor is not available (owned by the Host), the transmission returns to the Suspend state and the Bit 2 (TU) of Register 5 (Status Register) is asserted. If the descriptor is available, the transmission resumes.	RW	0x0

dmagrp_receive_poll_demand

Register 2 (Receive Poll Demand Register)

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns. When this register is read, it always returns zero.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801008
i_emac_emac1	0xFF802000	0xFF803008

rpd RW 0x0															

dmagrp_receive_poll_demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	Receive Poll Demand When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

dmagrp_receive_descriptor_list_address

Register 3 (Receive Descriptor List Address Register)

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when

reception is stopped. When stopped, this register must be written to before the receive Start command is given.

You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80100C
i_emac_emac1	0xFF802000	0xFF80300C
i_emac_emac2	0xFF804000	0xFF80500C

Offset: 0x100C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

dmagrp_receive_descriptor_list_address Fields

Bit	Name	Description	Access	Reset
31:2	rdesla_32bit	This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

dmagrp_transmit_descriptor_list_address

Register 4 (Transmit Descriptor List Address Register)

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address.

If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801010

31:2	tdesla_32bit	This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) are ignored (32-bit wide bus) and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO).	RW	0x0

dmagrp_status

Register 5 (Status Register)

The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
16	nis	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0

Bit	Name	Description	Access	Reset
15	ais	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0
14	eri	Early Receive Interrupt This bit indicates that the DMA filled the first data buffer of the packet. This bit is cleared when the software writes 1 to this bit or Bit 6 (RI) of this register is set (whichever occurs earlier).	RW	0x0
13	fbi	Fatal Bus Error Interrupt This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
12:11	reserved_12_11	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
10	eti	Early Transmit Interrupt This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer expired while receiving the current frame and the current frame is truncated after the watchdog timeout.	RW	0x0
8	rps	Receive Process Stopped This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0
7	ru	Receive Buffer Unavailable This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	Receive Interrupt This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0

Bit	Name	Description	Access	Reset
5	unf	Transmit Underflow This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	Receive Overflow This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0
3	tjt	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled). When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	Transmit Buffer Unavailable This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	Transmit Process Stopped This bit is set when the transmission is stopped.	RW	0x0

Bit	Name	Description	Access	Reset
0	ti	Transmit Interrupt This bit indicates that the frame transmission is complete. When transmission is complete, Bit 31 (OWN) of TDES0 is reset, and the specific frame status information is updated in the descriptor.	RW	0x0

dmagrp_operation_mode

Register 6 (Operation Mode Register)

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization. This register is also present in the GMAC-MTL configuration with unused and reserved bits 24, 13, 2, and 1.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801018
i_emac_emac1	0xFF802000	0xFF803018
i_emac_emac2	0xFF804000	0xFF805018

Offset: 0x1018

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

dmagrp_operation_mode Fields

Bit	Name	Description	Access	Reset
31:27	reserved_31_27	Reserved	RO	0x0
26	dt	Disable Dropping of TCP/IP Checksum Error Frames When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. If the IPC Full Checksum Offload Engine (Type 2) is disabled, this bit is reserved (RO with value 1'b0). **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
25	rsf	Receive Store and Forward When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
24	dff	Disable Flushing of Received Frames When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. This bit is reserved (and RO) in the GMAC-MTL configuration. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
23	rfa_2	MSB of Threshold for Activating Flow Control If the DWC_gmac is configured for an Rx FIFO depth of 8 KB or more, this bit (when set) provides additional threshold levels for activating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFA (Bits[10:9]) gives the following thresholds for activating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.	RO	0x0

Bit	Name	Description	Access	Reset
22	rfd_2	MSB of Threshold for Deactivating Flow Control If the DWC_gmac is configured for Rx FIFO size of 8 KB or more, this bit (when set) provides additional threshold levels for deactivating the flow control in both half-duplex and full-duplex modes. This bit (as Most Significant Bit) along with the RFD (Bits[12:11]) gives the following thresholds for deactivating flow control: * 100: Full minus 5 KB, that is, FULL - 5KB * 101: Full minus 6 KB, that is, FULL - 6KB * 110: Full minus 7 KB, that is, FULL - 7KB * 111: Reserved This bit is reserved (and RO) if the Rx FIFO is 4 KB or less deep.	RO	0x0
21	tsf	Transmit Store and Forward When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
20	ftf	Flush Transmit FIFO When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock (clk_tx_i) is required to be active. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
19:17	reserved_19_17	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
16:14	ttc	Transmit Threshold Control These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. * 000: 64 * 001: 128 * 010: 192 * 011: 256 * 100: 40 * 101: 32 * 110: 24 * 111: 16 **Value** **Description** 0x0 TTCTHESH64 0x1 TTCTHRES128 0x2 TTCTHRES192 0x3 TTCTHRES256 0x4 TTCTHRES40 0x5 TTCTHRES32 0x6 TTCTHRES24 0x7 TTCTHRES16	RW	0x0

Bit	Name	Description	Access	Reset
13	st	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
12:11	rfd	Threshold for Deactivating Flow Control (in half-duplex and full-duplex) These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB The de-assertion is effective only after flow control is asserted. If the Rx FIFO is 8 KB or more, an additional bit (RFD_2) is used for more threshold levels as described in Bit 22. These bits are reserved and read-only when the Rx FIFO depth is less than 4 KB. Note: For proper flow control, the value programmed in the "RFD_2, RFD" fields should be equal to or more than the value programmed in the "RFA_2, RFA" fields. **Value** — **Description** 0x0 — FIFOFULL_1K 0x1 — FIFOFULL_2K 0x2 — FIFOFULL_3K 0x3 — FIFOFULL_4K	RO	0x0

Bit	Name	Description	Access	Reset
10:9	rfa	Threshold for Activating Flow Control (in half-duplex and full-duplex) These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. - 00: Full minus 1 KB, that is, FULL - 1KB - 01: Full minus 2 KB, that is, FULL - 2KB - 10: Full minus 3 KB, that is, FULL - 3KB - 11: Full minus 4 KB, that is, FULL - 4KB These values are applicable only to Rx FIFOs of 4 KB or more and when Bit 8 (EFC) is set high. If the Rx FIFO is 8 KB or more, an additional Bit (RFA_2) is used for more threshold levels as described in Bit 23. These bits are reserved and read-only when the depth of Rx FIFO is less than 4 KB. Note: When FIFO size is exactly 4 KB, although the DWC_gmac allows you to program the value of these bits to 11, the software should not program these bits to 2'b11. The value 2'b11 means flow control on FIFO empty condition. **Value** **Description** 0x0 FIFOFULL_1K 0x1 FIFOFULL_2K 0x2 FIFOFULL_3K 0x3 FIFOFULL_4K	RO	0x0
8	efc	Reserved **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0

Bit	Name	Description	Access	Reset
7	fef	Forward Error Frames When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode) , then the frame is not dropped. In the GMAC-MTL configuration in which the Frame Length FIFO is also enabled during core configuration, the Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA. Note: When FEF bit is reset, the giant frames are dropped if the giant frame status is given in Rx Status in the following configura-tions: * The IP checksum engine (Type 1) and full checksum offload engine (Type 2) are not selected. * The advanced timestamp feature is not selected but the extended status is selected. The extended status is available with the following features: - L3-L4 filter in GMAC-CORE or GMAC-MTL configurations - Full checksum offload engine (Type 2) with enhanced descriptor format in the GMAC-DMA, GMAC-AHB, or GMAC-AXI configurations. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
6	fuf	Forward Undersized Good Frames When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
5	dgf	Drop Giant Frames When set, the MAC drops the received giant frames in the Rx FIFO, that is, frames that are larger than the computed giant frame limit. When reset, the MAC does not drop the giant frames in the Rx FIFO. Note: This bit is available in the following configurations in which the giant frame status is not provided in Rx status and giant frames are not dropped by default: * Configurations in which IP Checksum Offload (Type 1) is selected in Rx * Configurations in which the IPC Full Checksum Offload Engine (Type 2) is selected in Rx with normal descriptor format * Configurations in which the Advanced Timestamp feature is selected In all other configurations, this bit is not used (reserved and always reset).	RW	0x0

Bit	Name	Description	Access	Reset
4:3	rtc	Receive Threshold Control These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. The value of 11 is not applicable if the configured Receive FIFO size is 128 bytes. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. * 00: 64 * 01: 32 * 10: 96 * 11: 128 **Value** **Description** 0x0 THRFIFO64 0x1 THRFIFO32 0x2 THRFIFO96 0x3 THRFIFO128	RW	0x0
2	osf	Operate on Second Frame When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
1	sr	Start or Stop Receive When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
0	reserved_0	Reserved	RO	0x0

dmagrp_interrupt_enable

Register 7 (Interrupt Enable Register)

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80101C
i_emac_emac1	0xFF802000	0xFF80301C
i_emac_emac2	0xFF804000	0xFF80501C

Offset: 0x101C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dmagrp_missed_frame_and_buffer_overflow_counter

Register 8 (Missed Frame and Buffer Overflow Counter Register)

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0]

indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF801020
i_emac_emac1	0xFF802000	0xFF803020
i_emac_emac2	0xFF804000	0xFF805020

Offset: 0x1020

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit	Name	Description	Access	Reset
31	en_lpi	When set to 1, this bit enables the LPI mode supported by the AXI master and accepts the LPI request from the AXI System Clock controller. When set to 0, this bit disables the LPI mode and always denies the LPI request from the AXI System Clock controller. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
30	lpi_xit_frm	When set to 1, this bit enables the GMAC-AXI to come out of the LPI mode only when the Magic Packet or Remote Wake Up Packet is received. When set to 0, this bit enables the GMAC-AXI to come out of LPI mode when any frame is received. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
23:20	wr_osr_lmt	AXI Maximum Write OutStanding Request Limit	RW	0x1
19:16	rd_osr_lmt	This value limits the maximum outstanding request on the AXI read interface. Maximum outstanding requests = RD_OSR_LMT+1	RW	0x1

Bit	Name	Description	Access	Reset
13	onekbbe	1 KB Boundary Crossing Enable for the GMAC-AXI Master When set, the GMAC-AXI Master performs burst transfers that do not cross 1 KB boundary. When reset, the GMAC-AXI Master performs burst transfers that do not cross 4 KB boundary. **Value** **Description** 0x0 FOUR_K_BOUNDARY 0x1 ONE_K_BOUNDARY	RW	0x0
12	axi_aal	This bit is read-only bit and reflects the Bit 25 (AAL) of Register 0 (Bus Mode Register). When this bit is set to 1, the GMAC-AXI performs address-aligned burst transfers on both read and write channels. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0
3	blen16	When this bit is set to 1 or UNDEFINED is set to 1, the GMAC-AXI is allowed to select a burst length of 16 on the AXI Master interface. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
2	blen8	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 8 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
1	blen4	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 4 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
0	undefined	This bit is read-only bit and indicates the complement (invert) value of Bit 16 (FB) in Register 0 (Bus Mode Register[16]). * When this bit is set to 1, the GMAC-AXI is allowed to perform any burst length equal to or below the maximum allowed burst length programmed in Bits[7:1]. * When this bit is set to 0, the GMAC-AXI is allowed to perform only fixed burst lengths as indicated by BLEN16, BLEN8, or BLEN4, or a burst length of 1. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x1

dmagrp_ahb_or_axi_status

Register 11 (AHB or AXI Status Register)

This register provides the active status of the AHB master interface or AXI interface's read and write channels. This register is present and valid only in the GMAC-AHB and GMAC-AXI configurations. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80102C
i_emac_emac1	0xFF802000	0xFF80302C
i_emac_emac2	0xFF804000	0xFF80502C

Offset: 0x102C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0890
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1090
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address RO 0x0											

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
11:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

emac_tx_ecc Address Map

Module Instance	Base Address	End Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0FFF
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C17FF
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-82	0x0	32	RO	0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C2C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C142C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C30
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1430
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

Document Revision History

Table 17-29: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	• Bit 16 updated **Table 17-6** • Updated **Figure 17-15** • Added **Figure 17-16**
May 2016	2016.05.27	Removed references to the Application Interface (also known as the switch interface). This feature is not supported in this device.
May 2016	2016.05.03	Maintenance release.

November 2015	2015.11.02	• Added emac_phy_mac_speed_o signals to "FPGA EMAC I/O Signals" section
		• Added the following subsections in the "Layer 3 and Layer 4 Filters" section:
		  • Layer 3 and Layer 4 Filters Register Set
		  • Layer 3 Filtering
		  • Layer 4 Filtering
		• Added internal clock diagram to "Clock Structure" section

Date	Version	Changes
May 2015	2015.05.04	• Corrected IEEE 1588 timestamp resolution in the "EMAC Block Diagram and System Integration" section and the "IEEE 1588-2002 Timestamps" section • Added clarification for `phy_txclk_o` and `phy_clk_rx_i` in the "HPS EMAC I/O Signals" • Added subsections "Ordinary Clock," "Boundary Clock," "End-to-End Transparent Clock" and "Peer-to-Peer Transparent Clock" in the "Clock Type" section • Added clarification in the "EMAC Module Clock Inputs and Outputs" table for the description of `phy_clk_rx_i` in the "Clock Structure" section • Added "EMAC ECC RAM Reset" subsection in "Taking the Ethernet Out of Reset" section • Added address map and register definitions
December 2014	2014.12.06	• Added *Application Interface* sub-section to *Features* Section. • Updated *EMAC Block Diagram and System Integration* section with new diagram and information. • Added *Signal Descriptions* section. • Added *EMAC Internal Interfaces* section. • Added *TX FIFO* and *RX FIFO* subsection to the *Transmit and Receive Data FIFO Buffers* section. • Updated *Descriptor Overview* section to clarify support for only enhanced (alternate) descriptors. • Added *Destination and Source Address Filtering Summary* in *Frame Filtering* Section. • Added *Clock Structure* sub-section to *Clocks and Resets* section • Added *Application Interface to FPGA Fabric* section in *Functional Description of EMAC* • Added *System Level EMAC Configuration Registers* section in *Ethernet Programming Model* • Added *EMAC Interface Initialization for FPGA GMII/MII Mode* section in Ethernet Programming Model • Added *EMAC Interface Initialization for RGMII/RMII Mode* section in Ethernet Programming Model • Corrected *DMA Initialization* and *EMAC Initialization and Configuration* titles to appear on correct initialization information • Removed duplicate programming information for DMA • Added *Taking the Ethernet MAC Out of Reset* section.
August 2014	2014.08.18	Initial release.

USB 2.0 OTG Controller 18

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys® (†)DesignWare® Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Can operate in Host or Device mode
- Supports multi-point applications with hub and split support
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)

  Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.
- Integrated scatter-gather DMA supports moving data between memory and the controller
- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
  - Control transfers
  - Bulk transfers
  - Isochronous transfers
  - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

  Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports up to 16 bidirectional endpoints, including control endpoint 0

  Note: Only seven periodic device IN endpoints are supported.
- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- 8-bit ULPI PHY data width
- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
  - PHY clock gating support
  - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

Refer to the *Arria 10 Device Datasheet* for specific timing information.

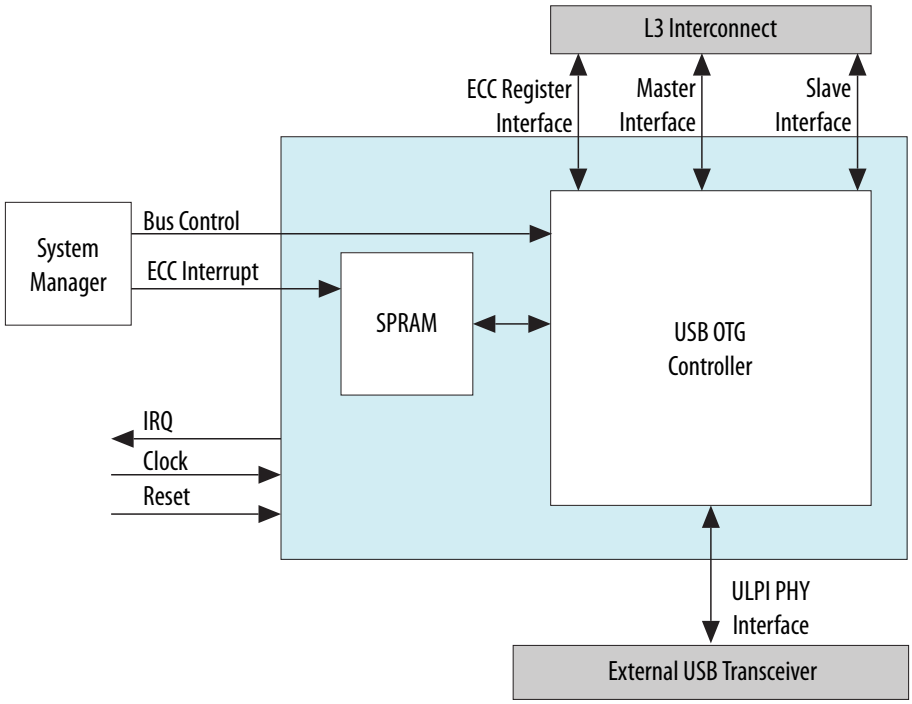
USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.



The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB Controller signals are routed to the dedicated HPS pins.

USB 2.0 ULPI PHY Signal Description

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Note: For more information on how the USB signals are routed to the HPS I/O, refer to the *HPS Component Interfaces* chapter.

Port Name	Bit Width	Direction	Description
`ulpi_clk`	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
`ulpi_dir`	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
`ulpi_nxt`	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
`ulpi_stp`	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.

Port Name	Bit Width	Direction	Description
ulpi_data[7:0]	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

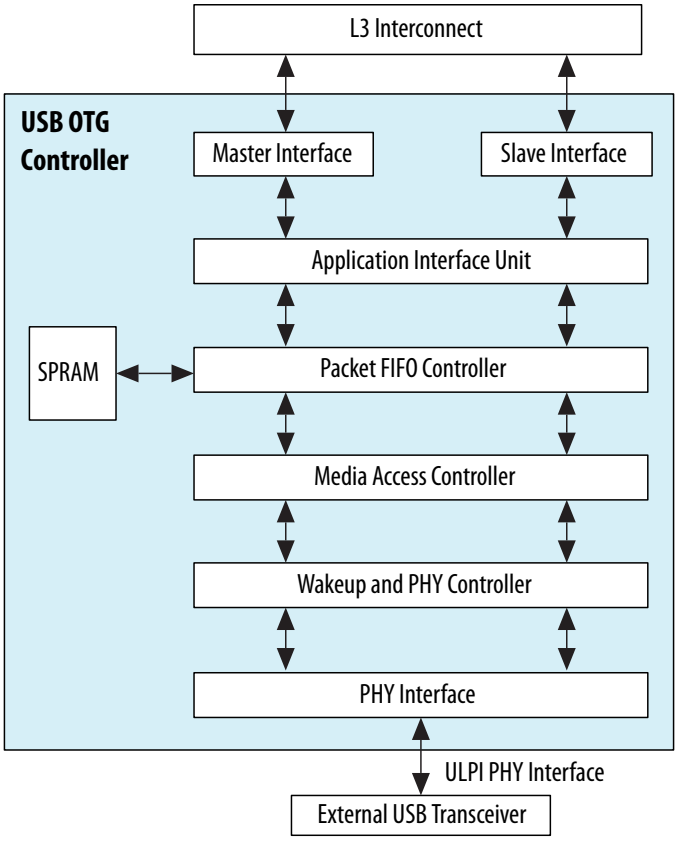
Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.



Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the single port RAM (SPRAM).

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

DMA

The DMA has two modes of operation. You program your software to select between scatter-gather DMA mode or buffer DMA mode depending on the controllers function.

If the controller is functioning as a generic root hub, you should program your software to select the buffer DMA mode that supports split transfers.

If generic root hub functionlaity is not required, or if the controller is configured in Device mode, you can program your software to select scatter-gather DMA mode.

If you wish to dynamically switch the mode of operation based on the queried device status or capability, your software driver must cleanly switch between the two modes of operation. For example, you may want the controller to default to scatter-gather DMA mode and only change mode when it detects a generic HUB with fast-speed and low-speed capability. Some basic requirements for switching include:

- A soft reset must be issued before changing modes.
- If buffer DMA mode is selected, then the Host mode periodic request queue depth must not be set to 16.
- Devices must be re-enumerated.

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 x 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Clock Gating

You can clock gate the ulpi_clk through software. By programming the usbclken bit of the en register in the perpllgrp you can enable or disable the ulpi_clk to the USB.

Related Information

Clock Manager Address Map and Register Definitions on page 2-18

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the ulpi_clk clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the ulpi_stp signal. The PHY outputs a clock when it sees

the ulpi_stp signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the ulpi_stp signal. As a result, the ulpi_clk clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two usb_mp_c lk cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (permodrst) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the usb_mp_clk domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (csftrst) bit in the Reset Register (grstctl) in the Global Registers (globgrp) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Modules Requiring Software Deassert on page 3-13

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes

Condition	Mode
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

To enable the ECC feature, refer to the ECC chapter in the *Arria 10 Hard Processor System Technical Reference Manual*.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Related Information

Error Checking and Correction Controller on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtpwr`) bit to 1 in the Host Port Control and Status Register (`hprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

   The controller waits for a connection to be detected on the USB link.
2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDet`) bit in `hprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtenchng`) and Port Speed (`prtspd`) bits, in `hprt`, are set to reflect the enumerated speed of the device that attached.

   At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

   The Host Frame Interval Register (`hfir`) is updated with the corresponding PHY clock settings. The `hfir`, used for sending SOF packets, is in the Host Mode Registers (`host grp`) group.
7. The software driver must program the following registers in the Global Registers (`globgrp`) group, in the order listed:

   a. Receive FIFO Size Register (`grxfsiz`)—selects the size of the receive FIFO buffer
   b. Non-periodic Transmit FIFO Size Register (`gnptxfsiz`)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
   c. Host Periodic Transmit FIFO Size Register (`hptxfsiz`)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each

packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (`devspd`) bits in the Device Configuration Register (`dcfg`) in the Device Mode Registers (`devgrp`) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.
2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (`usbrst`) bit in the Interrupt (`port reset`) register in the Global Registers (`globgrp`) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB 2.0 OTG Controller Address Map and Register Definitions

gotgctl Fields

Bit	Name	Description	Access	Reset
21	curmod	Mode: Host and Device Current Mode of Operation (CurMod) Indicates the current mode. 1'b0: Device mode 1'b1: Host mode	RO	0x0

Bit	Name	Description	Access	Reset
20	otgver	OTG Version (OTGVer) Indicates the OTG revision. 1'b0: OTG Version 1.3. In this version the core supports Data line pulsing and VBus pulsing for SRP. 1'b1: OTG Version 2.0. In this version the core supports only Data line pulsing for SRP. **Value** **Description** 0x0 VER13 0x1 VER20	RW	0x0
19	bsesvld	Mode: Device only B-Session Valid (BSesVld) Indicates the Device mode transceiver status. 1'b0: B-session is not valid. 1'b1: B-session is valid. In OTG mode, you can use this bit to determine IF the device is connected or disconnected. Note: If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non- SRP or non-HNP configurations. **Value** **Description** 0x0 NOTVALID 0x1 VALID	RO	0x0

Bit	Name	Description	Access	Reset
18	asesvld	Mode: Host only A-Session Valid (ASesVld) Indicates the Host mode transceiver status. 1'b0: A-session is not valid 1'b1: A-session is valid Note: If you do not enabled OTG features (such as SRP and HNP), the read reset value will be 1.The vbus assigns the values internally for non- SRP or non-HNP configurations. **Value** **Description** 0x0 VALID 0x1 NOTVALID	RO	0x0
17	dbnctime	Mode: Host only Long/Short Debounce Time (DbncTime) Indicates the debounce time of a detected connection. 1'b0: Long debounce time, used FOR physical connections (100 ms + 2.5 micro-sec) 1'b1: Short debounce time, used FOR soft connections (2.5 micro-sec) **Value** **Description** 0x0 LONG 0x1 SHORT	RO	0x0
16	conidsts	Mode: Host and Device Connector ID Status (ConIDSts) Indicates the connector ID status on a connect event. 1'b0: The DWC_otg core is in A-Device mode 1'b1: The DWC_otg core is in B-Device mode **Value** **Description** 0x0 MODEA 0x1 MODEB	RO	0x1

Bit	Name	Description	Access	Reset
14	ehen	Mode: SRP Capable Host Embedded Host Enable (EHEn) 1'b1 : Enable Embedded Host Mode. 1'b0: Disable Embedded Host Mode.	RW	0x0
11	devhnpen	Mode: Device only Device HNP Enabled (DevHNPEn) The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host. 1'b0: HNP is not enabled in the application 1'b1: HNP is enabled in the application **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
10	hstsethnpen	Mode: Host only Host Set HNP Enable (HstSetHNPEn) The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device. 1'b0: Host Set HNP is not enabled 1'b1: Host Set HNP is enabled **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
9	hnpreq	Mode: Device only HNP Request (HNPReq) The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET. The core clears this bit when the HstNegSucStsChng bit is cleared. 1'b0: No HNP request 1'b1: HNP request **Value: Description** 0x0: DISABLED 0x1: ENABLED	RW	0x0
8	hstnegscs	Mode: Device only Host Negotiation Success (HstNegScs) The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPReq) bit in this register is SET. 1'b0: Host negotiation failure 1'b1: Host negotiation success **Value: Description** 0x0: FAIL 0x1: SUCCESS	RO	0x0

Bit	Name	Description	Access	Reset
7	bvalidovval	B-Peripheral Session Valid Override-Value (BvalidOvVal) This bit is used to set Override value for Bvalid signal when GOTGCTL.BvalidOvEn is set. 1'b0 : Bvalid value is 1'b0 when GOTGCTL.BvalidOvEn =1 1'b1 : Bvalid value is 1'b1 when GOTGCTL.BvalidOvEn =1 **Value** **Description** 0x0 VALUE0 0x1 VALUE1	RW	0x0
6	bvalidoven	B-Peripheral Session Valid Override Enable (BvalidOvEn) This bit is used to enable/disable the software to override the Bvalid signal using the GOTGCTL.BvalidOvVal. 1'b1 : Internally Bvalid received from the PHY is overridden with GOTGCTL.BvalidOvVal. 1'b0 : Override is disabled and bvalid signal from the respective PHY selected is used internally by the force **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
5	avalidovval	A-Peripheral Session Valid Override-Value (AvalidOvVal) This bit is used to set Override value for Avalid signal when GOTGCTL.AvalidOvEn is set. 1'b0 : Avalid value is 1'b0 when GOTGCTL.AvalidOvEn =1 1'b1 : Avalid value is 1'b1 when GOTGCTL.AvalidOvEn =1 **Value** **Description** 0x0 VALUE0 0x1 VALUE1	RW	0x0
4	avalidoven	A-Peripheral Session Valid Override Enable (AvalidOvEn) This bit is used to enable/disable the software to override the Avalid signal using the GOTGCTL.AvalidOvVal. 1'b1 : Internally Avalid received from the PHY is overridden with GOTGCTL.AvalidOvVal. 1'b0 : Override is disabled and avalid signal from the respective PHY selected is used internally by the core **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
3	vbvalidovval	VBUS Valid OverrideValue (VbvalidOvVal) This bit is used to set Override value for vbusvalid signal when GOTGCTL.VbvalidOvEn is set. 1'b0 : vbusvalid value is 1'b0 when GOTGCTL.VbvalidOvEn =1 1'b1 : vbusvalid value is 1'b1 when GOTGCTL.VbvalidOvEn =1 **Value** **Description** 0x0 SET0 0x1 SET1	RW	0x0
2	vbvalidoven	VBUS Valid Override Enable (VbvalidOvEn) This bit is used to enable/disable the software to override the Bvalid signal using the GOTGCTL.VbvalidOvVal. 1'b1 : Internally Bvalid received from the PHY is overridden with GOTGCTL.VbvalidOvVal. 1'b0 : Override is disabled and bvalid signal from the respective PHY selected is used internally by the core **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
1	sesreq	Mode: Device only Session Request (SesReq) The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is SET. The core clears this bit when the HstNegSucStsChng bit is cleared. If you use the USB 1.1 Full-Speed Serial Transceiver interface to initiate the session request, the application must wait until the VBUS discharges to 0.2 V, after the B-Session Valid bit in this register (GOTGCTL.BSesVld) is cleared. This discharge time varies between different PHYs and can be obtained from the PHY vendor. 1'b0: No session request 1'b1: Session request **Value: Description** 0x0: NOREQUEST 0x1: REQUEST	RW	0x0
0	sesreqscs	Mode: Device only Session Request Success (SesReqScs) The core sets this bit when a session request initiation is successful. 1'b0: Session request failure 1'b1: Session request success **Value: Description** 0x0: FAIL 0x1: SUCCESS	RO	0x0

gotgint Fields

Bit	Name	Description	Access	Reset
19	dbncedone	Mode: Host only Debounce Done (DbnceDone) The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is SET in the Core USB Configuration register (GUSBCFG.HNPCap or GUSBCFG.SRPCap, respectively).This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
18	adevtoutchg	Mode:Host and Device A-Device Timeout Change (ADevTOUTChg) The core sets this bit to indicate that the A-device has timed out WHILE waiting FOR the B-device to connect.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
17	hstnegdet	Mode:Host and Device Host Negotiation Detected (HstNegDet) The core sets this bit when it detects a host negotiation request on the USB.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	hstnegsucstschng	Mode:Host and Device Host Negotiation Success Status Change (HstNegSucStsChng) The core sets this bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit of the OTG Control and Status register (GOTGCTL.HstNegScs) to check For success or failure.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	sesreqsucstschng	Mode:Host and Device Session Request Success Status Change (SesReqSucStsChng) The core sets this bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (GOTGCTL.SesReqScs) to check For success or failure.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	sesenddet	Mode:Host and Device Session End Detected (SesEndDet) The core sets this bit when the utmiotg_bvalid signal is deasserted.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

gahbcfg Fields

Bit	Name	Description	Access	Reset
24	invdescendianess	Invert Descriptor Endianess (InvDescEndianess) 1'b0: Descriptor Endianness is same as AHB Master Endianness 1'b1: Descriptor Endianness is Little Endian if AHB Master Endianness is Big Endian. Descriptor Endianness is Big Endian if AHB Master Endianness is Little Endian.	RW	0x0

Bit	Name	Description	Access	Reset
23	ahbsingle	AHB Single Support (AHBSingle) This bit when programmed supports Single transfers for the remaining data in a transfer when the DWC_otg core is operating in DMA mode. 1'b0: This is the default mode. When this bit is set to 1'b0, the remaining data in the transfer is sent using INCR burst size. 1'b1: When set to 1'b1, the remaining data in a transfer is sent using Single burst size. Note: if this feature is enabled, the AHB RETRY and SPLIT transfers still have INCR burst type. Enable this feature when the AHB Slave connected to the DWC_otg core does not support INCR burst (and when Split, and Retry transactions are not being used in the bus).	RW	0x0

Bit	Name	Description	Access	Reset
22	notialldmawrit	Notify All Dma Write Transactions (NotiAllDmaWrit) This bit is programmed to enable the System DMA Done functionality for all the DMA write Transactions corresponding to the Channel/ Endpoint. This bit is valid only when GAHBCFG.RemMemSupp is set to 1. GAHBCFG.NotiAllDmaWrit = 1 - HSOTG core asserts int_dma_req for all the DMA write transactions on the AHB interface along with int_ dma_done, chep_last_transact and chep_number signal informations. The core waits for sys_dma_done signal for all the DMA write transactions in order to complete the transfer of a particular Channel/Endpoint. GAHBCFG.NotiAllDmaWrit = 0 - HSOTG core asserts int_dma_req signal only for the last transac- tion of DMA write transfer corresponding to a particular Channel/Endpoint. Similarly, the core waits for sys_ dma_done signal only for that transaction of DMA write to complete the transfer of a particular Channel/Endpoint. **Value** **Description** 0x0 LASTTRANS 0x1 ALLTRANS	RW	0x0

Bit	Name	Description	Access	Reset
21	remmemsupp	Remote Memory Support (RemMemSupp) This bit is programmed to enable the functionality to wait for the system DMA Done Signal for the DMA Write Transfers. GAHBCFG.RemMemSupp=1 - The int_dma_req output signal is asserted when HSOTG DMA starts write transfer to the external memory. When the core is done with the Transfers it asserts int_dma_done signal to flag the completion of DMA writes from HSOTG. The core then waits for sys_dma_done signal from the system to proceed further and complete the Data Transfer corresponding to a particular Channel/Endpoint. GAHBCFG.RemMemSupp=0 - The int_dma_req and int_dma_done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as the DMA write transfer is done at the HSOTG Core Boundary and it doesn't wait for the sys_dma_done signal to complete the DATA transfers **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
8	ptxfemplvl	Mode:Host only Periodic TxFIFO Empty Level (PTxFEmpLvl) Indicates when the Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.PTxFEmp) is triggered. This bit is used only in Slave mode. 1'b0: GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is half empty 1'b1: GINTSTS.PTxFEmp interrupt indicates that the Periodic TxFIFO is completely empty **Value** **Description** 0x0 HALFEMPTY 0x1 EMPTY	RW	0x0

Bit	Name	Description	Access	Reset
7	nptxfemplvl	Mode:Host and device Non-Periodic TxFIFO Empty Level (NPTxFEmpLvl) This bit is used only in Slave mode. In host mode and with Shared FIFO with device mode, this bit indicates when the Non-Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (GINTSTS.NPTxFEmp) is triggered. With dedicated FIFO in device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (DIEPINTn.TxFEmp) is triggered. Host mode and with Shared FIFO with device mode:- 1'b0: GINTSTS.NPTxFEmp interrupt indicates that the Non-Periodic TxFIFO is half empty 1'b1: GINTSTS.NPTxFEmp interrupt indicates that the Non-Periodic TxFIFO is completely empty Dedicated FIFO in device mode :- 1'b0: DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is half empty 1'b1: DIEPINTn.TxFEmp interrupt indicates that the IN Endpoint TxFIFO is completely empty **Value** **Description** 0x0 HALFEMPTY 0x1 EMPTY	RW	0x0

Bit	Name	Description	Access	Reset
31	corrupttxpkt	Mode:Host and device Corrupt Tx packet This bit is FOr debug purposes only. Never Set this bit to 1.The application should always write 1'b0 to this bit. **Value** — **Description** 0x0 — NODEBUG 0x1 — DEBUG	WO	0x0
30	forcedevmode	Mode:Host and device Force Device Mode (ForceDevMode) Writing a 1 to this bit forces the core to device mode irrespective of utmiotg_iddig input pin. 1'b0 : Normal Mode. 1'b1 : Force Device Mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro sec is sufficient. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
29	forcehstmode	Mode:Host and device Force Host Mode (ForceHstMode) Writing a 1 to this bit forces the core to host mode irrespective of utmiotg_iddig input pin. 1'b0 : Normal Mode. 1'b1 : Force Host Mode. After setting the force bit, the application must wait at least 25 ms before the change to take effect. When the simulation is in scale down mode, waiting for 500 micro sec is sufficient. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
28	txenddelay	Mode: Device only Tx End Delay (TxEndDelay) Writing 1'b1 to this bit enables the core to follow the TxEndDelay timings as per UTMI+ specification 1.05 section 4.1.5 for opmode signal during remote wakeup. 1'b0 : Normal Mode. 1'b1 : Tx End delay. **Value** **Description** 0x0 DISABLED	RW	0x0
26	ic_usbcap	IC_USB-Capable (IC_USBCap) The application uses this bit to control the DWC_otg core's IC_USB capabilities. 1'b0: IC_USB PHY Interface is not selected. 1'b1: IC_USB PHY Interface is selected. This bit is writable only if IC_USB is selected	RO	0x0

Bit	Name	Description	Access	Reset
25	ulpi	Mode:Host only ULPI Interface Protect Disable Controls circuitry built into the PHY For protecting the ULPI interface when the link tri-states STP and data. Any pull-ups or pull-downs employed by this feature can be disabled. Please refer to the ULPI Specification For more detail. 1'b0: Enables the interface protect circuit 1'b1: Disables the interface protect circuit **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0
24	indicator	Mode:Host only Indicator Pass Through Controls wether the Complement Output is qualified with the Internal Vbus Valid comparator before being used in the Vbus State in the RX CMD. Please refer to the ULPI Spec for more detail. 1'b0: Complement Output signal is qualified with the Internal VbusValid comparator. 1'b1: Complement Output signal is not qualified with the Internal VbusValid comparator. **Value** **Description** 0x0 QUALIFIED 0x1 NONQUALIFIED	RW	0x0

Bit	Name	Description	Access	Reset
23	complement	Mode:Host only Indicator Complement Controls the PHY to invert the ExternalVbusIndicator input signal, generating the Complement Output. Please refer to the ULPI Spec For more detail 1'b0: PHY does not invert External-VbusIndicator signal 1'b1: PHY does invert ExternalVbu-sIndicator signal **Value: Description** 0x0: NONINVERT 0x1: INVERT	RW	0x0
22	termseldlpulse	Mode:Device only TermSel DLine Pulsing Selection (TermSelDLPulse) This bit selects utmi_termselect to drive data line pulse during SRP. 1'b0: Data line pulsing using utmi_txvalid (Default). 1'b1: Data line pulsing using utmi_termsel. **Value: Description** 0x0: TXVALID 0x1: TERMSEL	RW	0x0
21	ulpiextvbusindicator	Mode:Host only ULPI External VBUS Indicator (ULPIExtVbusIndicator) This bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator. 1'b0: PHY uses internal VBUS valid comparator. 1'b1: PHY uses external VBUS valid comparator. **Value: Description** 0x0: INTERN 0x1: EXTERN	RW	0x0

Bit	Name	Description	Access	Reset
20	ulpiextvbusdrv	Mode:Host only ULPI External VBUS Drive (ULPIExtV-busDrv) This bit selects between internal or external supply to drive 5V on VBUS, in ULPI PHY. 1'b0: PHY drives VBUS using internal charge pump (Default). 1'b1: PHY drives VBUS using external supply. **Value** **Description** 0x0 INTERN 0x1 EXTERN	RW	0x0
19	ulpiclksusm	Mode:Host and Device ULPI Clock SuspendM (ULPIClkSusM) This bit sets the ClockSuspendM bit in the Interface Control register on the ULPI PHY. This bit applies only in serial or carkit modes. 1'b0: PHY powers down internal clock during suspend. 1'b1: PHY does not power down internal clock. **Value** **Description** 0x0 PWDCLK 0x1 NONPWDCLK	RW	0x0
18	ulpiautores	Mode:Host and Device ULPI Auto Resume (ULPIAutoRes) This bit sets the AutoResume bit in the Interface Control register on the ULPI PHY. 1'b0: PHY does not use AutoResume feature. 1'b1: PHY uses AutoResume feature. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
13:10	usbtrdtim	Mode: Device only USB Turnaround Time (USBTrdTim) Sets the turnaround time in PHY clocks. Specifies the response time For a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). This must be programmed to 4'h5: When the MAC interface is 16-bit UTMI+ . 4'h9: When the MAC interface is 8-bit UTMI+ . Note: The values above are calculated For the minimum AHB frequency of 30 MHz. USB turnaround time is critical For certification where long cables and 5-Hubs are used, so If you need the AHB to run at less than 30 MHz, and If USB turnaround time is not critical, these bits can be programmed to a larger value. **Value** **Description** 0x9 TURNTIME	RW	0x5
9	hnpcap	Mode:Host and Device HNP-Capable (HNPCap) The application uses this bit to control the DWC_otg core's HNP capabilities. 1'b0: HNP capability is not enabled. 1'b1: HNP capability is enabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
8	srpcap	Mode:Host and Device SRP-Capable (SRPCap) The application uses this bit to control the DWC_otg core SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. 1'b0: SRP capability is not enabled. 1'b1: SRP capability is enabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
7	ddrsel	Mode:Host and Device ULPI DDR Select (DDRSel) The application uses this bit to select a Single Data Rate (SDR) or Double Data Rate (DDR) or ULPI interface. 1'b0: Single Data Rate ULPI Interface, with 8-bit-wide data bus 1'b1: Double Data Rate ULPI Interface, with 4-bit-wide data bus **Value** **Description** 0x0 SDR 0x1 DDR	RW	0x0

Bit	Name	Description	Access	Reset
6	physel	Mode:Host and Device USB 2.0 High-Speed PHY or USB 1.1 Full-Speed Serial Transceiver Select (PHYSel) The application uses this bit to select either a high-speed UTMI+ or ULPI PHY, or a full-speed transceiver. 1'b0: USB 2.0 high-speed UTMI+ or ULPI PHY 1'b1: USB 1.1 full-speed serial transceiver If a USB 1.1 Full-Speed Serial Transceiver interface was not selected in, this bit is always 0, with Write Only access. If a high-speed PHY interface was not selected in, this bit is always 1, with Write Only access. If both interface types were selected (parameters have non-zero values), the application uses this bit to select which interface is active, and access is Read and Write. **Value** **Description** 0x0 USB20	RO	0x0

Bit	Name	Description	Access	Reset
5	fsintf	Mode:Host and Device Full-Speed Serial Interface Select (FSIntf) The application uses this bit to select either a unidirectional or bidirectional USB 1.1 full-speed serial transceiver interface. 1'b0: 6-pin unidirectional full-speed serial interface 1'b1: 3-pin bidirectional full-speed serial interface If a USB 1.1 Full-Speed Serial Transceiver interface was not selected, this bit is always 0, with Write Only access. If a USB 1.1 FS interface was selected, Then the application can Set this bit to select between the 3- and 6-pin interfaces, and access is Read and Write. **Value** **Description** 0x0 FS6PIN 0x1 FS3PIN	RO	0x0
4	ulpi_utmi_sel	Mode:Host and Device ULPI or UTMI+ Select (ULPI_UTMI_Sel) The application uses this bit to select either a UTMI+ interface or ULPI Interface. 1'b0: UTMI+ Interface 1'b1: ULPI Interface This bit is writable only If UTMI+ and ULPI was specified For High-Speed PHY Interface(s). **Value** **Description** 0x0 ULPI	RO	0x1

Bit	Name	Description	Access	Reset
3	phyif	Mode:Host and Device PHY Interface (PHYIf) The application uses this bit to configure the core To support a UTMI+ PHY with an 8- or 16-bit interface. When a ULPI PHY is chosen, this must be Set to 8-bit mode. 1'b0: 8 bits 1'b1: 16 bits This bit is writable only If UTMI+ and ULPI were selected **Value** **Description** 0x0 BITS8	RO	0x0
2:0	toutcal	Mode:Host and Device HS/FS Timeout Calibration (TOutCal) The number of PHY clocks that the application programs in this field is added to the high-speed/ full-speed interpacket timeout duration in the core to account For any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the linestate condition can vary from one PHY to another. The USB standard timeout value For high-speed operation is 736 to 816 (inclusive) bit times. The USB standard timeout value For full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock are: High-speed operation: One 30-MHz PHY clock = 16 bit times One 60-MHz PHY clock = 8 bit times Full-speed operation: One 30-MHz PHY clock = 0.4 bit times One 60-MHz PHY clock = 0.2 bit times One 48-MHz PHY clock = 0.25 bit times	RW	0x0

grstctl Fields

Bit	Name	Description	Access	Reset
31	ahbidle	Mode:Host and Device AHB Master Idle (AHBIdle) Indicates that the AHB Master State Machine is in the IDLE condition. Value — Description 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
30	dmareq	Mode:Host and Device DMA Request Signal (DMAReq) Indicates that the DMA request is in progress. Used For debug. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
10:6	txfnum	Mode:Host and Device TxFIFO Number (TxFNum) This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit. 5'h0: - Non-periodic TxFIFO flush in Host mode - Non-periodic TxFIFO flush in device mode when in shared FIFO operation - Tx FIFO 0 flush in device mode when in dedicated FIFO mode 5'h1: - Periodic TxFIFO flush in Host mode - Periodic TxFIFO 1 flush in Device mode when in shared FIFO operation - TXFIFO 1 flush in device mode when in dedicated FIFO mode 5'h2: - Periodic TxFIFO 2 flush in Device mode when in shared FIFO operation - TXFIFO 2 flush in device mode when in dedicated FIFO mode ... 5'hF: - Periodic TxFIFO 15 flush in Device mode when in shared FIFO operation - TXFIFO 15 flush in device mode when in dedicated FIFO mode 5'h10: Flush all the transmit FIFOs in device or host mode. **Value** **Description** 0xf TXF15 0x0 TXF0 0x1 TXF1 0x2 TXF2 0x10 TXF16	RW	0x0

Bit	Name	Description	Access	Reset
5	txfflsh	Mode:Host and Device TxFIFO Flush (TxFFlsh) This bit selectively flushes a single or all transmit FIFOs, but cannot do so If the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers: ReadNAK Effective Interrupt ensures the core is not reading from the FIFO WriteGRSTCTL.AHBIdle ensures the core is not writing anything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured or when switching between Shared FIFO and Dedicated Transmit FIFO operation. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	rxfflsh	Mode:Host and Device RxFIFO Flush (RxFFlsh) The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction. The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO. The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	frmcntrrst	Mode:Host only Host Frame Counter Reset (FrmCntrRst) The application writes this bit to reset the (micro)frame number counter inside the core. When the (micro)frame counter is reset, the subsequent SOF sent out by the core has a (micro)frame number of 0.When application writes 1 to the bit, it might not be able to read back the value as it will get cleared by the core in a few clock cycles. **Value** **Description** 0x0 NOTACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	piufssftrst	Mode:Host and Device PIU FS Dedicated Controller Soft Reset (PIUFSSftRst) Resets the PIU FS Dedicated Controller All module state machines in FS Dedicated Controller of PIU are reset to the IDLE state. Used to reset the FS Dedicated controller in PIU in case of any PHY Errors like Loss of activity or Babble Error resulting in the PHY remaining in RX state for more than one frame boundary	RW	0x0
0	csftrst	Mode:Host and Device Core Soft Reset (CSftRst) Resets the hclk and phy_clock domains as follows: Clears the interrupts and all the CSR registers except the following register bits: • PCGCCTL.RstPdwnModule • PCGCCTL.GateHclk • PCGCCTL.PwrClmp • PCGCCTL.StopPPhyLPwrClkSelclk • GUSBCFG.PhyLPwrClkSel • GUSBCFG.DDRSel • GUSBCFG.PHYSel • GUSBCFG.FSIntf • GUSBCFG.ULPI_UTMI_Sel • GUSBCFG.PHYIf • GUSBCFG.TxEndDelay • GUSBCFG.TermSelDLPulse • GUSBCFG.ULPIClkSusM • GUSBCFG.ULPIAutoRes • GUSBCFG.ULPIFsLs • GGPIO • GPWRDN • GADPCTL • HCFG.FSLSPclkSel • DCFG.DevSpd • DCTL.SftDiscon • All module state machines All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed.	RW	0x0

Bit	Name	Description	Access	Reset
		Any transactions on the AHB Master are terminated as soon as possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. When Hibernation or ADP feature is enabled, the PMU module is not reset by the Core Soft Reset. The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation. Typically software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock For the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation. **Value** **Description** 0x0 NOTACTIVE 0x1 ACTIVE

Bit	Name	Description	Access	Reset
31	wkupint	Mode:Host and Device Resume/Remote Wakeup Detected Interrupt (WkUpInt) Wakeup Interrupt during Suspend(L2) or LPM(L1) state. During Suspend(L2): - Device Mode - This interrupt is asserted only when Host Initiated Resume is detected on USB. - Host Mode - This interrupt is asserted only when Device Initiated Remote Wakeup is detected on USB. For more information, see 'Partial Power-Down and Clock Gating Programming Model'. During LPM(L1):- - Device Mode - This interrupt is asserted for either Host Initiated Resume or Device Initiated Remote Wakeup on USB. - Host Mode - This interrupt is asserted for either Host Initiated Resume or Device Initiated Remote Wakeup on USB. For more information, see 'LPM Entry and Exit Programming Model' **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	sessreqint	Mode:Host and Device Session Request/New Session Detected Interrupt (SessReqInt) In Host mode, this interrupt is asserted when a session request is detected from the device. In Host mode, this interrupt is asserted when a session request is detected from the device. In Device mode, this interrupt is asserted when the utmisrp_bvalid signal goes high. For more information on how to use this interrupt, see 'Partial Power-Down and Clock Gating Programming Model'. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
29	disconnint	Mode:Host only Disconnect Detected Interrupt (DisconnInt) Asserted when a device disconnect is detected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
28	conidstschng	Mode:Host and Device Connector ID Status Change (ConIDStsChng) The core sets this bit when there is a change in connector ID status. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x1

Bit	Name	Description	Access	Reset
26	ptxfemp	Mode:Host only Periodic TxFIFO Empty (PTxFEmp) This interrupt is asserted when the Periodic Transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the Periodic Request Queue. The half or completely empty status is determined by the Periodic TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.PTxFEmpLvl). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1
25	hchint	Mode:Host only Host Channels Interrupt (HChInt) The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the Host All Channels Interrupt (HAINT) register to determine the exact number of the channel on which the interrupt occurred, and Then read the corresponding Host Channel-n Interrupt (HCINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the HCINTn register to clear this bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
24	prtint	Mode:Host only Host Port Interrupt (PrtInt) The core sets this bit to indicate a change in port status of one of the DWC_otg core ports in Host mode. The application must read the Host Port Control and Status (HPRT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host Port Control and Status register to clear this bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0
23	resetdet	Mode: Device only Reset detected Interrupt (ResetDet) In Device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in Suspend. In Host mode, this interrupt is not asserted. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
22	fetsusp	Mode: Device only Data Fetch Suspended (FetSusp) This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data For IN endpoints due to the unavailability of TxFIFO space or Request Queue space. This interrupt is used by the application For an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application: Sets a Global non-periodic IN NAK handshake Disables In endpoints Flushes the FIFO Determines the token sequence from the IN Token Sequence Learning Queue Re-enables the endpoints Clears the Global non-periodic IN NAK handshake If the Global non-periodic IN NAK is cleared, the core has not yet fetched data For the IN endpoint, and the IN token is received: the core generates an 'IN token received when FIFO empty' interrupt. The OTG Then sends the host a NAK response. To avoid this scenario, the application can check the GINTSTS.FetSusp interrupt, which ensures that the FIFO is full before clearing a Global NAK handshake. Alternatively, the application can mask the “IN token received when FIFO empty” interrupt when clearing a Global IN NAK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
21	incomplp	Incomplete Periodic Transfer (incomplP) In Host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending which are scheduled For the current microframe. Incomplete Isochronous OUT Transfer (incompISOOUT) The Device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
20	incompisoin	Mode: Device only Incomplete Isochronous IN Transfer (incompISOIN) The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current microframe. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. Note: This interrupt is not asserted in Scatter/Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
19	oepint	Mode: Device only OUT Endpoints Interrupt (OEPInt) The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the OUT endpoint on which the interrupt occurred, and Then read the corresponding Device OUT Endpoint-n Interrupt (DOEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DOEPINTn register to clear this bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
18	iepint	Mode: Device only IN Endpoints Interrupt (IEPInt) The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the IN endpoint on Device IN Endpoint-n Interrupt (DIEPINTn) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DIEPINTn register to clear this bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
17	epmis	Mode: Device only Endpoint Mismatch Interrupt (EPMis) Note: This interrupt is valid only in shared FIFO operation. Indicates that an IN token has been received For a non-periodic endpoint, but the data For another endpoint is present in the top of the Non-periodic Transmit FIFO and the IN endpoint mismatch count programmed by the application has expired. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
15	eopf	Mode: Device only End of Periodic Frame Interrupt (EOPF) Indicates that the period specified in the Periodic Frame Interval field of the Device Configuration register (DCFG.PerFrInt) has been reached in the current microframe.	RW	0x0
14	isooutdrop	Mode: Device only Isochronous OUT Packet Dropped Interrupt (ISOOutDrop) The core sets this bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
13	enumdone	Mode: Device only Enumeration Done (EnumDone) The core sets this bit to indicate that speed enumeration is complete. The application must read the Device Status (DSTS) register to obtain the enumerated speed. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	usbrst	Mode: Device only USB Reset (USBRst) The core sets this bit to indicate that a reset is detected on the USB. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	usbsusp	Mode: Device only USB Suspend (USBSusp) The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the linestate signal For an extended period of time. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
10	erlysusp	Mode: Device only Early Suspend (ErlySusp) The core sets this bit to indicate that an Idle state has been detected on the USB For 3 ms. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	goutnakeff	Mode: Device only Global OUT NAK Effective (GOUTNakEff) Indicates that the Set Global OUT NAK bit in the Device Control register (DCTL.SGOUTNak), Set by the application, has taken effect in the core. This bit can be cleared by writing the Clear Global OUT NAK bit in the Device Control register (DCTL.CGOUTNak). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
6	ginnakeff	Mode: Device only Global IN Non-periodic NAK Effective (GINNakEff) Indicates that the Set Global Non-periodic IN NAK bit in the Device Control register (DCTL.SGNPInNak), Set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit Set by the application. This bit can be cleared by clearing the Clear Global Non-periodic IN NAK bit in the Device Control register (DCTL.CGNPInNak). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
5	nptxfemp	Mode: Host and Device Non-periodic TxFIFO Empty (NPTxFEmp) This interrupt is asserted when the Non-periodic TxFIFO is either half or completely empty, and there is space For at least one Entry to be written to the Non-periodic Transmit Request Queue. The half or completely empty status is determined by the Non-periodic TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl).	RO	0x1
4	rxflvl	Mode: Host and Device RxFIFO Non-Empty (RxFLvl) Indicates that there is at least one packet pending to be read from the RxFIFO. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
3	sof	Mode: Host and Device Start of (micro)Frame (Sof) In Host mode, the core sets this bit to indicate that an SOF (FS), micro-SOF (HS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In Device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current (micro)Frame number. This interrupt is seen only when the core is operating at either HS or FS. Note: This register may return 1'b1 if read immediately after power on reset. If the register bit reads 1'b1 immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit. **Value** — **Description** 0x0 — INTACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	otgint	Mode: Host and Device OTG Interrupt (OTGInt) The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the GOTGINT register to clear this bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
1	modemis	Mode: Host and Device Mode Mismatch Interrupt (ModeMis) The core sets this bit when the application is trying to access: A Host mode register, when the core is operating in Device mode A Device mode register, when the core is operating in Host mode The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.This bit can be set only by the core and the application should write 1 to clear it **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	curmod	Mode: Host and Device Current Mode of Operation (CurMod) Indicates the current mode. 1'b0: Device mode 1'b1: Host mode Value: 0x0 — Description: DEVICE Value: 0x1 — Description: HOST	RO	0x0

gpvndctl Fields

Bit	Name	Description	Access	Reset
31	disulpidrvr	Disable ULPI Drivers (DisUlpiDrvr) The application sets this bit when it has finished processing the ULPI Carkit Interrupt (GINTSTS.ULPICKINT). When Set, the DWC_otg core disables drivers For output signals and masks input signal For the ULPI interface. DWC_otg clears this bit before enabling the ULPI interface. **Value** — **Description** 0x0 — ENABLED 0x1 — DISABLED	RW	0x0
27	vstsdone	VStatus Done (VStsDone) The core sets this bit when the vendor control access is done. This bit is cleared by the core when the application sets the New Register Request bit (bit 25). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
26	vstsbsy	VStatus Busy (VStsBsy) The core sets this bit when the vendor control access is in progress and clears this bit when done. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
25	newregreq	New Register Request (NewRegReq) The application sets this bit For a new vendor control access. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
22	regwr	Register Write (RegWr) Set this bit For register writes, and clear it For register reads. **Value** — **Description** 0x0 — READ 0x1 — WRITE	RW	0x0
21:16	regaddr	Register Address (RegAddr) The 6-bit PHY register address For immediate PHY Register Set access. Set to 6'h2F For Extended PHY Register Set access.	RW	0x0
15:8	vctrl	UTMI+ Vendor Control Register Address (VCtrl) The 4-bit register address a vendor defined 4-bit parallel output bus. Bits 11:8 of this field are placed on utmi_vcontrol[3:0]. ULPI Extended Register Address (ExtRegAddr) The 6-bit PHY extended register address.	RW	0x0
7:0	regdata	Register Data (RegData) Contains the write data For register write. Read data For register read, valid when VStatus Done is Set.	RW	0x0

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved		inepntxfdep RW 0x2000													
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
inepntxfstaddr RW 0x0															

dieptxf15 Fields

Bit	Name	Description	Access	Reset
29:16	inepntxfdep	IN Endpoint TxFIFO Depth (INEPnTxFDep) This value is in terms of 32-bit words. Minimum value is 16 Maximum value is 32,768 The power-on reset value of this register is specified as the Largest IN Endpoint FIFO number Depth Programmed values must not exceed the power-on value	RW	0x2000
15:0	inepntxfstaddr	IN Endpoint FIFOn Transmit RAM Start Address (INEPnTxFStAddr) This field contains the memory start address For IN endpoint Transmit FIFOn (0<n< = 15). The power-on reset value of this register is specified as the Largest Rx Data FIFO Depth Programmed values must not exceed the power-on value.	RW	0x0

usb_hostgrp Address Map

Module Instance	Base Address	End Address
i_usbotg_0_hostgrp	0xFFB00400	0xFFB007FF
i_usbotg_1_hostgrp	0xFFB40400	0xFFB407FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

hcfg

Host Configuration Register

Module Instance	Base Address	Register Address
i_usbotg_0_hostgrp	0xFFB00400	0xFFB00400
i_usbotg_1_hostgrp	0xFFB40400	0xFFB40400

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

hcfg Fields

Bit	Name	Description	Access	Reset
31	modechtimen	Mode Change Ready Timer Enable (ModeChTimEn) This bit is used to enable/disable the Host core to wait 200 PHY clock cycles at the end of Resumeto change the opmode signal to the PHY to 00 after Suspend or LPM. 1'b0 : The Host core waits for either 200 PHY clock cycles or a linestate of SE0 at the end of resume to the change the opmode from 2'b10 to 2'b00 1'b1 : The Host core waits only for a linstate of SE0 at the end of resume to change the opmode from 2'b10 to 2'b00. **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0

Bit	Name	Description	Access	Reset
26	perschedena	Enable Periodic Scheduling (PerSchedEna): Applicable in host DDMA mode only. Enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. As soon as this bit is set, the core will get ready to start scheduling periodic channels and sets HCFG.PerSchedStat. The setting of HCFG.PerSchedStat indicates the core has enabled periodic scheduling. Once HCFG.PerSchedEna is set, the application is not supposed to again reset the bit unless HCFG.PerSchedStat is set. As soon as this bit is reset, the core will get ready to stop scheduling periodic channels and resets HCFG.PerSchedStat. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
25:24	frlisten	Frame List Entries(FrListEn). The value in the register specifies the number of entries in the Frame list. This field is valid only in Scatter/Gather DMA mode. 2'b00: 8 Entries 2'b01: 16 Entries 2'b10: 32 Entries 2'b11: 63 Entries **Value** — **Description** 0x0 — RESERVED 0x1 — ENTRY8 0x2 — ENTRY16 0x3 — ENTRY32	RW	0x0

Bit	Name	Description	Access	Reset
23	descdma	Enable Scatter/gather DMA in Host mode (DescDMA). When the Scatter/Gather DMA option selected during configuration of the RTL, the application can set this bit during initialization to enable the Scatter/Gather DMA operation. NOTE: This bit must be modified only once after a reset. \The following combinations are available for programming: GAHBCFG.DMAEn=0,HCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0,HCFG.DescDMA=1 => Invalid GAHBCFG.DMAEn=1,HCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1,HCFG.DescDMA=1 => Scatter/Gather DMA mode **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15:8	resvalid	Resume Validation Period (ResValid) This field is effective only when HCFG.Ena32KHzS is set. It will control the resume period when the core resumes from suspend. The core counts for 'ResValid' number of clock cycles to detect a valid resume when this is set.	RW	0x2

Bit	Name	Description	Access	Reset
7	ena32khzs	Enable 32 KHz Suspend mode (Ena32KHzS) This bit can be set only in FS PHY interface is selected. Else, this bit needs to be set to zero. When FS PHY interface is chosen and this bit is set, the core expects that the PHY clock during Suspend is switched from 48 MHz to 32 KHz. **Value** / **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
2	fslssupp	FS- and LS-Only Support (FSLSSupp) The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as a FS host, even If the connected device supports HS traffic. Do not make changes to this field after initial programming. 1'b0: HS/FS/LS, based on the maximum speed supported by the connected device 1'b1: FS/LS-only, even If the connected device can support HS **Value** / **Description** 0x0 — HSFSLS 0x1 — FSLS	RW	0x0

Bit	Name	Description	Access	Reset
1:0	fslspclksel	FS/LS PHY Clock Select (FSLSPclkSel) When the core is in FS Host mode 2'b00: PHY clock is running at 30/60 MHz 2'b01: PHY clock is running at 48 MHz Others: Reserved When the core is in LS Host mode 2'b00: PHY clock is running at 30/60 MHz. When the UTMI+/ULPI PHY Low Power mode is not selected, use 30/60 MHz. 2'b01: PHY clock is running at 48 MHz. When the UTMI+ PHY Low Power mode is selected, use 48MHz If the PHY supplies a 48 MHz clock during LS mode. 2'b10: PHY clock is running at 6 MHz. In USB 1.1 FS mode, use 6 MHz when the UTMI+ PHY Low Power mode is selected and the PHY supplies a 6 MHz clock during LS mode. If you select a 6 MHz clock during LS mode, you must do a soft reset. 2'b11: Reserved Notes: When Core in FS mode, the internal and external clocks have the same frequency. When Core in LS mode, - If FSLSPclkSel = 2'b00: Internal and external clocks have the same frequency - If FSLSPclkSel = 2'b10: Internal clock is the divided by eight version of external 48 MHz clock **Value** — **Description** 0x0 — CLK3060 0x1 — CLK48 0x2 — CLK6	RW	0x0

hfir Fields

Bit	Name	Description	Access	Reset
16	hfirrldctrl	Reload Control (HFIRRldCtrl) This bit allows dynamic reloading of the HFIR register during run time. 1'b0 : The HFIR cannot be reloaded dynamically 1'b1: the HFIR can be dynamically reloaded during runtime. This bit needs to be programmed during initial configuration and its value should not be changed during runtime. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
15:0	frint	Frame Interval (FrInt) The value that the application programs to this field specifies the interval between two consecutive SOFs (FS) or micro-SOFs (HS) or Keep-Alive tokens (HS). This field contains the number of PHY clocks that constitute the required frame interval. The Default value Set in this field For a FS operation when the PHY clock frequency is 60 MHz. The application can write a value to this register only after the Port Enable bit of the Host Port Control and Status register (HPRT.PrtEnaPort) has been Set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY Clock Select field of the Host Configuration register (HCFG.FSLSPclkSel). Do not change the value of this field after the initial configuration. 125 s * (PHY clock frequency For HS) 1 ms * (PHY clock frequency For FS/LS)	RW	0xEA60

18:17	prtspd	Port Speed (PrtSpd) Indicates the speed of the device attached to this port. 2'b00: High speed 2'b01: Full speed 2'b10: Low speed 2'b11: Reserved Value — Description 0x0 — HIGHSPD 0x1 — FULLSPD 0x2 — LOWSPD 0x3 — RESERVED	RO	0x0

Bit	Name	Description	Access	Reset
16:13	prttstctl	Port Test Control (PrtTstCtl) The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port. 4'b0000: Test mode disabled 4'b0001: Test_J mode 4'b0010: Test_K mode 4'b0011: Test_SE0_NAK mode 4'b0100: Test_Packet mode 4'b0101: Test_Force_Enable Others: Reserved **Value** / **Description** 0x0 DISABLED 0x1 TESTJ 0x2 TESTK 0x3 TESTSN 0x4 TESTPM 0x5 TESTFENB	RW	0x0
12	prtpwr	Port Power (PrtPwr) The application uses this field to control power to this port (write 1'b1 to set to 1'b1 and write 1'b0 to set to 1'b0), and the core can clear this bit on an over current condition. 1'b0: Power off 1'b1: Power on **Value** / **Description** 0x0 OFF 0x1 ON	RW	0x0

Bit	Name	Description	Access	Reset
11:10	prtlnsts	Port Line Status (PrtLnSts) Indicates the current logic level USB data lines Bit [10]: Logic level of D+ Bit [11]: Logic level of D- **Value** / **Description** 0x1 — PLUSD 0x2 — MINUSD	RO	0x0
8	prtrst	Port Reset (PrtRst) When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete. 1'b0: Port not in reset 1'b1: Port in reset The application must leave this bit Set For at least a minimum duration mentioned below to start a reset on the port. The application can leave it Set For another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit Set by the USB standard.This bit is cleared by the core even if there is no device connected to the Host. High speed: 50 ms Full speed/Low speed: 10 ms **Value** / **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
7	prtsusp	Port Suspend (PrtSusp) The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is Set. To stop the PHY clock, the application must Set the Port Clock Stop bit, which asserts the suspend input pin of the PHY. The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the Port Reset bit or Port Resume bit in this register or the Resume/Remote Wakeup Detected Interrupt bit or Disconnect Detected Interrupt bit in the Core Interrupt register (GINTSTS.WkUpInt or GINTSTS.DisconnInt, respectively).This bit is cleared by the core even if there is no device connected to the Host. 1'b0: Port not in Suspend mode 1'b1: Port in Suspend mode **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	prtres	Port Resume (PrtRes) The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the Port Resume/Remote Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.WkUpInt), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling. 1'b0: No resume driven 1'b1: Resume driven When LPM is enabled, In L1 state the behavior of this bit is as follows: The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until a pre-determined time specified in GLPMCFG.HIRD_Thres[3:0] field. If the core detects a USB remote wakeup sequence, as indicated by the Port L1Resume/Remote L1Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.L1WkUpInt), the core starts driving resume signaling without application intervention and clears this bit at the end of resume.This bit can be set by both core or application and also cleared by core or application. This bit is cleared by the core even if there is no device connected to the Host. **Value** — **Description** 0x0 — NORESUME 0x1 — RESUME	RW	0x0

Bit	Name	Description	Access	Reset
5	prtovrcurrchng	Port Overcurrent Change (PrtOvrCurrChng) The core sets this bit when the status of the Port Overcurrent Active bit (bit 4) in this register changes.This bit can be set only by the core and the application should write 1 to clear it **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	prtovrcurract	Port Overcurrent Active (PrtOvrCur-rAct) Indicates the overcurrent condition of the port. 1'b0: No overcurrent condition 1'b1: Overcurrent condition **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
3	prtenchng	Port Enable/Disable Change (PrtEnChng) The core sets this bit when the status of the Port Enable bit [2] of this register changes.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	prtena	Port Enable (PrtEna) A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot Set this bit by a register write. It can only clear it to disable the port by writing 1.. This bit does not trigger any interrupt to the application. 1'b0: Port disabled 1'b1: Port enabled **Value** / **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
1	prtconndet	Port Connect Detected (PrtConnDet) The core sets this bit when a device connection is detected to trigger an interrupt to the application using the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt).This bit can be set only by the core and the application should write 1 to clear it.The application must write a 1 to this bit to clear the interrupt. **Value** / **Description** 0x0 ACTIVE 0x1 INACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	prtconnsts	Port Connect Status (PrtConnSts) 0: No device is attached to the port. 1: A device is attached to the port. Value: 0x0 Description: NOTATTACHED Value: 0x1 Description: ATTACHED	RO	0x0

hcint0 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz0 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

hcdma0 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma0	Buffer DMA Mode: [31:0] DMA Address (DMAAddr) This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction. Scatter-Gather DMA (DescDMA) Mode: [31:9] (Non Isoc) Non-Isochronous: [31:N] (Isoc) Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value.	RW	0x0

Bit	Name	Description	Access	Reset
		This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC nTD N 7 6 15 7 31 8 63 9 127 10 255 11 FS ISOC nTD N 1 4 3 5 7 6 15 7 31 8 63 9 [N-1:3] (Isoc): [8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. • 0 - 1 descriptor. • 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr.		

Bit	Name	Description	Access	Reset
		Isochronous: CTD for isochronous is based on the current frame/ (micro)frame value. Need to be set to zero by application.Scatter-Gather DMA (DescDMA) Mode: [31:9] (Non Isoc) Non-Isochronous: [31:N] (Isoc) Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC nTD N 7 6 15 7 31 8 63 9 127 10 255 11 FS ISOC nTD N 1 4 3 5 7 6 15 7 31 8 63 9		

Bit	Name	Description	Access	Reset
		[N-1:3] (Isoc): [8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. • 0 - 1 descriptor. • 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/ (micro)frame value. Need to be set to zero by application.

epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar1 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hctsiz1 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar2 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint2 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

xfersize RW 0x0															

hctsiz2 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar3 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 NOTREADY 0x1 READY	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** / **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** / **Description** 0x0 — NONLOWSPEED 0x1 — LOWSPEED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** / **Description** 0x0 — OUTDIR 0x1 — INDIR	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint3 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hcint4 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC nTD N 7 6 15 7 31 8 63 9 127 10 255 11 FS ISOC nTD N 1 4 3 5 7 6 15 7 31 8 63 9 [N-1:3] (Isoc): [8:3] (Non Isoc): Current Transfer Desc(CTD):		

Bit	Name	Description	Access	Reset
		Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/(micro)frame value. Need to be set to zero by application.

hcchar5 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 NOTREADY 0x1 READY	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — NONLOWSPEED 0x1 — LOWSPEED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUTDIR 0x1 — INDIR	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint5 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hcchar6 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint6 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz6 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

hcint7 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hcchar8 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CTRL 0x1 ISOC 0x2 BULK 0x3 INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** **Description** 0x0 OUT 0x1 IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint8 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz8 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

hcchar9 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CTRL 0x1 ISOC 0x2 BULK 0x3 INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** **Description** 0x0 OUT 0x1 IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

xfersize RW 0x0															

hctsiz9 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

hcchar10 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint10 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz10 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar11 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CTRL 0x1 ISOC 0x2 BULK 0x3 INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** **Description** 0x0 OUT 0x1 IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value: Description 0xa: ENDPT10 0xb: ENDPT11 0xc: ENDPT12 0xd: ENDPT13 0xe: ENDPT14 0xf: ENDPT15 0x0: ENDPT0 0x1: ENDPT1 0x2: ENDPT2 0x3: ENDPT3 0x4: ENDPT4 0x5: ENDPT5 0x6: ENDPT6 0x7: ENDPT7 0x8: ENDPT8 0x9: ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint11 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz11 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar12 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint12 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hctsiz12 Fields

Bit	Name	Description	Access	Reset
31	dopng	Do Ping (DoPng) This bit is used only For OUT transfers. Setting this field to 1 directs the host to do PING protocol. Note: Do not Set this bit For IN transfers. If this bit is Set For for IN transfers it disables the channel. **Value** — **Description** 0x0 — NOPING 0x1 — PING	RW	0x0

Bit	Name	Description	Access	Reset
30:29	pid	PID (Pid) The application programs this field with the type of PID to use For the initial transaction. The host maintains this field For the rest of the transfer. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA (non-control)/SETUP (control) **Value** **Description** 0x0 DATA0 0x1 DATA2 0x2 DATA1 0x3 MDATA	RW	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. The width of this counter is specified as Width of Packet Counters	RW	0x0
18:0	xfersize	Transfer Size (XferSize) For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has Reserved For the transfer. The application is expected to program this field as an integer multiple of the maximum packet size For IN transactions (periodic and non-periodic). The width of this counter is specified as Width of Transfer Size Counters	RW	0x0

epdir RW 0x0	epnum RW 0x0				mps RW 0x0										

hcchar13 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** / **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** / **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** / **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint13 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

hcdma13 Fields

Bit	Name	Description	Access	Reset
31:0	hcdma13	Buffer DMA Mode: [31:0] DMA Address (DMAAddr) This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transac- tion. Scatter-Gather DMA (DescDMA) Mode: [31:9] (Non Isoc) Non-Isochronous: [31:N] (Isoc) Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first	RW	0x0

Bit	Name	Description	Access	Reset
		descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC nTD N 7 6 15 7 31 8 63 9 127 10 255 11 FS ISOC nTD N 1 4 3 5 7 6 15 7 31 8 63 9 [N-1:3] (Isoc): [8:3] (Non Isoc): Current Transfer Desc(CTD): Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained		

Bit	Name	Description	Access	Reset
		by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/(micro)frame value. Need to be set to zero by application.Scatter-Gather DMA (DescDMA) Mode: [31:9] (Non Isoc) Non-Isochronous: [31:N] (Isoc) Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. This field holds the address of the 2*(nTD+1) bytes of locations in which the isochronous descriptors are present where N is based on nTD as per Table below [31:N] Base Address [N-1:3] Offset [2:0] 000 HS ISOC nTD N 7 6 15 7 31 8 63 9 127 10 255 11 FS ISOC nTD N 1 4 3 5 7 6 15 7 31 8 63 9 [N-1:3] (Isoc): [8:3] (Non Isoc): Current Transfer Desc(CTD):		

Bit	Name	Description	Access	Reset
		Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/(micro)frame value. Need to be set to zero by application.

hcchar14 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the application and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** / **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** / **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** / **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint14 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

		Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0 - 1 descriptor. 63 - 64 descriptors. This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8bytes*5=) 40(decimal) to DMAAddr. Isochronous: CTD for isochronous is based on the current frame/(micro)frame value. Need to be set to zero by application.		

hcdmab14

Host Channel 14 DMA Buffer Address Register

Module Instance	Base Address	Register Address
i_usbotg_0_hostgrp	0xFFB00400	0xFFB006DC
i_usbotg_1_hostgrp	0xFFB40400	0xFFB406DC

Offset: 0x2DC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

hcchar15 Fields

Bit	Name	Description	Access	Reset
31	chena	Channel Enable (ChEna) When Scatter/Gather mode is enabled 1'b0: Indicates that the descriptor structure is not yet ready. 1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. When Scatter/Gather mode is disabled This field is set by the applica-tion and cleared by the OTG host. 1'b0: Channel disabled 1'b1: Channel enabled **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	chdis	Channel Disable (ChDis) The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer For that channel is complete. The application must wait For the Channel Disabled interrupt before treating the channel as disabled. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	oddfrm	Odd Frame (OddFrm) This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd (micro)frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame	RW	0x0
28:22	devaddr	Device Address (DevAddr) This field selects the specific device serving as the data source or sink.	RW	0x0

Bit	Name	Description	Access	Reset
21:20	ec	Multi Count (MC) / Error Count (EC) When the Split Enable bit of the Host Channel-n Split Control register (HCSPLTn.SpltEna) is reset (1'b0), this field indicates to the host the number of transactions that must be executed per microframe For this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched For this channel before the internal DMA engine changes arbitration. 2'b00: Reserved This field yields undefined results. 2'b01: 1 transaction 2'b10: 2 transactions to be issued For this endpoint per microframe 2'b11: 3 transactions to be issued For this endpoint per microframe When HCSPLTn.SpltEna is Set (1'b1), this field indicates the number of immediate retries to be performed For a periodic split transactions on transaction errors. This field must be Set to at least 2'b01. **Value** **Description** 0x0 RESERVED 0x1 TRANSONE 0x2 TRANSTWO 0x3 TRANSTHREE	RW	0x0

Bit	Name	Description	Access	Reset
19:18	eptype	Endpoint Type (EPType) Indicates the transfer type selected. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CTRL 0x1 — ISOC 0x2 — BULK 0x3 — INTERR	RW	0x0
17	lspddev	Low-Speed Device (LSpdDev) This field is Set by the application to indicate that this channel is communicating to a low-speed device. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
15	epdir	Endpoint Direction (EPDir) Indicates whether the transaction is IN or OUT. 1'b0: OUT 1'b1: IN **Value** — **Description** 0x0 — OUT 0x1 — IN	RW	0x0

Bit	Name	Description	Access	Reset
14:11	epnum	Endpoint Number (EPNum) Indicates the endpoint number on the device serving as the data source or sink. Value — Description 0xa — ENDPT10 0xb — ENDPT11 0xc — ENDPT12 0xd — ENDPT13 0xe — ENDPT14 0xf — ENDPT15 0x0 — ENDPT0 0x1 — ENDPT1 0x2 — ENDPT2 0x3 — ENDPT3 0x4 — ENDPT4 0x5 — ENDPT5 0x6 — ENDPT6 0x7 — ENDPT7 0x8 — ENDPT8 0x9 — ENDPT9	RW	0x0
10:0	mps	Maximum Packet Size (MPS) Indicates the maximum packet size of the associated endpoint.	RW	0x0

hcint15 Fields

Bit	Name	Description	Access	Reset
13	desc_lst_rollintr	Descriptor rollover interrupt (DESC_LST_ROLLIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel's descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	xcs_xact_err	Excessive Transaction Error (XCS_XACT_ERR) This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACVTIVE	RW	0x0
11	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the Core to process. BNA will not be generated for Isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
10	datatglerr	Data Toggle Error (DataTglErr).This bit can be set only by the core and the application should write 1 to clear it.In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	frmovrun	Frame Overrun (FrmOvrun).In Scatter/ Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
8	bblerr	Babble Error (BblErr) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core..This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	xacterr	Transaction Error (XactErr) Indicates one of the following errors occurred on the USB. CRC check failure Timeout Bit stuff error False EOP In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the applica- tion should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	nyet	NYET Response Received Interrupt (NYET) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	ack	ACK Response Received/Transmitted Interrupt (ACK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	nak	NAK Response Received Interrupt (NAK) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	stall	STALL Response Received Interrupt (STALL) In Scatter/Gather DMA mode, the interrupt due to this bit is masked in the core.This bit can be set only by the core and the application should write 1 to clear it. **Value** / **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) This is generated only in Internal DMA mode when there is an AHB error during AHB read/write. The application can read the corresponding channel's DMA address register to get the error address. **Value** / **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	chhltd	Channel Halted (ChHltd) In non Scatter/Gather DMA mode, it indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application or because of a completed transfer. in Scatter/gather DMA mode, this indicates that transfer completed due to any of the following . EOL being set in descriptor . AHB error . Excessive transaction errors . Babble . Stall **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
0	xfercompl	Transfer Completed (XferCompl) Transfer completed normally without any errors.This bit can be set only by the core and the application should write 1 to clear it. For Scatter/Gather DMA mode, it indicates that current descriptor processing got completed with IOC bit set in its descriptor. In non Scatter/Gather DMA mode, it indicates that Transfer completed normally without any errors. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dcfg Fields

Bit	Name	Description	Access	Reset
31:26	resvalid	Resume Validation Period (ResValid) This field is effective only when DCFG.Ena32KHzSusp is set. It will control the resume period when the core resumes from suspend. The core counts for “ResValid” number of clock cycles to detect a valid resume when this is set	RW	0x2

Bit	Name	Description	Access	Reset
25:24	perschintvl	Periodic Scheduling Interval (PerSchIntvl) PerSchIntvl must be programmed only For Scatter/Gather DMA mode. Description: This field specifies the amount of time the Internal DMA engine must allocate For fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25,50 or 75% of (micro) frame. When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data . When no periodic endpoints are active, Then the internal DMA engine services non-periodic endpoints, ignoring this field. After the specified time within a (micro)frame, the DMA switches to fetching For non-periodic endpoints. 2'b00: 25% of (micro)frame. 2'b01: 50% of (micro)frame. 2'b10: 75% of (micro)frame. 2'b11: Reserved. Reset: 2'b00 **Value** **Description** 0x0 MF25 0x1 MF50 0x2 MF75 0x3 RESERVED	RW	0x0

Bit	Name	Description	Access	Reset
23	descdma	Enable Scatter/gather DMA in device mode (DescDMA). When the Scatter/Gather DMA option selected during configuration of the RTL, the application can Set this bit during initialization to enable the Scatter/Gather DMA operation. NOTE: This bit must be modified only once after a reset. The following combinations are available For programming: GAHBCFG.DMAEn=0,DCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0,DCFG.DescDMA=1 => Invalid GAHBCFG.DMAEn=1,DCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1,DCFG.DescDMA=1 => Scatter/Gather DMA mode **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15	erraticintmsk	Erratic Error Interrupt Mask 1'b1: Mask early suspend interrupt on erratic error 1'b0: Early suspend interrupt is generated on erratic error	RW	0x0
14	xcvrdly	1'b1: Enable delay between xcvr_sel and txvalid during Device chirp 1'b0: No delay between xcvr_sel and txvalid during Device chirp	RW	0x0

Bit	Name	Description	Access	Reset
13	endevoutnak	Enable Device OUT NAK (EnDevOutNak) This bit enables setting NAK for Bulk OUT endpoints after the transfer is completed for Device mode Descriptor DMA 1'b0 : The core does not set NAK after Bulk OUT transfer complete 1'b1 : The core sets NAK after Bulk OUT transfer complete It is one time programmable after reset like any other DCFG register bits. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
12:11	perfrint	Periodic Frame Interval (PerFrInt) Indicates the time within a (micro) frame at which the application must be notified using the End Of Periodic Frame Interrupt. This can be used to determine If all the isochronous traffic For that (micro)frame is complete. 2'b00: 80% of the (micro)frame interval 2'b01: 85% 2'b10: 90% 2'b11: 95% **Value** **Description** 0x0 EOPF80 0x1 EOPF85 0x2 EOPF90 0x3 EOPF95	RW	0x0
10:4	devaddr	Device Address (DevAddr) The application must program this field after every SetAddress control command.	RW	0x0

Bit	Name	Description	Access	Reset
3	ena32khzsusp	Enable 32 KHz Suspend mode (Ena32KHzSusp) This bit can be set only if FS PHY interface is selected. Else, this bit needs to be set to zero. When FS PHY interface is chosen and this bit is set, the core expects that the PHY clock during Suspend is switched from 48 MHz to 32 KHz. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
2	nzstsouthshk	Non-Zero-Length Status OUT Handshake (NZStsOUTHShk) The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage. 1'b1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application. 1'b0: Send the received OUT packet to the application (zerolength or nonzero-length) and send a handshake based on the NAK and STALL bits For the endpoint in the Device Endpoint Control register. **Value** **Description** 0x0 SENDOUT 0x1 SENDSTALL	RW	0x0

Bit	Name	Description	Access	Reset
1:0	devspd	Device Speed (DevSpd) Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected. See “Device Initialization” . 2'b00: High speed (USB 2.0 PHY clock is 30 MHz or 60 MHz) 2'b01: Full speed (USB 2.0 PHY clock is 30 MHz or 60 MHz) 2'b10: Low speed (USB 1.1 transceiver clock is 6 MHz). If you select 6 MHz LS mode, you must do a soft reset. 2'b11: Full speed (USB 1.1 transceiver clock is 48 MHz) **Value** — **Description** 0x0 — USBHS20 0x1 — USBFS20 0x2 — USBLS116 0x3 — USBLS1148	RW	0x0

dctl Fields

Bit	Name	Description	Access	Reset
17	encontonbna	Enable Continue on BNA (EnContOnBNA) This bit enables the DWC_otg core to continue on BNA for Bulk OUT endpoints. With this feature enabled, when a Bulk OUT endpoint receives a BNA interrupt the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. 1'b0: After receiving BNA interrupt,the core disables the endpoint. When the endpoint is re-enabled by the application,the core starts processing from the DOEPDMA descriptor. 1'b1: After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the descriptor that received the BNA interrupt. This bit is valid only when OTG_EN_DESC_DMA == 1'b1. It is a one-time programmable after reset bit like any other DCTL register bits.	RW	0x0
16	nakonbble	NAK on Babble Error (NakOnBble) Set NAK automatically on babble (NakOnBble). The core sets NAK automatically for the endpoint on which babble is received. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
15	ignrfrmnum	Ignore Frame number For Isochronous End points (IgnrFrmNum) Do NOT program IgnrFrmNum bit to 1'b1 when the core is operating in threshold mode. Note: When Scatter/Gather DMA mode is enabled this feature is not applicable to High Speed, High bandwidth transfers. When this bit is enabled, there must be only one packet per descriptor. 0: The core transmits the packets only in the frame number in which they are intended to be transmitted. 1: The core ignores the frame number, sending packets immediately as the packets are ready. In Scatter/Gather DMA mode, if this bit is enabled, the packets are not flushed when a ISOC IN token is received for an elapsed frame. When Scatter/Gather DMA mode is disabled, this field is used by the application to enable periodic transfer interrupt. The application can program periodic endpoint transfers for multiple (micro) frames. 0: periodic transfer interrupt feature is disabled, application needs to program transfers for periodic endpoints every (micro) frame 1: periodic transfer interrupt feature is enabled, application can program transfers for multiple (micro)frames for periodic endpoints. In non Scatter/Gather DMA mode the application will receive transfer complete interrupt after transfers for multiple (micro)frames are completed. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
14:13	gmc	Global Multi Count (GMC) GMC must be programmed only once after initialization. Applicable only For Scatter/Gather DMA mode. This indicates the number of packets to be serviced For that end point before moving to the next end point. It is only For non-periodic end points. 2'b00: Invalid. 2'b01: 1 packet. 2'b10: 2 packets. 2'b11: 3 packets. When Scatter/Gather DMA mode is disabled, this field is reserved. and reads 2'b00. **Value** **Description** 0x0 NOTVALID 0x1 ONEPACKET 0x2 TWOPACKET 0x3 THREEPACKET	RW	0x0
11	pwronprgdone	Power-On Programming Done (PWROnPrg-Done) The application uses this bit to indicate that register programming is completed after a wake-up from Power Down mode. **Value** **Description** 0x0 NOTDONE 0x1 DONE	RW	0x0
10	cgoutnak	Clear Global OUT NAK (CGOUTNak) A write to this field clears the Global OUT NAK. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
9	sgoutnak	Set Global OUT NAK (SGOUTNak) A write to this field sets the Global OUT NAK. The application uses this bit to send a NAK handshake on all OUT endpoints. The application must Set the this bit only after making sure that the Global OUT NAK Effective bit in the Core Interrupt Register (GINTSTS.GOUTNakEff) is cleared. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	WO	0x0
8	cgnpinnak	Clear Global Non-periodic IN NAK (CGNPInNak) A write to this field clears the Global Non-periodic IN NAK. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	WO	0x0

Bit	Name	Description	Access	Reset
7	sgnpinnak	Set Global Non-periodic IN NAK (SGNPInNak) A write to this field sets the Global Non-periodic IN NAK.The application uses this bit to send a NAK handshake on all nonperiodic IN endpoints. The core can also Set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must Set this bit only after making sure that the Global IN NAK Effective bit in the Core Interrupt Register (GINTSTS.GINNakEff) is cleared **Value** **Description** 0x0 DISABLED 0x1 ENABLED	WO	0x0
6:4	tstctl	Test Control (TstCtl) 3'b000: Test mode disabled 3'b001: Test_J mode 3'b010: Test_K mode 3'b011: Test_SE0_NAK mode 3'b100: Test_Packet mode 3'b101: Test_Force_Enable Others: Reserved **Value** **Description** 0x0 DISABLED 0x1 TESTJ 0x2 TESTK 0x3 TESTSN 0x4 TESTPM 0x5 TESTFE	RW	0x0

Bit	Name	Description	Access	Reset
3	goutnaksts	Global OUT NAK Status (GOUTNakSts) 1'b0: A handshake is sent based on the FIFO Status and the NAK and STALL bit settings. 1'b1: No data is written to the RxFIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
2	gnpinnaksts	Global Non-periodic IN NAK Status (GNPINNakSts) 1'b0: A handshake is sent out based on the data availability in the transmit FIFO. 1'b1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
1	sftdiscon	Soft Disconnect (SftDiscon) The application uses this bit to signal the DWC_otg core to do a soft disconnect. As long as this bit is Set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. The minimum duration For which the core must keep this bit Set is specified in Table 5-46. 1'b0: Normal operation. When this bit is cleared after a soft disconnect, the core drives the phy_opmode_o signal on the UTMI+ to 2'b00, which generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration. 1'b1: The core drives the phy_opmode_o signal on the UTMI+ to 2'b01, which generates a device disconnect event to the USB host. Note: This bit can be also used for ULPI/FS Serial interfaces. Note: This bit is not impacted by a soft reset. **Value** **Description** 0x0 NODISCONNECT 0x1 DISCONNECT	RW	0x1

Bit	Name	Description	Access	Reset
0	rmtwkupsig	Remote Wakeup Signaling (RmtWkUpSig) When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must Set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1-15 ms after setting it. Remote Wakeup Signaling (RmtWkUpSig) When LPM is enabled, In L1 state the behavior of this bit is as follows: When the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the Sleep state. As specified in the LPM specification, the hardware will automatically clear this bit after a time of 50 micro sec (TL1DevDrvResume) after set by application. Application should not set this bit when GLPMCFG bRemoteWake from the previous LPM transaction was zero. **Value** **Description** 0x0 NOEXIT 0x1 EXIT	RW	0x0

dsts Fields

Bit	Name	Description	Access	Reset
23:22	devlnsts	Device Line Status (DevLnSts) Indicates the current logic level USB data lines DevLnSts[1]: Logic level of D+ DevLnSts[0]: Logic level of D-	RO	0x0
21:8	soffn	Frame or Microframe Number of the Received SOF (SOFFN) When the core is operating at high speed, this field contains a microframe number. When the core is operating at full or low speed, this field contains a Frame number. Note: This register may return a non zero value if read immediately after power on reset. In case the register bit reads non zero immediately after power on reset it does not indicate that SOF has been received from the host. The read value of this interrupt is valid only after a valid connection between host and device is established.	RO	0x0

Bit	Name	Description	Access	Reset
3	errticerr	Erratic Error (ErrticErr) The core sets this bit to report any erratic errors (phy_rxvalid_i/phy_rxvldh_i or phy_rxactive_i is asserted For at least 2 ms, due to PHY error) seen on the UTMI+ . Due to erratic errors, the DWC_otg core goes into Suspended state and an interrupt is generated to the application with Early Suspend bit of the Core Interrupt register (GINTSTS.ErlySusp). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
2:1	enumspd	Enumerated Speed (EnumSpd) Indicates the speed at which the DWC_otg core has come up after speed detection through a chirp sequence. 2'b00: High speed (PHY clock is running at 30 or 60 MHz) 2'b01: Full speed (PHY clock is running at 30 or 60 MHz) 2'b10: Low speed (PHY clock is running at 6 MHz) 2'b11: Full speed (PHY clock is running at 48 MHz) Low speed is not supported For devices using a UTMI+ PHY. **Value** **Description** 0x0 HS3060 0x1 FS3060 0x2 LS6 0x3 FS48	RO	0x1

Bit	Name	Description	Access	Reset
0	suspsts	Suspend Status (SuspSts) In Device mode, this bit is Set as long as a Suspend condition is detected on the USB. The core enters the Suspended state when there is no activity on the phy_line_state_i signal For an extended period of time. The core comes out of the suspend: When there is any activity on the phy_line_state_i signal When the application writes to the Remote Wakeup Signaling bit in the Device Control register (DCTL.RmtWkUpSig). **Value** / **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Reserved			ahbthrratio RW 0x0		txthrlen RW 0x8									isothren RW 0x0	nonisothren RW 0x0

dthrctl Fields

Bit	Name	Description	Access	Reset
27	arbprken	Arbiter Parking Enable (ArbPrkEn) This bit controls internal DMA arbiter parking For IN endpoints. When thresholding is enabled and this bit is Set to one, Then the arbiter parks on the IN endpoint For which there is a token received on the USB. This is done to avoid getting into underrun conditions. By Default the parking is enabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x1
25:17	rxthrlen	Receive Threshold Length (RxThrLen) This field specifies Receive thresholding size in DWORDS. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight DWORDS. The recommended value For ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	RW	0x8

Bit	Name	Description	Access	Reset
16	rxthren	Receive Threshold Enable (RxThrEn) When this bit is Set, the core enables thresholding in the receive direction. Note: We recommends that you do not enable RxThrEn, because it may cause issues in the RxFIFO especially during error conditions such as RxError and Babble. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
12:11	ahbthrratio	AHB Threshold Ratio (AHBThrRatio) These bits define the ratio between the AHB threshold and the MAC threshold for the transmit path only. The AHB threshold always remains less than or equal to the USB threshold, because this does not increase overhead. Both the AHB and the MAC threshold must be DWORD-aligned. The application needs to program TxThrLen and the AHBThrRatio to make the AHB Threshold value DWORD aligned. If the AHB threshold value is not DWORD aligned, the core might not behave correctly. When programming the TxThrLen and AHBThrRatio, the application must ensure that the minimum AHB threshold value does not go below 8 DWORDS to meet the USB turnaround time requirements. 2'b00: AHB threshold = MAC threshold 2'b01: AHB threshold = MAC threshold / 2 2'b10: AHB threshold = MAC threshold / 4 2'b11: AHB threshold = MAC threshold / 8 **Value** **Description** 0x0 THRESZERO 0x1 THRESONE 0x2 THRESTWO 0x3 THRESTHREE	RW	0x0

Bit	Name	Description	Access	Reset
10:2	txthrlen	Transmit Threshold Length (TxThrLen) This field specifies Transmit thresholding size in DWORDS. This also forms the MAC threshold and specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmit on the USB. The threshold length has to be at least eight DWORDS when the value of AHBThrRatio is 2'h00. In case the AHBThrRatio is non zero the application needs to ensure that the AHB Threshold value does not go below the recommended eight DWORD. This field controls both isochronous and non-isochronous IN endpoint thresholds. The recommended value for ThrLen is to be the same as the programmed AHB Burst Length (GAHBCFG.HBstLen).	RW	0x8
1	isothren	ISO IN Endpoints Threshold Enable. (ISOThrEn) When this bit is Set, the core enables thresholding For isochronous IN endpoints. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
0	nonisothren	Non-ISO IN Endpoints Threshold Enable. (NonISOThrEn) When this bit is Set, the core enables thresholding For Non Isochronous IN endpoints. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

diepctl0 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. When Scatter/Gather DMA mode is disabled such as in buffer pointer based DMA mode this bit indicates that data is ready to be transmitted on the endpoint. The core clears this bit before setting the following interrupts on this endpoint: Endpoint Disabled Transfer Completed **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
30	epdis	Endpoint Disable (EPDis) The application sets this bit to stop transmitting data on an endpoint, even before the transfer For that endpoint is complete. The applica-tion must wait For the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled Interrupt. The application must Set this bit only If Endpoint Enable is already Set For this endpoint. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** **Description** 0x0 NOSET 0x1 SET	WO	0x0
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** **Description** 0x0 NOCLEAR 0x1 CLEAR	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) For Shared FIFO operation, this value is always Set to 0, indicating that control IN endpoint 0 data is always written in the Non-Periodic Transmit FIFO. For Dedicated FIFO operation, this value is Set to the FIFO number that is assigned to IN Endpoint 0.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) The application can only Set this bit, and the core clears it, when a SETUP token is received For this endpoint. If a NAK bit, Global Nonperiodic IN NAK, or Global OUT NAK is Set along with this bit, the STALL bit takes priority. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) Hardcoded to 00 For control. **Value** **Description** 0x0 ACTIVE	RO	0x0
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status 1'b1: The core is transmitting NAK handshakes on this endpoint. When this bit is Set, either by the application or core, the core stops transmitting data, even If there is data available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) This bit is always SET to 1, indicating that control endpoint 0 is always active in all configurations and interfaces. **Value** **Description** 0x1 ACTIVE0	RO	0x1
1:0	mps	Maximum Packet Size (MPS) Applies to IN and OUT endpoints. The application must program this field with the maximum packet size For the current logical endpoint. 2'b00: 64 bytes 2'b01: 32 bytes 2'b10: 16 bytes 2'b11: 8 bytes **Value** **Description** 0x0 BYTES64 0x1 BYTES32 0x2 BYTES16 0x3 BYTES8	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only The core generates this interrupt when it detects a transmit FIFO underrun condition in threshold mode For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz0

Device IN Endpoint 0 Transfer Size Register

Module Instance	Base Address	Register Address

Reserved									xfersize RW 0x0						

dieptsiz0 Fields

Bit	Name	Description	Access	Reset
20:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. In Endpoints : This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO. OUT Endpoints: This field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.	RW	0x0

Bit	Name	Description	Access	Reset
6:0	xfersize	Transfer Size (XferSize) This field contains the transfer size in bytes for the current endpoint. The transfer size (XferSize) = Sum of buffer sizes across all descriptors in the list for the endpoint. In Buffer DMA, the core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. IN Endpoints: The core decrements this field every time a packet from the external memory is written to the TxFIFO. OUT Endpoints: The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	RW	0x0

diepdma0 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma0	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl1 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint1 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	RW	0x0

diepdma1 RW 0x0															

diepdma1 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma1	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl2 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint2 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz2

Device IN Endpoint 2 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00950
i_usbotg_1_devgrp	0xFFB40800	0xFFB40950

Offset: 0x150

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dieptsiz2 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint3

diepint3 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz3

Device IN Endpoint 3 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00970

dieptsiz3 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma3	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl4 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint4 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz4

Device IN Endpoint 4 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00990
i_usbotg_1_devgrp	0xFFB40800	0xFFB40990

Offset: 0x190

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dieptsiz4 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma4

Device IN Endpoint 4 DMA Address Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00994

diepdma4 RW 0x0															

diepdma4 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma4	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts4

Device IN Endpoint Transmit FIFO Status Register 4

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00998

diepctl5 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma5

diepctl6 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value: Description** 0x0: DISABLED 0x1: ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint6 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint7

Device IN Endpoint 7 Interrupt Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB009E8
i_usbotg_1_devgrp	0xFFB40800	0xFFB409E8

Offset: 0x1E8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

diepint7 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz7

Device IN Endpoint 7 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB009F0
i_usbotg_1_devgrp	0xFFB40800	0xFFB409F0

Offset: 0x1F0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

dieptsiz7 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma7 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma7	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint8 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz8

Device IN Endpoint 8 Transfer Size Register

xfersize RW 0x0															

dieptsiz8 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 PACKETONE 0x2 PACKETTWO 0x3 PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma8

Device IN Endpoint 8 DMA Address Register

Module Instance	Base Address	Register Address

diepdma8 RW 0x0															

diepdma8 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma8	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts8

Device IN Endpoint Transmit FIFO Status Register 8

Module Instance	Base Address	Register Address

usbactep RW 0x0	Reserved				mps RW 0x0										

diepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value: Description** 0x0: DISABLED 0x1: ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint9 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz9

dieptsiz9 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma9

diepctl10 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint10 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

diepctl11 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint11 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

dieptsiz11

Device IN Endpoint 11 Transfer Size Register

Module Instance	Base Address	Register Address

dieptsiz11 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 PACKETONE 0x2 PACKETTWO 0x3 PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepctl12 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint12 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	RW	0x0

dieptsiz12

Device IN Endpoint 12 Transfer Size Register

Module Instance	Base Address	Register Address

dieptsiz12 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 PACKETONE 0x2 PACKETTWO 0x3 PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma12

diepdma12 RW 0x0															

diepdma12 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma12	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl13 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 NONNAK 0x1 NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz13

Device IN Endpoint 13 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00AB0
i_usbotg_1_devgrp	0xFFB40800	0xFFB40AB0

dieptsiz13 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** — **Description** 0x1 — PACKETONE 0x2 — PACKETTWO 0x3 — PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

diepdma13 RW 0x0															

diepdma13 Fields

Bit	Name	Description	Access	Reset
31:0	diepdma13	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

dtxfsts13

diepctl14 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint14 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. Value: 0x0 — INACTIVE; 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
31:0	diepdma14	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

diepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE; 0x1 — ACTIVE	WO	0x0
25:22	txfnum	TxFIFO Number (TxFNum) Shared FIFO Operation non-periodic endpoints must set this bit to zero. Periodic endpoints must map this to the corresponding Periodic TxFIFO number. 4'h0: Non-Periodic TxFIFO Others: Specified Periodic TxFIFO.number Note: An interrupt IN endpoint can be configured as a non-periodic endpoint for applications such as mass storage. The core treats an IN endpoint as a non-periodic endpoint if the TxFNum field is set to 0. Otherwise, a separate periodic FIFO must be allocated for an interrupt IN endpoint, and the number of this FIFO must be programmed into the TxFNum field. Configuring an interrupt IN endpoint as a non-periodic endpoint saves the extra periodic FIFO area. Dedicated FIFO Operationthese bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.	RW	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value: Description** 0x0: CONTROL 0x1: ISOCHRONOUS 0x2: BULK 0x3: INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

diepint15 Fields

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
8	txfifoundrn	Fifo Underrun (TxfifoUndrn) Applies to IN endpoints Only This bit is valid only If thresholding is enabled. The core generates this interrupt when it detects a transmit FIFO underrun condition For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
7	txfemp	Transmit FIFO Empty (TxFEmp) This bit is valid only For IN Endpoints This interrupt is asserted when the TxFIFO For this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO Empty Level bit in the Core AHB Configuration register (GAHBCFG.NPTxFEmpLvl)). **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
6	inepnakeff	IN Endpoint NAK Effective (INEPNakEff) Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLn.CNAK. This interrupt indicates that the core has sampled the NAK bit Set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit Set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	intknepmis	IN Token Received with EP Mismatch (INTknEPMis) Applies to non-periodic IN endpoints only. Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one For which the IN token was received. This interrupt is asserted on the endpoint For which the IN token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	intkntxfemp	IN Token Received When TxFIFO is Empty (INTknTXFEmp) Applies to non-periodic IN endpoints only. Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint For which the IN token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	timeout	Timeout Condition (TimeOUT) In shared TX FIFO mode, applies to non-isochronous IN endpoints only. In dedicated FIFO mode, applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB For the last IN token on this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

dieptsiz15

dieptsiz15 Fields

Bit	Name	Description	Access	Reset
30:29	mc	Applies to IN endpoints only. For periodic IN endpoints, this field indicates the number of packets that must be transmitted per microframe on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets For non-periodic IN endpoints, this field is valid only in Internal DMA mode. It specifies the number of packets the core must fetchfor an IN endpoint before it switches to the endpoint pointed to by the Next Endpoint field of the Device Endpoint-n Control register (DIEPCTLn.NextEp) **Value** **Description** 0x1 PACKETONE 0x2 PACKETTWO 0x3 PACKETTHREE	RW	0x0

Bit	Name	Description	Access	Reset
28:19	pktcnt	Packet Count (PktCnt) Indicates the total number of USB packets that constitute the Transfer Size amount of data For endpoint 0. This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet from the external memory is written to the TxFIFO.	RW	0x0

doepctl0 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) When Scatter/Gather DMA mode is enabled, For OUT endpoints this bit indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is disabled(such as For buffer-pointer based DMA mode)this bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: In DMA mode, this bit must be Set For the core to transfer SETUP data packets into memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) The application cannot disable control OUT endpoint 0. **Value** / **Description** 0x0 — INACTIVE	RO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. **Value** / **Description** 0x0 — NOSET 0x1 — SET	WO	0x0
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** / **Description** 0x0 — NOCLEAR 0x1 — CLEAR	WO	0x0

Bit	Name	Description	Access	Reset
21	stall	STALL Handshake (Stall) The application can only Set this bit, and the core clears it, when a SETUP token is received For this endpoint. If a NAK bit or Global OUT NAK is Set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
20	snp	Snoop Mode (Snp) This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correct-ness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
19:18	eptype	Endpoint Type (EPType) Hardcoded to 2'b00 For control. **Value** **Description** 0x0 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit, the core stops receiving data, even If there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
15	usbactep	USB Active Endpoint (USBActEP) This bit is always Set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces. **Value** **Description** 0x1 ACTIVE	RO	0x1

Bit	Name	Description	Access	Reset
1:0	mps	Maximum Packet Size (MPS) The maximum packet size For control OUT endpoint 0 is the same as what is programmed in control IN Endpoint 0. 2'b00: 64 bytes 2'b01: 32 bytes 2'b10: 16 bytes 2'b11: 8 bytes **Value** / **Description** 0x0 BYTE64 0x1 BYTE32 0x2 BYTE16 0x3 BYTE8	RO	0x0

doepint0 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1'b0	RW	0x0
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the applica-tion that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/ Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

doepctl1 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — Description: INACTIVE Value: 0x1 — Description: ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only. This is the data PID received in the last packet for this endpoint. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA SETUP Packet Count (SUPCnt) Applies to control OUT Endpoints only. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets **Value** **Description** 0x0 DATA0 0x1 DATA2PACKET1 0x2 DATA1PACKET2 0x3 MDATAPACKET3	RO	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is decremented to zero after a packet is written into the RxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	RW	0x0

doepdma1

Device OUT Endpoint 1 DMA Address Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00B34

doepdma1 RW 0x0															

doepdma1 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma1	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl2 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value: Description** 0x0: DISABLED 0x1: ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — DISABLE 0x1 — ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint2 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doepctl3 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — DISABLE 0x1 — ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint3 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz3

doepdma3 RW 0x0															

doepdma3 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma3	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab3

Device OUT Endpoint 3 Buffer Address Register

doepctl4 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint4 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz4

doepctl5 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint5 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint6 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz6

doepctl7 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value: Description** 0x0: DISABLED 0x1: ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value: Description** 0x0: INACTIVE 0x1: ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz7

Device OUT Endpoint 7 Transfer Size Register

doepctl8 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint8 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doepctl9 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — DISABLE 0x1 — ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint9 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The application has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz9

Device OUT Endpoint 9 Transfer Size Register

Module Instance	Base Address	Register Address
i_usbotg_0_devgrp	0xFFB00800	0xFFB00C30

doeptsiz9 Fields

Bit	Name	Description	Access	Reset
30:29	rxdpid	Applies to isochronous OUT endpoints only. This is the data PID received in the last packet for this endpoint. 2'b00: DATA0 2'b01: DATA2 2'b10: DATA1 2'b11: MDATA SETUP Packet Count (SUPCnt) Applies to control OUT Endpoints only. This field specifies the number of back-to-back SETUP data packets the endpoint can receive. 2'b01: 1 packet 2'b10: 2 packets 2'b11: 3 packets **Value** **Description** 0x0 DATA0 0x1 DATA2PACKET1 0x2 DATA1PACKET2 0x3 MDATAPACKET3	RO	0x0
28:19	pktcnt	Packet Count (PktCnt) This field is decremented to zero after a packet is written into the RxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	RW	0x0

doepdma9

doepdma9 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma9	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepdmab9

Device OUT Endpoint 9 Buffer Address Register

doepctl10 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — DISABLE 0x1 — ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint10 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doepdma10 RW 0x0															

doepdma10 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma10	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl11 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: Description 0x0: INACTIVE 0x1: ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: Description 0x0: INACTIVE 0x1: ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint11 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

28:19	pktcnt	Packet Count (PktCnt) This field is decremented to zero after a packet is written into the RxFIFO.	RW	0x0
18:0	xfersize	Transfer Size (XferSize) Indicates the transfer size in bytes For endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be Set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.	RW	0x0

doepdma11 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma11	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl12 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint12 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doepctl13 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint13 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doepdma13 Fields

Bit	Name	Description	Access	Reset
31:0	doepdma13	Holds the start address of the external memory for storing or fetching endpoint data. Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. When Scatter/Gather DMA mode is not enabled, the application programs the start address value in this field. When Scatter/Gather DMA mode is enabled, this field indicates the base pointer for the descriptor list.	RW	0x0

doepctl14 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. Value: 0x0 — INACTIVE Value: 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** — **Description** 0x0 — DISABLE 0x1 — ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** — **Description** 0x0 — CONTROL 0x1 — ISOCHRONOUS 0x2 — BULK 0x3 — INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the applica-tion must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint14 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

doeptsiz14

doepctl15 Fields

Bit	Name	Description	Access	Reset
31	epena	Endpoint Enable (EPEna) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabledsuch as for buffer-pointer based DMA mode: - For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. - For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. - The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done Endpoint Disabled Transfer Completed Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
30	epdis	Endpoint Disable (EPDis) Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
29	setd1pid	Set DATA1 PID (SetD1PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. Set Odd (micro)frame (SetOddFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to odd (micro)frame. This field is not applicable for Scatter/Gather DMA mode. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
28	setd0pid	Set DATA0 PID (SetD0PID) Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 WO In non-Scatter/Gather DMA mode: Set Even (micro)frame (SetEvenFr) Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd (micro)frame (EO_FrNum) field to even (micro) frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	WO	0x0
27	snak	Set NAK (SNAK) A write to this bit sets the NAK bit For the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also Set this bit For an endpoint after a SETUP packet is received on that endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	WO	0x0

Bit	Name	Description	Access	Reset
26	cnak	Clear NAK (CNAK) A write to this bit clears the NAK bit For the endpoint. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	WO	0x0
21	stall	STALL Handshake (Stall) Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. 1'b0 R_W Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** / **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
20	snp	Snoop Mode (Snp) Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0
19:18	eptype	Endpoint Type (EPType) This is the transfer type supported by this logical endpoint. 2'b00: Control 2'b01: Isochronous 2'b10: Bulk 2'b11: Interrupt **Value** **Description** 0x0 CONTROL 0x1 ISOCHRONOUS 0x2 BULK 0x3 INTERRUP	RW	0x0

Bit	Name	Description	Access	Reset
17	naksts	NAK Status (NAKSts) Indicates the following: 1'b0: The core is transmitting non-NAK handshakes based on the FIFO status. 1'b1: The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. **Value** — **Description** 0x0 — NONNAK 0x1 — NAK	RO	0x0

Bit	Name	Description	Access	Reset
16	dpid	Endpoint Data PID (DPID) Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 1'b0: DATA0 1'b1: DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. 1'b0 RO Even/Odd (Micro)Frame (EO_FrNum) In non-Scatter/Gather DMA mode: Applies to isochronous IN and OUT endpoints only. Indicates the (micro)frame number in which the core transmits/ receives isochronous data for this endpoint. The application must program the even/odd (micro) frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register. 1'b0: Even (micro)frame 1'b1: Odd (micro)frame When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
15	usbactep	USB Active Endpoint (USBActEP) Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
10:0	mps	Maximum Packet Size (MPS) The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.	RW	0x0

doepint15 Fields

Bit	Name	Description	Access	Reset
15	stuppktrcvd	Setup Packet Received Applicable for Control OUT Endpoints in only in the Buffer DMA Mode Set by the DWC_otg core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one Setup packet per buffer. On receiving a Setup packet, the DWC_otg core closes the buffer and disables the corresponding endpoint. The applica-tion has to re-enable the endpoint to receive any OUT data for the Control Transfer and reprogram the buffer start address. Note: Because of the above behavior, the DWC_otg core can receive any number of back to back setup packets and one buffer for every setup packet is used. 1'b0: No Setup packet received 1'b1: Setup packet received Reset: 1’b0	RW	0x0

Bit	Name	Description	Access	Reset
14	nyetintrpt	NYET Interrupt (NYETIntrpt) The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
13	nakintrpt	NAK Interrupt (NAKInterrupt) The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to un-availability of data in the TXFifo. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
12	bbleerr	NAK Interrupt (BbleErr) The core generates this interrupt when babble is received for the endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
11	pktdrpsts	Packet Drop Status (PktDrpSts) This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. Dependency: This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
9	bnaintr	BNA (Buffer Not Available) Interrupt (BNAIntr) This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready For the Core to process, such as Host busy or DMA done **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
8	outpkterr	OUT Packet Error (OutPktErr) Applies to OUT endpoints Only This interrupt is valid only when thresholding is enabled. This interrupt is asserted when the core detects an overflow or a CRC error For non-Isochronous OUT packet. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
6	back2backsetup	Back-to-Back SETUP Packets Received (Back2BackSETup) Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets For this particular endpoint. For information about handling this interrupt, **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
5	stsphsercvd	Status Phase Received For Control Write (StsPhseRcvd) This interrupt is valid only For Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in Case of Scatter Gather DMA mode. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
4	outtknepdis	OUT Token Received When Endpoint Disabled (OUTTknEPdis) Applies only to control OUT endpoints. Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint For which the OUT token was received. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
3	setup	SETUP Phase Done (SetUp) Applies to control OUT endpoints only. Indicates that the SETUP phase For the control endpoint is complete and no more back-to-back SETUP packets were received For the current control transfer. On this interrupt, the application can decode the received SETUP data packet. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0
2	ahberr	AHB Error (AHBErr) Applies to IN and OUT endpoints. This is generated only in Internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	epdisbld	Endpoint Disabled Interrupt (EPDisbld) Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0
0	xfercompl	Transfer Completed Interrupt (XferCompl) Applies to IN and OUT endpoints. When Scatter/Gather DMA mode is enabled - For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. - For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit For the corresponding descriptor is Set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, For this endpoint. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RW	0x0

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								l1suspended RO 0x0	physleep RO 0x0	Reserved		rstpdwnmodule RW 0x0	Reserved		stoppclk RW 0x0

pcgcctl Fields

Bit	Name	Description	Access	Reset
7	l1suspended	L1 Deep Sleep Indicates that the PHY is in deep sleep when in L1 state. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0
6	physleep	PHY In Sleep Indicates that the PHY is in Sleep State. **Value** — **Description** 0x0 — INACTIVE 0x1 — ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
3	rstpdwnmodule	Reset Power-Down Modules (RstPdwnModule) This bit is valid only in Partial Power-Down mode. The application sets this bit when the power is turned off. The application clears this bit after the power is turned on and the PHY clock is up.Note: The R/W of all core registers are possible only when this bit is set to 1b0. **Value** — **Description** 0x0 — ON 0x1 — OFF	RW	0x0
0	stoppclk	Stop Pclk (StopPclk) The application sets this bit to stop the PHY clock (phy_clk) when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

SPI Controller 19

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two serial peripheral interface (SPI) masters and two SPI slaves. The SPI masters and slaves are instances of the Synopsys® DesignWare® Synchronous Serial Interface (SSI) controller (DW_apb_ssi). †[52]

Features of the SPI Controller

The SPI controller has the following features: †

- Serial master and serial slave controllers – Enable serial communication with serial-master or serial-slave peripheral devices. †
- Each SPI master has a maximum bit rate of 60Mbps
- Each SPI slave has a maximum bit rate of 50Mbps
- Serial interface operation – Programmable choice of the following protocols:
  - Motorola SPI protocol
  - Texas Instruments Synchronous Serial Protocol
  - National Semiconductor Microwire
- DMA controller interface integrated with HPS DMA controller
- SPI master supports received serial data bit (RXD) sample delay
- Transmit and receive FIFO buffers are 256 words deep
- SPI master supports up to four slave selects
- Programmable master serial bit rate
- Programmable data item size of 4 to 16 bits
- Support for Multi-master mode

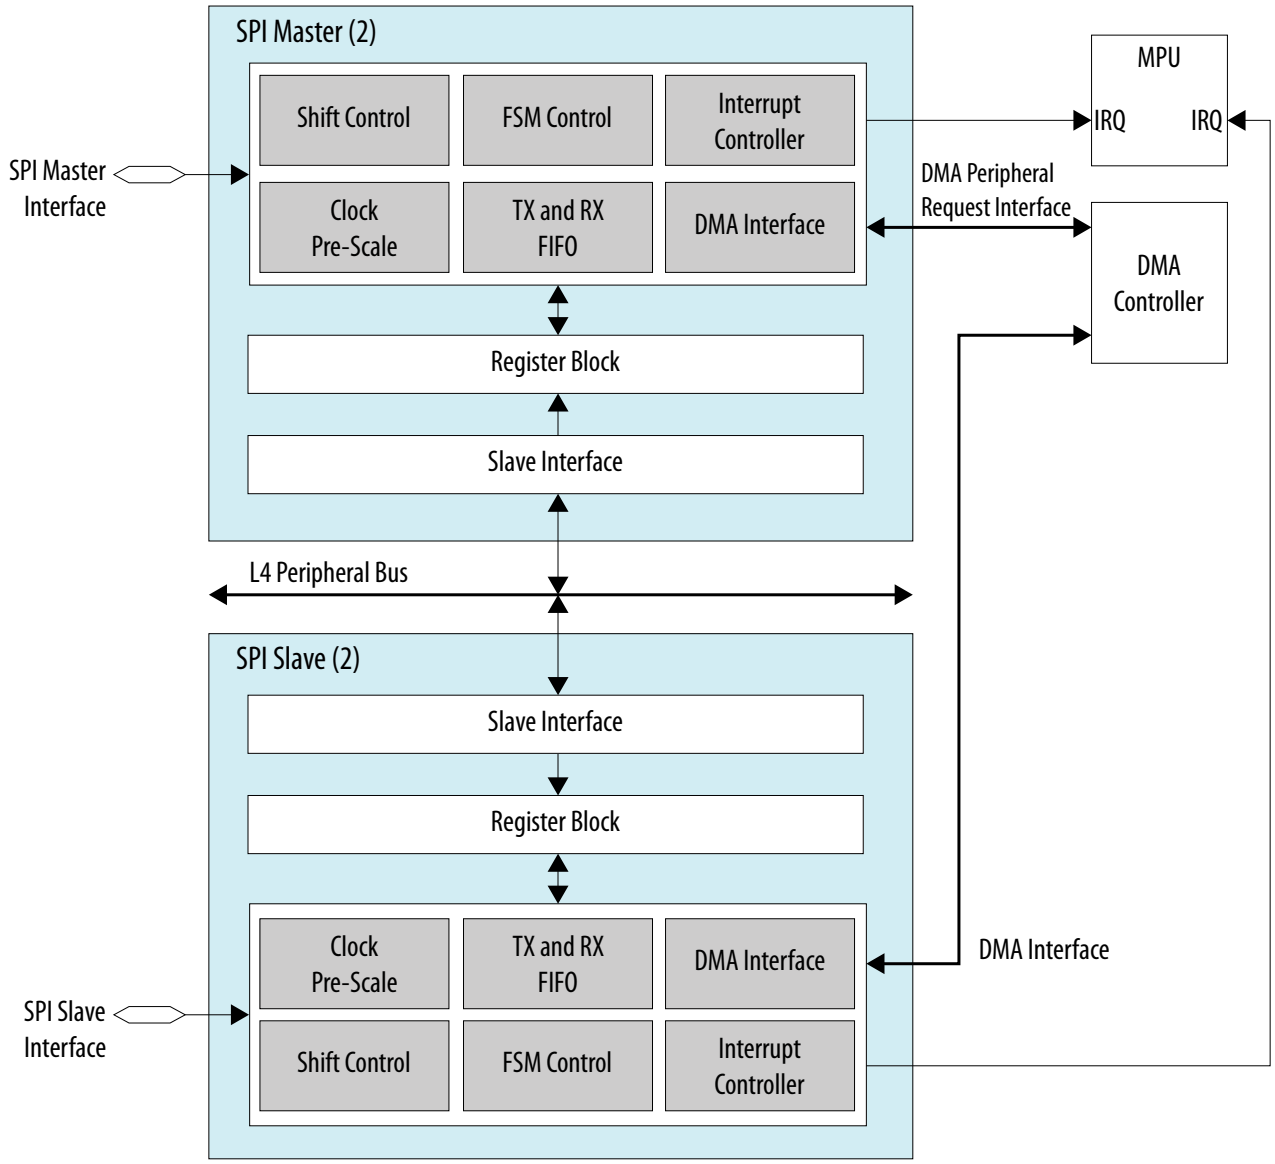
SPI Block Diagram and System Integration

The SPI supports data bus widths of 32 bits. †

SPI Block Diagram

Figure 19-1: SPI Block Diagram



The functional groupings of the main interfaces to the SPI block are as follows: †

- System bus interface
- DMA peripheral request interface
- Interrupt interface
- SPI interface

SPI Controller Signal Description

Signals from the two SPI masters and two SPI slaves can be routed to the FPGA or the HPS I/O pins. The following sections describe the signals available.

Interface to HPS I/O

Two sets of SPI Master and two sets of SPI Slave Pins are available to the HPS I/O. The pin names are shown below. For more information on routing SPI signals to HPS I/O, refer to the *HPS Component Interfaces* chapter.

Table 19-1: SPI Master Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	Out	Serial clock output from the SPI master
MOSI	1	Out	Transmit data line for the SPI master
MISO	1	In	Receive data line for the SPI master
SS0_N	1	Out	Slave Select 0: Slave select signal from SPI master
SS1_N	1	Out	Slave Select 1: Slave select signal from SPI master

Table 19-2: SPI Slave Interface Pins

Signal Name	Signal Width	Direction	Description
CLK	1	In	Serial clock input to the SPI slave
MOSI	1	In	Receive data line for the SPI slave
MISO	1	Out	Transmit data line for the SPI slave
SS0_N	1	In	Slave select input to the SPI slave

Related Information

Functional Description of the SPI Controller

Protocol Details and Standards Compliance

This section describes the functional operation of the SPI controller.

The host processor accesses data, control, and status information about the SPI controller through the system bus interface. The SPI also interfaces with the DMA Controller. †

The HPS includes two general-purpose SPI master controllers and two general-purpose SPI slave controllers.

The SPI controller can connect to any other SPI device using any of the following protocols:

- Motorola SPI Protocol †
- Texas Instruments Serial Protocol (SSP) †
- National Semiconductor Microwire Protocol †

SPI Controller Overview

In order for the SPI controller to connect to a serial-master or serial-slave peripheral device, the peripheral must have a least one of the following interfaces: †

- Motorola SPI protocol – A four-wire, full-duplex serial protocol from Motorola. The slave select line is held high when the SPI controller is idle or disabled. For more information, refer to "Motorola SPI Protocol". †
- Texas Instruments Serial Protocol (SSP) – A four-wire, full-duplex serial protocol. The slave select line used for SPI and Microwire protocols doubles as the frame indicator for the SSP protocol. For more information, refer to "Texas Instruments Synchronous Serial Protocol (SSP)". †
- National Semiconductor Microwire – A half-duplex serial protocol, which uses a control word transmitted from the serial master to the target serial slave. For more information, refer to "National Semiconductor Microwire Protocol". You can program the FRF (frame format) bit field in the Control Register 0 (`CTRLR0`) to select which protocol is used. †

The serial protocols supported by the SPI controller allow for serial slaves to be selected or addressed using hardware. Serial slaves are selected under the control of dedicated hardware select lines. The number of select lines generated from the serial master is equal to the number of serial slaves present on the bus. The serial-master device asserts the select line of the target serial slave before data transfer begins. This architecture is illustrated in part A of **Figure 19-2**. †

When implemented in software, the input select line for all serial slave devices should originate from a single slave select output on the serial master. In this mode it is assumed that the serial master has only a single slave select output. If there are multiple serial masters in the system, the slave select output from all masters can be logically ANDed to generate a single slave select input for all serial slave devices. †

The main program in the software domain controls selection of the target slave device; this architecture is illustrated in part B of the **Figure 19-2** figure below. Software would control which slave is to respond to the serial transfer request from the master device. †

Figure 19-2: Hardware/Software Slave Selection

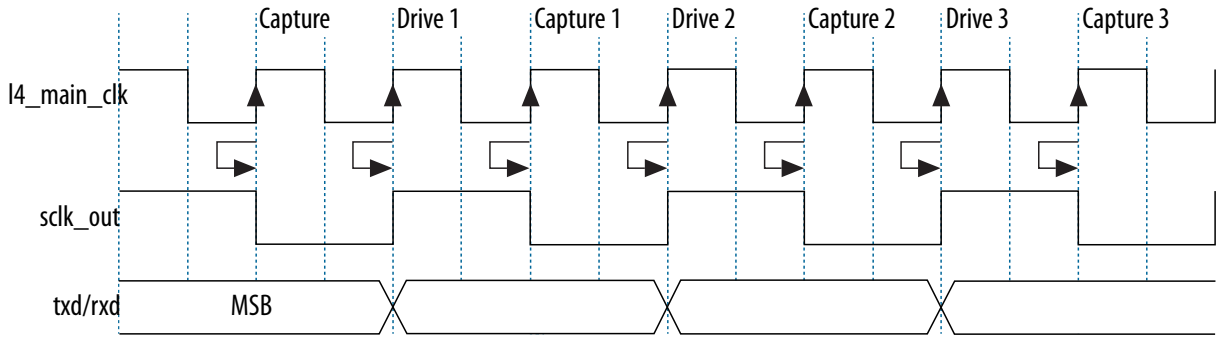
Serial Bit-Rate Clocks

SPI Master Bit-Rate Clock

The maximum frequency of the SPI master bit-rate clock (`sclk_out`) is one-half the frequency of SPI master clock (`l4_main_clk`). This allows the shift control logic to capture data on one clock edge of `sclk_out` and propagate data on the opposite edge. The `sclk_out` line toggles only when an active transfer is in progress. At all other times it is held in an inactive state, as defined by the serial protocol under which it operates. †

Figure 19-3: Maximum sclk_out/l4_main_clk Ratio



The frequency of `sclk_out` can be derived from the equation below, where <*SPI clock*> is `l4_main_clk` for both master and slave modules. †

Fsclk_out = F<*SPI clock*> / SCKDV

SCKDV is a bit field in the register BAUDR, holding any even value in the range 2 to 65,534. If SCKDV is 0, then sclk_out is disabled. †

The following equation describes the frequency ratio restrictions between the bit-rate clock sclk_out and the SPI master peripheral clock. The SPI master peripheral clock must be at least double the offchip master clock. †

Table 19-5: SPI Master Peripheral Clock

SPI Master Peripheral Clock
Fl4_main_clk >= 2 x (maximum $_{Fsclk\_out}$) †

SPI Slave Bit-Rate Clock

The minimum frequency of l4_main_clk depends on the operation of the slave peripheral. If the slave device is *receive only*, the minimum frequency of l4_main_clk is six times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). The sclk_in signal is double synchronized to the l4_main_clk domain, and then it is edge detected; this synchronization requires three l4_main_clk periods. †

If the slave device is *transmit and receive*, the minimum frequency of l4_main_clk is eight times the maximum expected frequency of the bit-rate clock from the master device (sclk_in). This ensures that data on the master rxd line is stable before the master shift control logic captures the data. †

The frequency ratio restrictions between the bit-rate clock sclk_in and the SPI slave peripheral clock are as follows: †

- Slave (receive only): $F_{l4\_main\_clk}$ >= 6 multiply (maximum $_{Fsclk\_in}$) †
- Slave: $F_{l4\_main\_clk}$ >= 8 multiply (maximum F_{sclk_in}) †

Transmit and Receive FIFO Buffers

There are two 16-bit FIFO buffers, a transmit FIFO buffer and a receive FIFO buffer, with a depth of 256. Data frames that are less than 16 bits in size must be right-justified when written into the transmit FIFO buffer. The shift control logic automatically right-justifies receive data in the receive FIFO buffer. †

Each data entry in the FIFO buffers contains a single data frame. It is impossible to store multiple data frames in a single FIFO buffer location; for example, you may not store two 8-bit data frames in a single FIFO buffer location. If an 8-bit data frame is required, the upper 8-bits of the FIFO buffer entry are ignored or unused when the serial shifter transmits the data. †

The transmit and receive FIFO buffers are cleared when the SPI controller is disabled (SSIENR=0) or reset.

The transmit FIFO buffer is loaded by write commands to the SPI data register (DR). Data are popped (removed) from the transmit FIFO buffer by the shift control logic into the transmit shift register. The transmit FIFO buffer generates a transmit FIFO empty interrupt request when the number of entries in the FIFO buffer is less than or equal to the FIFO buffer threshold value. The threshold value, set through the register TXFTLR, determines the level of FIFO buffer entries at which an interrupt is generated. The threshold value allows you to provide early indication to the processor that the transmit FIFO buffer is nearly empty. A Transmit FIFO Overflow Interrupt is generated if you attempt to write data into an already full transmit FIFO buffer. †

Data are popped from the receive FIFO buffer by read commands to the SPI data register (DR). The receive FIFO buffer is loaded from the receive shift register by the shift control logic. The receive FIFO buffer generates a receive FIFO full interrupt request when the number of entries in the FIFO buffer is greater than or equal to the FIFO buffer threshold value plus one. The threshold value, set through register RXFTLR, determines the level of FIFO buffer entries at which an interrupt is generated. †

The threshold value allows you to provide early indication to the processor that the receive FIFO buffer is nearly full. A Receive FIFO Overrun Interrupt is generated when the receive shift logic attempts to load data into a completely full receive FIFO buffer. However, the newly received data are lost. A Receive FIFO Underflow Interrupt is generated if you attempt to read from an empty receive FIFO buffer. This alerts the processor that the read data are invalid. †

For more information, refer to the*Reset Manager* chapter.

SPI Interrupts

The SPI controller supports combined interrupt requests, which can be masked. The combined interrupt request is the ORed result of all other SPI interrupts after masking. All SPI interrupts have active-high polarity level. The SPI interrupts are described as follows: †

- Transmit FIFO Empty Interrupt – Set when the transmit FIFO buffer is equal to or below its threshold value and requires service to prevent an underrun. The threshold value, set through a software-programmable register, determines the level of transmit FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are written into the transmit FIFO buffer, bringing it over the threshold level. †
- Transmit FIFO Overflow Interrupt – Set when a master attempts to write data into the transmit FIFO buffer after it has been completely filled. When set, new data writes are discarded. This interrupt remains set until you read the transmit FIFO overflow interrupt clear register (TXOICR). †
- Receive FIFO Full Interrupt – Set when the receive FIFO buffer is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through a software-programmable register, determines the level of receive FIFO buffer entries at which an interrupt is generated. This interrupt is cleared by hardware when data are read from the receive FIFO buffer, bringing it below the threshold level. †
- Receive FIFO Overflow Interrupt – Set when the receive logic attempts to place data into the receive FIFO buffer after it has been completely filled. When set, newly received data are discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (RXOICR). †
- Receive FIFO Underflow Interrupt – Set when a system bus access attempts to read from the receive FIFO buffer when it is empty. When set, zeros are read back from the receive FIFO buffer. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (RXUICR). †
- Combined Interrupt Request – ORed result of all the above interrupt requests after masking. To mask this interrupt signal, you must mask all other SPI interrupt requests. †

Transmit FIFO Overflow, Transmit FIFO Empty, Receive FIFO Full, Receive FIFO Underflow, and Receive FIFO Overflow interrupts can all be masked independently, using the Interrupt Mask Register (IMR). †

Transfer Modes

When transferring data on the serial bus, the SPI controller operates one of several modes. The transfer mode (TMOD) is set by writing to the TMOD field in control register 0 (CTRLR0).

Note: The transfer mode setting does not affect the duplex of the serial transfer. TMOD is ignored for Microwire transfers, which are controlled by the MWCR register. †

Transmit and Receive

When TMOD = 0, both transmit and receive logic are valid. The data transfer occurs as normal according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. †

Transmit Only

When TMOD = 1, any receive data are ignored. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO buffer and sent through the `txd` line to the target device, which replies with data on the `rxd` line. At the end of the data frame, the receive shift register does not load its newly received data into the receive FIFO buffer. The data in the receive shift register is overwritten by the next transfer. You should mask interrupts originating from the receive logic when this mode is entered. †

Receive Only

When TMOD = 2, the transmit data are invalid. In the case of the SPI slave, the transmit FIFO buffer is never popped in Receive Only mode. The `txd` output remains at a constant logic level during the transmission. The data transfer occurs as normal according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO buffer at the end of each data frame. You should mask interrupts originating from the transmit logic when this mode is entered. †

EEPROM Read

Note: This transfer mode is only valid for serial masters. †

When TMOD = 3, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. This takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the SPI master is transmitting data on its `txd` line, data on the `rxd` line is ignored). The SPI master continues to transmit data until the transmit FIFO buffer is empty. You should ONLY have enough data frames in the transmit FIFO buffer to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO buffer than are needed, then Read data is lost. †

When the transmit FIFO buffer becomes empty (all control information has been sent), data on the receive line (`rxd`) is valid and is stored in the receive FIFO buffer; the `txd` output is held at a constant logic level. The serial transfer continues until the number of data frames received by the SPI master matches the value of the NDF field in the `CTRLR1` register plus one. †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

SPI Master

The SPI master initiates and controls all serial transfers with serial-slave peripheral devices. †

The serial bit-rate clock, generated and controlled by the SPI controller, is driven out on the `sclk_out` line. When the SPI controller is disabled, no serial transfers can occur and `sclk_out` is held in "inactive" state, as defined by the serial protocol under which it operates. †

Related Information

SPI Block Diagram on page 19-2

RXD Sample Delay

The SPI master device is capable of delaying the default sample time of the `rxd` signal in order to increase the maximum achievable frequency on the serial bus.

Round trip routing delays on the `sclk_out` signal from the master and the `rxd` signal from the slave can mean that the timing of the `rxd` signal, as seen by the master, has moved away from the normal sampling time.

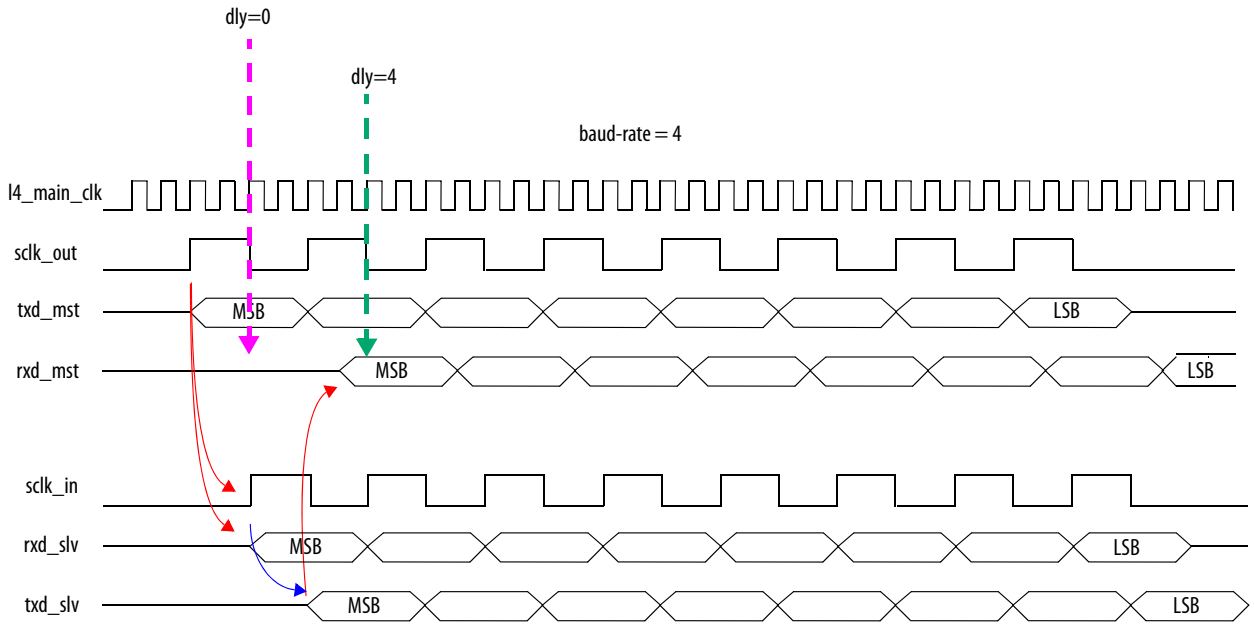
Without the RXD sample delay, you must increase the baud rate for the transfer in order to ensure that the setup times on the `rxd` signal are within range. This reduces the frequency of the serial interface.

Additional logic is included in the SPI master to delay the default sample time of the `rxd` signal. This additional logic can help to increase the maximum achievable frequency on the serial bus. †

By writing to the `rsd` field of the RXD sample delay register (`rx_sample_dly`), you specify an additional amount of delay applied to the `rxd` sample. The delay is in number of `l4_main_clk` clock cycles, with 64 maximum cycles allowed (zero is reserved). If the `rsd` field is programmed with a value exceeding 64, a zero delay is applied to the `rxd` sample.

The sample delay logic has a resolution of one `l4_main_clk` cycle. Software can "train" the serial bus by coding a loop that continually reads from the slave and increments the master's RXD sample delay value until the correct data is received by the master. †

Figure 19-4: Effects of Round Trip Routing Delays on sclk_out Signal



Red arrows indicates routing delay between master and slave devices
Blue arrow indicates sampling delay within slave from receiving slk_in to driving txd out

Data Transfers

The SPI master starts data transfers when all the following conditions are met:

- The SPI master is enabled
- There is at least one valid entry in the transmit FIFO buffer
- A slave device is selected

When actively transferring data, the busy flag (BUSY) in the status register (SR) is set. You must wait until the busy flag is cleared before attempting a new serial transfer. †

Note: The BUSY status is not set when the data are written into the transmit FIFO buffer. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO buffer, the shift logic does not begin the serial transfer until a positive edge of the sclk_out signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the BUSY status, you should first poll the Transit FIFO Empty (TFE) status (waiting for 1) or wait for (BAUDR * SPI clock) clock cycles. †

Master SPI and SSP Serial Transfers

"Motorola SPI Protocol" and "Texas Instruments Synchronous Serial Protocol (SSP)" describe the SPI and SSP serial protocols, respectively. †

When the transfer mode is "transmit and receive" or "transmit only" (TMOD = 0 or TMOD = 1, respectively), transfers are terminated by the shift control logic when the transmit FIFO buffer is empty. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor indicating that the transmit FIFO buffer is nearly empty. †

When the DMA is used in conjunction with the SPI master, the transmit data level (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. The user may also write a block of data (at least two FIFO buffer entries) into the transmit FIFO buffer before enabling a serial slave. This ensures that serial transmission does not begin until the number of data frames that make up the continuous transfer are present in the transmit FIFO buffer. †

When the transfer mode is "receive only" (TMOD = 2), a serial transfer is started by writing one "dummy" data word into the transmit FIFO buffer when a serial slave is selected. The txd output from the SPI controller is held at a constant logic level for the duration of the serial transfer. The transmit FIFO buffer is popped only once at the beginning and may remain empty for the duration of the serial transfer. The end of the serial transfer is controlled by the "number of data frames" (NDF) field in control register 1 (CTRLR1). †

If, for example, you want to receive 24 data frames from a serial-slave peripheral, you should program the NDF field with the value 23; the receive logic terminates the serial transfer when the number of frames received is equal to the NDF value plus one. This transfer mode increases the bandwidth of the system bus as the transmit FIFO buffer never needs to be serviced during the transfer. The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. †

When the transfer mode is "eeprom_read" (TMOD = 3), a serial transfer is started by writing the opcode and/or address into the transmit FIFO buffer when a serial slave (EEPROM) is selected. The opcode and address are transmitted to the EEPROM device, after which read data is received from the EEPROM device and stored in the receive FIFO buffer. The end of the serial transfer is controlled by the NDF field in the control register 1 (CTRLR1). †

Note: EEPROM read mode is not supported when the SPI controller is configured to be in the SSP mode. †

The receive FIFO threshold level (RXF TLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA is used, the receive data level (DMARDLR) can be used to early request the DMA Controller, indicating that the receive FIFO buffer is nearly full. †

Master Microwire Serial Transfers

"National Semiconductor Microwire Protocol" describes the Microwire serial protocol in detail. †

Microwire serial transfers from the SPI serial master are controlled by the Microwire Control Register (MWCR). The MHS bit field enables and disables the Microwire handshaking interface. The MDD bit field controls the direction of the data frame (the control frame is always transmitted by the master and received by the slave). The MWMOD bit field defines whether the transfer is sequential or nonsequential. †

All Microwire transfers are started by the SPI serial master when there is at least one control word in the transmit FIFO buffer and a slave is enabled. When the SPI master transmits the data frame (MDD =1), the transfer is terminated by the shift logic when the transmit FIFO buffer is empty. When the SPI master receives the data frame (MDD = 1), the termination of the transfer depends on the setting of the MWMOD bit field. If the transfer is nonsequential (MWMOD = 0), it is terminated when the transmit FIFO buffer is empty after shifting in the data frame from the slave. When the transfer is sequential (MWMOD = 1), it is terminated by the shift logic when the number of data frames received is equal to the value in the CTRLR1 register plus one. †

When the handshaking interface on the SPI master is enabled (MHS =1), the status of the target slave is polled after transmission. Only when the slave reports a *ready status* does the SPI master complete the transfer and clear its BUSY status. If the transfer is continuous, the next control/data frame is not sent until the slave device returns a *ready status*. †

SPI Slave

The SPI slave handles serial communication with transfer initiated and controlled by serial master peripheral devices.

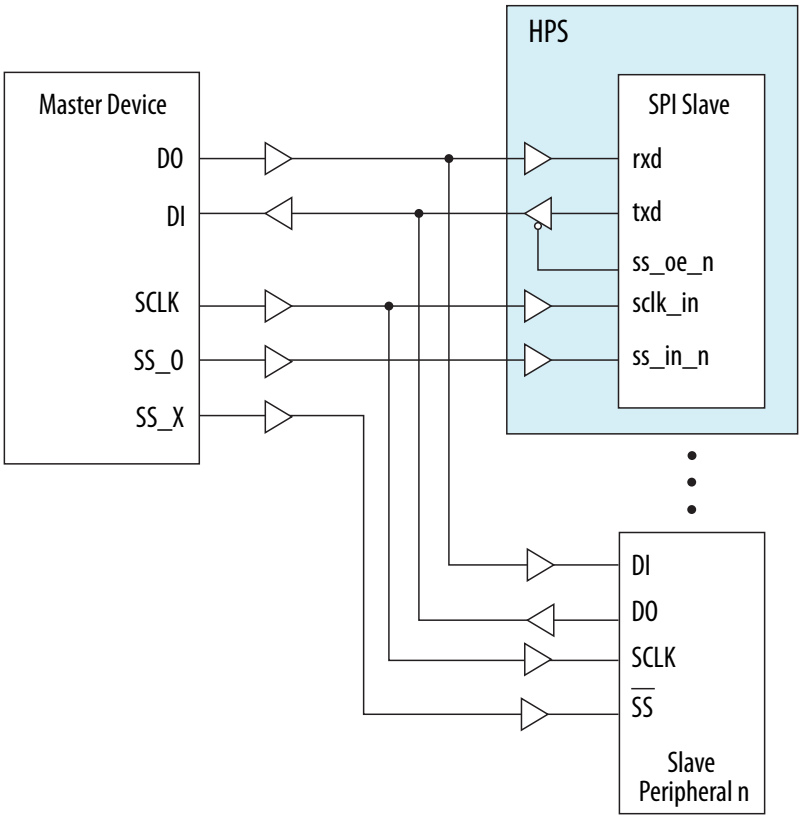
- sclk_in—serial clock to the SPI slave †
- ss_in_n—slave select input to the SPI slave †
- ss_oe_n—output enable for the SPI master or slave †
- txd—transmit data line for the SPI master or slave †
- rxd—receive data line for the SPI master or slave †

When the SPI serial slave is selected, it enables its txd data onto the serial bus. All data transfers to and from the serial slave are regulated on the serial clock line (sclk_in), driven from the SPI master device. Data are propagated from the serial slave on one edge of the serial clock line and sampled on the opposite edge. †

When the SPI serial slave is not selected, it must not interfere with data transfers between the serial-master and other serial-slave devices. When the serial slave is not selected, its txd output is buffered, resulting in a high impedance drive onto the SPI master rxd line. The buffers shown in the **Figure 19-5** figure are external to the SPI controller. spi_oe_n is the SPI slave output enable signal. †

The serial clock that regulates the data transfer is generated by the serial-master device and input to the SPI slave on `sclk_in`. The slave remains in an idle state until selected by the bus master. When not actively transmitting data, the slave must hold its `txd` line in a high impedance state to avoid interference with serial transfers to other slave devices. The SPI slave output enable (`ss_oe_n`) signal is available for use to control the `txd` output buffer. The slave continues to transfer data to and from the master device as long as it is selected. If the master transmits to all serial slaves, a control bit (`SLV_OE`) in the SPI control register 0 (`CTRLR0`) can be programmed to inform the slave if it should respond with data from its `txd` line. †

Figure 19-5: SPI Slave



The `slv_oe` bit in the control register is only valid if the SPI slave interface is routed to the FPGA. To use the SPI slave in a multi master system or in a system that requires the SPI slave TXD to be tri-stated, you can do the following:

- If you want the SPI slave to control the tri-state of TXD, it must be routed to the FPGA first and use the FPGA IO. HPS I/O can also be used via the Loan I/O interface (timing permitting).
- If you do not want to route to the FPGA, then software control of the TXD (tri-state) must be performed with the already included code to control via an HPS GPIO input. Please refer to the pin connection guidelines to find which GPIO pins correspond to which HPS SPI slave SS ports.

Slave SPI and SSP Serial Transfers

"Motorola SPI Protocol" and the "Texas Instruments Synchronous Serial Protocol (SSP)" contain a description of the SPI and SSP serial protocols, respectively. †

If the SPI slave is *receive only* (TMOD=2), the transmit FIFO buffer need not contain valid data because the data currently in the transmit shift register is resent each time the slave device is selected. The TXE

error flag in the status register (SR) is not set when TMOD=2. You should mask the Transmit FIFO Empty Interrupt when this mode is used. †

If the SPI slave transmits data to the master, you must ensure that data exists in the transmit FIFO buffer before a transfer is initiated by the serial-master device. If the master initiates a transfer to the SPI slave when no data exists in the transmit FIFO buffer, an error flag (TXE) is set in the SPI status register, and the previously transmitted data frame is resent on txd. For continuous data transfers, you must ensure that the transmit FIFO buffer does not become empty before all the data have been transmitted. The transmit FIFO threshold level register (TXFTLR) can be used to early interrupt (Transmit FIFO Empty Interrupt) the processor, indicating that the transmit FIFO buffer is nearly empty. When a DMA Controller is used, the DMA transmit data level register (DMATDLR) can be used to early request the DMA Controller, indicating that the transmit FIFO buffer is nearly empty. The FIFO buffer can then be refilled with data to continue the serial transfer. †

The receive FIFO buffer should be read each time the receive FIFO buffer generates a FIFO full interrupt request to prevent an overflow. The receive FIFO threshold level register (RXFTLR) can be used to give early indication that the receive FIFO buffer is nearly full. When a DMA Controller is used, the DMA receive data level register (DMARDLR) can be used to early request the DMA controller, indicating that the receive FIFO buffer is nearly full. †

Serial Transfers

"National Semiconductor Microwire Protocol" describes the Microwire serial protocol in detail, including timing diagrams and information about how data are structured in the transmit and receive FIFO buffers before and after a serial transfer. The Microwire protocol operates in much the same way as the SPI protocol. There is no decode of the control frame by the SPI slave device. †

Related Information

National Semiconductor Microwire Protocol on page 19-19

Glue Logic for Master Port ss_in_n

When configured as a master, the SPI has an input, `ssi_in_n`, which can be used by the deciding logic in a multi-master system to disable one master when another has priority. The polarity of this signal depends on the serial protocol in use, and the protocol is dynamically selectable.

The table below lists the three protocols and the effect of `ss_in_n` on the ability of the master to transfer data. Note that for the SSP protocol the effect of `ss_in_n` is inverted with respect to the other protocols.

Protocol	ss_in_n value	Effect on Serial Transfer
Motorola SPI	1	Enabled
	0	Disabled
National Semiconductor Microwire	1	Enabled
	0	Disabled
Texas Instruments Serial Protocol (SSP)	1	Disabled
	0	Enabled

Figure 19-6: Arbitration Between Multiple Serial Masters

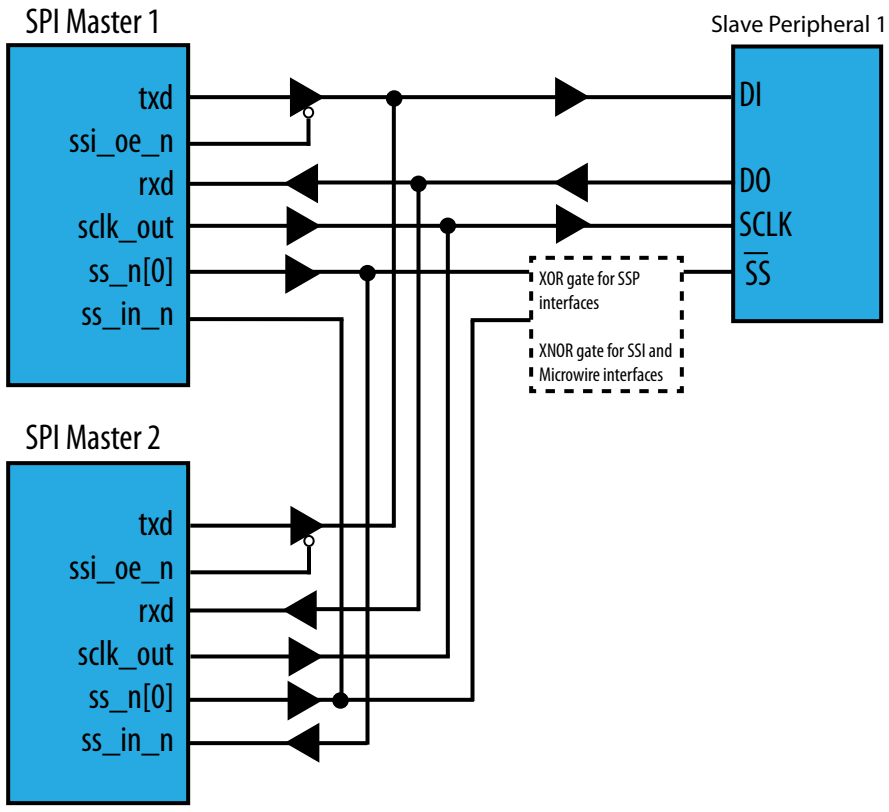

Figure 19-7: SPI Configured as Master Device

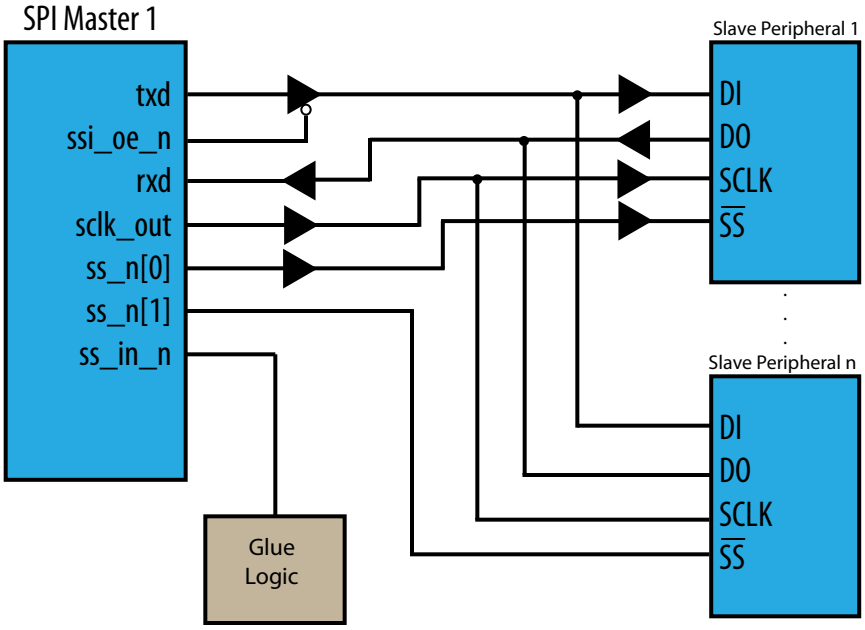


Partner Connection Interfaces

The SPI can connect to any serial-master or serial-slave peripheral device using one of several interfaces.

Motorola SPI Protocol

With SPI, the clock polarity (SCPOL) configuration parameter determines whether the inactive state of the serial clock is high or low. The data frame can be 4 to 16 bits in length. †

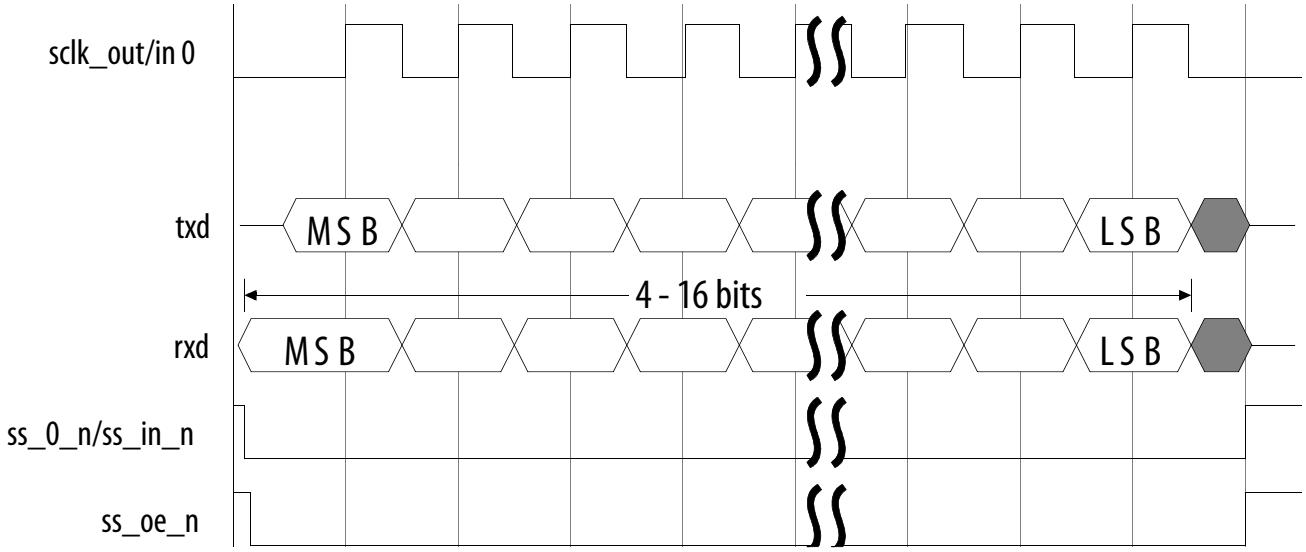
When the configuration parameter (SCPH = 0), data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the `txd` and `rxd` lines prior to the first serial clock edge. †

The slave select signal takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

The following signals are illustrated in the timing diagrams in this section: †

- sclk_out—serial clock from SPI master †
- sclk_in—serial clock from SPI slave †
- ss_0_n—slave select signal from SPI master †
- ss_oe_n—output enable for the SPI master or slave †
- txd—transmit data line for the SPI master or slave †
- rxd—receive data line for the SPI master or slave †

Figure 19-8: SPI Serial Format (SCPH = 0)



There are four possible transfer modes on the SPI controller for performing SPI serial transactions; refer to "Transfer Modes" . For *transmit and receive transfers* (transfer mode field (9:8) of the Control Register 0 = 0), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

Note: For *transmit only* transfers (transfer mode field (9:8) of the Control Register 0 = 1), data transmitted from the SPI controller to the external serial device is written into the transmit FIFO buffer. As the data received from the external serial device is deemed invalid, it is not stored in the SPI receive FIFO buffer. †

For *receive only* transfers (transfer mode field (9:8) of the Control Register 0 = 2), data transmitted from the SPI controller to the external serial device is invalid, so a single dummy word is written into the transmit FIFO buffer to begin the serial transfer. The txd output from the SPI controller is held at a constant logic level for the duration of the serial transfer. Data received from the external serial device into the SPI controller is pushed into the receive FIFO buffer. †

For EEPROM read transfers (transfer mode field [9:8] of the Control Register 0 = 3), opcode and/or EEPROM address are written into the transmit FIFO buffer. During transmission of these control frames, received data is not captured by the SPI master. After the control frames have been transmitted, receive data from the EEPROM is stored in the receive FIFO buffer.

SPI Serial Format

Two different modes of continuous data transfers are supported when SCPH = 0 and 1.†

- When clock phase SCPH = 0, the SPI Controller deasserts the slave select signal between each data word and the serial clock is held to its default value while the slave select signal is deasserted.†
- When SCPH = 1, the slave select is held asserted (active low) for the duration of the transfer.†

Figure 19-9: Serial Format Continuous Transfers (SCPH =0)

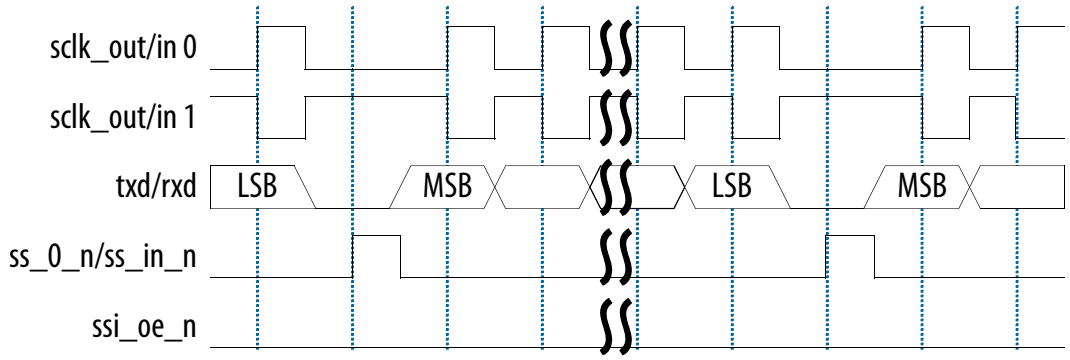


Figure 19-10: Serial Format Continuous Transfers (SCPH =1)

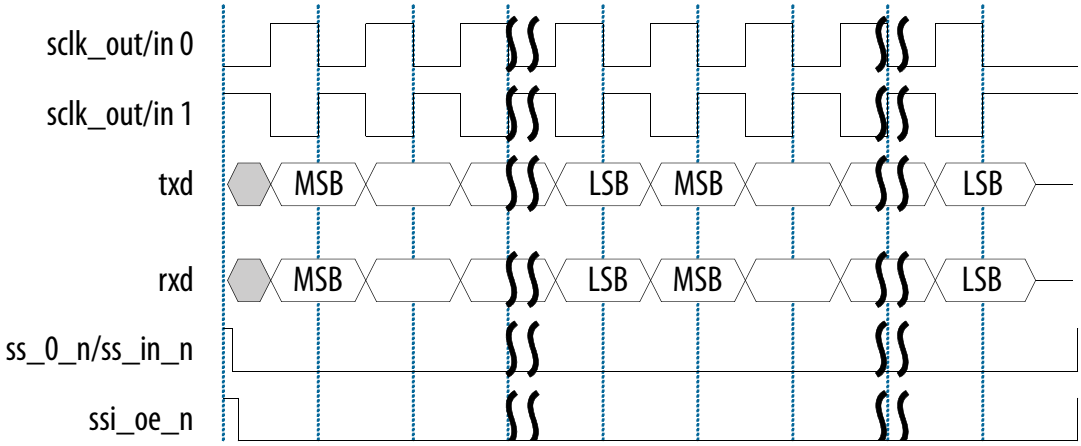


Related Information

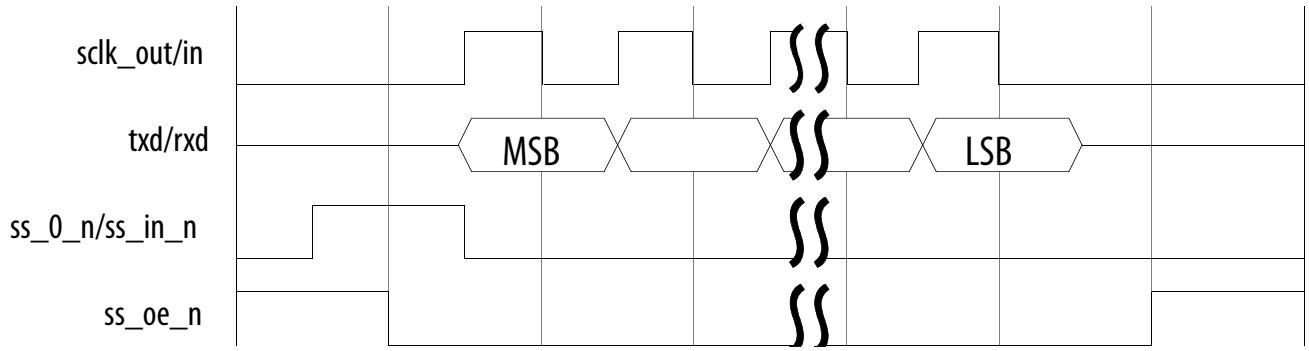
Transfer Modes on page 19-8

Texas Instruments Synchronous Serial Protocol (SSP)

Data transfers begin by asserting the frame indicator line (`ss_0_n`) for one serial clock period. Data to be transmitted are driven onto the `txd` line one serial clock cycle later; similarly data from the slave are driven onto the `rxd` line. Data are propagated on the rising edge of the serial clock (`sclk_out/sclk_in`) and captured on the falling edge. The length of the data frame ranges from 4 to 16 bits.

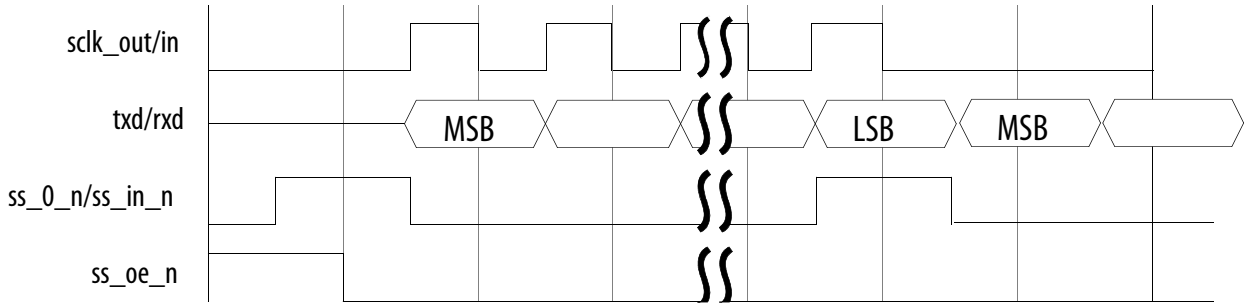
Note: The slave select signal (`ss_0_n`) takes effect only when used as slave SPI. For master SPI, the data transmission begins as soon as the output enable signal is deasserted.

Figure 19-11: SSP Serial Format



Continuous data frames are transferred in the same way as single data frames. The frame indicator is asserted for one clock period during the same cycle as the LSB from the current transfer, indicating that another data frame follows. †

Figure 19-12: SSP Serial Format Continuous Transfer



National Semiconductor Microwire Protocol

For the master SPI, data transmission begins as soon as the output enable signal is deasserted. One-half serial clock (`sclk_out`) period later, the first bit of the control is sent out on the `txd` line. The length of the control word can be in the range 1 to 16 bits and is set by writing bit field CFS (bits 15:12) in `CTRLR0`. The remainder of the control word is transmitted (propagated on the falling edge of `sclk_ou t`) by the SPI serial master. During this transmission, no data are present (high impedance) on the serial master's `rxd` line. †

The direction of the data word is controlled by the `MDD` bit field (bit 1) in the Microwire Control Register (`MWCR`). When `MDD`=0, this indicates that the SPI serial master receives data from the external serial slave. One clock cycle after the LSB of the control word is transmitted, the slave peripheral responds with a dummy 0 bit, followed by the data frame, which can be 4 to 16 bits in length. Data are propagated on the falling edge of the serial clock and captured on the rising edge. †

Continuous transfers from the Microwire protocol can be sequential or nonsequential, and are controlled by the `MWMOD` bit field (bit 0) in the `MWCR`. †

Nonsequential continuous transfers occur, with the control word for the next transfer following immediately after the LSB of the current data word. †

The only modification needed to perform a continuous nonsequential transfer is to write more control words into the transmit FIFO buffer. †

During sequential continuous transfers, only one control word is transmitted from the SPI master. The transfer is started in the same manner as with nonsequential read operations, but the cycle is continued to read further data. The slave device automatically increments its address pointer to the next location and continues to provide data from that location. Any number of locations can be read in this manner; the SPI master terminates the transfer when the number of words received is equal to the value in the CTRLR1 register plus one. †

When MDD = 1, this indicates that the SPI serial master transmits data to the external serial slave. Immediately after the LSB of the control word is transmitted, the SPI master begins transmitting the data frame to the slave peripheral. †

Note: The SPI controller does not support continuous sequential Microwire writes, where MDD = 1 and MWMOD = 1. †

Continuous transfers occur with the control word for the next transfer following immediately after the LSB of the current data word.

The Microwire handshaking interface can also be enabled for SPI master write operations to external serial-slave devices. To enable the handshaking interface, you must write 1 into the MHS bit field (bit 2) on the MWCR register. When MHS is set to 1, the SPI serial master checks for a ready status from the slave device before completing the transfer, or transmitting the next control word for continuous transfers. †

After the first data word has been transmitted to the serial-slave device, the SPI master polls the rxd input waiting for a ready status from the slave device. Upon reception of the ready status, the SPI master begins transmission of the next control word. After transmission of the last data frame has completed, the SPI master transmits a start bit to clear the ready status of the slave device before completing the transfer. †

In the SPI slave, data transmission begins with the falling edge of the slave select signal (ss_in_0). One-half serial clock (sclk_in) period later, the first bit of the control is present on the rxd line. The length of the control word can be in the range of 1 to 16 bits and is set by writing bit field CFS in the CTRLR0 register. The CFS bit field must be set to the size of the expected control word from the serial master. The remainder of the control word is received (captured on the rising edge of sclk_in) by the SPI serial slave. During this reception, no data are driven (high impedance) on the serial slave's txd line. †

The direction of the data word is controlled by the MDD bit field (bit 1) MWCR register. When MDD=0, this indicates that the SPI serial slave is to receive data from the external serial master. Immediately after the control word is transmitted, the serial master begins to drive the data frame onto the SPI slave rxd line. Data are propagated on the falling edge of the serial clock and captured on the rising edge. The slave-select signal is held active-low during the transfer and is deasserted one-half clock cycle later after the data are transferred. The SPI slave output enable signal is held inactive for the duration of the transfer. †

When MDD=1, this indicates that the SPI serial slave transmits data to the external serial master. Immediately after the LSB of the control word is transmitted, the SPI slave transmits a dummy 0 bit, followed by the 4- to 16-bit data frame on the txd line. †

Continuous transfers for a SPI slave occur in the same way as those specified for the SPI master. The SPI slave does not support the handshaking interface, as there is never a busy period. †

Figure 19-13: Single SPI Serial Master Microwire Serial Transfer (MDD=0)

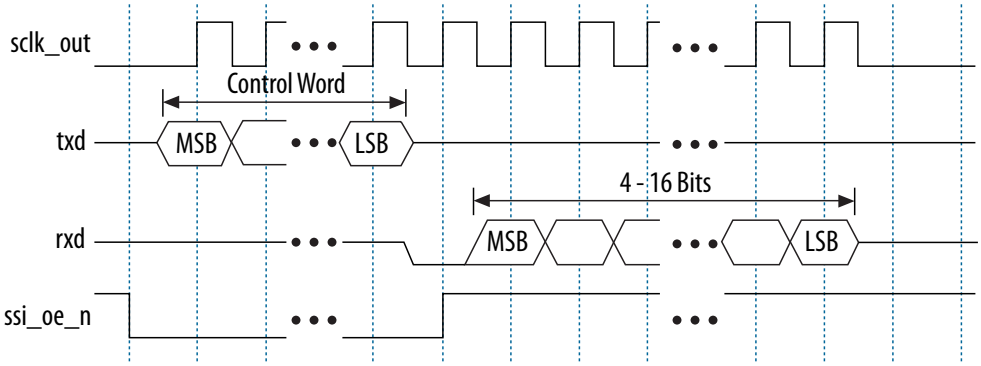


Figure 19-14: Single SPI Slave Microwire Serial Transfer (MDD=1)

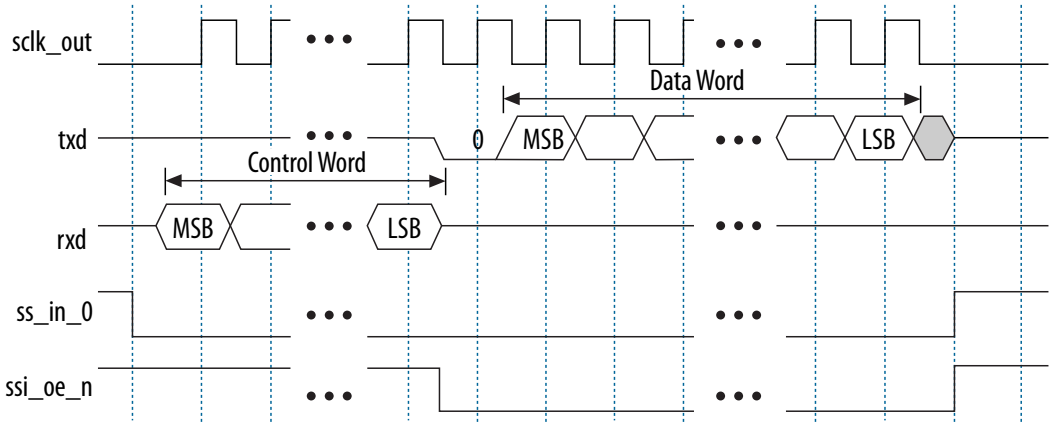

DMA Controller Interface

The SPI controller supports DMA signaling to indicate when the receive FIFO buffer has data ready to be read or when the transmit FIFO buffer needs data. It requires two DMA channels, one for transmit data and one for receive data. The SPI controller can issue single or burst DMA transfers and accepts burst acknowledges from the DMA. System software can trigger the DMA burst mode by programming an appropriate value into the threshold registers. The typical setting of the threshold register value is half full.

To enable the DMA Controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 into the TDMAE bit field of DMACR register enables the SPI transmit handshaking interface. Writing a 1 into the RDMAE bit field of the DMACR register enables the SPI receive handshaking interface. †

Slave Interface

The host processor accesses data, control, and status information about the SPI controller through the slave interface. The SPI supports a data bus width of 32 bits.

Control and Status Register Access

Control and status registers within the SPI controller are byte-addressable. The maximum width of the control or status register in the SPI controller is 16 bits. Therefore, all read and write operations to the SPI control and status registers require only one access. †

Data Register Access

The data register (DR) within the SPI controller is 16 bits wide in order to remain consistent with the maximum serial transfer size (data frame). A write operation to DR moves data from the slave write data bus into the transmit FIFO buffer. An read operation from DR moves data from the receive FIFO buffer onto the slave readback data bus. †

Note: The DR register in the SPI controller occupies sixty-four 32-bit locations of the memory map to facilitate burst transfers. There are no burst transactions on the system bus itself, but SPI supports bursts on the system interconnect. Writing to any of these address locations has the same effect as pushing the data from the slave write data bus into the transmit FIFO buffer. Reading from any of these locations has the same effect as popping data from the receive FIFO buffer onto the slave readback data bus. The FIFO buffers on the SPI controller are not addressable.

Clocks and Resets

The SPI controller uses the clock and reset signals shown in the following table.

Table 19-6: SPI Controller Clocks and Resets

	Master	Slave
SPI clock	l4_main_clk	l4_main_clk
SPI bit-rate clock	sclk_out	sclk_in
Reset	spim_rst_n	spis_rst_n

Clock Gating

You can locally clock gate the l4_main_clk to the Master SPI by programming the spimclken bit of the en register in the perpllgroup.

Note: This option is not available for SPI slaves.

Clock Manager Address Map and Register Definitions on page 2-18

Taking the SPI Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Modules Requiring Software Deassert on page 3-13

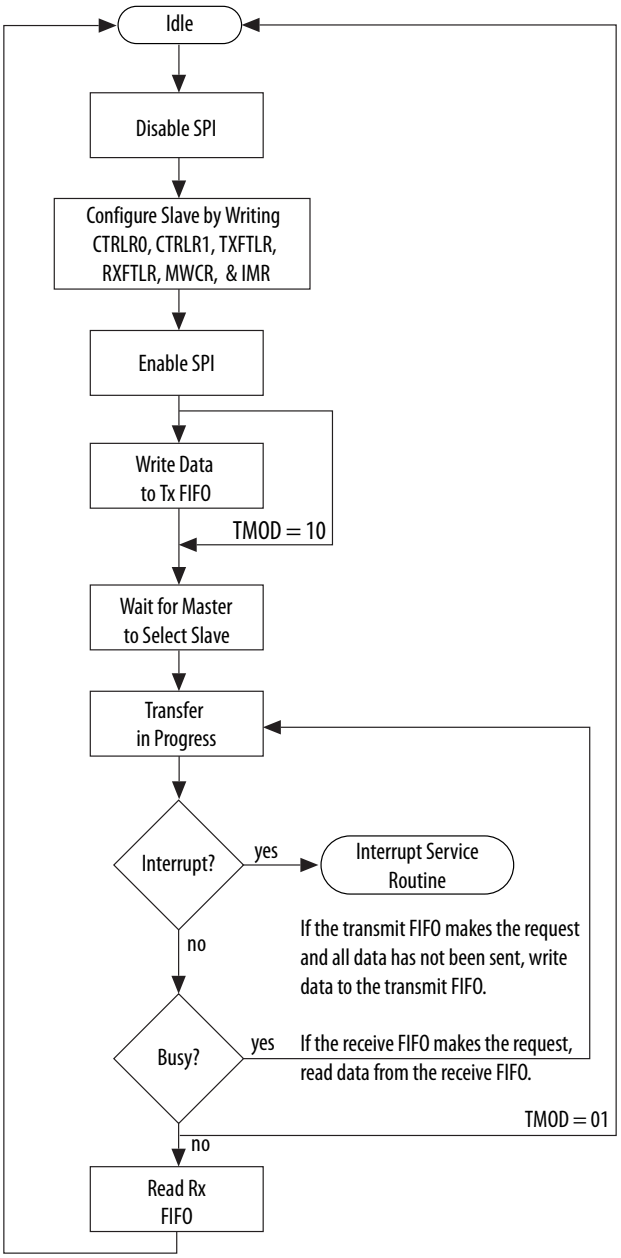
SPI Programming Model

This section describes the programming model for the SPI controller, for the following master and slave transfer types:

- Master SPI and SSP serial transfers
- Master Microwire serial transfers
- Slave SPI and SSP serial transfers
- Slave Microwire serial transfers
- Software Control for slave selection

Master SPI and SSP Serial Transfers

Figure 19-15: Master SPI or SSP Serial Transfer Software Flow



To complete an SPI or SSP serial transfer from the SPI master, follow these steps:

1. If the SPI master is enabled, disable it by writing 0 to the SSI Enable register (`SSIENR`).
2. Set up the SPI master control registers for the transfer. You can set these registers in any order.

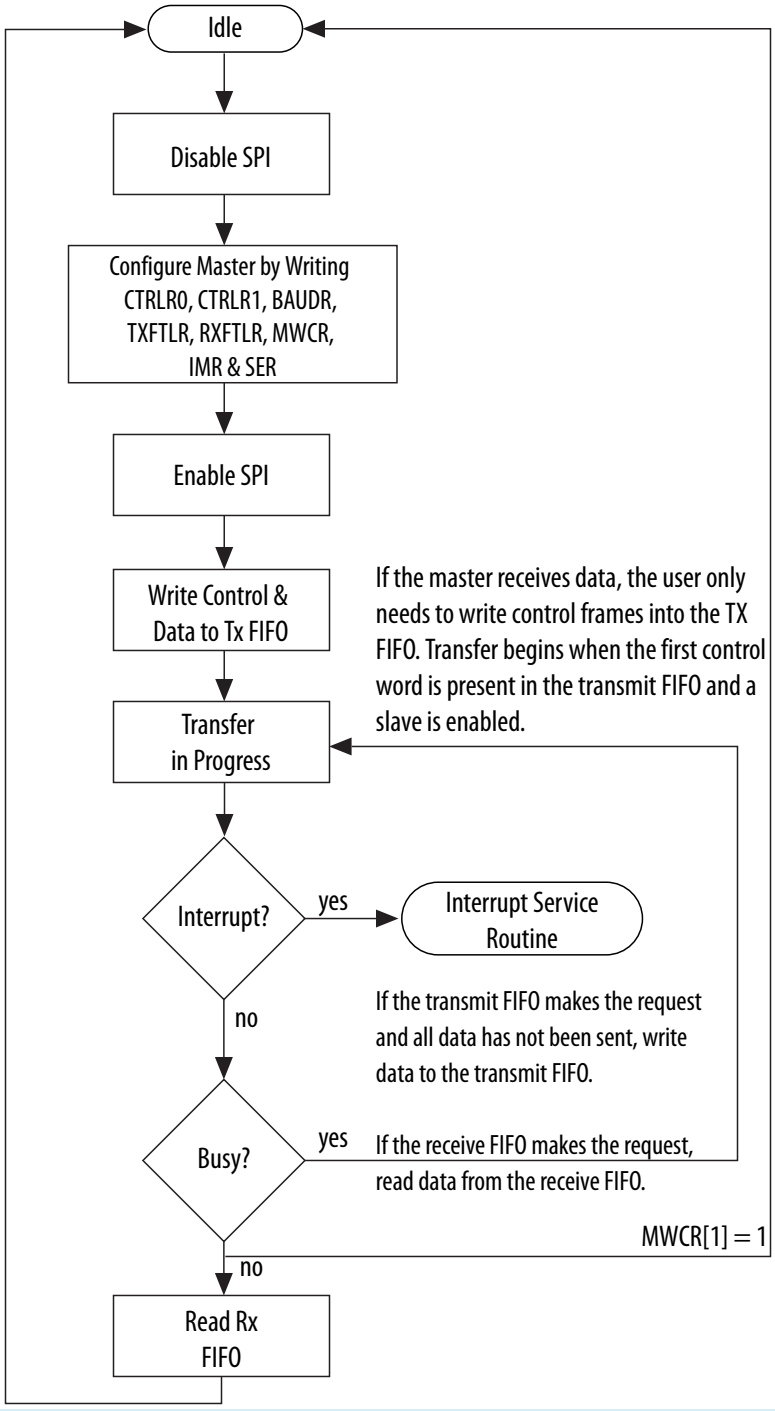
- Write Control Register 0 (CTRLLR0). For SPI transfers, you must set the serial clock polarity and serial clock phase parameters identical to the target slave device.
- If the transfer mode is receive only, write Control Register 1 (CTRLR1) with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
- Write the Baud Rate Select Register (BAUDR) to set the baud rate for the transfer.
- Write the Transmit and Receive FIFO Threshold Level registers (TXFTLR and RXFTLR) to set FIFO buffer threshold levels.
- Write the IMR register to set up interrupt masks.
- Write the Slave Enable Register (SER) register to enable the target slave for selection. If a slave is enabled at this time, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the Data Register (DR), the transfer does not begin until a slave is enabled.

3. Enable the SPI master by writing 1 to the SSIENR register.
4. Write data for transmission to the target slave into the transmit FIFO buffer (write DR). If no slaves were enabled in the SER register at this point, enable it now to begin the transfer.
5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).

6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is receive only (TMOD = 2), the shift control logic stops the transfer when the specified number of frames have been received. When the transfer is done, the BUSY status is reset to 0.
7. If the transfer mode is not transmit only (TMOD is not equal to 1), read the receive FIFO buffer until it is empty
8. Disable the SPI master by writing 0 to SSIENR.

Master Microwire Serial Transfers

Figure 19-16: Microwire Serial



To complete a Microwire serial transfer from the SPI master, follow these steps:

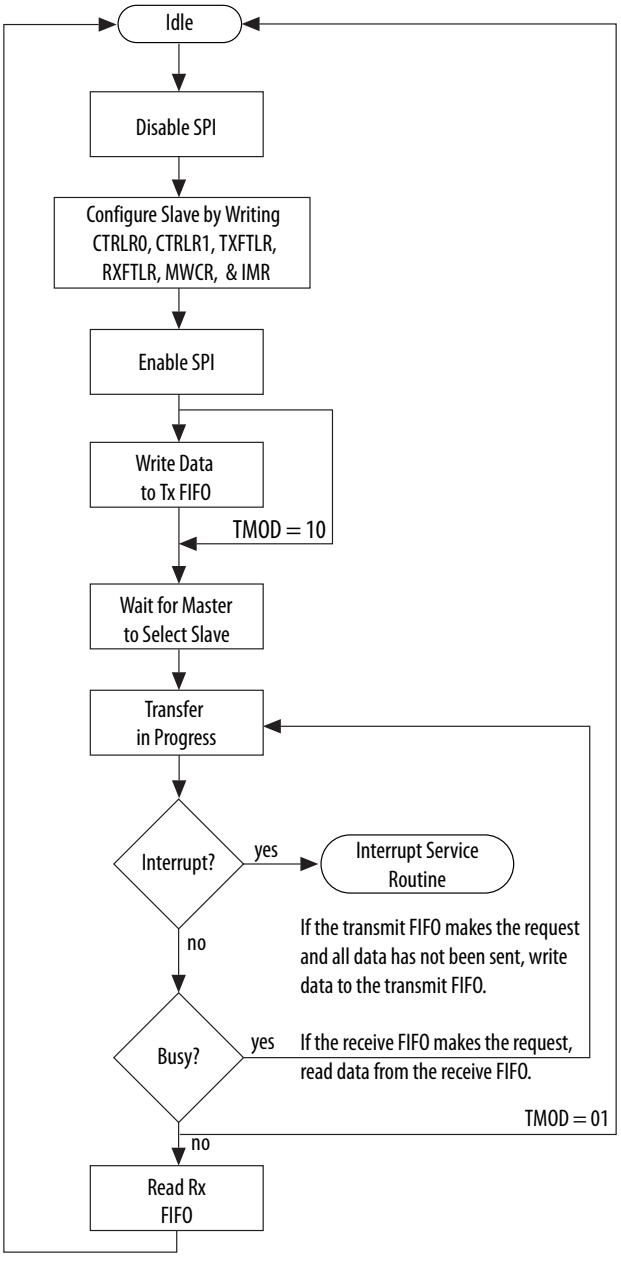
1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
   - Write CTRLR0 to set transfer parameters. If the transfer is sequential and the SPI master receives data, write CTRLR1 with the number of frames in the transfer minus 1. For example, if you want to receive four data frames, write 3 to this register.
   - Write BAUDR to set the baud rate for the transfer.
   - Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
   - Write the IMR register to set up interrupt masks.

   You can write the SER register to enable the target slave for selection. If a slave is enabled here, the transfer begins as soon as one valid data entry is present in the transmit FIFO buffer. If no slaves are enabled prior to writing to the DR register, the transfer does not begin until a slave is enabled.
3. Enable the SPI master by writing 1 to the SSIENR register.
4. If the SPI master transmits data, write the control and data words into the transmit FIFO buffer (write DR). If the SPI master receives data, write the control word or words into the transmit FIFO buffer. If no slaves were enabled in the SER register at this point, enable now to begin the transfer.
5. Poll the BUSY status to wait for the transfer to complete. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).

6. The shift control logic stops the transfer when the transmit FIFO buffer is empty. If the transfer mode is sequential and the SPI master receives data, the shift control logic stops the transfer when the specified number of data frames is received. When the transfer is done, the BUSY status is reset to 0.
7. If the SPI master receives data, read the receive FIFO buffer until it is empty.
8. Disable the SPI master by writing 0 to SSIENR.

Slave SPI and SSP Serial Transfers

Figure 19-17: Slave SPI or SSP Serial Transfer Software Flow



To complete a continuous serial transfer from a serial master to the SPI slave, follow these steps:

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Set up the SPI control registers for the transfer. You can set these registers in any order.
   - Write CTRLR0 (for SPI transfers, set SCPH and SCPOL identical to the master device).
   - Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
   - Write the IMR register to set up interrupt masks.
3. Enable the SPI slave by writing 1 to the SSIENR register.
4. If the transfer mode is transmit and receive (TMOD= 0) or transmit only (TMOD= 1), write data for transmission to the master into the transmit FIFO buffer (write DR). If the transfer mode is receive only (TMOD= 2), you need not write data into the transmit FIFO buffer. The current value in the transmit shift register is retransmitted.
5. The SPI slave is now ready for the serial transfer. The transfer begins when a serial-master device selects the SPI slave.
6. When the transfer is underway, the BUSY status can be polled to return the transfer status. If a transmit FIFO empty interrupt request is made, write the transmit FIFO buffer (write DR). If a receive FIFO full interrupt request is made, read the receive FIFO buffer (read DR).
7. The transfer ends when the serial master removes the select input to the SPI slave. When the transfer is completed, the BUSY status is reset to 0.
8. If the transfer mode is not transmit only (TMOD != 1), read the receive FIFO buffer until empty.
9. Disable the SPI slave by writing 0 to SSIENR.

Slave Microwire Serial Transfers

For the SPI slave, the Microwire protocol operates in much the same way as the SPI protocol. The SPI slave does not decode the control frame.

Software Control for Slave Selection

When using software to select slave devices, the input select lines from serial slave devices is connected to a single slave select output on the SPI master.

Example: Slave Selection Software Flow for SPI Master

1. If the SPI master is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. If the transfer is receive only, write the number of frames into CTRLR1.
4. Write BAUDR to set the transfer baud rate.
5. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
6. Write IMR register to set interrupt masks.
7. Write SER register bit 0 to 1 to select slave 1 in this example.
8. Write SSIENR register bit 0 to 1 to enable SPI master.

Example: Slave Selection Software Flow for SPI Slave

1. If the SPI slave is enabled, disable it by writing 0 to SSIENR.
2. Write CTRLR0 to match the required transfer.
3. Write TXFTLR and RXFTLR to set FIFO buffer threshold levels.
4. Write IMR register to set interrupt masks.
5. Write SSIENR register bit 0 to 1 to enable SPI slave.
6. If the SPI slave transmits data, write data into TX FIFO buffer.

Note: All other SPI slaves are disabled (SSIENR = 0) and therefore will not respond to an active level on their ss_in_n port.

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the SPI controller is 256 entries.

DMA Controller Operation

To enable the DMA controller interface on the SPI controller, you must write the DMA Control Register (DMACR). Writing a 1 to the TDMAE bit field of DMACR register enables the SPI controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the DMACR register enables the SPI controller receive handshaking.†

Related Information

DMA Controller on page 16-1
For details about the DMA controller, refer to the *DMA Controller* chapter.

Transmit FIFO Buffer Underflow

During SPI serial transfers, transmit FIFO buffer requests are made to the DMA Controller whenever the number of entries in the transmit FIFO buffer is less or equal to the value in DMA Transmit Data Level Register (DMATDLR); also known as the watermark level. The DMA Controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length.†

Note: Data should be fetched from the DMA often enough for the transmit FIFO buffer to perform serial transfers continuously, that is, when the FIFO buffer begins to empty, another DMA request should be triggered. Otherwise, the FIFO buffer will run out of data (underflow). To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA Controller* chapter.

Transmit FIFO Watermark

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the SPI transmits data to the rate at which the DMA can respond to destination burst requests. †

Example 1: Transmit FIFO Watermark Level = 64

Consider the example where the assumption is made: †

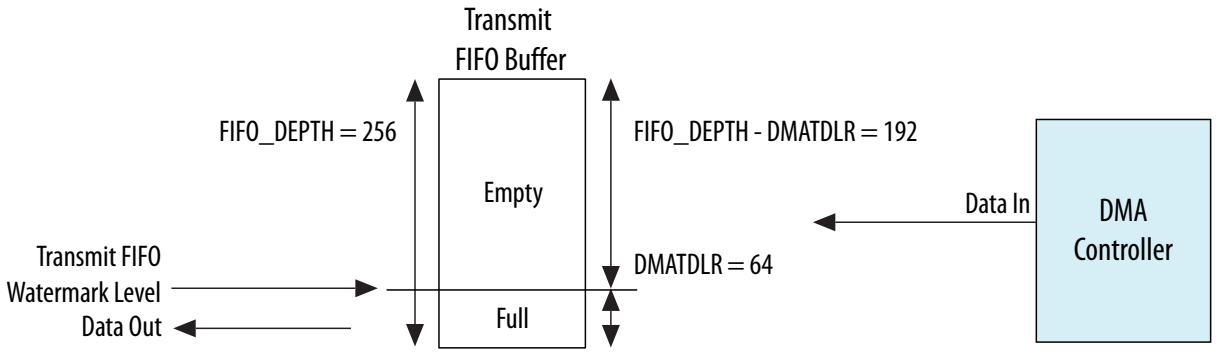
DMA burst length = FIFO_DEPTH - DMATDLR

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer.

Consider the following:

- Transmit FIFO watermark level = DMATDLR = 64 †
- DMA burst length = FIFO_DEPTH - DMATDLR = 192 †
- SPI transmit FIFO_DEPTH = 256 †
- Block transaction size = 960 †

Figure 19-18: Transmit FIFO Watermark Level = 64



The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 960/192 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, `DMATDLR`, is quite low. Therefore, there is a high probability that the SPI serial transmit line will need to transmit data when there is no data left in the transmit FIFO buffer. This is a transmit underflow condition. This occurs because the DMA has not had time to service the DMA request before the FIFO buffer becomes empty.

Example 2: Transmit FIFO Watermark Level = 192

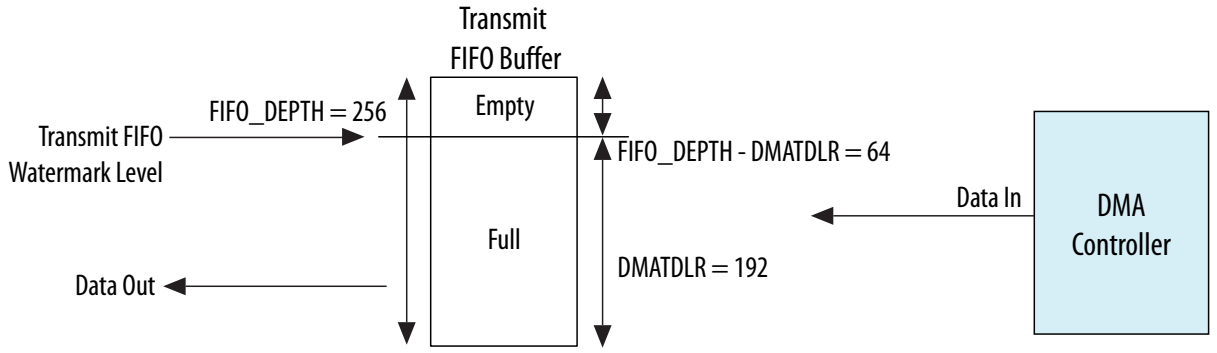
Consider the example where the assumption is made: †

DMA burst length = `FIFO_DEPTH - DMATDLR`

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO buffer. Consider the following:

- Transmit FIFO watermark level = `DMATDLR` = 192 †
- DMA burst length = `FIFO_DEPTH - DMATDLR` = 64 †
- SPI transmit `FIFO_DEPTH` = 256 †
- Block transaction size = 960 †

Figure 19-19: Transmit FIFO Watermark Level = 192



Number of burst transactions in block: †

Block transaction size/DMA burst length = 960/64 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, DMATDLR, is high. Therefore, the probability of SPI transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the SPI transmit FIFO buffer becomes empty. †

This case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case.

Transmit FIFO Buffer Overflow

Setting the DMA transaction burst length to a value greater than the watermark level that triggers the DMA request may cause overflow when there is not enough space in the transmit FIFO buffer to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= FIFO_DEPTH - DMATDLR

In Example 2: Transmit Watermark Level = 192, the amount of space in the transmit FIFO buffer at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO buffer may be full, but not overflowed, at the completion of the burst transaction.

Therefore, for optimal operation, DMA burst length should be set at the FIFO buffer level that triggers a transmit DMA request; that is: †

DMA burst length = FIFO_DEPTH - DMATDLR

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO buffer will not be full at the end of a DMA burst transfer if the SPI controller has successfully transmitted one data item or more on the serial transmit line during the transfer. †

Related Information

Transmit FIFO Watermark on page 19-30

Receive FIFO Buffer Overflow

During SPI serial transfers, receive FIFO buffer requests are made to the DMA whenever the number of entries in the receive FIFO buffer is at or above the DMA Receive Data Level Register, that is DMATDLR + 1.This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO buffer. †

Data should be fetched by the DMA often enough for the receive FIFO buffer to accept serial transfers continuously, that is, when the FIFO buffer begins to fill, another DMA transfer is requested. Otherwise the FIFO buffer will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Choosing Receive Watermark Level

Similar to choosing the transmit watermark level, the receive watermark level, DMATDLR + 1, should be set to minimize the probability of overflow. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Related Information

Texas Instruments Synchronous Serial Protocol (SSP) on page 19-18

Receive FIFO Buffer Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

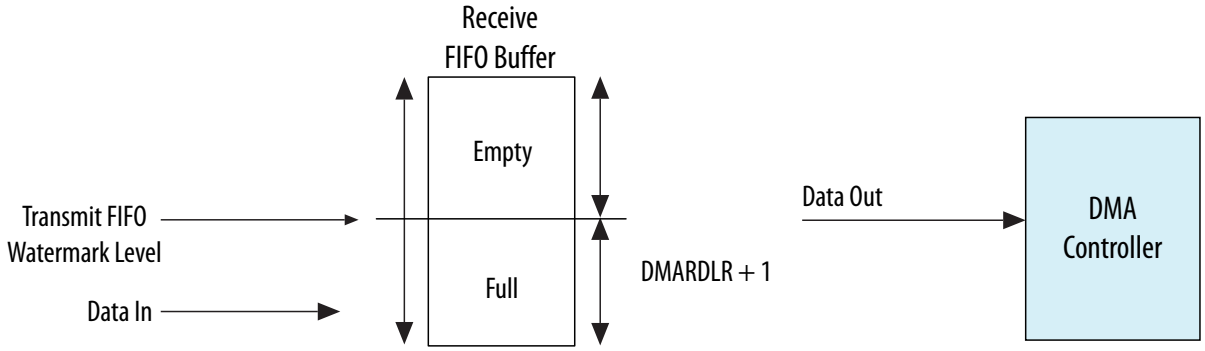
DMA burst length = `DMATDLR` + 1

If the number of data items in the receive FIFO buffer is equal to the source burst length at the time of the burst request is made, the receive FIFO buffer may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, `DMATDLR` + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can improve bus utilization. †

Note: The receive FIFO buffer will not be empty at the end of the source burst transaction if the SPI controller has successfully received one data item or more on the serial receive line during the burst. †

Figure 19-20: Receive FIFO Buffer



SPI Controller Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

spim Address Map

Module Instance	Base Address	End Address
i_spim_0_spim	0xFFDA4000	0xFFDA4FFF
i_spim_1_spim	0xFFDA5000	0xFFDFFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
ctrlr0 on page 19-50	0x0	32	RW	0x7	Control Register 0: This register controls the serial data transfer. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.
ctrlr1 on page 19-55	0x4	32	RW	0x0	Control Register 1 This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Bit	Name	Description	Access	Reset
15:12	cfs	Control Frame Size. Selects the length of the control word for the Microwire frame format Value: Description 0xa: SIZE11BIT 0xb: SIZE12BIT 0xc: SIZE13BIT 0xd: SIZE14BIT 0xe: SIZE15BIT 0xf: SIZE16BIT 0x0: SIZE1BIT 0x1: SIZE2BIT 0x2: SIZE3BIT 0x3: SIZE4BIT 0x4: SIZE5BIT 0x05: SIZE6BIT 0x6: SIZE7BIT 0x7: SIZE8BIT 0x8: SIZE9BIT 0x9: SIZE10BIT	RW	0x0
11	srl	Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. 0 - Normal Mode Operation 1 - Test Mode Operation Value: Description 0x0: NORMMODE 0x1: TESTMODE	RW	0x0

Bit	Name	Description	Access	Reset
9:8	tmod	Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - Reserved **Value** **Description** 0x0 TXRX 0x1 TXONLY 0x2 RXONLY 0x3 EERD	RW	0x0

Bit	Name	Description	Access	Reset
7	scpol	Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus. 0 - Inactive state of serial clock is low 1 - Inactive state of serial clock is high **Value** **Description** 0x0 INACTIVELOW 0x1 INACTIVEHIGH	RW	0x0
6	scph	Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relation-ship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. 0: Serial clock toggles in middle of first data bit 1: Serial clock toggles at start of first data bit **Value** **Description** 0x0 MIDBIT 0x1 STARTBIT	RW	0x0

Bit	Name	Description	Access	Reset
5:4	frf	Frame Format. Selects which serial protocol transfers the data. 00 - Motorola SPI 01 - Texas Instruments SSP 10 - National Semiconductors Microwire 11 - Reserved **Value** **Description** 0x0 MOTSPI 0x1 TISSP 0x2 NATMW	RW	0x0

Bit	Name	Description	Access	Reset
3:0	dfs	Data Frame Size. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data **Value** — **Description** 0xa — WIDTH11BIT 0xb — WIDTH12BIT 0xc — WIDTH13BIT 0xd — WIDTH14BIT 0xe — WIDTH15BIT 0xf — WIDTH16BIT 0x3 — WIDTH4BIT 0x4 — WIDTH5BIT 0x5 — WIDTH6BIT 0x6 — WIDTH7BIT 0x7 — WIDTH8BIT 0x8 — WIDTH9BIT 0x9 — WIDTH10BIT	RW	0x7

ctrlr1

Control Register 1
This register exists only when the DW_apb_ssi is configured as a master device. When the DW_apb_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4004
i_spim_1_spim	0xFFDA5000	0xFFDA5004

Offset: 0x4

ctrlr1 Fields

Bit	Name	Description	Access	Reset
15:0	ndf	Number of Data Frames. When TMOD = 10 or TMOD = 11, this register field sets the number of data frames to be continuously received by the DW_apb_ssi. The DW_apb_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When the DW_apb_ssi is configured as a serial slave, the transfer continues for as long as the slave is selected. Therefore, this register serves no purpose and is not present when the DW_apb_ssi is configured as a serial slave.	RW	0x0

mwcr Fields

Bit	Name	Description	Access	Reset
2	mhs	Microwire Handshaking. Relevant only when the DW_apb_ssi is configured as a serial-master device. When configured as a serial slave, this bit field has no functionality. Used to enable and disable the busy/ ready handshaking interface for the Microwire protocol. When enabled, the DW_apb_ssi checks for a ready status from the target slave, after the transfer of the last data/control bit, before clearing the BUSY status in the SR register. 0: handshaking interface is disabled 1: handshaking interface is enabled **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
1	mdd	Microwire Control. Defines the direction of the data word when the Microwire serial protocol is used. When this bit is set to 0, the data word is received by the DW_apb_ssi MacroCell from the external serial device. When this bit is set to 1, the data word is transmitted from the DW_apb_ssi MacroCell to the external serial device. **Value** — **Description** 0x0 — RXMODE 0x1 — TXMODE	RW	0x0

Bit	Name	Description	Access	Reset
0	mwmod	Microwire Transfer Mode. Defines whether the Microwire transfer is sequential or non-sequential. When sequential mode is used, only one control word is needed to transmit or receive a block of data words. When non-sequential mode is used, there must be a control word for each data word that is transmitted or received. 0: non-sequential transfer 1: sequential transfer **Value** **Description** 0x0 NONSEQ 0x1 SEQ	RW	0x0

ser

Slave Enable Register.
This register is valid only when the DW_apb_ssi is configured as a master
device. When the DW_apb_ssi is configured as a serial slave, writing to
this location has no effect; reading from this location returns 0. The register enables the individual slave select output lines from the DW_apb_ssi master. Up to 16 slave-select output pins are available on the
DW_apb_ssi master. You cannot write to this register when DW_apb_ssi is
busy and when SSI_EN = 1.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4010
i_spim_1_spim	0xFFDA5000	0xFFDA5010

Offset: 0x10

ser Fields

Bit	Name	Description	Access	Reset
3:0	ser	Slave Select Enable Flag. Each bit in this register corresponds to a slave select line (ss_x_n]) from the DW_apb_ssi master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set. 1: Selected 0: Not Selected **Value** **Description** 0x0 NOTSELECTED 0x1 SELECTED	RW	0x0

baudr

Baud Rate Select.
This register is valid only when the DW_apb_ssi is configured as a master
device. When the DW_apb_ssi is configured as a serial slave, writing to
this location has no effect; reading from this location returns 0. The

register derives the frequency of the serial clock that regulates the data
transfer. The 16-bit field in this register defines the ssi_clk divider
value. It is impossible to write to this register when the DW_apb_ssi is
enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR
register.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4014

dr

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0.Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the RxFIFO onto the bus.

Module Instance	Base Address	Register Address
i_spim_0_spim	0xFFDA4000	0xFFDA4060 to 0xFFDA40EC
i_spim_1_spim	0xFFDA5000	0xFFDA5060 to 0xFFDA50EC

ctrlr0

Control Register 0:
This register controls the serial data transfer. It is impossible to write to this register when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and disabled by writing to the SSIENR register.

Module Instance	Base Address	Register Address
i_spis_0_spis	0xFFDA2000	0xFFDA2000
i_spis_1_spis	0xFFDA3000	0xFFDA3000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ctrlr0 Fields

Bit	Name	Description	Access	Reset
15:12	cfs	Control Frame Size. Selects the length of the control word for the Microwire frame format Value — Description 0xa — SIZE11BIT 0xb — SIZE12BIT 0xc — SIZE13BIT 0xd — SIZE14BIT 0xe — SIZE15BIT 0xf — SIZE16BIT 0x0 — SIZE1BIT 0x1 — SIZE2BIT 0x2 — SIZE3BIT 0x3 — SIZE4BIT 0x4 — SIZE5BIT 0x5 — SIZE6BIT 0x6 — SIZE7BIT 0x7 — SIZE8BIT 0x8 — SIZE9BIT 0x9 — SIZE10BIT	RW	0x0

Bit	Name	Description	Access	Reset
11	srl	Shift Register Loop. Used for testing purposes only. When internally active, connects the transmit shift register output to the receive shift register input. 0 - Normal Mode Operation 1 - Test Mode Operation **Value** / **Description** 0x0 NORMMODE 0x1 TESTMODE	RW	0x0
10	slv_oe	Slave Output Enable. Relevant only when the DW_apb_ssi is configured as a serial-slave device. When configured as a serial master, this bit field has no functionality. This bit enables or disables the setting of the ssi_oe_n output from the DW_apb_ssi serial slave. When SLV_OE = 1, the ssi_oe_n output can never be active. When the ssi_oe_n output controls the tri-state buffer on the txd output from the slave, a high impedance state is always present on the slave txd output when SLV_OE = 1. This is useful when the master transmits in broadcast mode (master transmits data to all slave devices). Only one slave may respond with data on the master rxd line. This bit is enabled after reset and must be disabled by software (when broadcast mode is used), if you do not want this device to respond with data. 0 - Slave txd is enabled 1 - Slave txd is disabled **Value** / **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0

Bit	Name	Description	Access	Reset
9:8	tmod	Transfer Mode. Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. 00 - Transmit & Receive 01 - Transmit Only 10 - Receive Only 11 - Reserved **Value** **Description** 0x0 TXRX 0x1 TXONLY 0x2 RXONLY	RW	0x0

Bit	Name	Description	Access	Reset
7	scpol	Serial Clock Polarity. Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DW_apb_ssi master is not actively transferring data on the serial bus. 0 - Inactive state of serial clock is low 1 - Inactive state of serial clock is high **Value** **Description** 0x0 INACTIVELOW 0x1 INACTIVEHIGH	RW	0x0
6	scph	Serial Clock Phase. Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relation-ship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. 0: Serial clock toggles in middle of first data bit 1: Serial clock toggles at start of first data bit **Value** **Description** 0x0 MIDBIT 0x1 STARTBIT	RW	0x0

Bit	Name	Description	Access	Reset
5:4	frf	Frame Format. Selects which serial protocol transfers the data. 00 - Motorola SPI 01 - Texas Instruments SSP 10 - National Semiconductors Microwire 11 - Reserved **Value** **Description** 0x0 MOTSPI 0x1 TISSP 0x2 NATMW	RW	0x0

Bit	Name	Description	Access	Reset
3:0	dfs	Data Frame Size. Selects the data frame length. When the data frame size is programmed to be less than 16 bits, the receive data are automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data **Value** — **Description** 0xa — WIDTH11BIT 0xb — WIDTH12BIT 0xc — WIDTH13BIT 0xd — WIDTH14BIT 0xe — WIDTH15BIT 0xf — WIDTH16BIT 0x3 — WIDTH4BIT 0x4 — WIDTH5BIT 0x5 — WIDTH6BIT 0x6 — WIDTH7BIT 0x7 — WIDTH8BIT 0x8 — WIDTH9BIT 0x9 — WIDTH10BIT	RW	0x7

spienr Fields

Bit	Name	Description	Access	Reset
0	spi_en	SSI Enable. Enables and disables all DW_apb_ssi operations. When disabled, all serial transfers are halted immediately. Transmit and receive FIFO buffers are cleared when the device is disabled. It is impossible to program some of the DW_apb_ssi control registers when enabled. When disabled, the ssi_ sleep output is set (after delay) to inform the system that it is safe to remove the ssi_clk, thus saving power consumption in the system. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

mwcr

```
        Microwire Control Register.
This register controls the direction of the data word for the half-
duplex
Microwire serial protocol. It is impossible to write to this register
when the DW_apb_ssi is enabled. The DW_apb_ssi is enabled and
disabled by
writing to the SSIENR register.
```

Module Instance	Base Address	Register Address

The data register is a 16-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSI_EN = 1. FIFOs are reset when SSI_EN = 0.Note that the data register occupies thirty-six 32-bit address locations of the memory map to facilitate burst transfers. Writing to any of these address locations has the same effect as pushing the data from the bus into the TxFIFO and reading from any of these location has the same effect as popping data from the RxFIFO onto the bus.

I²C Controller 20

2016.10.28

a10_5v4

The I²C controller provides support for a communication link between integrated circuits on a board. It is a simple two-wire bus which consists of a serial data line (SDA) and a serial clock (SCL) for use in applications such as temperature sensors and voltage level translators to EEPROMs, A/D and D/A converters, CODECs, and many types of microprocessors. †

The hard processor system (HPS) provides five I²C controllers to enable system software to communicate serially with I²C buses. Each I²C controller can operate in master or slave mode, and support standard mode of up to 100 Kbps or fast mode of up to 400 Kbps. These I²C controllers are instances of the Synopsys® DesignWare® APB I²C (DW_apb_i2c) controller.

Each I²C controller must be programmed to operate in either master or slave mode only. Operating as a master and slave simultaneously is not supported. † (53)

Features of the I²C Controller

The I²C controller has the following features:

- Maximum clock speed of up to 400 Kbps
- Standard clock speed 100 kbps
- One of the following I²C operations:
  - A master in an I²C system and programmed only as a master †
  - A slave in an I²C system and programmed only as a slave †
- 7- or 10-bit addressing †
- Mixed read and write combined-format transactions in both 7-bit and 10-bit addressing mode †
- Bulk transmit mode †

(53) Portions © 2016 Synopsys, Inc. Used with permission. All rights reserved. Synopsys & DesignWare are registered trademarks of Synopsys, Inc. All documentation is provided "as is" and without any warranty. Synopsys expressly disclaims any and all warranties, express, implied, or otherwise, including the implied warranties of merchantability, fitness for a particular purpose, and non-infringement, and any warranties arising out of a course of dealing or usage of trade.

†Paragraphs marked with the dagger (†) symbol are Synopsys Proprietary. Used with permission.

- Transmit and receive buffers †
- Handles bit and byte waiting at all bus speeds †
- DMA handshaking interface †

Three of the five I²Cs, provide support for EMAC communication. They provide flexibility for the EMACs to use MDIO or I²C for PHY communication and can also be used as general purpose.

- `I2C_EMAC0`
- `I2C_EMAC1`
- `I2C_EMAC2`

The remaining two I²Cs are intended for general purpose.

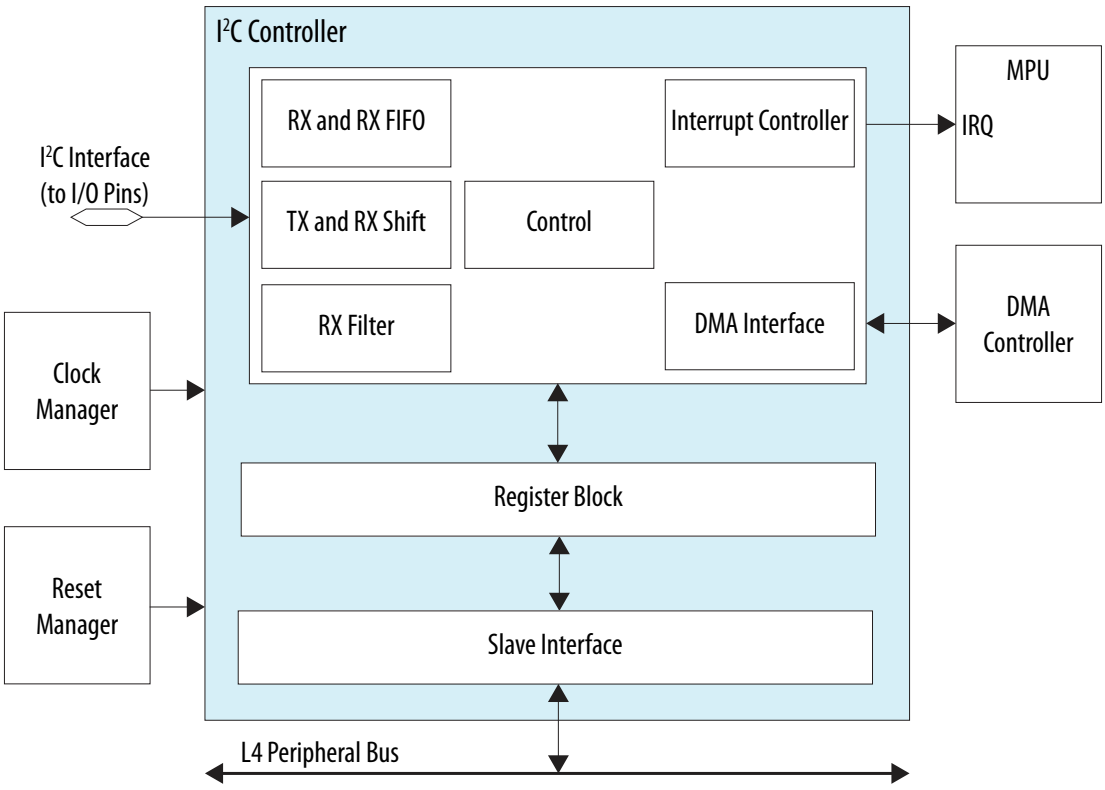
- `I2C0`
- `I2C1`

I²C Controller Block Diagram and System Integration

The I²C controller consists of an internal slave interface, an I²C interface, and FIFO logic to buffer data between the two interfaces. †

The host processor accesses data, control, and status information about the I²C controller through a 32-bit slave interface.

Figure 20-1: I²C Controller Block Diagram



The I²C controller consists of the following modules and interfaces:

- Slave interface for control and status register (CSR) accesses and DMA transfers, allowing a master to access the CSRs and the DMA to read or write data directly.
- Two FIFO buffers for transmit and receive data, which hold the Rx FIFO and Tx FIFO buffer register banks and controllers, along with their status levels. †
- Shift logic for parallel-to-serial and serial-to-parallel conversion
  - Rx shift – Receives data into the design and extracts it in byte format. †
  - Tx shift – Presents data supplied by CPU for transfer on the I²C bus. †
- Control logic responsible for implementing the I²C protocol.
- DMA interface that generates handshaking signals to the DMA controller in order to automate the data transfer without CPU intervention. †
- Interrupt controller that generates raw interrupts and interrupt flags, allowing them to be set and cleared. †
- Receive filter for detecting events, such as start and stop conditions, in the bus; for example, start, stop and arbitration lost. †

I²C Controller Signal Description

All instances of the I²C controller connect to external pins through pin multiplexers. Pin multiplexing allows all instances to function simultaneously and independently. The pins must be connected to a pull-up resistors and the I²C bus capacitance cannot exceed 400 pF.

There are five instances of the I²C which can be routed to the HPS I/O pins. Three of these I²C modules can be used for PHY management by the three Ethernet Media Access Controllers within the HPS. For more information about routing the I²C signals to the FPGA and HPS I/O pins, refer to the *HPS Component Interfaces* chapter.

Table 20-1: I²C Controller Interface HPS I/O Pins

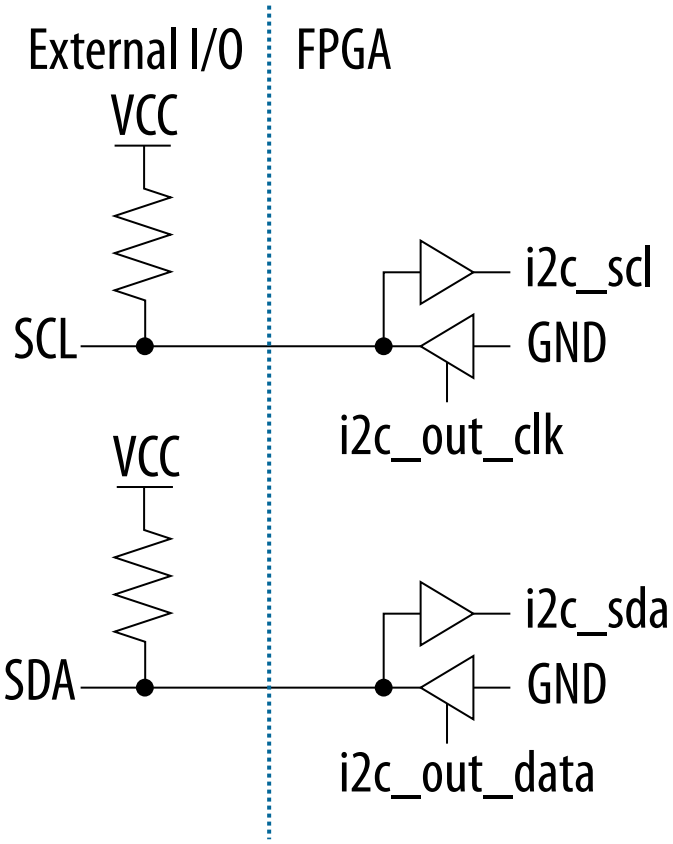
Pin Name	Signal Width	Direction	Description
SCL	1 bit	Bidirectional	Serial clock
SDA	1 bit	Bidirectional	Serial data

Table 20-2: HPS I²C Signals for FPGA Routing

Signal Name	Signal Width	Direction	Description
i2c<#>_scl	1 bit	Input	Incoming I²C clock source. This is the input SCL signal

Signal Name	Signal Width	Direction	Description
i2c<#>_out_clk	1 bit	Output	Outgoing I²C clock enable. Output SCL signal. This signal is logically inverted and is synchronous to the HPS peripheral clock
i2c<#>_sda	1 bit	Input	Incoming I²C data. This is the input SDA signal.
i2c<#>_out_data	1 bit	Output	Outgoing I²C data enable. Output SDA signal. This signal is logically inverted and is synchronous to the HPS peripheral clock.

Figure 20-2: I²C Interface in FPGA Fabric



The figure above shows the typical connection on the I²C interface in FPGA fabric with `alt_iobuff`.

For both I2C clock and data, external IO pins are open drain connection. When output enables `i2c_out_data` and `i2c_out_clk` are asserted, external signal will be driven to ground.

For more information on how the I2C Signals are routed to the FPGA and HPS I/O pins, refer to this chapter.

Functional Description of the I2C Controller

Feature Usage

The I2C controller can operate in standard mode (with data rates of up to 100 Kbps) or fast mode (with data rates less than or equal to 400 Kbps). Additionally, fast mode devices are downward compatible. For instance, fast mode devices can communicate with standard mode devices in 0 to 100 Kbps I2C bus system. However, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I2C bus system as they cannot follow the higher transfer rate and therefore unpredictable states would occur. †

You can attach any I2C controller to an I2C-bus and every device can talk with any master, passing information back and forth. There needs to be at least one master (such as a microcontroller or DSP) on the bus and there can be multiple masters, which require them to arbitrate for ownership. Multiple masters and arbitration are explained later in this chapter. †

Behavior

You can control the I2C controller via software to be in either mode:

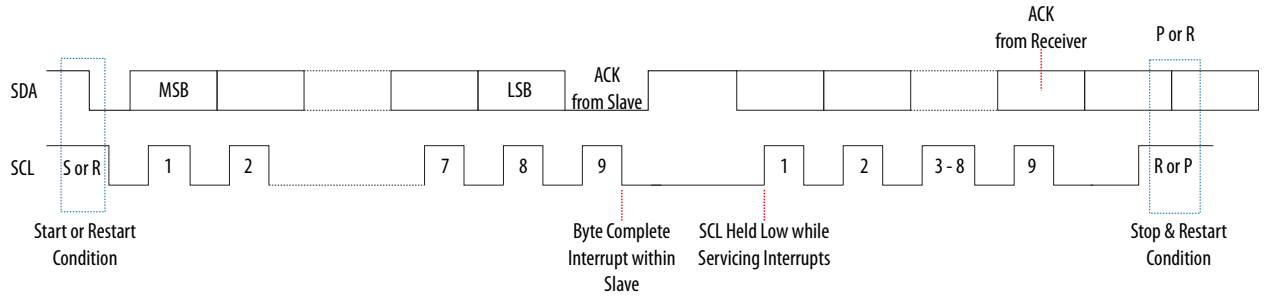
- An I2C master only, communicating with other I2C slaves.
- An I2C slave only, communicating with one or more I2C masters.

The master is responsible for generating the clock and controlling the transfer of data. The slave is responsible for either transmitting or receiving data to/from the master. The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave. As mentioned previously, the I2C protocol also allows multiple masters to reside on the I2C bus and uses an arbitration procedure to determine bus ownership. †

Each slave has a unique address that is determined by the system designer. When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W) to determine if the master wants to transmit data or receive data from the slave. The slave then sends an acknowledge (ACK) pulse after the address. †

If the master (master-transmitter) is writing to the slave (slave-receiver), the receiver receives one byte of data. This transaction continues until the master terminates the transmission with a STOP condition. If the master is reading from a slave (master-receiver), the slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with an ACK pulse. This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. †

Figure 20-3: Data Transfer on the I²C Bus †



The I²C controller is a synchronous serial interface. The SDA line is a bidirectional signal and changes only while the SCL line is low, except for STOP, START, and RESTART conditions. The output drivers are open-drain or open-collector to perform wire-AND functions on the bus. The maximum number of devices on the bus is limited by only the maximum capacitance specification of 400 pF. Data is transmitted in byte packages. †

START and STOP Generation

When operating as a master, putting data into the transmit FIFO causes the I²C controller to generate a START condition on the I²C bus. In order for the master to complete the transfer and issue a STOP condition it must find a transmit FIFO entry tagged with a stop bit. Allowing the transmit FIFO to empty without a stop bit set, the master will stall the transfer by holding the SCL line low. †

When operating as a slave, the I²C controller does not generate START and STOP conditions, as per the protocol. However, if a read request is made to the I²C controller, it holds the SCL line low until read data has been supplied to it. This stalls the I²C bus until read data is provided to the slave I²C controller, or the I²C controller slave is disabled by writing a 0 to bit 0 of `IC_ENABLE` register. †

Combined Formats

The I²C controller supports mixed read and write combined format transactions in both 7-bit and 10-bit addressing modes. †

The I²C controller does not support mixed address and mixed address format—that is, a 7-bit address transaction followed by a 10-bit address transaction or vice versa—combined format transactions. †

To initiate combined format transfers, the `IC_RESTART_EN` bit in the `IC_CON` register should be set to 1. With this value set and operating as a master, when the I²C controller completes an I²C transfer, it checks the transmit FIFO and executes the next transfer. If the direction of this transfer differs from the previous transfer, the combined format is used to issue the transfer. If the `IC_RESTART_EN` is 0, a STOP will be issued followed by a START condition. Another way to generate the RESTART condition is to set the Restart bit [10] of the `DATA_CMD` register. Regardless if the direction of the transfer changes or not the RESTART condition will be generated.†

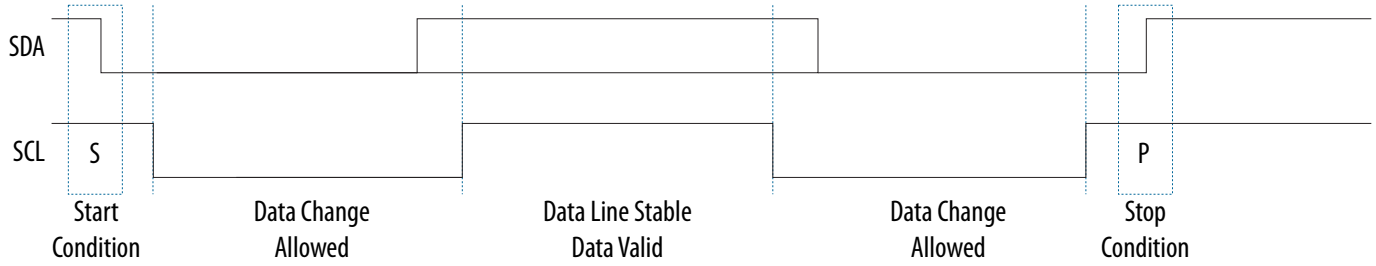
Protocol Details

START and STOP Conditions

When the bus is idle, both the SCL and SDA signals are pulled high through pull-up resistors on the bus. When the master wants to start a transmission on the bus, the master issues a START condition. This is defined to be a high-to-low transition of the SDA signal while SCL is 1. When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the SDA line while SCL is 1. †

The following figure shows the timing of the START and STOP conditions. When data is being transmitted on the bus, the SDA line must be stable when SCL is 1. †

Figure 20-4: Timing Diagram for START and STOP Conditions



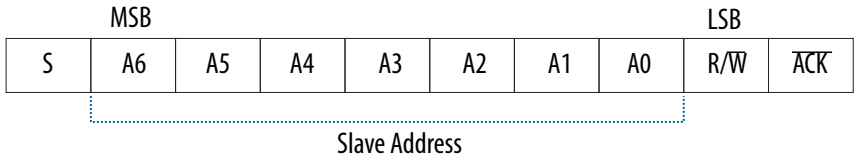
The signal transitions for the START or STOP condition, as shown in the figure, reflect those observed at the output signals of the master driving the I^2C bus. Care should be taken when observing the SDA or SCL signals at the input signals of the slave(s), because unequal line delays may result in an incorrect SDA or SCL timing relationship. †

Addressing Slave Protocol

7-Bit Address Format

During the 7-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in the following figure. When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave. †

Figure 20-5: 7- Bit Address Format

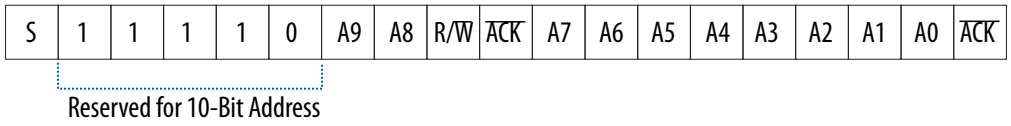


S: Start Condition
R/W: Read/Write Pulse
ACK: Acknowledge (Sent by Slave)

10-Bit Address Format

During 10-bit addressing, two bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition. The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer followed by the next two bits (bits 2:1), which set the slaves address bits 9:8, and the LSB bit (bit 0) is the R/W bit. The second byte transferred sets bits 7:0 of the slave address. †

Figure 20-6: 10-Bit Address Format



S: Start Condition
R/W: Read/Write Pulse
ACK: Acknowledge (Sent by Slave)

The following table defines the special purpose and reserved first byte addresses. †

Table 20-3: I²C Definition of Bits in First Byte

Slave Address	R/W Bit	Description
0000 000	0	General call address. The I²C controller places the data in the receive buffer and issues a general call interrupt.
0000 000	1	START byte. For more details, refer to "START BYTE Transfer Protocol"
0000 001	X	CBUS address. The I²C controller ignores these accesses.
0000 010	X	Reserved
0000 011	X	Reserved
0000 1XX	X	Unused
1111 1XX	X	Reserved
1111 0XX	X	10-bit slave addressing.

Note to Table: 'X' indicates do not care.

Related Information

START BYTE Transfer Protocol on page 20-10

Transmitting and Receiving Protocol

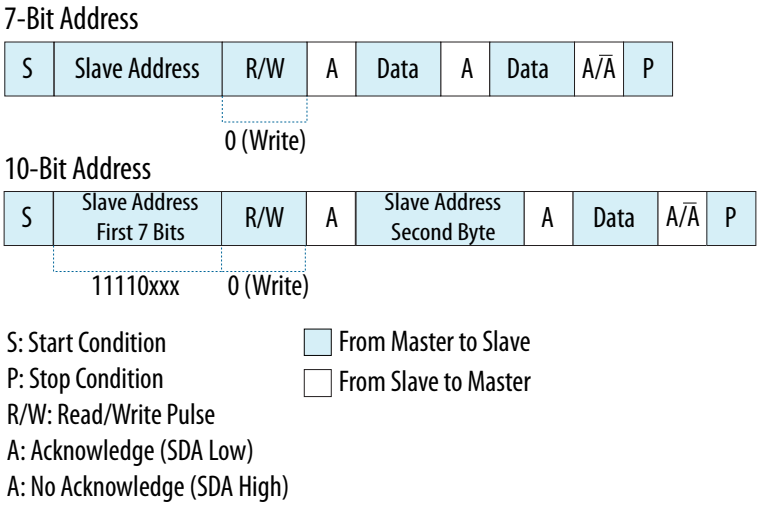
The master can initiate data transmission and reception to or from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master to either transmit data or receive data to or from the bus, acting as either a slave-transmitter or slave-receiver, respectively. †

Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and R/W bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the SDA line high so that the master can abort the transfer. †

If the master-transmitter is transmitting data as shown in the following figure, then the slave-receiver responds to the master-transmitter with an ACK pulse after every byte of data is received. †

Figure 20-7: Master-Transmitter Protocol †



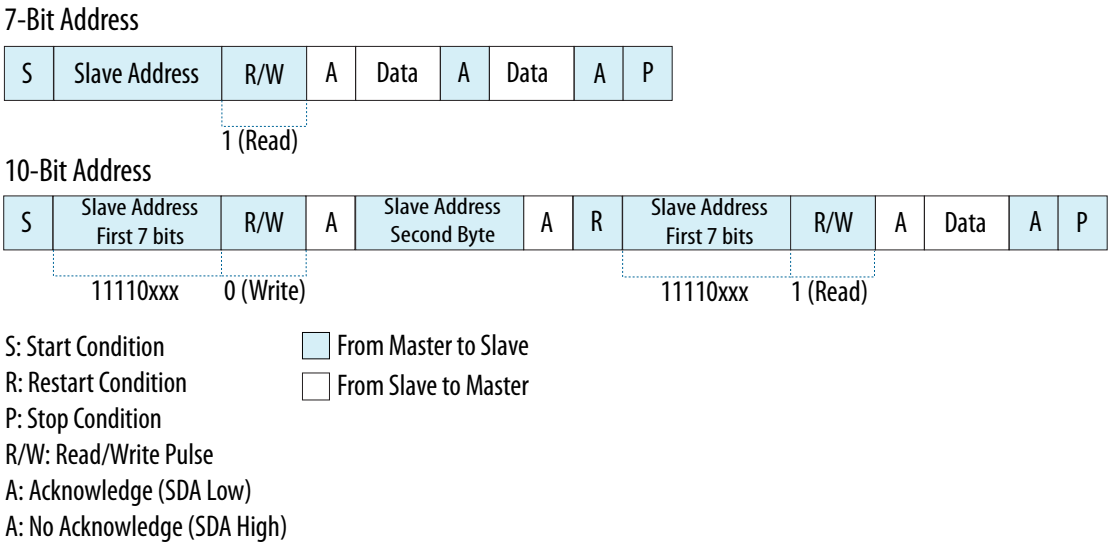
Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in the following figure, then the master responds to the slave-transmitter with an ACK pulse after a byte of data has been received, except for the last byte. This is the way the master-receiver notifies the slave-transmitter that this is the last byte. The slave-transmitter relinquishes the SDA line after detecting the No Acknowledge (NACK) bit so that the master can issue a STOP condition. †

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. Operating in master mode, the I^2C controller can then communicate with the same slave using a transfer of a different direction. For a description of the combined format transactions that the I^2C controller supports, refer to "Combined Formats" section of this chapter. †

Note: The I^2C controller must be inactive on the serial port before the target slave address register, `IC_TAR`, can be reprogrammed. †

Figure 20-8: Master-Receiver Protocol †



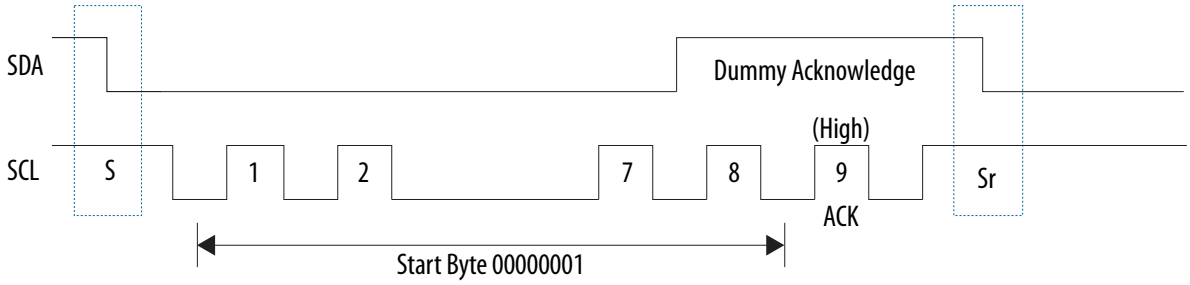
Related Information

Combined Formats on page 20-6

START BYTE Transfer Protocol

The START BYTE transfer protocol is set up for systems that do not have an on-board dedicated I^2C hardware module. When the I^2C controller is set as a slave, it always samples the I^2C bus at the highest speed supported so that it never requires a START BYTE transfer. However, when I^2C controller is set as a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it. This protocol consists of seven zeros being transmitted followed by a 1, as illustrated in the following figure. This allows the processor that is polling the bus to under-sample the address phase until the microcontroller detects a 0. Once the microcontroller detects a 0, it switches from the under sampling rate to the correct rate of the master. †

Figure 20-9: START BYTE Transfer †



The START BYTE has the following procedure: †

1. Master generates a START condition. †
2. Master transmits the START byte (0000 0001). †
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus) †
4. No slave sets the ACK signal to 0. †
5. Master generates a RESTART (R) condition. †

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated. †

Multiple Master Arbitration

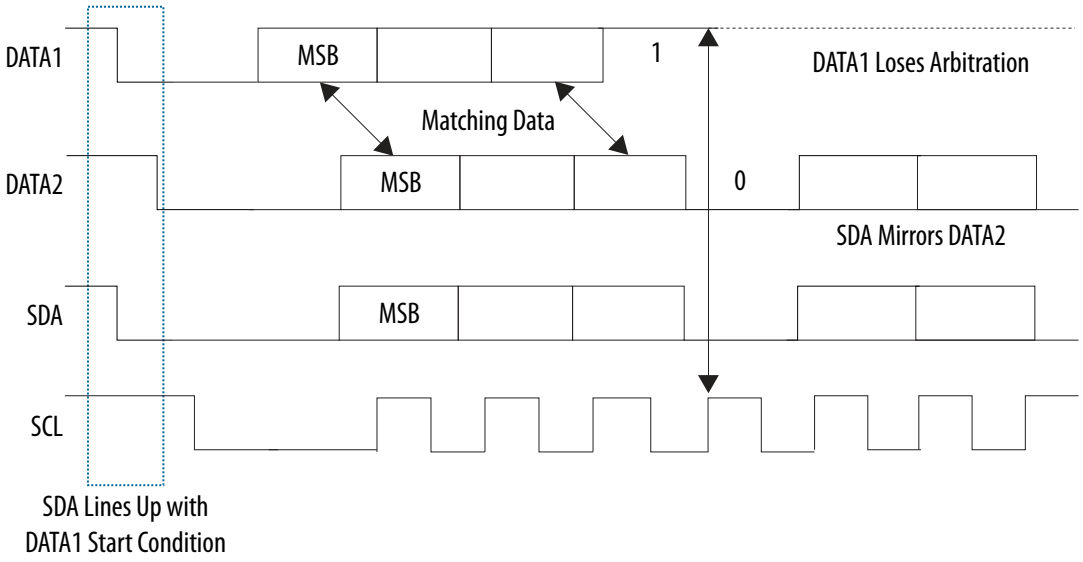
The I^2C controller bus protocol allows multiple masters to reside on the same bus. If there are two masters on the same I^2C-bus, there is an arbitration procedure if both try to take control of the bus at the same time by simultaneously generating a START condition. Once a master (for example, a microcontroller) has control of the bus, no other master can take control until the first master sends a STOP condition and places the bus in an idle state. †

Arbitration takes place on the SDA line, while the SCL line is 1. The master, which transmits a 1 while the other master transmits 0, loses arbitration and turns off its data output stage. The master that lost arbitration can continue to generate clocks until the end of the byte transfer. If both masters are addressing the same slave device, the arbitration could go into the data phase. †

Upon detecting that it has lost arbitration to another master, the I^2C controller stops generating SCL. †

The following figure illustrates the timing of two masters arbitrating on the bus.

Figure 20-10: Multiple Master Arbitration †



The bus control is determined by address or master code and data sent by competing masters, so there is no central master nor any order of priority on the bus. †

Arbitration is not allowed between the following conditions: †

- A RESTART condition and a data bit †
- A STOP condition and a data bit †
- A RESTART condition and a STOP condition †

Slaves are not involved in the arbitration process. †

Clock Synchronization

When two or more masters try to transfer information on the bus at the same time, they must arbitrate and synchronize the SCL clock. All masters generate their own clock to transfer messages. Data is valid only during the high period of SCL clock. Clock synchronization is performed using the wired-AND connection to the SCL signal. When the master transitions the SCL clock to 0, the master starts counting the low time of the SCL clock and transitions the SCL clock signal to 1 at the beginning of the next clock period. However, if another master is holding the SCL line to 0, then the master goes into a HIGH wait state until the SCL clock line transitions to 1. †

All masters then count off their high time, and the master with the shortest high time transitions the SCL line to 0. The masters then counts out their low time and the one with the longest low time forces the other master into a HIGH wait state. Therefore, a synchronized SCL clock is generated, which is illustrated in the following figure. Optionally, slaves may hold the SCL line low to slow down the timing on the I^2C bus. †

Figure 20-11: Multiple Master Clock Synchronization †

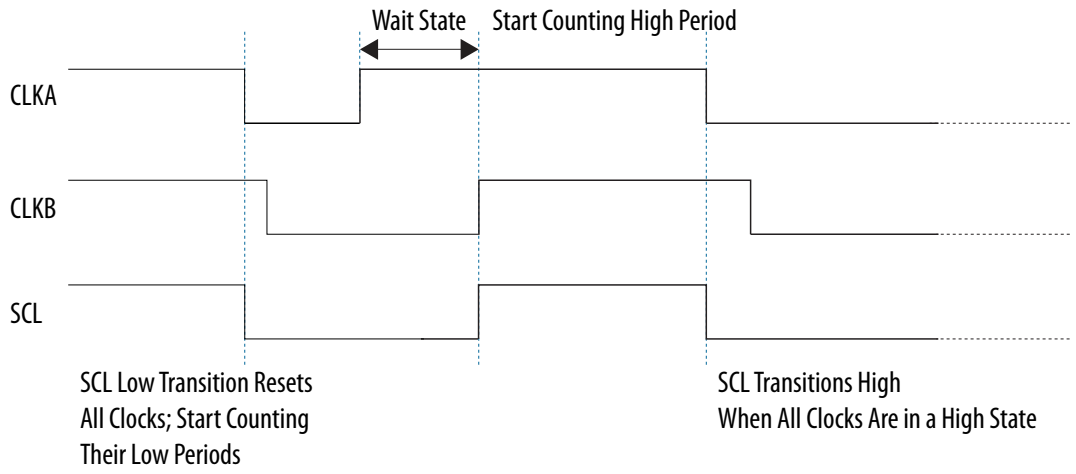


Figure 20-12: Impact of SCL Rise Time and Fall Time on Generated SCL

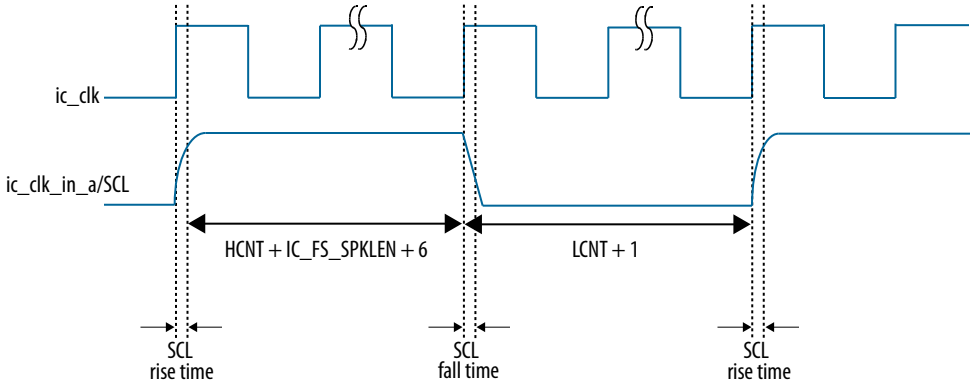

The following equations can be used to compute SCL high and low time:

```
SCL_High_time = [(HCNT + IC_FS_SPKLEN + 6)*ic_clk] + SCL_Fall_time
SCL_Low_time = [(LCNT + 1)*ic_clk] - SCL_Fall_time + SCL_Rise_time
```

Clock Frequency Configuration

When you configure the I²C controller as a master, the SCL count registers must be set before any I²C bus transaction can take place in order to ensure proper I/O timing. † There are four SCL count registers:

- Standard speed I²C clock SCL high count, `IC_SS_SCL_HCNT` †
- Standard speed I²C clock SCL low count, `IC_SS_SCL_LCNT` †
- Fast speed I²C clock SCL high count, `IC_FS_SCL_HCNT` †
- Fast speed I²C clock SCL low count, `IC_FS_SCL_LCNT` †

It is not necessary to program any of the SCL count registers if the I²C controller is enabled to operate only as an I²C slave, since these registers are used only to determine the SCL timing requirements for operation as an I²C master. †

Minimum High and Low Counts

When the I²C controller operates as an I²C master in both transmit and receive transfers, the minimum value that can be programmed in the SCL low count registers is 8 while the minimum value allowed for the SCL high count registers is 6. †

The minimum value of 8 for the low count registers is due to the time required for the I²C controller to drive SDA after a negative edge of SCL. The minimum value of 6 for the high count register is due to the time required for the I²C controller to sample SDA during the high period of SCL. †

The I²C controller adds one cycle to the low count register values in order to generate the low period of the SCL clock.

The I²C controller adds seven cycles to the high count register values in order to generate the high period of the SCL clock. This is due to the following factors: †

- The digital filtering applied to the SCL line incurs a delay of four `l4_sp_clk` cycles. This filtering includes metastability removal and a 2-out-of-3 majority vote processing on SDA and SCL edges. †
- Whenever SCL is driven 1 to 0 by the I^2C controller—that is, completing the SCL high time—an internal logic latency of three `l4_sp_clk` cycles incurs. †

Consequently, the minimum SCL low time of which the I^2C controller is capable is nine (9) `l4_sp_clk` periods (8+1), while the minimum SCL high time is thirteen (13) `l4_sp_clk` periods (6+1+3+3). †

Note: The `ic_fs_spklen` register must be set before any I^2C bus transaction can take place to ensure stable operation. This register sets the duration measured in `ic_clk` cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic.†

Calculating High and Low Counts

The calculations below show an example of how to calculate SCL high and low counts for each speed mode in the I^2C controller.

The equation to calculate the proper number of `l4_sp_clk` clock pulses required for setting the proper SCL clocks high and low times is as follows: †

Table 20-4: Equation

IC_HCNT = ceil(MIN_SCL_`HIGHtime`*OSCFREQ)

IC_LCNT = ceil(MIN_SCL_`LOWtime`*OSCFREQ)

MIN_SCL_HIGHtime = minimum high period

MIN_SCL_HIGHtime =

4000 ns for 100 kbps

600 ns for 400 kbps

60 ns for 3.4 Mbs, bus loading = 100pF

160 ns for 3.4 Mbs, bus loading = 400pF

MIN_SCL_LOWtime = minimum low period

MIN_SCL_LOWtime =

4700 ns for 100 kbps

1300 ns for 400 kbps

120 ns for 3.4Mbs, bus loading = 100pF

320 ns for 3.4Mbs, bus loading = 400pF

OSCFREQ = `l4_sp_clk` clock frequency (Hz)

Example 20-1: Calculating High and Low Counts

```
OSCFREQ = 100 MHz
I2Cmode = fast, 400 kbps
```

```
MIN_SCL_HIGHtime = 600 ns
MIN_SCL_LOWtime = 1300 ns

IC_HCNT = ceil(600 ns * 100 MHz) IC_HCNTSCL PERIOD = 60
IC_LCNT = ceil(1300 ns * 100 MHz) IC_LCNTSCL PERIOD = 130
Actual MIN_SCL_HIGHtime = 60*(1/100 MHz) = 600 ns
Actual MIN_SCL_LOWtime = 130*(1/100 MHz) = 1300 ns †
```

SDA Hold Time

The I²C protocol specification requires 300 ns of hold time on the SDA signal in standard and fast speed modes. Board delays on the SCL and SDA signals can mean that the hold time requirement is met at the I²C master, but not at the I²C slave (or vice-versa). As each application encounters differing board delays, the I²C controller contains a software programmable register, `IC_SDA_HOLD`, to enable dynamic adjustment of the SDA hold time. `IC_SDA_HOLD` effects both slave-transmitter and master mode.

DMA Controller Interface

The I²C controller supports DMA signaling to indicate when data is ready to be read or when the transmit FIFO needs data. This support requires 2 DMA channels, one for transmit data and one for receive data. The I²C controller supports both single and burst DMA transfers. System software can choose the DMA burst mode by programming an appropriate value into the threshold registers. The recommended setting of the FIFO threshold register value is half full.

To enable the DMA controller interface on the I²C controller, you must write to the DMA control register (`DMACR`) bits. Writing a 1 into the `TDMAE` bit field of `DMACR` register enables the I²C controller transmit handshaking interface. Writing a 1 into the `RDMAE` bit field of the `DMACR` register enables the I²C controller receive handshaking interface. †

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Clocks

Each I²C controller is connected to the `l4_sp_clk` clock, which clocks transfers in standard and fast mode. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to *Clock Manager* chapter.

Resets

Each I²C controller has a separate reset signal. The reset manager drives the signals on a cold or warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to *Reset Manager* chapter.

Taking the I2C Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Modules Requiring Software Deassert on page 3-13

I2C Controller Programming Model

This section describes the programming model for the I2C controllers based on the two master and slave operation modes. †

Note: Each I2C controller should be set to operate only as an I2C master or as an I2C slave, never set both simultaneously. Ensure that bit 6 (`IC_SLAVE_DISABLE`) and 0 (`IC_MASTER_MODE`) of the `IC_CON` register are never set to 0 and 1, respectively. †

Slave Mode Operation

Initial Configuration

To use the I2C controller as a slave, perform the following steps: †

1. Disable the I2C controller by writing a 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_SAR` register (bits 9:0) to set the slave address. This is the address to which the I2C controller responds. †

   Note: The reset value for the I2C controller slave address is 0x55. If you are using 0x55 as the slave address, you can safely skip this step.
3. Write to the `IC_CON` register to specify which type of addressing is supported (7- or 10-bit by setting bit 3). Enable the I2C controller in slave-only mode by writing a 0 into bit 6 (`IC_SLAVE_DISABLE`) and a 0 to bit 0 (`MASTER_MODE`). †

   Note: Slaves and masters do not have to be programmed with the same type of addressing 7- or 10-bit address. For instance, a slave can be programmed with 7-bit addressing and a master with 10-bit addressing, and vice versa. †
4. Enable the I2C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †

   Note: It is recommended that the I2C Slave be brought out of reset only when the I2C bus is `IDLE`. De-asserting the reset when a transfer is ongoing on the bus causes internal flip-flops used to synchronize `SDA` and `SCL` to toggle from a reset value of 1 to the actual value on the bus. In this scenario, if `SDA` toggling from 1 to 0 while `SCL` is 1, thereby causing a false START condition to be detected by the I2C Slave by configuring the I2C with `IC_SLAVE_DISABLE` = 1 and `IC_MASTER_MODE` = 1 so that the Slave interface is disabled after reset. It can then be enabled by programming IC_CON[0] = 0 and IC_CON[6] = 0 after the internal `SDA` and `SCL` have synchronized to the value on the bus; this takes approximately 6 `ic_clk` cycles after reset de-assertion.†

Slave-Transmitter Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and requests data, the I²C controller acts as a slave-transmitter and the following steps occur: †

1. The other I²C master device initiates an I²C transfer with an address that matches the slave address in the IC_SAR register of the I²C controller †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that it is acting as a slave-transmitter. †
3. The I²C controller asserts the RD_REQ interrupt (bit 5 of the IC_RAW_INTR_STAT register) and waits for software to respond. †

   If the RD_REQ interrupt has been masked, due to bit 5 of the IC_INTR_MASK register (M_RD_REQ bit field) being set to 0, then it is recommended that you instruct the CPU to perform periodic reads of the IC_RAW_INTR_STAT register. †

   - Reads that indicate bit 5 of the IC_RAW_INTR_STAT register (R_RD_REQ bit field) being set to 1 must be treated as the equivalent of the RD_REQ interrupt being asserted. †
   - Software must then act to satisfy the I²C transfer. †
   - The timing interval used should be in the order of 10 times the fastest SCL clock period the I²C controller can handle. For example, for 400 Kbps, the timing interval is 25 us. †

     Note: The value of 10 is recommended here because this is approximately the amount of time required for a single byte of data transferred on the I²C bus.†
4. If there is any data remaining in the TX FIFO before receiving the read request, the I²C controller asserts a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register) to flush the old data from the TX FIFO. †

   Note: Because the I²C controller's TX FIFO is forced into a flushed/reset state whenever a TX_ABRT event occurs, it is necessary for software to release the I²C controller from this state by reading the IC_CLR_TX_ABRT register before attempting to write into the TX FIFO. For more information, refer to the C_RAW_INTR_STAT register description in the register map.†

   If the TX_ABRT interrupt has been masked, due to of IC_INTR_MASK[6] register (M_TX_ABRT bit field) being set to 0, then it is recommended that the CPU performs periodic reads of the IC_RAW_INTR_STAT register. †

   - Reads that indicate bit 6 (R_TX_ABRT) being set to 1 must be treated as the equivalent of the TX_ABRT interrupt being asserted. †
   - There is no further action required from software. †
   - The timing interval used should be similar to that described in the previous step for the IC_RAW_INTR_STAT[5] register. †
5. Software writes to the DAT bits of the IC_DATA_CMD register with the data to be written and writes a 0 in bit 8.†
6. Software must clear the RD_REQ and TX_ABRT interrupts (bits 5 and 6, respectively) of the IC_RAW_INTR_STAT register before proceeding. †

   If the RD_REQ and/or TX_ABRT interrupts have been masked, then clearing of the IC_RAW_INTR_STAT register will have already been performed when either the R_RD_REQ or R_TX_ABRT bit has been read as 1. †
7. The I²C controller transmits the byte. †
8. The master may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Receiver Operation for a Single Byte

When another I²C master device on the bus addresses the I²C controller and is sending data, the I²C controller acts as a slave-receiver and the following steps occur:†

1. The other I²C master device initiates an I²C transfer with an address that matches the I²C controller's slave address in the IC_SAR register. †
2. The I²C controller acknowledges the sent address and recognizes the direction of the transfer to indicate that the I²C controller is acting as a slave-receiver. †
3. I²C controller receives the transmitted byte and places it in the receive buffer. †

   Note: If the RX FIFO is completely filled with data when a byte is pushed, then an overflow occurs and the I²C controller continues with subsequent I²C transfers. Because a NACK is not generated, software must recognize the overflow when indicated by the I²C controller (by the R_RX_OVER bit in the IC_INTR_STAT register) and take appropriate actions to recover from lost data. Hence, there is a real time constraint on software to service the RX FIFO before the latter overflow as there is no way to reapply pressure to the remote transmitting master. †
4. I²C controller asserts the RX_FULL interrupt (IC_RAW_INTR_STAT[2] register). †

   If the RX_FULL interrupt has been masked, due to setting IC_INTR_MASK[2] register to 0 or setting IC_TX_TL to a value larger than 0, then it is recommended that the CPU does periodic reads of the IC_STATUS register. Reads of the IC_STATUS register, with bit 3 (RFNE) set at 1, must then be treated by software as the equivalent of the RX_FULL interrupt being asserted. †
5. Software may read the byte from the IC_DATA_CMD register (bits 7:0). †
6. The other master device may hold the I²C bus by issuing a RESTART condition or release the bus by issuing a STOP condition. †

Slave-Transfer Operation for Bulk Transfers

In the standard I²C protocol, all transactions are single byte transactions and the programmer responds to a remote master read request by writing one byte into the slave's TX FIFO. When a slave (slave-transmitter) is issued with a read request (RD_REQ) from the remote master (master-receiver), at a minimum there should be at least one entry placed into the slave-transmitter's TX FIFO. The I²C controller is designed to handle more data in the TX FIFO so that subsequent read requests can receive that data without raising an interrupt to request more data. Ultimately, this eliminates the possibility of significant latencies being incurred between raising the interrupt for data each time had there been a restriction of having only one entry placed in the TX FIFO. †

This mode only occurs when I²C controller is acting as a slave-transmitter. If the remote master acknowledges the data sent by the slave-transmitter and there is no data in the slave's TX FIFO, the I²C controller raises the read request interrupt (RD_REQ) and waits for data to be written into the TX FIFO before it can be sent to the remote master. †

If the RD_REQ interrupt is masked, due to bit 5 (M_RD_REQ) of the IC_INTR_STAT register being set to 0, then it is recommended that the CPU does periodic reads of the IC_RAW_INTR_STAT register. Reads of IC_RAW_INTR_STAT that return bit 5 (R_RD_REQ) set to 1 must be treated as the equivalent of the RD_REQ interrupt referred to in this section.†

The RD_REQ interrupt is raised upon a read request, and like interrupts, must be cleared when exiting the interrupt service handling routine (ISR). The ISR allows you to either write 1 byte or more than 1 byte into the TX FIFO. During the transmission of these bytes to the master, if the master acknowledges the last byte then the slave must raise the RD_REQ again because the master is requesting for more data. †

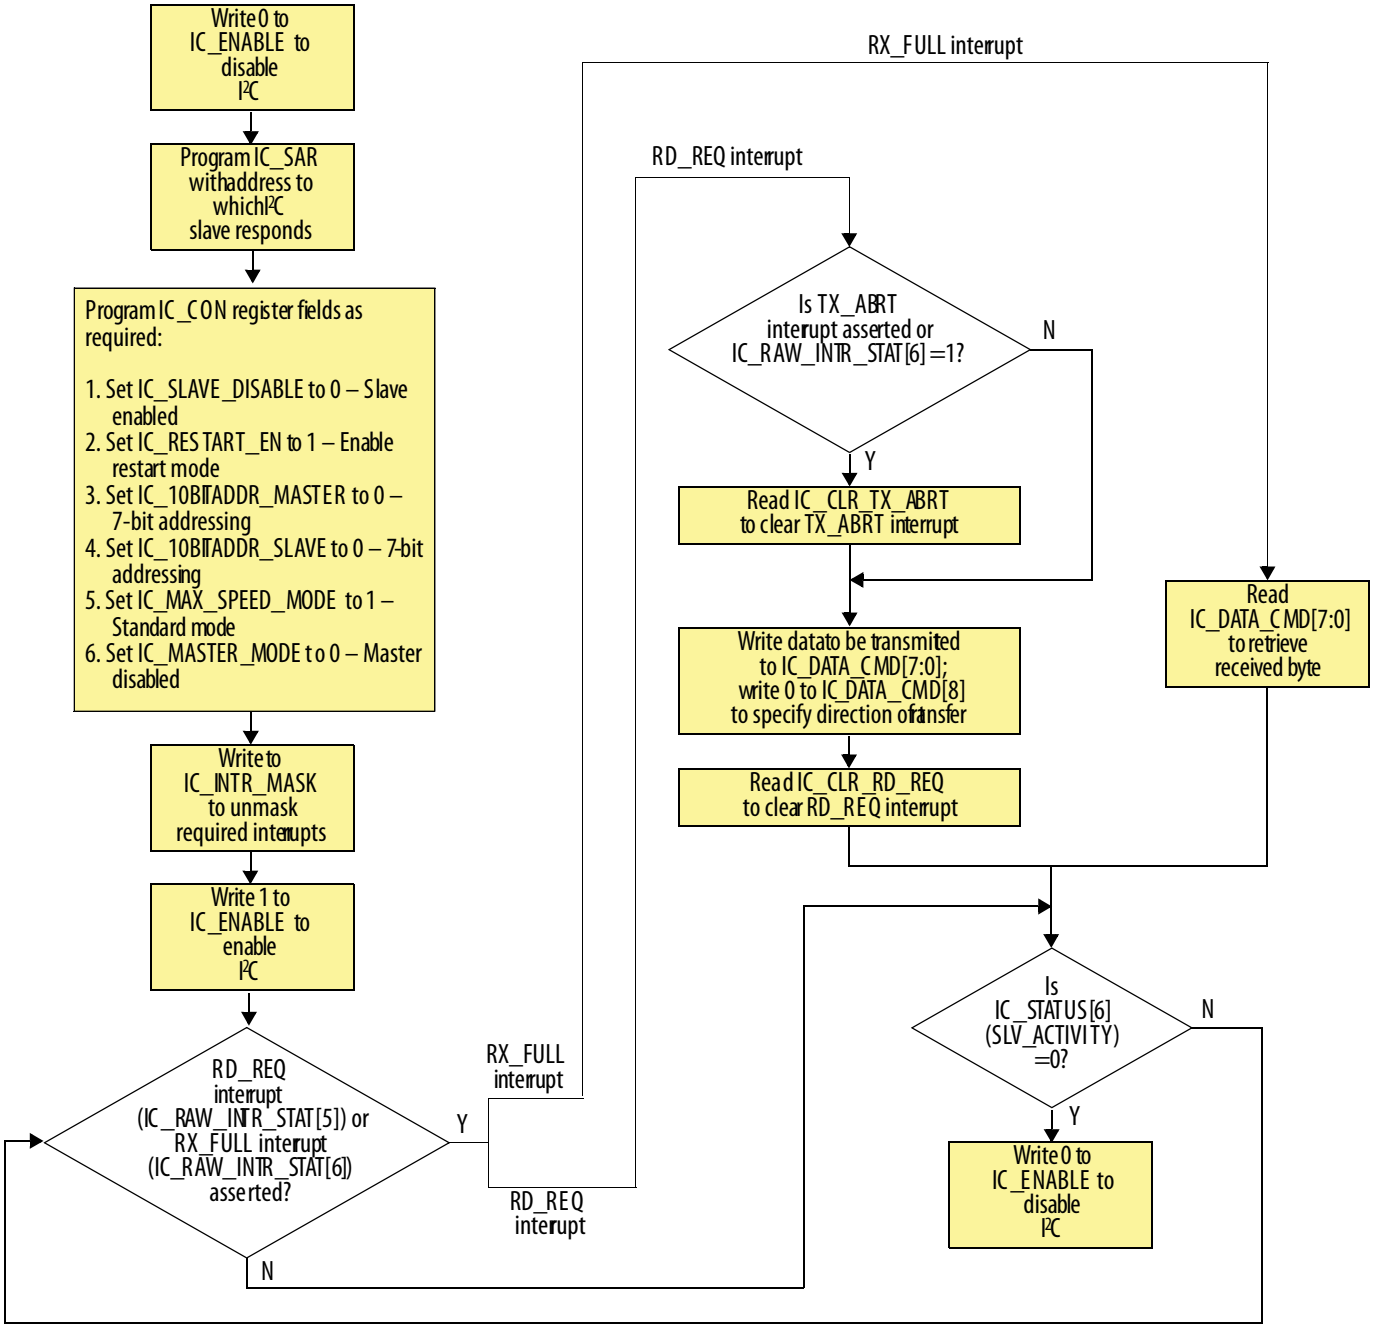
If the programmer knows in advance that the remote master is requesting a packet of n bytes, then when another master addresses the I²C controller and requests data, the TX FIFO could be written with n number bytes and the remote master receives it as a continuous stream of data. For example, the I²C

controller slave continues to send data to the remote master as long as the remote master is acknowledging the data sent and there is data available in the TX FIFO. There is no need to issue RD_REQ again. †

If the remote master is to receive n bytes from the I^2C controller but the programmer wrote a number of bytes larger than n to the TX FIFO, then when the slave finishes sending the requested n bytes, it clears the TX FIFO and ignores any excess bytes. †

The I^2C controller generates a transmit abort (TX_ABRT) event to indicate the clearing of the TX FIFO in this example. At the time an ACK/NACK is expected, if a NACK is received, then the remote master has all the data it wants. At this time, a flag is raised within the slave's state machine to clear the leftover data in the TX FIFO. This flag is transferred to the processor bus clock domain where the FIFO exists and the contents of the TX FIFO are cleared at that time. †

Slave Programming Model



Master Mode Operation

Initial Configuration

For master mode operation, the target address and address format can be changed dynamically without having to disable the I^2C controller. This feature is only applicable when the I^2C controller is acting as a master because the slave requires the component to be disabled before any changes can be made to the address. To use the I^2C controller as a master, perform the following steps: †

For multiple I²C transfers, perform additional writes to the Tx FIFO such that the Tx FIFO does not become empty during the I²C transaction. IF the Tx FIFO is completely emptied at any stage, then the master stalls the transfer by holding the SCL line low because there was no stop bit indicating the master to issue a STOP. The master will complete the transfer when it finds a Tx FIFO entry tagged with a Stop bit.

1. Disable the I²C controller by writing 0 to bit 0 of the `IC_ENABLE` register. †
2. Write to the `IC_CON` register to set the maximum speed mode supported for slave operation (bits 2:1) and to specify whether the I²C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (bit 3). †
3. Write to the `IC_TAR` register the address of the I²C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I²C. The desired speed of the I²C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the `IC_10BITADDR_MASTER` bit field (bit 12). †
4. Enable the I²C controller by writing a 1 in bit 0 of the `IC_ENABLE` register. †
5. Now write the transfer direction and data to be sent to the `IC_DATA_CMD` register. If the `IC_DATA_CMD` register is written before the I²C controller is enabled, the data and commands are lost as the buffers are kept cleared when the I²C controller is not enabled. †

Dynamic IC_TAR or IC_10BITADDR_MASTER Update

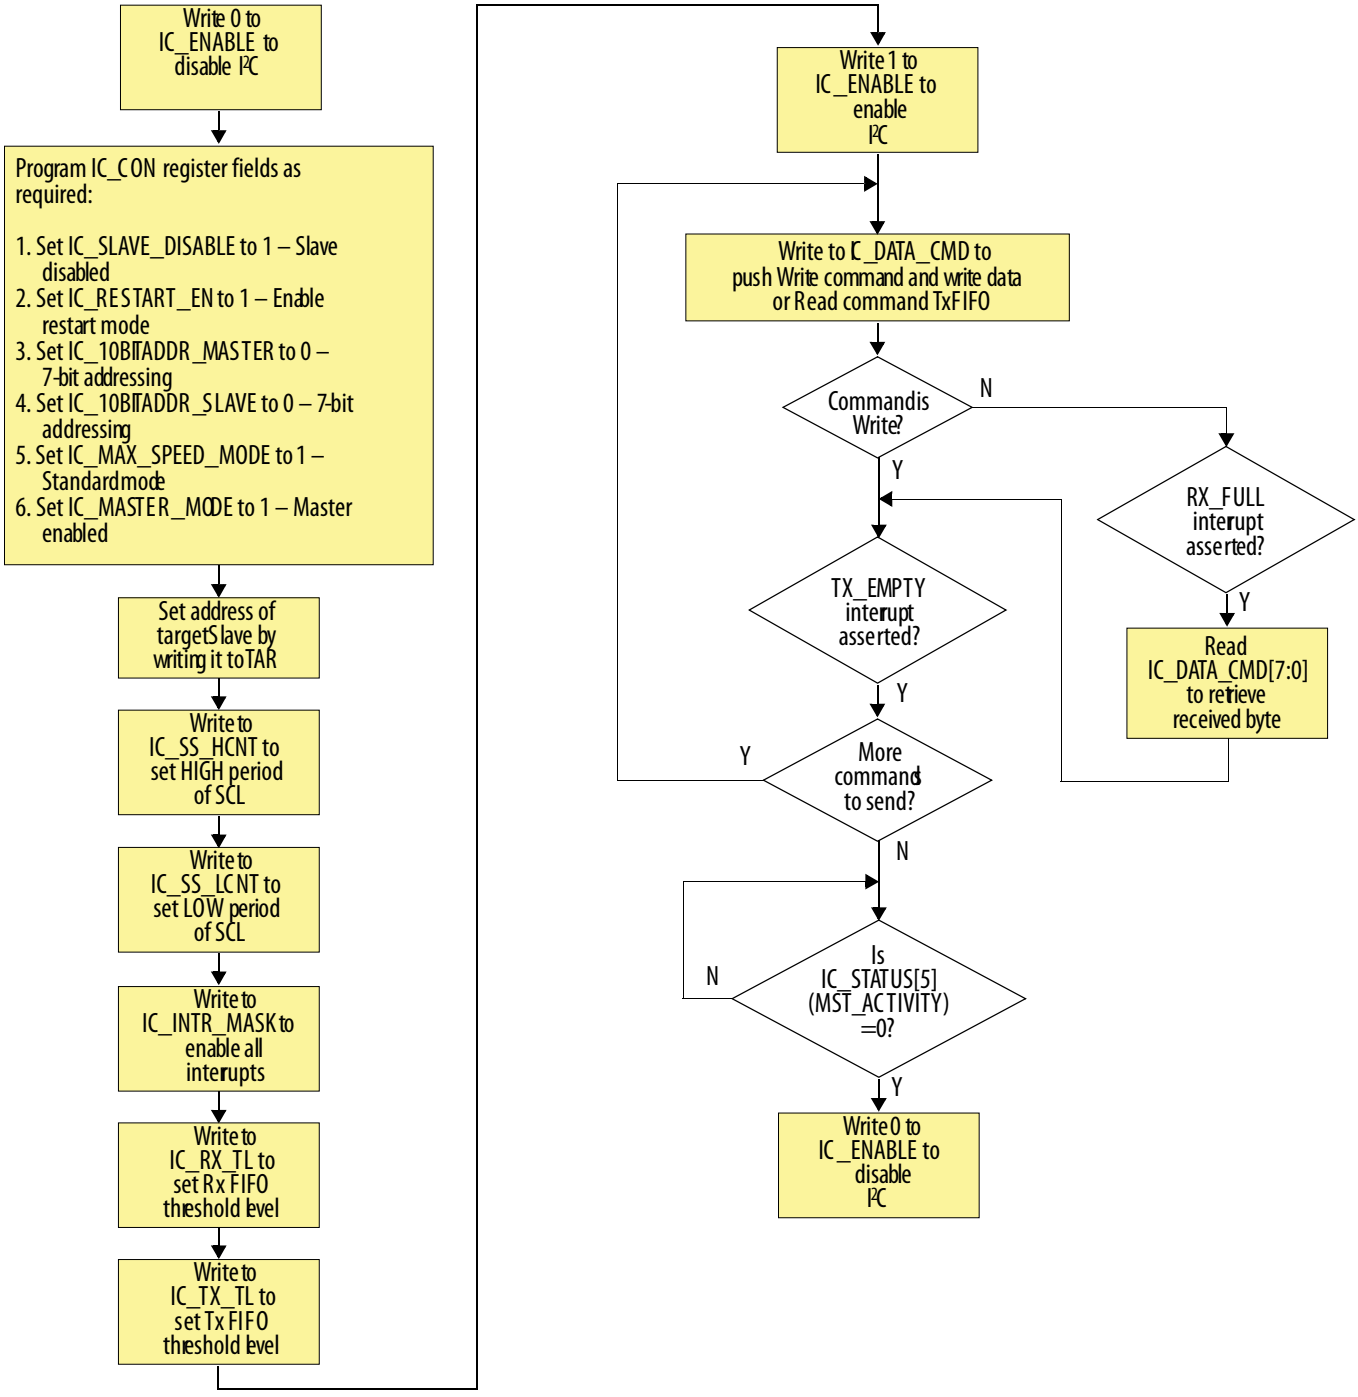
The I²C controller supports dynamic updating of the `IC_TAR` (bits 9:0) and `IC_10BITADDR_MASTER` (bit 12) bit fields of the `IC_TAR` register. You can dynamically write to the `IC_TAR` register provided the following conditions are met: †

- The I²C controller is not enabled (`IC_ENABLE`=0); †
- The I²C controller is enabled (`IC_ENABLE`=1); AND I²C controller is NOT engaged in any Master (TX, RX) operation (`IC_STATUS[5]`=0); AND I²C controller is enabled to operate in Master mode (`IC_CON[0]`=1); AND there are no entries in the TX FIFO (`IC_STATUS[2]`=1) †

Master Transmit and Master Receive

The I²C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I²C Rx/Tx Data Buffer and Command Register (`IC_DATA_CMD`). The CMD bit [8] should be written to 0 for I²C write operations. Subsequently, a read command may be issued by writing "don't cares" to the lower byte of the `IC_DATA_CMD` register, and a 1 should be written to the CMD bit.†

Master Programming Model



Disabling the I2C Controller

The register IC_ENABLE_STATUS is added to allow software to unambiguously determine when the hardware has completely shutdown in response to the IC_ENABLE register being set from 1 to 0. †

1. Define a timer interval (ti2c_poll) equal to the 10 times the signaling period for the highest I2C transfer speed used in the system and supported by the I2C controller. For example, if the highest I2C transfer mode is 400 Kbps, then ti2c_poll is 25 us. †
2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported. †
3. Execute a blocking thread/process/function that prevents any further I2C master transactions to be started by software, but allows any pending transfers to be completed.
   - This step can be ignored if the I2C controller is programmed to operate as an I2C slave only. †
4. The variable POLL_COUNT is initialized to zero. †
5. Set IC_ENABLE to 0. †
6. Read the IC_ENABLE_STATUS register and test the IC_EN bit (bit 0). Increment POLL_COUNT by one. If POLL_COUNT >= MAX_T_POLL_COUNT, exit with the relevant error code. †
7. If IC_ENABLE_STATUS[0] is 1, then sleep for ti2c_poll and proceed to the previous step. Otherwise, exit with a relevant success code. †

Abort Transfer

The ABORT control bit of the IC_ENABLE register allows the software to relinquish the I2C bus before completing the issued transfer commands from the Tx FIFO. In response to an ABORT request, the controller issues the STOP condition over the I2C bus, followed by Tx FIFO flush. Aborting the transfer is allowed only in master mode of operation.†

1. Stop filling the Tx FIFO (IC_DATA_CMD) with new commands.†
2. When operating in DMA mode, disable the transmit DMA by setting TDMAE to 0. †
3. Set bit 1 of the IC_ENABLE register (ABORT) to 1.†
4. Wait for the M_TX_ABRT interrupt.†
5. Read the IC_TX_ABRT_SOURCE register to identify the source as ABRT_USER_ABRT.†

DMA Controller Operation

To enable the DMA controller interface on the I2C controller, you must write the DMA Control Register (IC_DMA_CR). Writing a 1 to the TDMAE bit field of IC_DMA_CR register enables the I2C controller transmit handshaking interface. Writing a 1 to the RDMAE bit field of the IC_DMA_CR register enables the I2C controller receive handshaking interface.†

The FIFO buffer depth (FIFO_DEPTH) for both the RX and TX buffers in the I2C controller is 64 entries.

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit FIFO Underflow

During I2C serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the value in DMA Transmit Data Level Register

(IC_DMA_TDLR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Note: Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of the data (underflow) causing the maser to stall the transfer by holding the SCL line low. To prevent this condition, you must set the watermark level correctly.†

Related Information

DMA Controller on page 16-1
For details about the DMA burst length microcode setup, refer to the *DMA controller* chapter.

Transmit Watermark Level

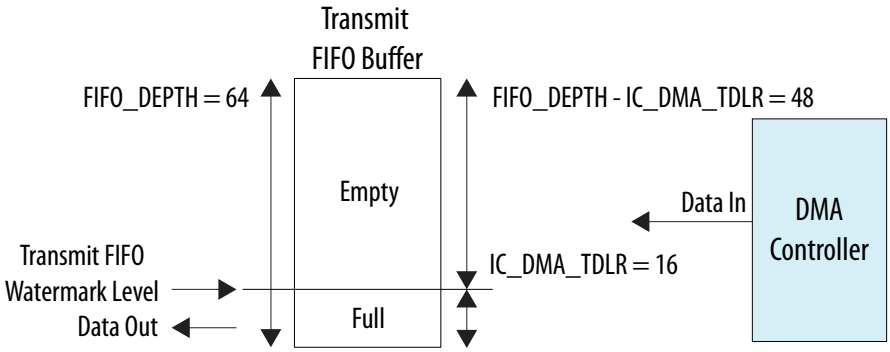
Consider the example where the assumption is made: †

DMA burst length = FIFO_DEPTH - IC_DMA_TDLR †

Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

- Case 1: IC_DMA_TDLR = 16: †
  - Transmit FIFO watermark level = IC_DMA_TDLR = 16: †
  - DMA burst length = FIFO_DEPTH - IC_DMA_TDLR = 48: †
  - I^2C transmit FIFO_DEPTH = 64: †
  - Block transaction size = 240: †

Figure 20-13: Transmit FIFO Watermark Level = 16



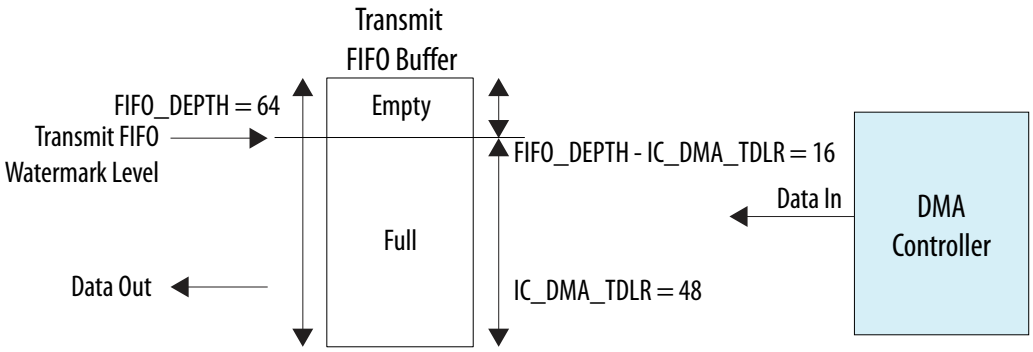
The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 240/48 = 5

The number of burst transactions in the DMA block transfer is 5. But the watermark level, IC_DMA_TDLR, is quite low. Therefore, the probability of transmit underflow is high where the I^2C serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

- Case 2: IC_DMA_TDLR = 48 †
  - Transmit FIFO watermark level = IC_DMA_TDLR = 48 †
  - DMA burst length = FIFO_DEPTH - IC_DMA_TDLR = 16 †
  - I²C transmit FIFO_DEPTH = 64 †
  - Block transaction size = 240 †

Figure 20-14: Transmit FIFO Watermark Level = 48



Number of burst transactions in block: †

Block transaction size/DMA burst length = 240/16 = 15 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, IC_ DMA_TDLR, is high. Therefore, the probability of I²C transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the I²C transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the I²C transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= FIFO_DEPTH - IC_DMA_TDLR

In case 2: IC_DMA_TDLR = 48, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length should be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = FIFO_DEPTH - IC_DMA_TDLR

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the I^2C controller has successfully transmitted one data item or more on the I^2C serial transmit line during the transfer. †

Receive FIFO Overflow

During I^2C serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the DMA Receive Data Level Register, that is `IC_DMA_RDLR` + 1. This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, `IC_DMA_RDLR` + 1, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a trade off between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = `IC_DMA_RDLR` + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, `IC_DMA_RDLR` + 1. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

Note: The receive FIFO will not be empty at the end of the source burst transaction if the I^2C controller has successfully received one data item or more on the I^2C serial receive line during the burst. †

ic_con Fields

Bit	Name	Description	Access	Reset
31:9	rsvd_ic_con_31to9	Reserved bits [31:9] - Read Only	RO	0x0
8	tx_empty_ctrl	This bit controls the generation of the TX_EMPTY interrupt, as described in the IC_RAW_INTR_STAT register. Reset value: 0x0.	RW	0x0
7	stop_det_ifaddressed	In slave mode: 1: issues the STOP_DET interrrupt only when it is addressed. 0: issues the STOP_DET irrespec-tive of whether it’s addressed or not. Dependencies: This register bit value is applicable in the slave mode only (MASTER_MODE = 1’b0) Reset value: 0x0 NOTE: During a general call address, this slave does not issue the STOP_DET interrupt if STOP_DET_IF_ADDRESSED = 1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR).	RW	0x0

Bit	Name	Description	Access	Reset
6	ic_slave_disable	This bit controls whether I2C has its slave disabled. Once the presetn signal is applied, then this bit is set to 1. When this bit is set (slave is disabled), the I2C module functions only as a master and does not perform any action that requires a slave. 0: slave is enabled 1: slave is disabled NOTE: Software should ensure that if this bit is written with 0, then bit 0 should also be written with a 0. **Value** **Description** 0x0 ENABLE 0x1 DISABLE	RW	0x1

Bit	Name	Description	Access	Reset
5	ic_restart_en	Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several DW_apb_i2c operations. 0: disable 1: enable When RESTART is disabled, the master is prohibited from performing the following functions: - Change direction within a transfer (split) - Send a START BYTE - High-speed mode operation - Combined format transfers in 7-bit addressing modes - Read operation with a 10-bit address - Send multiple bytes per transfer By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple I2C transfers. If the above operations are performed, it will result in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. Reset value: 0x1 **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x1
4	ic_10bitaddr_master	The bit is read-only. 0: 7-bit addressing 1: 10-bit addressing Reset value: 0x1 **Value** **Description** 0x0 MSTADDR7BIT 0x1 MSTADDR10BIT	RO	0x1

Bit	Name	Description	Access	Reset
3	ic_10bitaddr_slave	When acting as a slave, this bit controls whether the I2C module responds to 7- or 10-bit addresses. 0: 7-bit addressing. The I2C module ignores transactions that involve 10-bit addressing; for 7-bit addressing, only the lower 7 bits of the IC_SAR register are compared. 1: 10-bit addressing. The I2C module responds to only 10-bit addressing transfers that match the full 10 bits of the IC_SAR register. Reset value: 0x1 **Value** **Description** 0x0 SLVADDR7BIT 0x1 SLVADDR10BIT	RW	0x1
2:1	speed	These bits control at which speed the I2C operates; its setting is relevant only if one is operating the I2C module in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to 400 kbits/s; otherwise, hardware updates this register with the value of 400 kbits/s. 1: standard mode (100 kbit/s) 2: fast mode (<=400 kbit/s) or fast mode plus (<=1000Kbit/s) Reset value: 0x2 **Value** **Description** 0x1 STANDARD 0x2 FAST	RW	0x2

Bit	Name	Description	Access	Reset
0	master_mode	This bit controls whether the I2C master is enabled. 0: master disabled 1: master enabled Reset value: 0x1 NOTE: Software should ensure that if this bit is written with '1' then bit 6 should also be written with a '1'. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x1

ic_tar

```
Name: I2C Target Address Register

All bits can be dynamically updated as long as any set of the
following
conditions are true:
- The I2C is NOT enabled (IC_ENABLE[0] is set to 0);
   or
- The I2C is enabled (IC_ENABLE[0]=1);
   AND
  the I2C is NOT engaged in any Master (tx, rx) operation
(IC_STATUS[5]=0);
   AND
  I2C is enabled to operate in Master mode (IC_CON[0]=1);
   AND
  there are NO entries in the TX FIFO (IC_STATUS[2]=1)
```

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02204
i_i2c_1_i2c	0xFFC02300	0xFFC02304

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			ic_10bit addr_master RW 0x1	special RW 0x0	gc_or_start RW 0x0	ic_tar RW 0x55									

ic_tar Fields

Bit	Name	Description	Access	Reset
12	ic_10bitaddr_master	This bit controls whether the I2C starts its transfers in 7- or 10-bit addressing mode when acting as a master. 0: 7-bit addressing 1: 10-bit addressing Reset value: 0x1 **Value** **Description** 0x0 START7 0x1 START10	RW	0x1
11	special	This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally 1: perform special I2C command as specified in GC_OR_START bit Reset value: 0x0 **Value** **Description** 0x0 GENCALL 0x1 STARTBYTE	RW	0x0

Bit	Name	Description	Access	Reset
10	gc_or_start	If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call or START byte command is to be performed by the I2C. 0: General Call Address after issuing a General Call, only writes may be performed. Attempting to issue a read command results in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. The I2C remains in General Call mode until the SPECIAL bit value (bit 11) is cleared. 1: START BYTE Reset value: 0x0 **Value / Description** 0x0 GENCALL 0x1 STARTBYTE	RW	0x0
9:0	ic_tar	This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits. Reset value: 0x55 If the IC_TAR and IC_SAR are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.	RW	0x55

ic_sar

Name: I2C Slave Address Register

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02208
i_i2c_1_i2c	0xFFC02300	0xFFC02308

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					restart WO 0x0	stop WO 0x0	cmd WO 0x0	dat RW 0x0							

ic_data_cmd Fields

Bit	Name	Description	Access	Reset
10	restart	This bit controls whether a RESTART is issued before the byte is sent or received. 1 - If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 - If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. Reset value: 0x0	WO	0x0
9	stop	This bit controls whether a STOP is issued after the byte is sent or received. 1 - STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. 0 - STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. Reset value: 0x0	WO	0x0

Bit	Name	Description	Access	Reset
8	cmd	This bit controls whether a read or a write is performed. This bit does not control the direction when the I2C acts as a slave. It controls only the direction when it acts as a master. 1 = Read 0 = Write When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that CPU data is to be transmitted and as DAT or IC_DATA_CMD[7:0]. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABRT interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing the I2C module. In this type of scenario, the I2C mmodule ignores the IC_DATA_CMD write, generates a TX_ABRT interrupt, and waits to service the RD_REQ interrupt. Reset value: 0x0 **Value** **Description** 0x0 WR	WO	0x0

Bit	Name	Description	Access	Reset
		Value Description 0x1 RD		
7:0	dat	This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the I2C module. However, when you read this register, these bits return the value of data received on the I2C interface. Reset value: 0x0	RW	0x0

ic_ss_scl_hcnt

Name: Standard Speed I2C Clock SCL High Count Register

Module Instance	Base Address	Register Address

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
13	r_master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
12	r_restart_det	Indicates a RESTART condition has occurred on the I2C interface when the I2C module is operating in slave mode and addressed. Reset value: 0x0	RO	0x0
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C is operating in slave or master mode. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
9	r_stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED =0 : Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 : In Master Mode (MASTER_MODE = 1'b1) , indicates a STOP condition has occurred on the I2C interface. In Slave Mode (MASTER_MODE = 1'b0) ,STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_ IFADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
8	r_activity	This bit captures the I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
7	r_rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	r_tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
5	r_rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from it. The I2C module holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
4	r_tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
2	r_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	r_rx_over	Set if the receive buffer is completely filled to the Rx buffer depth of 64 and an additional byte is received from an external I2C device. The I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

ic_intr_mask

Name: I2C Interrupt Mask Register

These bits mask their corresponding interrupt status bits. They are active high; a value of 0 prevents a bit from generating an interrupt.

Bit	Name	Description	Access	Reset

9	stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register
		When STOP_DET_IFADDRESSED =0
		  Indicates whether a STOP condition has occurred on the I2C interface regardless
		  of whether the I2C module is operating in slave or master mode. In slave mode,
		  a STOP_DET interrupt is generated irrespective of whether the
		  slave is addressed or not.
		When STOP_DET_IFADDRESSED = 1
		  In Master Mode (MASTER_MODE = 1), indicates a STOP condition has occured on the I2C interface.
		  In Slave Mode (MASTER_MODE = 0), a STOP_DET interrupt is generated only if the slave is addressed.
		
		NOTE: During a general call address, this slave does not issue a STOP_DET
		interrupt if STOP_DET_IFADDRESSED=1, even if the slave responds to the
		general call address by generating ACK. The STOP_DET interrupt is generated
		only when the transmitted address matches the slave address (SAR).
		Reset value: 0x0.
			RO	0x0

Bit	Name	Description	Access	Reset
8	activity	This bit captures the I2C activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
7	rx_done	When the I2C is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	tx_abrt	This bit indicates if the I2C, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
5	rd_req	This bit is set to 1 when the I2C is acting as a slave and another I2C master is attempting to read data from it. The HPS I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
4	tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value. set in the IC_TX_TL register and the transmission of the address/ data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_ en=0, this bit is set to 0. Reset value: 0x0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to its maximum TxFIFO buffer depth (64) and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_ en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	rx_over	Set if the receive buffer is completely filled to its maximum RxFIFO depth (64) and an additional byte is received from an external I2C device. The HPS I2C acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

ic_rx_tl

Name: I2C Receive FIFO Threshold Register

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02238
i_i2c_1_i2c	0xFFC02300	0xFFC02338

Offset: 0x38

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								rx_tl RW 0x0							

ic_rx_tl Fields

Bit	Name	Description	Access	Reset
7:0	rx_tl	Receive FIFO Threshold Level Controls the level of entries (or above) that triggers the RX_FULL interrupt (bit 2 in IC_RAW_INTR_STAT register). The valid range is 0-255, with the additional restriction that hardware does not allow this value to be set to a value larger than the depth of the buffer. If an attempt is made to do that, the actual value set will be the maximum depth of the buffer. A value of 0 sets the threshold for 1 entry, and a value of 255 sets the threshold for 256 entries.	RW	0x0

ic_tx_tl

I2C Transmit FIFO Threshold Register

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0223C

I2C Enable Register

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0226C
i_i2c_1_i2c	0xFFC02300	0xFFC0236C

Offset: 0x6C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														txabort RW 0x0	enable RW 0x0

ic_enable Fields

Bit	Name	Description	Access	Reset
1	txabort	When set, the controller initiates the transfer abort. 0: ABORT not initiated or ABORT done 1: ABORT operation in progress The software can abort the I2C transfer in master mode by setting this bit. The software can set this bit only when ENABLE is already set; otherwise, the controller ignores any write to ABORT bit. The software cannot clear the ABORT bit once set. In response to an ABORT, the controller issues a STOP and flushes the Tx FIFO after completing the current transfer, then sets the TX_ABORT interrupt after the abort operation. The ABORT bit is cleared automatically after the abort operation. Reset value: 0x0	RW	0x0

Bit	Name	Description	Access	Reset
0	enable	Controls whether the I2C module is enabled. 0: Disables the I2C module (TX and RX FIFOs are held in an erased state) 1: Enables the I2C module Software can disable the I2C module while it is active. However, it is important that care be taken to ensure that the I2C module is disabled properly. When the I2C module is disabled, the following occurs: - The TX FIFO and RX FIFO get flushed. - Status bits in the IC_INTR_STAT register are still active until the I2C goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the I2C stops the current transfer at the end of the current byte and does not acknowledge the transfer. Reset value: 0x0 **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0

ic_status

```
          Name: I2C Status Register

This is a read-only register used to indicate the current
transfer status and FIFO status. The status register may be
read at any time. None of the bits in this register request
an interrupt.
When the I2C is disabled by writing 0 in bit 0 of the
IC_ENABLE register:
- Bits 1 and 2 are set to 1
- Bits 3 and 4 are set to 0
When the master or slave state machines goes to idle
```

```
and ic_en=0:
- Bits 5 and 6 are set to 0
```

Name: I2C SDA Hold Time Length Register

The bits [15:0] of this register are used to control the hold time of
SDA during
transmit in both slave and master mode (after SCL goes from HIGH to
LOW).
The bits [23:16] of this register are used to extend the SDA
transition (if any)
whenever SCL is HIGH in the receiver in either master or slave mode.
The values in this register are in units of ic_clk period.
This register controls the amount of time delay.
The relevant I2C requirement is thd:DAT as detailed in the I2C
Bus Specification.
```

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0227C

ic_tx_abrt_source

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02280
i_i2c_1_i2c	0xFFC02300	0xFFC02380

Offset: 0x80

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
31:23	tx_flush_cnt	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
22:17	rsvd_ic_tx_abrt_source_22to17	Reserved Reset value: 0x0	RO	0x0
16	abrt_user_abrt	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
15	abrt_slvrd_intx	1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Reset value: 0x0 Role of I2C module: Slave-Transmitter	RO	0x0

Bit	Name	Description	Access	Reset
14	abrt_slv_arblost	1: Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then the I2C module no longer own the bus. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
13	abrt_slvflush_txfifo	1: Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
12	arb_lost	1: Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
11	abrt_master_dis	1: User tries to initiate a Master operation with the Master mode disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

Bit	Name	Description	Access	Reset
10	abrt_10b_rd_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the master sends a read command in 10-bit addressing mode. Reset value: 0x0 Role of the I2C module: Master-Receiver	RO	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; restart must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to send a START Byte. Reset value: 0x0 Role of the I2C module: Master	RO	0x0
8	abrt_hs_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

Bit	Name	Description	Access	Reset
7	abrt_sbyte_ackdet	1: Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
6	abrt_hs_ackdet	1: Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
5	abrt_gcall_read	1: DW_apb_i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
4	abrt_gcall_noack	1: DW_apb_i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call. Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
3	abrt_txdata_noack	1: This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0

Bit	Name	Description	Access	Reset
2	abrt_10addr2_noack	1: Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
1	abrt_10addr1_noack	1: Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
0	abrt_7b_addr_noack	1: Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

ic_slv_data_nack_only

Generate Slave Data NACK Register

The register is used to generate a NACK for the data part of a transfer when the I2C is acting as a slave-receiver.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02284
i_i2c_1_i2c	0xFFC02300	0xFFC02384

Offset: 0x84

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Reserved										dmardl RW 0x0					

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmardl	Receive Data Level. This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO. Reset value: 0x0	RW	0x0

ic_sda_setup

I2C SDA Setup Register

This register controls the amount of time delay
(in terms of number of l4_sp_clk clock periods) introduced
in the rising edge of SCL, relative to SDA changing, when
the I2C module services a read request in a slave-transmitter
operation.
The relevant I2C requirement is tSU:DAT (note 4) as detailed in the
I2C Bus Specification.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC02294
i_i2c_1_i2c	0xFFC02300	0xFFC02394

Offset: 0x94

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Name	Description	Access	Reset
31:1	rsvd_ic_ack_gen_31to1	Reserved bits [31:1] - Read Only	RO	0x0
0	ack_gen_call	ACK General Call. When set to 1, the I2C module responds with a ACK (by asserting ic_data_oe) when it receives a General Call. Otherwise, the I2C module responds with a NACK (by negating ic_data_oe). Default Reset value: 0x1 **Value** **Description** 0x0 NACK 0x1 ACK	RW	0x1

ic_enable_status

I2C Enable Status Register

The register is used to report the I2C hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when the I2C module is disabled.
If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'.
Note
When IC_ENABLE[0] has been written with '0'a delay occurs for bit 0 to be read as '0' because disabling the I2C module depends on I2C bus activities.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC0229C
i_i2c_1_i2c	0xFFC02300	0xFFC0239C

Offset: 0x9C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													slv_rx_data_lost RO 0x0	slv_disabled_while_busy RO 0x0	ic_en RO 0x0

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	slv_rx_data_lost	Slave Received Data Lost. This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting bit 0 of IC_ENABLE from 1 to 0. When read as 1, the I2C module is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit is also set to 1. When read as 0, the I2C module is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
1	slv_disabled_while_busy	Slave Disabled While Busy (Transmit, Receive). This bit indicates if a potential or active Slave operation has been aborted due to the setting bit 0 of the IC_ENABLE register from 1 to 0. This bit is set when the CPU writes a 0 to the IC_ENABLE register while: (a) The I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, the I2C module is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in the I2C (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit will also be set to 1. When read as 0, the I2C module is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
0	ic_en	ic_en Status. This bit always reflects the value driven on the output port ic_en. When read as 1, the I2C module is deemed to be in an enabled state. When read as 0, the I2C module is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read SLV_RX_DATA_LOST (bit 2) and SLV_DISABLED_WHILE_BUSY (bit 1). Reset value: 0x0	RO	0x0

ic_comp_param_1

Component Parameter Register 1

Note
This is a constant read-only register that contains encoded information about the component's parameter settings.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
31:0	ic_comp_type	Designware Component Type number = 0x44_57_01_40. This assigned unique hex value is constant and is derived from the two ASCII letters 'DW' followed by a 16-bit unsigned number.	RO	0x44570140

ic_fs_spklen

I2C SS, FS or FM+ spike suppression limit

This register is used to store the duration, measured in l4_sp_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS, FS or FM+ modes. The relevant I2C requirement is tSP (table 4) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1.

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC022A0
i_i2c_1_i2c	0xFFC02300	0xFFC023A0

Offset: 0xA0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved								ic_fs_spklen RW 0x2							

ic_fs_spklen Fields

Bit	Name	Description	Access	Reset
7:0	ic_fs_spklen	This register must be set before any I2C bus transaction can take place to ensure stable operation. This register sets the duration, measured in l4_sp_clk cycles, of the longest spike in the SCL or SDA lines that will be filtered out by the spike suppression logic. This register can be written only when the I2C interface is disabled which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 1 being set.	RW	0x2

ic_clr_restart_det

Clear RESTART_DET Interrupt Register

Module Instance	Base Address	Register Address
i_i2c_0_i2c	0xFFC02200	0xFFC022A8
i_i2c_1_i2c	0xFFC02300	0xFFC023A8

Offset: 0xA8

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															clr_restart_det RO 0x0

ic_clr_restart_det Fields

Bit	Name	Description	Access	Reset
0	clr_restart_det	Read this register to clear the RESTART_DET interrupt (bit 12) of IC_RAW_INTR_STAT register. Reset value: 0x0	RO	0x0

i2c_emac Address Map

Module Instance	Base Address	End Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC024FF
i_i2c_emac_1_i2c	0xFFC02500	0xFFC025FF
i_i2c_emac_2_i2c	0xFFC02600	0xFFC026FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
ic_con on page 20-163	0x0	32	RW	0x7D	Name: I2C Control Register Size: 10 bits Address Offset: 0x00 Read/Write Access: If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write. If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only. This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect.

Register	Offset	Width	Access	Reset Value	Description
ic_tar on page 20-168	0x4	32	RW	0x1055	Name: I2C Target Address Register Size: 12 bits or 13 bits; 13 bits only when I2C_DYNAMIC_TAR_UPDATE = 1 Address Offset: 0x04 Read/Write Access: Read/Write If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to 'No' (0), this register is 12 bits wide, and bits 31:12 are reserved. This register can be written to only when IC_ENABLE[0] is set to 0. However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. All bits can be dynamically updated as long as any set of the following conditions are true: - DW_apb_i2c is NOT enabled (IC_ENABLE[0] is set to 0); or - DW_apb_i2c is enabled (IC_ENABLE[0]=1); AND DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0); AND DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1); AND there are NO entries in the TX FIFO (IC_STATUS[2]=1)

Register	Offset	Width	Access	Reset Value	Description
ic_sar on page 20-170	0x8	32	RW	0x55	Name: I2C Slave Address Register Size: 10 bits Address Offset: 0x08 Read/Write Access: Read/Write
ic_data_cmd on page 20-171	0x10	32	RW	0x0	Name: I2C Rx/Tx Data Buffer and Command Register; this is the register the CPU writes to when filling the TX FIFO and the CPU reads from when retrieving bytes from RX FIFO Size: When IC_EMPTYFIFO_HOLD_MASTER_EN=1 - 11 bits (writes), 8 bits (read) When IC_EMPTYFIFO_HOLD_MASTER_EN=0 - 9 bits (writes), 8 bits (read) Address Offset: 0x10 Read/Write Access: Read/Write NOTE: With nine bits required for writes, the DW_apb_i2c requires 16-bit data on the APB bus transfers when writing into the transmit FIFO. Eight-bit transfers remain for reads from the receive FIFO.
ic_ss_scl_hcnt on page 20-175	0x14	32	RW	0x190	Name: Standard Speed I2C Clock SCL High Count Register Size: 16 bits Address Offset: 0x14 Read/Write Access: Read/Write

Register	Offset	Width	Access	Reset Value	Description
ic_ss_scl_lcnt on page 20-176	0x18	32	RW	0x1D6	Name: Standard Speed I2C Clock SCL Low Count Register Size: 16 bits Address Offset: 0x18 Read/Write Access: Read/Write
ic_fs_scl_hcnt on page 20-177	0x1C	32	RW	0x3C	Name: Fast Mode or Fast Mode Plus I2C Clock SCL High Count Register Size: 16 bits Address Offset: 0x1c Read/Write Access: Read/Write
ic_fs_scl_lcnt on page 20-178	0x20	32	RW	0x82	Name: Fast Mode or Fast Mode Plus I2C Clock SCL Low Count Register Size: 16 bits Address Offset: 0x20 Read/Write Access: Read/Write
ic_intr_stat on page 20-179	0x2C	32	RO	0x0	Name: I2C Interrupt Status Register Size: 14 bits Address Offset: 0x2C Read/Write Access: Read Each bit in this register has a corresponding mask bit in the IC_INTR_MASK register. These bits are cleared by reading the matching interrupt clear register. The unmasked raw versions of these bits are available in the IC_RAW_INTR_STAT register.

Register	Offset	Width	Access	Reset Value	Description
ic_intr_mask on page 20-187	0x30	32	RW	0x8FF	Name: I2C Interrupt Mask Register Size: 14 bits Address Offset: 0x30 Read/Write Access: Read/Write However, if configuration parameter IC_SLV_RESTART_DET = 0, bit 13 is read only; if configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0 or IC_EMPTYFIFO_HOLD_MASTER_EN = 0, bit 14 is read only. These bits mask their corresponding interrupt status bits. They are active high; a value of 0 prevents a bit from generating an interrupt.
ic_raw_intr_stat on page 20-189	0x34	32	RO	0x0	Name: I2C Raw Interrupt Status Register Size: 14 bits Address Offset: 0x34 Read/Write Access: Read Unlike the IC_INTR_STAT register, these bits are not masked so they always show the true status of the DW_apb_i2c.

ic_status on page 20-210	0x70	32	RO	0x6	Name: I2C Status Register Size: 7 bits Address Offset: 0x70 Read/Write Access: Read This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt. When the I2C is disabled by writing 0 in bit 0 of the IC_ENABLE register: - Bits 1 and 2 are set to 1 - Bits 3 and 4 are set to 0 When the master or slave state machines goes to idle and ic_en=0: - Bits 5 and 6 are set to 0

Register	Offset	Width	Access	Reset Value	Description
ic_txflr on page 20-214	0x74	32	RO	0x0	Name: I2C Transmit FIFO Level Register Size: TX_ABW + 1 Address Offset: 0x74 Read/Write Access: Read This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever: - The I2C is disabled - There is a transmit abort that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register - The slave bulk transmit mode is aborted The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Register	Offset	Width	Access	Reset Value	Description
ic_rxflr on page 20-215	0x78	32	RO	0x0	Name: I2C Receive FIFO Level Register Size: RX_ABW + 1 Address Offset: 0x78 Read/Write Access: Read This register contains the number of valid data entries in the receive FIFO buffer. It is cleared whenever: - The I2C is disabled - Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

Register	Offset	Width	Access	Reset Value	Description
ic_sda_hold on page 20-216	0x7C	32	RW	0x1	Name: I2C SDA Hold Time Length Register Size: 24 bits Address Offset: 0x7c Read/Write Access: Read/Write The bits [15:0] of this register are used to control the hold time of SDA during transmit in both slave and master mode (after SCL goes from HIGH to LOW). The bits [23:16] of this register are used to extend the SDA transition (if any) whenever SCL is HIGH in the receiver in either master or slave mode. The values in this register are in units of ic_clk period. This register controls the amount of time delay. The relevant I2C requirement is thd:DAT as detailed in the I2C Bus Specification.

Register	Offset	Width	Access	Reset Value	Description
ic_tx_abrt_source on page 20-217	0x80	32	RO	0x0	Name: I2C Transmit Abort Source Register Size: 32 bits Address Offset: 0x80 Read/Write Access: Read This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Register	Offset	Width	Access	Reset Value	Description
ic_slv_data_nack_only on page 20-222	0x84	32	RW	0x0	Name: Generate Slave Data NACK Register Size: 1 bit Address Offset: 0x84 Read/Write Access: Read/Write The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the register's address has no effect.

Register	Offset	Width	Access	Reset Value	Description
ic_dma_cr on page 20-223	0x88	32	RW	0x0	Name: DMA Control Register Size: 2 bits Address Offset: 0x88 Read/Write Access: Read/Write This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the register's address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

Register	Offset	Width	Access	Reset Value	Description
ic_dma_tdlr on page 20-225	0x8C	32	RW	0x0	Name: DMA Transmit Data Level Register Size: log2(IC_TX_BUFFER_DEPTH) bits Address Offset: 0x8c Read/Write Access: Read/Write This register is only valid when the DW_apb_i2c is configured with a set of DMA interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist; writing to its address has no effect; reading from its address returns zero.
ic_dma_rdlr on page 20-226	0x90	32	RW	0x0	Name: I2C Receive Data Level Register Size: log2(IC_RX_BUFFER_DEPTH) bits Address Offset: 0x90 Read/Write Access: Read/Write This register is only valid when DW_apb_i2c is configured with a set of DMA interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist; writing to its address has no effect; reading from its address returns zero.

Register	Offset	Width	Access	Reset Value	Description
ic_sda_setup on page 20-227	0x94	32	RW	0x64	Name: I2C SDA Setup Register Size: 8 bits Address Offset: 0x94 Read/Write Access: Read/Write This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL, relative to SDA changing, when DW_apb_i2c services a read request in a slave-transmitter operation. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification.
ic_ack_general_call on page 20-228	0x98	32	RW	0x1	Name: I2C ACK General Call Register Size: 1 bit Address Offset: 0x98 Read/Write Access: Read/Write The register controls whether DW_apb_i2c responds with a ACK or NACK when it receives an I2C General Call address. Note :This register is applicable only when the DW_apb_i2c is in slave mode

Register	Offset	Width	Access	Reset Value	Description
ic_enable_status on page 20-229	0x9C	32	RO	0x0	Name: I2C Enable Status Register Size: 3 bits Address Offset: 0x9C Read/Write Access: Read The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when DW_apb_i2c is disabled. If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1. If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'. Note When IC_ENABLE[0] has been written with '0'a delay occurs for bit 0 to be read as '0' because disabling the DW_apb_i2c depends on I2C bus activities.
ic_comp_param_1 on page 20-233	0xF4	32	RO	0x3F3FEA	Name: Component Parameter Register 1 Size: 32 bits Address Offset: 0xf4 Read/Write Access: Read Note This is a constant read-only register that contains encoded information about the component's parameter settings. The reset value depends on coreConsul-tant parameter(s).

Register	Offset	Width	Access	Reset Value	Description

ic_con Fields

Bit	Name	Description	Access	Reset
31:9	rsvd_ic_con_31to9	Reserved bits [31:9] - Read Only	RO	0x0
8	tx_empty_ctrl	This bit controls the generation of the TX_EMPTY interrupt, as described in the IC_RAW_INTR_STAT register. Reset value: 0x0.	RW	0x0
7	stop_det_ifaddressed	In slave mode: 1: issues the STOP_DET interrupt only when it is addressed. 0: issues the STOP_DET irrespective of whether it's addressed or not. Dependencies: This register bit value is applicable in the slave mode only (MASTER_MODE = 1'b0) Reset value: 0x0 NOTE: During a general call address, this slave does not issue the STOP_DET interrupt if STOP_DET_IF_ADDRESSED = 1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR).	RW	0x0

Bit	Name	Description	Access	Reset
6	ic_slave_disable	This bit controls whether I2C has its slave disabled, which means once the presetn signal is applied, then this bit is set to 1. When this bit is set (slave is disabled), I2C module functions only as a master and does not perform any action that requires a slave. 0: slave is enabled 1: slave is disabled NOTE: Software should ensure that if this bit is written with 0, then bit 0 should also be written with a 0. **Value** **Description** 0x0 ENABLE 0x1 DISABLE	RW	0x1

Bit	Name	Description	Access	Reset
5	ic_restart_en	Determines whether RESTART conditions may be sent when acting as a master. Some older slaves do not support handling RESTART conditions; however, RESTART conditions are used in several I2C operations. 0: disable 1: enable When RESTART is disabled, the master is prohibited from performing the following functions: - Change direction within a transfer (split) - Send a START BYTE - High-speed mode operation - Combined format transfers in 7-bit addressing modes - Read operation with a 10-bit address - Send multiple bytes per transfer By replacing RESTART condition followed by a STOP and a subsequent START condition, split operations are broken down into multiple I2C transfers. If the above operations are performed, it will result in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. Reset value: 0x1 **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x1
4	ic_10bitaddr_master	This bit is read only. 0: 7-bit addressing 1: 10-bit addressing Reset value: 0x1 **Value** **Description** 0x0 MSTADDR7BIT 0x1 MSTADDR10BIT	RO	0x1

Bit	Name	Description	Access	Reset
3	ic_10bitaddr_slave	When acting as a slave, this bit controls whether the I2C responds to 7- or 10-bit addresses. 0: 7-bit addressing. The I2C ignores transactions that involve 10-bit addressing; for 7-bit addressing, only the lower 7 bits of the IC_SAR register are compared. 1: 10-bit addressing. The I2C responds to only 10-bit addressing transfers that match the full 10 bits of the IC_SAR register. Reset value: 0x1 **Value** / **Description** 0x0 — SLVADDR7BIT 0x1 — SLVADDR10BIT	RW	0x1
2:1	speed	These bits control at which speed the I2C operates; its setting is relevant only if one is operating the I2C in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to 400 kbits/s; otherwise, hardware updates this register with the value of 400 kbits/s. 1: standard mode (100 kbit/s) 2: fast mode (<=400 kbit/s) or fast mode plus (<=1000Kbit/s) Reset value: 0x2 **Value** / **Description** 0x1 — STANDARD 0x2 — FAST	RW	0x2

Bit	Name	Description	Access	Reset
0	master_mode	This bit controls whether the I2C master is enabled. 0: master disabled 1: master enabled Reset value: 0x1 NOTE: Software should ensure that if this bit is written with '1' then bit 6 should also be written with a '1'. **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x1

ic_tar

```
Name: I2C Target Address Register

All bits can be dynamically updated as long as any set of the
following
conditions are true:
- The I2C is NOT enabled (IC_ENABLE[0] is set to 0);
   or
- The I2C is enabled (IC_ENABLE[0]=1);
   AND
  The I2C is NOT engaged in any Master (tx, rx) operation
(IC_STATUS[5]=0);
   AND
  The I2C is enabled to operate in Master mode (IC_CON[0]=1);
   AND
  there are NO entries in the TX FIFO (IC_STATUS[2]=1)
```

Module Instance	Base Address	Register Address

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			ic_10bit addr_master RW 0x1	special RW 0x0	gc_or_start RW 0x0	ic_tar RW 0x55									

ic_tar Fields

Bit	Name	Description	Access	Reset
12	ic_10bitaddr_master	This bit controls whether the I2C starts its transfers in 7- or 10-bit addressing mode when acting as a master. 0: 7-bit addressing 1: 10-bit addressing Reset value: 0x1 parameter **Value** **Description** 0x0 START7 0x1 START10	RW	0x1
11	special	This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally 1: perform special I2C command as specified in GC_OR_START bit Reset value: 0x0 **Value** **Description** 0x0 GENCALL 0x1 STARTBYTE	RW	0x0

Bit	Name	Description	Access	Reset
10	gc_or_start	If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call or START byte command is to be performed by the I2C. 0: General Call Address after issuing a General Call, only writes may be performed. Attempting to issue a read command results in setting bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register. The I2C remains in General Call mode until the SPECIAL bit value (bit 11) is cleared. 1: START BYTE Reset value: 0x0 **Value** / **Description** 0x0 GENCALL 0x1 STARTBYTE	RW	0x0
9:0	ic_tar	This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits. Reset value: 0x55 If the IC_TAR and IC_SAR are the same, loopback exists but the FIFOs are shared between master and slave, so full loopback is not feasible. Only one direction loopback mode is supported (simplex), not duplex. A master cannot transmit to itself; it can transmit to only a slave.	RW	0x55

ic_sar

ic_sar Fields

Bit	Name	Description	Access	Reset
9:0	ic_sar	The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE[0] register being set to 0. Writes at other times have no effect. Note: The default values cannot be any of the reserved address locations: that is, 0x00 to 0x07, or 0x78 to 0x7f. The correct operation of the device is not guaranteed if you program the IC_SAR or IC_TAR to a reserved value. Reset value: 0x55	RW	0x55

ic_data_cmd

I2C Rx/Tx Data Buffer and Command Register;

```
      this is the register the CPU writes to when
      filling the TX FIFO and the CPU reads from when
      retrieving bytes from RX FIFO
Size:
11 bits (writes), 8 bits (read)
```

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02410
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02510
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02610

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					restart WO 0x0	stop WO 0x0	cmd WO 0x0	dat RW 0x0							

ic_data_cmd Fields

Bit	Name	Description	Access	Reset
10	restart	This bit controls whether a RESTART is issued before the byte is sent or received. 1 - If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 - If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. Reset value: 0x0	WO	0x0
9	stop	This bit controls whether a STOP is issued after the byte is sent or received. 1 - STOP is issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master immediately tries to start a new transfer by issuing a START and arbitrating for the bus. 0 - STOP is not issued after this byte, regardless of whether or not the Tx FIFO is empty. If the Tx FIFO is not empty, the master continues the current transfer by sending/receiving data bytes according to the value of the CMD bit. If the Tx FIFO is empty, the master holds the SCL line low and stalls the bus until a new command is available in the Tx FIFO. Reset value: 0x0	WO	0x0

Bit	Name	Description	Access	Reset
8	cmd	This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read 0 = Write When a command is entered in the TX FIFO, this bit distinguishes the write and read commands. In slave-receiver mode, this bit is a 'don't care' because writes to this register are not required. In slave-transmitter mode, a '0' indicates that CPU data is to be transmitted and as DAT or IC_DATA_CMD[7:0]. When programming this bit, you should remember the following: attempting to perform a read operation after a General Call command has been sent results in a TX_ABRT interrupt (bit 6 of the IC_RAW_INTR_STAT register), unless bit 11 (SPECIAL) in the IC_TAR register has been cleared. If a '1' is written to this bit after receiving a RD_REQ interrupt, then a TX_ABRT interrupt occurs. NOTE: It is possible that while attempting a master I2C read transfer on the I2C, a RD_REQ interrupt may have occurred simultaneously due to a remote I2C master addressing the I2C module. In this type of scenario,the I2C module ignores the IC_DATA_CMD write, generates a TX_ABRT interrupt, and waits to service the RD_REQ interrupt. Reset value: 0x0 **Value** **Description** 0x0 WR	WO	0x0

Bit	Name	Description	Access	Reset
		Value Description 0x1 RD		
7:0	dat	This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the I2C moudle. However, when you read this register, these bits return the value of data received on the the I2C interface. Reset value: 0x0	RW	0x0

ic_ss_scl_hcnt

Standard Speed I2C Clock SCL High Count Register

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02414

ic_intr_stat Fields

Bit	Name	Description	Access	Reset
13	r_master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0
12	r_restart_det	Indicates a RESTART condition has occurred on the I2C interface when the I2C module is operating in slave mode and addressed. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
11	r_gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	r_start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C module is operating in slave or master mode. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
9	r_stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED =0 : Indicates whether a STOP condition has occurred on the I2C interface regardless of whether the I2C module is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 : In Master Mode (MASTER_MODE = 1'b1) , indicates a STOP condition has occured on the I2C interface. In Slave Mode (MASTER_MODE = 1'b0) ,STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_ IFADDRESSED=1'b1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
8	r_activity	This bit captures the I2C module activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
7	r_rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	r_tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C module flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
5	r_rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from the I2C module. The HPS I2C holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
4	r_tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register and the transmission of the address/data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_en=0, this bit is set to 0. Reset value: 0x0	RO	0x0
3	r_tx_over	Set during transmit if the transmit buffer is filled to the maximum buffer depth (64) and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
2	r_rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	r_rx_over	Set if the receive buffer is completely filled to its maximum receive buffer depth (64) and an additional byte is received from an external I2C device. The I2C module acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	r_rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

ic_intr_mask

I2C Interrupt Mask Register

These bits mask their corresponding interrupt status bits. They are active high; a value of 0 prevents a bit from generating an interrupt.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02430
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02530
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02630

Offset: 0x30

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ic_raw_intr_stat Fields

Bit	Name	Description	Access	Reset
13	master_on_hold	Indicates whether master is holding the bus and TX FIFO is empty. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
12	restart_det	Indicates whether a RESTART condition has occurred on the I2C interface when the I2C module is operating in Slave mode and the slave is being addressed. (Note:Following are exceptions where the Restart interrupt will not get generated. In the case of Startbyte transfer, where the Restart comes before the Address field as per the I2C protocol defined format, the Slave is still not in the addressed mode and hence will not generate the RESTART_DET interrupt.) Reset value: 0x0	RO	0x0
11	gen_call	Set only when a General Call address is received and it is acknowledged. It stays set until it is cleared either by disabling the I2C module or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register. The I2C stores the received data in the Rx buffer. Reset value: 0x0	RO	0x0
10	start_det	Indicates whether a START or RESTART condition has occurred on the I2C interface regardless of whether the I2C is operating in slave or master mode. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
9	stop_det	The behavior of the STOP_DET interrupt status differs based on the STOP_DET_IFADDRESSED selection in the IC_CON register When STOP_DET_IFADDRESSED =0 Indicates whether a STOP condition has occurred on the I2C interface regardless of whether DW_apb_i2c is operating in slave or master mode. In slave mode, a STOP_DET interrupt is generated irrespective of whether the slave is addressed or not. When STOP_DET_IFADDRESSED = 1 In Master Mode (MASTER_MODE = 1), indicates a STOP condition has occured on the I2C interface. In Slave Mode (MASTER_MODE = 0), a STOP_DET interrupt is generated only if the slave is addressed. NOTE: During a general call address, this slave does not issue a STOP_DET interrupt if STOP_DET_IFADDRESSED=1, even if the slave responds to the general call address by generating ACK. The STOP_DET interrupt is generated only when the transmitted address matches the slave address (SAR). Reset value: 0x0.	RO	0x0

Bit	Name	Description	Access	Reset
8	activity	This bit captures the I2C module activity and stays set until it is cleared. There are four ways to clear it: - Disabling the I2C module - Reading the IC_CLR_ACTIVITY register - Reading the IC_CLR_INTR register - System reset Once this bit is set, it stays set unless one of the four methods is used to clear it. Even if the I2C module is idle, this bit remains set until cleared, indicating that there was activity on the bus. Reset value: 0x0	RO	0x0
7	rx_done	When the I2C module is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done. Reset value: 0x0	RO	0x0
6	tx_abrt	This bit indicates if the I2C module, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO. This situation can occur both as an I2C master or an I2C slave, and is referred to as a 'transmit abort'. When this bit is set to 1, the IC_TX_ABRT_SOURCE register indicates the reason why the transmit abort takes places. NOTE: The I2C module flushes/resets/empties the TX FIFO whenever this bit is set. The TX FIFO remains in this flushed state until the register IC_CLR_TX_ABRT is read. Once this read is performed, the TX FIFO is then ready to accept more data bytes from the APB interface. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
5	rd_req	This bit is set to 1 when the I2C module is acting as a slave and another I2C master is attempting to read data from the I2C module. The I2C module holds the I2C bus in a wait state (SCL=0) until this interrupt is serviced, which means that the slave has been addressed by a remote master that is asking for data to be transferred. The processor must respond to this interrupt and then write the requested data to the IC_DATA_CMD register. This bit is set to 0 just after the processor reads the IC_CLR_RD_REQ register. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
4	tx_empty	The behavior of the TX_EMPTY interrupt status differs based on the TX_EMPTY_CTRL selection in the IC_CON register. When TX_EMPTY_CTRL = 0: This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register. When TX_EMPTY_CTRL = 1: This bit is set to 1 when the transmit buffer is at or below the threshold value. set in the IC_TX_TL register and the transmission of the address/ data from the internal shift register for the most recently popped command is completed. It is automatically cleared by hardware when the buffer level goes above the threshold. When IC_ENABLE[0] is set to 0, the TX FIFO is flushed and held in reset. There the TX FIFO looks like it has no data within it, so this bit is set to 1, provided there is activity in the master or slave state machines. When there is no longer any activity, then with ic_ en=0, this bit is set to 0. Reset value: 0x0.	RO	0x0
3	tx_over	Set during transmit if the transmit buffer is filled to the maximum TxFIFO buffer depth (64) and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register. When the module is disabled, this bit keeps its level until the master or slave state machines go into idle, and when ic_ en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
2	rx_full	Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register. It is automatically cleared by hardware when buffer level goes below the threshold. If the module is disabled (IC_ENABLE[0]=0), the RX FIFO is flushed and held in reset; therefore the RX FIFO is not full. So this bit is cleared once the IC_ENABLE bit 0 is programmed with a 0, regardless of the activity that continues. Reset value: 0x0	RO	0x0
1	rx_over	Set if the receive buffer is completely filled to the maximum Rx FIFO buffer depth (64) and an additional byte is received from an external I2C device. The I2C module acknowledges this, but any data bytes received after the FIFO is full are lost. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0
0	rx_under	Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register. If the module is disabled (IC_ENABLE[0]=0), this bit keeps its level until the master or slave state machines go into idle, and when ic_en goes to 0, this interrupt is cleared. Reset value: 0x0	RO	0x0

ic_rx_tl

I2C Receive FIFO Threshold Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														txabort RW 0x0	enable RW 0x0

ic_enable Fields

Bit	Name	Description	Access	Reset
1	txabort	When set, the controller initiates the transfer abort. 0: ABORT not initiated or ABORT done 1: ABORT operation in progress The software can abort the I2C transfer in master mode by setting this bit. The software can set this bit only when ENABLE is already set; otherwise, the controller ignores any write to ABORT bit. The software cannot clear the ABORT bit once set. In response to an ABORT, the controller issues a STOP and flushes the Tx FIFO after completing the current transfer, then sets the TX_ABORT interrupt after the abort operation. The ABORT bit is cleared automatically after the abort operation. Reset value: 0x0	RW	0x0

Bit	Name	Description	Access	Reset
0	enable	Controls whether the I2C module is enabled. 0: Disables the I2C module (TX and RX FIFOs are held in an erased state) 1: Enables the I2C module Software can disable the I2C module while it is active. However, it is important that care be taken to ensure that the I2C is disabled properly. When I2C module is disabled, the following occurs: - The TX FIFO and RX FIFO get flushed. - Status bits in the IC_INTR_STAT register are still active until I2C goes into IDLE state. If the module is transmitting, it stops as well as deletes the contents of the transmit buffer after the current transfer is complete. If the module is receiving, the I2C stops the current transfer at the end of the current byte and does not acknowledge the transfer. Reset value: 0x0 **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0

ic_status

```
          I2C Status Register

This is a read-only register used to indicate the current
transfer status and FIFO status. The status register may be
read at any time. None of the bits in this register request
an interrupt.
When the I2C is disabled by writing 0 in bit 0 of the
IC_ENABLE register:
- Bits 1 and 2 are set to 1
- Bits 3 and 4 are set to 0
When the master or slave state machines goes to idle
and ic_en=0:
```

- Bits 5 and 6 are set to 0

ic_tx_abrt_source

I2C Transmit Abort Source Register

This register has 32 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02480
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02580

ic_tx_abrt_source Fields

Bit	Name	Description	Access	Reset
31:23	tx_flush_cnt	This field indicates the number of Tx FIFO Data Commands which are flushed due to TX_ABRT interrupt. It is cleared whenever I2C is disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
22:17	rsvd_ic_tx_abrt_source_22to17	Reserved Reset value: 0x0	RO	0x0
16	abrt_user_abrt	This is a master-mode-only bit. Master has detected the transfer abort (IC_ENABLE[1]) Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
15	abrt_slvrd_intx	1: When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0

Bit	Name	Description	Access	Reset
14	abrt_slv_arblost	1: Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time. Note: Even though the slave never 'owns' the bus, something could go wrong on the bus. This is a fail safe check. For instance, during a data transmission at the low-to-high transition of SCL, if what is on the data bus is not what is supposed to be transmitted, then the I2C module no longer owns the bus. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
13	abrt_slvflush_txfifo	1: Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO. Reset value: 0x0 Role of the I2C module: Slave-Transmitter	RO	0x0
12	arb_lost	1: Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Slave-Transmitter	RO	0x0
11	abrt_master_dis	1: User tries to initiate a Master operation with the Master mode disabled. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

Bit	Name	Description	Access	Reset
10	abrt_10b_rd_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the master sends a read command in 10-bit addressing mode. Reset value: 0x0 Role of the I2C module: Master-Receiver	RO	0x0
9	abrt_sbyte_norstrt	To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; restart must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, bit 9 clears for one cycle and then gets reasserted. 1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to send a START Byte. Reset value: 0x0 Role of the I2C module: Master	RO	0x0
8	abrt_hs_norstrt	1: The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) =0) and the user is trying to use the master to transfer data in High Speed mode. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

Bit	Name	Description	Access	Reset
7	abrt_sbyte_ackdet	1: Master has sent a START Byte and the START Byte was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
6	abrt_hs_ackdet	1: Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior). Reset value: 0x0 Role of the I2C module: Master	RO	0x0
5	abrt_gcall_read	1: The I2C module in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
4	abrt_gcall_noack	1: The I2C module in master mode sent a General Call and no slave on the bus acknowledged the General Call. Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0
3	abrt_txdata_noack	1: This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s). Reset value: 0x0 Role of the I2C module: Master-Transmitter	RO	0x0

Bit	Name	Description	Access	Reset
2	abrt_10addr2_noack	1: Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
1	abrt_10addr1_noack	1: Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0
0	abrt_7b_addr_noack	1: Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave. Reset value: 0x0 Role of the I2C module: Master-Transmitter or Master-Receiver	RO	0x0

ic_slv_data_nack_only Fields

Bit	Name	Description	Access	Reset
0	nack	Generate NACK. This NACK generation only occurs when the I2C module is a slave-receiver. If this register is set to a value of 1, it can only generate a NACK after a data byte is received; hence, the data transfer is aborted and the data received is not pushed to the receive buffer. When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. 1 = generate NACK after data byte received 0 = generate NACK/ACK normally Reset value: 0x0 **Value** **Description** 0x0 NORM 0x1 AFTERDBYTE	RW	0x0

ic_dma_cr

DMA Control Register

The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be

programmed
regardless of the state of IC_ENABLE.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02488
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02588
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02688

Offset: 0x88

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Name	Description	Access	Reset
31:2	rsvd_ic_dma_cr_31to2	Reserved bits [31:1] - Read Only	RO	0x0
1	tdmae	Transmit DMA Enable. //This bit enables/disables the transmit FIFO DMA channel. 0 = Transmit DMA disabled 1 = Transmit DMA enabled Reset value: 0x0 **Value** **Description** 0x0 DISABLE 0x1 ENABLE	RW	0x0

Bit	Name	Description	Access	Reset
0	rdmae	Receive DMA Enable. This bit enables/disables the receive FIFO DMA channel. 0 = Receive DMA disabled 1 = Receive DMA enabled Reset value: 0x0 Value: Description 0x0: DISABLE 0x1: ENABLE	RW	0x0

ic_dma_tdlr

Name: DMA Transmit Data Level Register

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC0248C
i_i2c_emac_1_i2c	0xFFC02500	0xFFC0258C
i_i2c_emac_2_i2c	0xFFC02600	0xFFC0268C

Offset: 0x8C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										dmatdl RW 0x0					

ic_dma_tdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmatdl	Transmit Data Level. This bit field controls the level at which a DMA request is made by the transmit logic. It is equal to the watermark level; that is, the dma_tx_req signal is generated when the number of valid data entries in the transmit FIFO is equal to or below this field value, and TDMAE = 1. Reset value: 0x0	RW	0x0

ic_dma_rdlr

I2C Receive Data Level Register

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02490
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02590
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02690

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										dmardl RW 0x0					

ic_dma_rdlr Fields

Bit	Name	Description	Access	Reset
5:0	dmardl	Receive Data Level. This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO. Reset value: 0x0	RW	0x0

ic_sda_setup

I2C SDA Setup Register

This register controls the amount of time delay
(in terms of number of l4_sp_clk clock periods) introduced
in the rising edge of SCL, relative to SDA changing, when
the I2C module services a read request in a slave-transmitter
operation.
The relevant I2C requirement is tSU:DAT (note 4) as detailed in the
I2C Bus Specification.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02494
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02594
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02694

Offset: 0x94

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								sda_setup RW 0x64							

ic_sda_setup Fields

Bit	Name	Description	Access	Reset
7:0	sda_setup	SDA Setup. It is recommended that if the required delay is 1000ns, then for an l4_sp_clk frequency of 10 MHz, IC_SDA_SETUP should be programmed to a value of 11. Default Reset value: 0x64	RW	0x64

ic_ack_general_call

I2C ACK General Call Register

The register controls whether the I2C responds with a ACK or NACK when it receives an I2C General Call address.
Note :This register is applicable only when the I2C module is in slave mode

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC02498
i_i2c_emac_1_i2c	0xFFC02500	0xFFC02598
i_i2c_emac_2_i2c	0xFFC02600	0xFFC02698

Offset: 0x98

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
rsvd_ic_ack_gen_31to1 RO 0x0

rsvd_ic_ack_gen_31to1 RO 0x0															ack_gen_call RW 0x1

ic_ack_general_call Fields

Bit	Name	Description	Access	Reset
31:1	rsvd_ic_ack_gen_31to1	Reserved bits [31:1] - Read Only	RO	0x0
0	ack_gen_call	ACK General Call. When set to 1, the I2C module responds with a ACK (by asserting ic_data_oe) when it receives a General Call. Otherwise, the I2C module responds with a NACK (by negating ic_data_oe). Default Reset value: 0x1 **Value** **Description** 0x0 NACK 0x1 ACK	RW	0x1

ic_enable_status

I2C Enable Status Register

The register is used to report the I2C hardware status when the IC_ENABLE[0] register is set from 1 to 0; that is, when the I2C module is disabled.
If IC_ENABLE[0] has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
If IC_ENABLE[0] has been set to 0, bits 2:1 is only be valid as soon as bit 0 is read as '0'.
Note
When IC_ENABLE[0] has been written with '0'a delay occurs for bit 0 to be read as '0' because disabling the I2C module depends on I2C bus activities.

Module Instance	Base Address	Register Address
i_i2c_emac_0_i2c	0xFFC02400	0xFFC0249C
i_i2c_emac_1_i2c	0xFFC02500	0xFFC0259C
i_i2c_emac_2_i2c	0xFFC02600	0xFFC0269C

Offset: 0x9C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													slv_rx_data_lost RO 0x0	slv_disabled_while_busy RO 0x0	ic_en RO 0x0

ic_enable_status Fields

Bit	Name	Description	Access	Reset
2	slv_rx_data_lost	Slave Received Data Lost. This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting bit 0 of IC_ENABLE from 1 to 0. When read as 1, I2C module is deemed to have been actively engaged in an aborted I2C transfer (with matching address) and the data phase of the I2C transfer has been entered, even though a data byte has been responded with a NACK. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit is also set to 1. When read as 0, the I2C is deemed to have been disabled without being actively involved in the data phase of a Slave-Receiver transfer. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
1	slv_disabled_while_busy	Slave Disabled While Busy (Transmit, Receive). This bit indicates if a potential or active Slave operation has been aborted due to the setting bit 0 of the IC_ENABLE register from 1 to 0. This bit is set when the CPU writes a 0 to the IC_ENABLE register while: (a) the I2C is receiving the address byte of the Slave-Transmitter operation from a remote master; OR, (b) address and data bytes of the Slave-Receiver operation from a remote master. When read as 1, the I2C module is deemed to have forced a NACK during any part of an I2C transfer, irrespective of whether the I2C address matches the slave address set in the I2C (IC_SAR register) OR if the transfer is completed before IC_ENABLE is set to 0 but has not taken effect. NOTE: If the remote I2C master terminates the transfer with a STOP condition before the I2C module has a chance to NACK a transfer, and IC_ENABLE[0] has been set to 0, then this bit will also be set to 1. When read as 0, the I2C mdoule is deemed to have been disabled when there is master activity, or when the I2C bus is idle. NOTE: The CPU can safely read this bit when IC_EN (bit 0) is read as 0. Reset value: 0x0	RO	0x0

Bit	Name	Description	Access	Reset
0	ic_en	ic_en Status. This bit always reflects the value driven on the output port ic_en. When read as 1, the I2C module is deemed to be in an enabled state. When read as 0, the I2C module is deemed completely inactive. NOTE: The CPU can safely read this bit anytime. When this bit is read as 0, the CPU can safely read SLV_RX_DATA_LOST (bit 2) and SLV_DISABLED_WHILE_BUSY (bit 1). Reset value: 0x0	RO	0x0

ic_comp_param_1

Name: Component Parameter Register 1

Note
This is a constant read-only register that contains encoded information about the component's parameter settings.

Module Instance	Base Address	Register Address

UART Controller 21

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two UART controllers for asynchronous serial communication. The UART controllers are based on an industry standard 16550 UART controller. The UART controllers are instances of the Synopsys® DesignWare® APB Universal Asynchronous Receiver/Transmitter (DW_apb_uart) peripheral. (54)

UART Controller Features

The UART controller provides the following functionality and features:

- Programmable character properties, such as number of data bits per character, optional parity bits, and number of stop bits †
- Line break generation and detection †
- DMA controller handshaking interface
- Prioritized interrupt identification †
- Programmable baud rate
- False start bit detection †
- Automatic flow control mode per 16750 standard †
- Internal loopback mode support
- 128-byte transmit and receive FIFO buffers
  - FIFO buffer status registers †
  - FIFO buffer access mode (for FIFO buffer testing) enables write of receive FIFO buffer by master and read of transmit FIFO buffer by master †
- Shadow registers reduce software overhead and provide programmable reset †
- Transmitter holding register empty (THRE) interrupt mode †
- Separate thresholds for DMA request and handshake signals to maximize throughput

UART Controller Block Diagram and System Integration

Figure 21-1: UART Block Diagram

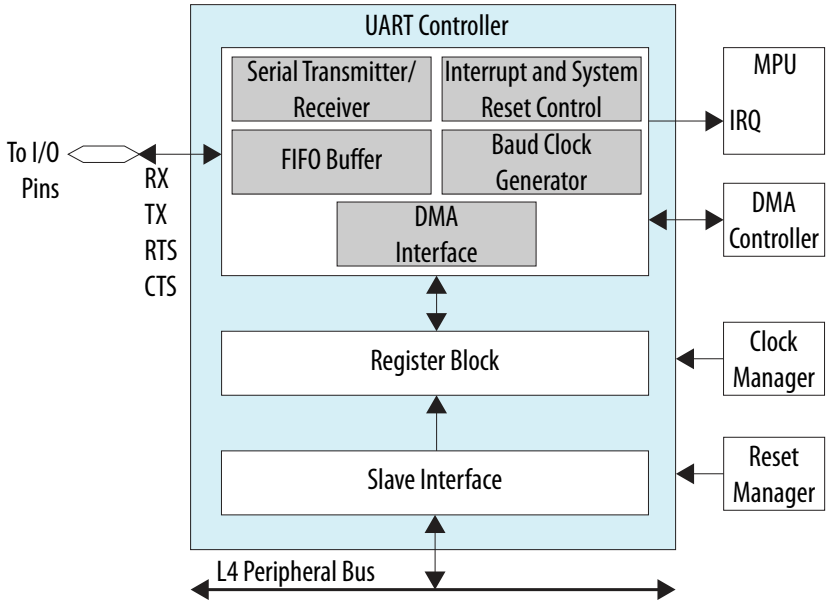

Table 21-1: UART Controller Block Descriptions

Block	Description
Slave interface	Slave interface between the component and L4 peripheral bus.
Register block	Provides main UART control, status, and interrupt generation functions.†
FIFO buffer	Provides FIFO buffer control and storage. †
Baud clock generator	Generates the transmitter and receiver baud clock. With a reference clock of 100 MHz, the UART controller supports transfer rates of 95 baud to 6.25 Mbaud. This supports communication with all known 16550 devices. The baud rate is controlled by programming the interrupt enable or divisor latch high (`IER_DLH`) and receive buffer, transmit holding, or divisor latch low (`RBR_THR_DLL`) registers.
Serial transmitter	Converts parallel data written to the UART into serial data and adds all additional bits, as specified by the control register, for transmission. This makeup of serial data, referred to as a character, exits the block in serial UART. †

Block	Description
Serial receiver	Converts the serial data character (as specified by the control register) received in the UART format to parallel form. Parity error detection, framing error detection and line break detection is carried out in this block. †
DMA interface	The UART controller includes a DMA controller interface to indicate when received data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports single and burst transfers. You can use DMA in FIFO buffer and non-FIFO buffer mode.

Related Information

For more information, refer to the DMA Controller chapter.

UART Controller Signal Description

HPS I/O Pins

There are two UARTs available in the HPS. Signals from both sets of UARTs can be routed to the HPS I/O. For more information on routing UART signals to the HPS I/O, refer to the *HPS Component Interfaces* chapter.

Table 21-2: HPS I/O UART Pin Descriptions

Pin	Width	Direction	Description
RX	1 bit	Input	Serial Input
TX	1 bit	Output	Serial Output
CTS	1 bit	Input	Clear to send
RTS	1 bit	Output	Request to send

Related Information

HPS Component Interfaces on page 28-14
For more information on how to route the UART signals to the FPGA and HPS I/O, refer to this chapter.

FPGA Routing

There are two UARTs provided in the HPS. Both sets of UART signals can be routed to the FPGA. For more information on routing UART signals to the FPGA, refer to the *HPS Component Interfaces* chapter.

Table 21-3: Signals for FPGA Routing

Signal	Width	Direction	Description
uart_rxd	1 bit	Input	Serial input
uart_txd	1 bit	Output	Serial output
uart_cts	1 bit	Input	Clear to send
uart_rts	1 bit	Output	Request to send
uart_dsr	1 bit	Input	Data set ready
uart_dcd	1 bit	Input	Data carrier detect
uart_ri	1 bit	Input	Ring indicator
uart_dtr	1 bit	Output	Data terminal ready
uart_out1_n	1 bit	Output	User defined output 1
uart_out2_n	1 bit	Output	User defined output 2

Related Information

HPS Component Interfaces on page 28-14
For more information on how to route the UART signals to the FPGA and HPS I/O, refer to this chapter.

Functional Description of the UART Controller

The HPS UART is based on an industry-standard 16550 UART. The UART supports serial communication with a peripheral, modem (data carrier equipment), or data set. The master (CPU) writes data over the slave bus to the UART. The UART converts the data to serial format and transmits to the destination device. The UART also receives serial data and stores it for the master (CPU). †

The UART's registers control the character length, baud rate, parity generation and checking, and interrupt generation. The UART's single interrupt output signal is supported by several prioritized interrupt types that trigger assertion. You can separately enable or disable each of the interrupt types with the control registers. †

FIFO Buffer Support

The UART controller includes 128-byte FIFO buffers to buffer transmit and receive data. FIFO buffer access mode allows the master to write the receive FIFO buffer and to read the transmit FIFO buffer for test purposes. FIFO buffer access mode is enabled with the FIFO access register (FAR). Once enabled, the

control portions of the transmit and receive FIFO buffers are reset and the FIFO buffers are treated as empty. †

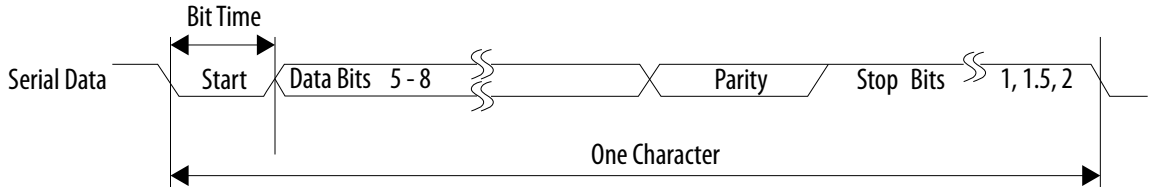
When FIFO buffer access mode is enabled, you can write data to the transmit FIFO buffer as normal; however, no serial transmission occurs in this mode and no data leaves the FIFO buffer. You can read back the data that is written to the transmit FIFO buffer with the transmit FIFO read (TFR) register. The TFR register provides the current data at the top of the transmit FIFO buffer. †

Similarly, you can also read data from the receive FIFO buffer in FIFO buffer access mode. Since the normal operation of the UART is halted in this mode, you must write data to the receive FIFO buffer to read it back. The receive FIFO write (RFW) register writes data to the receive FIFO buffer. The upper two bits of the 10-bit register write framing errors and parity error detection information to the receive FIFO buffer. Bit 9 of RFW indicates a framing error and bit 8 of RFW indicates a parity error. Although you cannot read these bits back from the receive buffer register, you can check the bits by reading the line status register (LSR), and by checking the corresponding bits when the data in question is at the top of the receive FIFO buffer. †

UART(RS232) Serial Protocol

Because the serial communication between the UART controller and the selected device is asynchronous, additional bits (start and stop) are added to the serial data to indicate the beginning and end. Utilizing these bits allows two devices to be synchronized. This structure of serial data accompanied by start and stop bits is referred to as a character, as shown in below.†

Figure 21-2: Serial Data Format



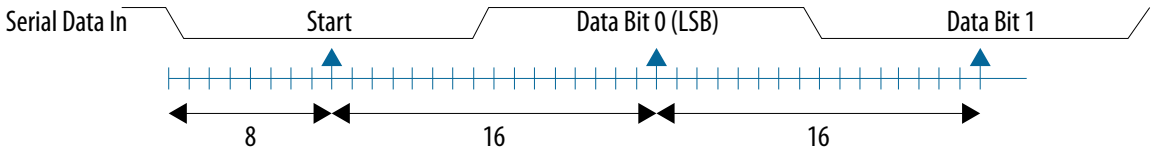
An additional parity bit may be added to the serial character. This bit appears after the last data bit and before the stop bit(s) in the character structure to provide the UART controller with the ability to perform simple error checking on the received data.†

The Control Register is used to control the serial character characteristics. The individual bits of the data word are sent after the start bit, starting with the least- significant bit (LSB). These are followed by the optional parity bit, followed by the stop bit(s), which can be 1, 1.5 or 2.†

All the bits in the transmission (with exception to the half stop bit when 1.5 stop bits are used) are transmitted for exactly the same time duration. This is referred to as a Bit Period or Bit Time. One Bit Time equals 16 baud clocks. To ensure stability on the line, the receiver samples the serial input data at approximately the midpoint of the Bit Time once the start bit has been detected. Because the exact number of baud clocks that each bit transmission is known, calculating the midpoint for sampling is not difficult. That is, every 16 baud clocks after the midpoint sample of the start bit.†

Together with serial input debouncing, this feature also contributes to avoid the detection of false start bits. Short glitches are filtered out by debouncing, and no transition is detected on the line. If a glitch is wide enough to avoid filtering by debouncing, a falling edge is detected. However, a start bit is detected only if the line is sampled low again after half a bit time has elapsed. †

Figure 21-3: Receiver Serial Data Sample Points



The baud rate of the UART controller is controlled by the serial clock and the Divisor Latch Register (DLH and DLL).†

Automatic Flow Control

The UART includes 16750-compatible request-to-send (RTS) and clear-to-send (CTS) serial data automatic flow control mode. You enable automatic flow control with the modem control register (`MCR.AFCE`). †

RTC Flow Control Trigger

RTC is an RX FIFO Almost-Full Trigger, where "almost full" refer to two available slots in the FIFO.

The UART controller uses two separate trigger levels for a DMA request and handshake signal (rts_n) in order to maximize throughput on the interface.

Automatic RTS mode

Automatic RTS mode becomes active when the following conditions occur: †

- RTS (`MCR.RTS` bit and `MCR.AFCE` bit are both set)
- FIFO buffers are enabled (`FCR.FIFOE` bit is set)

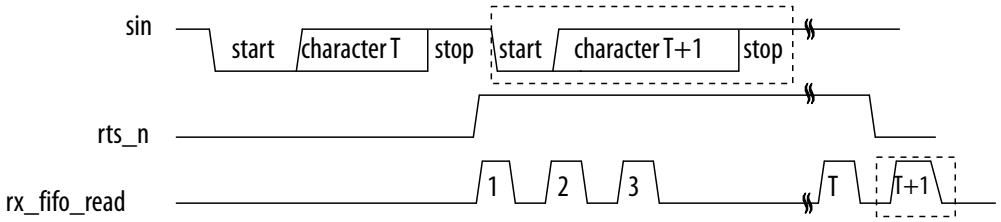
With automatic RTS enabled, the `rts_n` output pin is forced inactive (high) when the FIFO is almost full; where "almost full" refers to two available slots in the FIFO. When `rts_n` is connected to the `cts_n` input pin of another UART device, the other UART stops sending serial data until the receive FIFO buffer has available space (until it is completely empty). †

The selectable receive FIFO buffer threshold values are 1, ¼, ½, and 2 less than full. Because one additional character may be transmitted to the UART after `rts_n` is inactive (due to data already having entered the transmitter block in the other UART), setting the threshold to 2 less than full allows maximum use of the FIFO buffer with a margin of one character. †

Once the receive FIFO buffer is completely emptied by reading the receiver buffer register (`RBR_THR_DLL`), `rts_n` again becomes active (low), signaling the other UART to continue sending data.†

Even when you set the correct `MCR` bits, if the FIFO buffers are disabled through `FCR.FIFOE`, automatic flow control is also disabled. When auto RTS is not implemented or disabled, `rts_n` is controlled solely by `MCR.RTS`. In the Automatic RTS Timing diagram, the character T is received because `rts_n` is not detected prior to the next character entering the sending UART transmitter. †

Figure 21-4: Automatic RTS Timing



Automatic CTS mode

Automatic CTS mode becomes active when the following conditions occur: †

- AFCE (`MCR.AFCE` bit is set)
- FIFO buffers are enabled (through FIFO buffer control register `IIR_FCR.FIFOE`) bit

When automatic CTS is enabled (active), the UART transmitter is disabled whenever the `cts_n` input becomes inactive (high). This prevents overflowing the FIFO buffer of the receiving UART. †

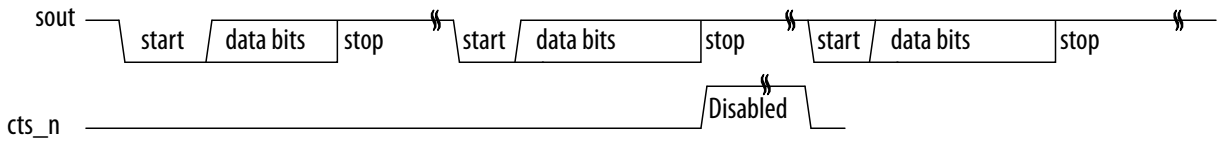
If the `cts_n` input is not deactivated before the middle of the last stop bit, another character is transmitted before the transmitter is disabled. While the transmitter is disabled, you can continue to write and even overflow to the transmit FIFO buffer. †

Automatic CTS mode requires the following sequence:

1. The UART status register are read to verify that the transmit FIFO buffer is full (UART status register `USR.TFNF` set to zero). †
2. The current FIFO buffer level is read via the transmit FIFO level (`TFL`) register. †
3. Programmable THRE interrupt mode must be enabled to access the FIFO buffer full status from the LSR. †

When using the FIFO buffer full status, software can poll this before each write to the transmit FIFO buffer. When the `cts_n` input becomes active (low) again, transmission resumes. If the FIFO buffers are disabled with the `FCR.FIFOE` bit, automatic flow control is also disabled regardless of any other settings. When auto CTS is not implemented or disabled, the transmitter is unaffected by `cts_n`.†

Figure 21-5: Automatic CTS Timing



Clocks

The UART controller is connected to the `l4_sp_clk` clock. The clock input is driven by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Resets

The UART controller is connected to the `uart_rst_n` reset signal. The reset manager drives the signal on a cold or warm reset.

Taking the UART Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Interrupts

The assertion of the UART interrupt output signal occurs when one of the following interrupt types are enabled and active: †

Table 21-4: Interrupt Types and Priority †

Interrupt Type	Priority	Source	Interrupt Reset Control
Receiver line status	Highest	Overrun, parity and framing errors, break condition.	Reading the line status Register.
Received data available	Second	Receiver data available (FIFOs disabled) or RCVR FIFO trigger level reached (FIFOs enabled).	Reading the receiver buffer register (FIFOs disabled) or the FIFO drops below the trigger level (FIFOs enabled)
Character timeout indication	Second	No characters in or out of the Receive FIFO during the last 4 character times and there is at least 1 character in it during this Time.	Reading the receiver buffer Register.
Transmit holding register empty	Third	Transmitter holding register empty (Programmable THRE Mode disabled) or Transmit FIFO at or below threshold (Programmable THRE Mode enabled).	Reading the `IIR` register (if source of interrupt); or, writing into `THR` (FIFOs or Programmable THRE Mode not enabled) or Transmit FIFO above threshold (FIFOs and Programmable THRE Mode enabled).

Interrupt Type	Priority	Source	Interrupt Reset Control
Modem Status	Fourth	Clear to send or data set ready or ring indicator or data carrier detect. If auto flow control mode is enabled, a change in CTS (that is, DCTS set) does not cause an interrupt.	Reading the Modem status Register.

You can enable the interrupt types with the interrupt enable register (`IER_DLH`).

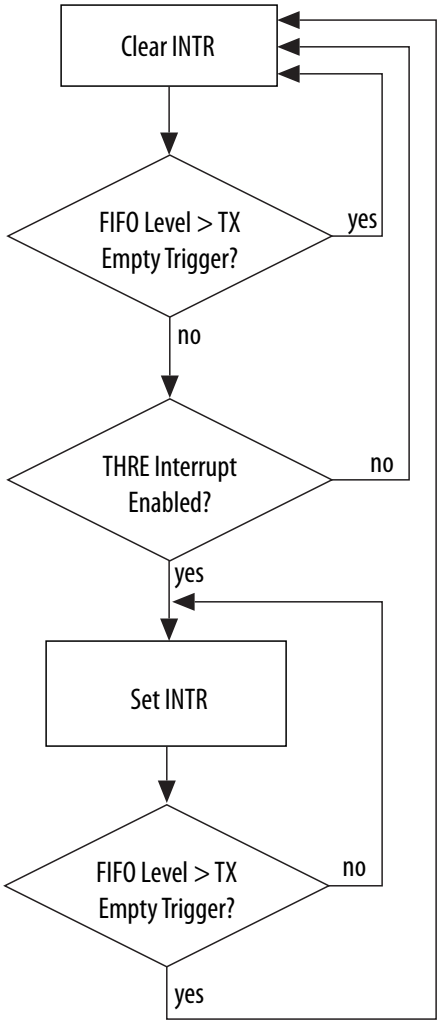
Note: Received Data Available" and "Character Timeout Indication" are enabled by a single bit in the IER_DLH register, because they have the same priority.

Once an interrupt is signaled, you can determine the interrupt source by reading the Interrupt Identity Register (IIR).

Programmable THRE Interrupt

The UART has a programmable THRE interrupt mode to increase system performance. You enable the programmable THRE interrupt mode with the interrupt enable register (`IER_DLH.PTIME`). When the THRE mode is enabled, THRE interrupts and the `dma_tx_req` signal are active at and below a programmed transmit FIFO buffer empty threshold level, as shown in the flowchart. †

Figure 21-6: Programmable THRE Interrupt

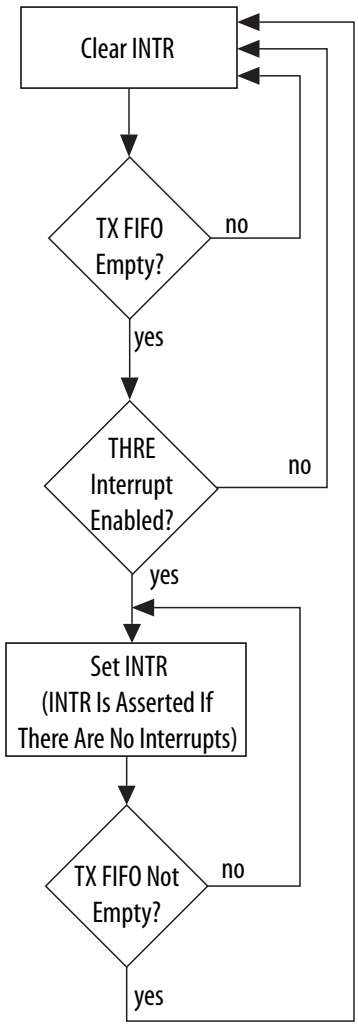


The threshold level is programmed into FCR.TET. The available empty thresholds are empty, 2, ¼, and ½. The optimum threshold value depends on the system's ability to begin a new transmission sequence in a timely manner. However, one of these thresholds should prove optimum in increasing system performance by preventing the transmit FIFO buffer from running empty.

In addition to the interrupt change, line status register (LSR.THRE) also switches from indicating that the transmit FIFO buffer is empty, to indicating that the FIFO buffer is full. This change allows software to fill the FIFO buffer for each transmit sequence by polling LSR.THRE before writing another character. This directs the UART to fill the transmit FIFO buffer whenever an interrupt occurs and there is data to transmit, instead of waiting until the FIFO buffer is completely empty. Waiting until the FIFO buffer is empty reduces performance whenever the system is too busy to respond immediately. You can increase system efficiency when this mode is enabled in combination with automatic flow control.

When not selected or disabled, THRE interrupts and LSR.THRE function normally, reflecting an empty THR or FIFO buffer.

Figure 21-7: Interrupt Generation without Programmable THRE Interrupt Mode



DMA Controller Operation

The UART controller includes a DMA controller interface to indicate when the receive FIFO buffer data is available or when the transmit FIFO buffer requires data. The DMA requires two channels, one for transmit and one for receive. The UART controller supports both single and burst transfers.

The FIFO buffer depth (`FIFO_DEPTH`) for both the RX and TX buffers in the UART controller is 128 entries.

Related Information

DMA Controller on page 16-1
For more information, refer to the DMA Controller chapter.

Transmit FIFO Underflow

During UART serial transfers, transmit FIFO requests are made to the DMA controller whenever the number of entries in the transmit FIFO is less than or equal to the decoded level of the Transmit Empty Trigger (TET) field in the FIFO Control Register (FCR), also known as the watermark level. The DMA controller responds by writing a burst of data to the transmit FIFO buffer, of length specified as DMA burst length. †

Data should be fetched from the DMA often enough for the transmit FIFO to perform serial transfers continuously, that is, when the FIFO begins to empty, another DMA request should be triggered. Otherwise, the FIFO will run out of data (underflow) causing a STOP to be inserted on the UART bus. To prevent this condition, you must set the watermark level correctly. †

Related Information

DMA Controller on page 16-1
For more information, refer to the DMA Controller chapter.

Transmit Watermark Level

Consider the example where the following assumption is made: †

DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET †

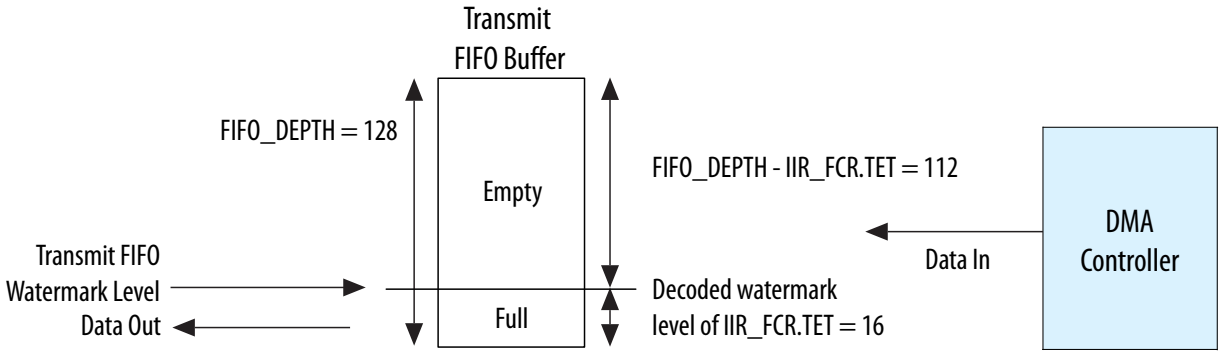
Here the number of data items to be transferred in a DMA burst is equal to the empty space in the transmit FIFO. Consider the following two different watermark level settings: †

IIR_FCR.TET = 1

IIR_FCR.TET = 1 decodes to a watermark level of 16.

- Transmit FIFO watermark level = decoded watermark level of IIR_FCR.TET = 16 †
- DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET = 112 †
- UART transmit FIFO_DEPTH = 128 †
- Block transaction size = 448†

Figure 21-8: Transmit FIFO Watermark Level = 16



The number of burst transactions needed equals the block size divided by the number of data items per burst:

Block transaction size/DMA burst length = 448/112 = 4

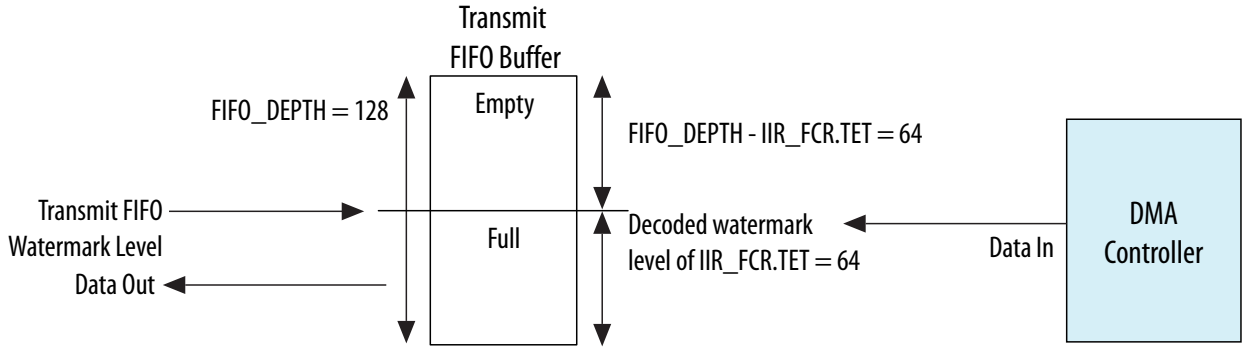
The number of burst transactions in the DMA block transfer is 4. But the watermark level, decoded level of IIR_FCR.TET, is quite low. Therefore, the probability of transmit underflow is high where the UART serial transmit line needs to transmit data, but there is no data left in the transmit FIFO. This occurs because the DMA has not had time to service the DMA request before the FIFO becomes empty.

IIR_FCR.TET = 3

IIR_FCR.TET = 3 decodes to a watermark level of 64.

- Transmit FIFO watermark level = decoded watermark level of IIR_FCR.TET = 64 †
- DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET = 64†
- UART transmit FIFO_DEPTH = 128 †
- Block transaction size = 448 †

Figure 21-9: Transmit FIFO Watermark Level = 64



Number of burst transactions in block: †

Block transaction size/DMA burst length = 448/64 = 7 †

In this block transfer, there are 15 destination burst transactions in a DMA block transfer. But the watermark level, decoded level of IIR_FCR.TET, is high. Therefore, the probability of UART transmit underflow is low because the DMA controller has plenty of time to service the destination burst transaction request before the UART transmit FIFO becomes empty. †

Thus, the second case has a lower probability of underflow at the expense of more burst transactions per block. This provides a potentially greater amount of bursts per block and worse bus utilization than the former case. †

Therefore, the goal in choosing a watermark level is to minimize the number of transactions per block, while at the same time keeping the probability of an underflow condition to an acceptable level. In practice, this is a function of the ratio of the rate at which the UART transmits data to the rate at which the DMA can respond to destination burst requests. †

Transmit FIFO Overflow

Setting the DMA burst length to a value greater than the watermark level that triggers the DMA request might cause overflow when there is not enough space in the transmit FIFO to service the destination burst request. Therefore, the following equation must be adhered to in order to avoid overflow: †

DMA burst length <= FIFO_DEPTH - decoded watermark level of IIR_FCR.TET

In case 2: decoded watermark level of IIR_FCR.TET = 64, the amount of space in the transmit FIFO at the time of the burst request is made is equal to the DMA burst length. Thus, the transmit FIFO may be full, but not overflowed, at the completion of the burst transaction. †

Therefore, for optimal operation, DMA burst length must be set at the FIFO level that triggers a transmit DMA request; that is: †

DMA burst length = FIFO_DEPTH - decoded watermark level of IIR_FCR.TET

Adhering to this equation reduces the number of DMA bursts needed for block transfer, and this in turn improves bus utilization. †

The transmit FIFO will not be full at the end of a DMA burst transfer if the UART controller has successfully transmitted one data item or more on the UART serial transmit line during the transfer. †

Receive FIFO Overflow

During UART serial transfers, receive FIFO requests are made to the DMA whenever the number of entries in the receive FIFO is at or above the decoded level of Receive Trigger (RT) field in the FIFO Control Register (IIR_FCR). This is known as the watermark level. The DMA responds by fetching a burst of data from the receive FIFO. †

Data should be fetched by the DMA often enough for the receive FIFO to accept serial transfers continuously, that is, when the FIFO begins to fill, another DMA transfer is requested. Otherwise the FIFO will fill with data (overflow). To prevent this condition, the user must set the watermark level correctly. †

Receive Watermark Level

Similar to choosing the transmit watermark level described earlier, the receive watermark level, decoded watermark level of IIR_FCR.RT, should be set to minimize the probability of overflow, as shown in the Receive FIFO Buffer diagram. It is a tradeoff between the number of DMA burst transactions required per block versus the probability of an overflow occurring. †

Receive FIFO Underflow

Setting the source transaction burst length greater than the watermark level can cause underflow where there is not enough data to service the source burst request. Therefore, the following equation must be adhered to avoid underflow: †

DMA burst length = decoded watermark level of IIR_FCR.RT + 1

If the number of data items in the receive FIFO is equal to the source burst length at the time of the burst request is made, the receive FIFO may be emptied, but not underflowed, at the completion of the burst transaction. For optimal operation, DMA burst length should be set at the watermark level, decoded watermark level of IIR_FCR.RT. †

Adhering to this equation reduces the number of DMA bursts in a block transfer, which in turn can avoid underflow and improve bus utilization. †

The receive FIFO will not be empty at the end of the source burst transaction if the UART controller has successfully received one data item or more on the UART serial receive line during the burst. †

rbr_thr_dll

This is a multi-function register. This register holds receives and transmit data and controls the least-signficant 8 bits of the baud rate divisor.

Module Instance	Base Address	Register Address
i_uart_0_uart	0xFFC02000	0xFFC02000
i_uart_1_uart	0xFFC02100	0xFFC02100

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

rbr_thr_dll Fields

Bit	Name	Description	Access	Reset
31:8	rsvd_rbr_thr_dll_31to8	Reserved bits [31:8] - Read Only	RO	0x0
7:0	value	Receive Buffer Register: This register contains the data byte received on the serial input port (uart_rxd). The data in this register is valid only if the Data Ready (bit [0] in the Line Status Register(LSR)) is set to 1. If FIFOs are disabled(bit[0] of Register FCR is set to 0) the data in the RBR must be read before the next data arrives, otherwise it will be overwritten, resulting in an overrun error. If FIFOs are enabled(bit [0] of Register FCR is set to 1) this register accesses the head of the receive FIFO. If the receive FIFO is full, and this register is not read before the next data character arrives, then the data already in the FIFO will be preserved but any incoming data will be lost. An overrun error will also occur. Transmit Holding Register: This register contains data to be transmitted on the serial output port. Data should only be written to the THR when the THR Empty bit [5] of the LSR Register is set to 1. If FIFOs are disabled (bit [0] of Register FCR) is set to 0 and THRE is set to 1, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If FIFO's are enabled bit [0] of Register FCR is set to 1 and THRE is set up to 128 characters of data may be written to the THR before the FIFO is full. Any attempt to write data when the FIFO is full results in the write data being lost. Divisor Latch Low: This register makes up the lower 8-bits of a 16-bit, Read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 1. The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows: baud rate = (serial clock freq) / (16 * divisor) Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.	RW	0x0

ier_dlh

This is a multi-function register. This register enables/ disables receive and transmit interrupts and also controls the most-significant 8-bits of the baud rate divisor.
Divisor Latch High Register:
This register is accessed when the DLAB bit [7] of the LCR Register is set to 1.Bits[7:0] contain the high order 8-bits of the baud rate divisor.The output baud rate is equal to the serial clock l4_sp_clk frequency divided by sixteen times the value of the baud rate divisor, as follows:
baud rate = (serial clock freq) / (16 * divisor):
Note that with the Divisor Latch Registers (DLLand DLH) set to zero, the baud clock is disabled and no serial communications will occur. Also, once the DLL is set, at least 8 l4_sp_clk clock cycles should be allowed to pass before transmitting or receiving data.
Interrupt Enable Register:
This register may only be accessed when the DLAB bit [7] of the LCR Register is set to 0.Allows control of the Interrupt Enables for transmit and receive functions.

Module Instance	Base Address	Register Address
i_uart_0_uart	0xFFC02000	0xFFC02004
i_uart_1_uart	0xFFC02100	0xFFC02104

Bit	Name	Description	Access	Reset
7:6	rt	Bits[7:6], RCVR Trigger (or RT):. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt will be generated. In auto flow control mode it is used to determine when the rts_n signal will be de-asserted. It also determines when the dma_rx_req_n signal will be asserted when in certain modes of operation. See section 5.9 on page 56 for details on DMA support. The following trigger levels are supported: 00 = 1 character in the FIFO 01 = FIFO 1/4 full 10 = FIFO 1/2 full 11 = FIFO 2 less than full **Value** **Description** 0 FIFO_CHAR_1 1 FIFO_QUARTER_FULL 2 FIFO_HALF_FULL 3 FIFO_FULL_2	WO	0x0

Bit	Name	Description	Access	Reset
5:4	tet	Bits[5:4], TX Empty Trigger (or TET): Writes will have no effect when THRE_MODE_USER == Disabled. This is used to select the empty threshold level at which the THRE Interrupts will be generated when the mode is active. It also determines when the dma_tx_req_n signal will be asserted when in certain modes of operation. See section 5.9 on page 56 for details on DMA support. The following trigger levels are supported: 00 = FIFO empty 01 = 2 characters in the FIFO 10 = FIFO 1/4 full 11 = FIFO full **Value** **Description** 0 FIFO_EMPTY 1 FIFO_CHAR_2 2 FIFO_QUARTER_FULL 3 FIFO_HALF_FULL	WO	0x0
3	dmam	Bit[3], DMA Mode (or DMAM): This determines the DMA signalling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == NO). See section 5.9 on page 56 for details on DMA support. 0 = mode 0 1 = mode 1 **Value** **Description** 0 MODE0 1 MODE1	WO	0x0

Bit	Name	Description	Access	Reset
2	xfifor	Bit[2], XMIT FIFO Reset (or XFIFOR): This resets the control portion of the transmit FIFO and treats the FIFO as empty. This will also de-assert the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing' and it is not necessary to clear this bit. **Value** **Description** 1 RESET	WO	0x0
1	rfifor	Bit[1], RCVR FIFO Reset (or RFIFOR): This resets the control portion of the receive FIFO and treats the FIFO as empty. This will also de-assert the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing' and it is not necessary to clear this bit. **Value** **Description** 1 RESET	WO	0x0
0	fifoe	Bit[0], FIFO Enable (or FIFOE): This enables/disables the transmit (XMIT) and receive (RCVR) FIFO's. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFO's will be reset. **Value** **Description** 0 DISABLED 1 ENABLED	WO	0x0

Bit	Name	Description	Access	Reset
31:8	rsvd_lcr_31to8	Reserved bits [31:8] - Read Only	RO	0x0
7	dlab	Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable, always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers.	RW	0x0

Bit	Name	Description	Access	Reset
6	break	Break Control Bit. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.	RW	0x0

5	sp	From DW_apb_uart_regfile.sv:
		// aaraujo @ 17/05/2011 : CRM_9000431453
		// Stick parity lcr_ir[5] is now programmable
		lcr_ir[5:0] <= ipwdata[5:0];
		Value **Description**
		0 DISABLED
		1 ENABLED
			RW	0x0

Bit	Name	Description	Access	Reset
4	eps	Even Parity Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable, always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic '1's is transmitted or checked. If set to zero, an odd number of logic '1's is transmitted or checked. **Value** **Description** 0 ODDPAR 1 EVENPAR	RW	0x0
3	pen	Parity Enable. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable, always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. 0 = parity disabled 1 = parity enabled **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
2	stop	Number of stop bits. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable, always readable. This is used to select the number of stop bits per character that the peripheral will transmit and receive. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected the receiver will only check the first stop bit. 0 = 1 stop bit 1 = 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit **Value** **Description** 0 ONESTOP 1 ONEPOINT5STOP	RW	0x0

Bit	Name	Description	Access	Reset
1:0	dls	Data Length Select. If UART_16550_COMPATIBLE == NO then, writeable only when UART is not busy (USR[0] is zero), otherwise always writable, always readable. This is used to select the number of data bits per character that the peripheral will transmit and receive. The number of bit that may be selected areas follows: 00 = 5 bits 01 = 6 bits 10 = 7 bits 11 = 8 bits **Value** **Description** 0 LENGTH5 1 LENGTH6 2 LENGTH7 3 LENGTH8	RW	0x0

Bit	Name	Description	Access	Reset
31:7	rsvd_mcr_31to7	Reserved bits [31:7] - Read Only	RO	0x0
6	sire	SIR Mode Enable. Writeable only when SIR_MODE == Enabled, always readable. This is used to enable/ disable the IrDA SIR Mode features as described in section 5.2 on page 47. 0 = IrDA SIR Mode disabled 1 = IrDA SIR Mode enabled	RO	0x0
5	afce	Auto Flow Control Enable. Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in section 5.6 on page 51. 0 = Auto Flow Control Mode disabled 1 = Auto Flow Control Mode enabled **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
4	loopback	LoopBack Bit. This is used to put the UART into a dDW_iagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled OR NOT active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.	RW	0x0
3	out2	OUT2. This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: 0 = out2_n de-asserted (logic 1) 1 = out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0 LOGIC1 1 LOGIC0	RW	0x0

Bit	Name	Description	Access	Reset
2	out1	OUT1. This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: 0 = out1_n de-asserted (logic 1) 1 = out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0 LOGIC1 1 LOGIC0	RW	0x0

Bit	Name	Description	Access	Reset
1	rts	Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal will be de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0 LOGIC1 1 LOGIC0	RW	0x0

Bit	Name	Description	Access	Reset
0	dtr	Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: 0 = dtr_n de-asserted (logic 1) 1 = dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communi-cations. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0 LOGIC1 1 LOGIC0	RW	0x0

lsr Fields

Bit	Name	Description	Access	Reset
31:8	rsvd_lsr_31to8	Reserved bits [31:8] - Read Only	RO	0x0
7	rfe	Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFO's are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. That is: 0 = no error in RX FIFO 1 = error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. **Value** **Description** 0 NOERR 1 ERR	RO	0x0

Bit	Name	Description	Access	Reset
6	temt	Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFO's enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in the non-FIFO mode or FIFO's are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. **Value** **Description** 0 NOTEMPTY 1 EMPTY	RO	0x1
5	thre	Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the function-ality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. Program-mable THRE interrupt mode operation is described in detail in section 5.7 on page 52.	RO	0x1

Bit	Name	Description	Access	Reset
4	bi	Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.	RO	0x0

Bit	Name	Description	Access	Reset
3	fe	Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs the UART will try resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no framing error 1 = framing error Reading the LSR clears the FE bit. **Value** **Description** 0 NOFRAMEERR 1 FRAMEERR	RO	0x0

Bit	Name	Description	Access	Reset
2	pe	Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) will be set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no parity error 1 = parity error Reading the LSR clears the PE bit. **Value** **Description** 0 NOPARITYERR 1 PARITYERR	RO	0x0

Bit	Name	Description	Access	Reset
1	oe	Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. 0 = no overrun error 1 = overrun error Reading the LSR clears the OE bit. **Value** / **Description** 0 — NOOVERRUN 1 — OVERRUN	RO	0x0
0	dr	Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. 0 = no data ready 1 = data ready This bit is cleared when the RBR is read in the non-FIFO mode, or when the receiver FIFO is empty, in the FIFO mode. **Value** / **Description** 0 — NODATARDY 1 — DATARDY	RO	0x0

msr

Modem Status Register

```
It should be noted that whenever bits 0, 1, 2 or 3 is set to logic
one, to indicate
a change on the modem control inputs, a modem status interrupt will
be generated
if enabled via the IER regardless of when the change occurred. Since
the delta bits
(bits 0, 1, 3) can get set after a reset if their respective modem
signals are
active (see individual bits for details), a read of the MSR after
reset can be
performed to prevent unwanted interrupts.
```

Bit	Name	Description	Access	Reset
7:0	srbr_sthr_0	This is shadow register for RBR and THR and has been allocated sixteen 32-bit locations so as to accomodate burst accesses from the master. srbr : This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO are preserved, but any incoming data is lost. An overrun error also occurs. sthr: This register contains data to be transmitted on the serial output port (sout) in UART mode or the serial infrared output (sir_out_n) in infrared mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] set to zero) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] set to one) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configura-tion. Any attempt to write data when the FIFO is full results in	RO	0x0

4	rff	Receive FIFO Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO is completely full. That is: 0 = Receive FIFO not full 1 = Receive FIFO Full This bit is cleared when the RX FIFO is no longer full. **Value** — **Description** 0 — NOTFULL 1 — FULL	RO	0x0
3	rfne	Receive FIFO Not Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO contains one or more entries. 0 = Receive FIFO is empty 1 = Receive FIFO is not empty This bit is cleared when the RX FIFO is empty. **Value** — **Description** 0 — EMPTY 1 — NOTEMPTY	RO	0x0

Bit	Name	Description	Access	Reset
2	tfe	Transmit FIFO Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO is completely empty. 0 = Transmit FIFO is not empty 1 = Transmit FIFO is empty This bit is cleared when the TX FIFO is no longer empty. **Value** **Description** 0 NOTEMPTY 1 EMPTY	RO	0x1
1	tfnf	Transmit FIFO Not Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO in not full. 0 = Transmit FIFO is full 1 = Transmit FIFO is not full This bit is cleared when the TX FIFO is full. **Value** **Description** 0 FULL 1 NOTFULL	RO	0x1

Bit	Name	Description	Access	Reset
0	rsvd_busy	UART Busy. This bit is only valid when UART_16550_COMPATIBLE == NO. This indicates that a serial transfer is in progress, when cleared indicates that the DW_apb_uart is idle or inactive. 0 = DW_apb_uart is idle or inactive 1 - DW_apb_uart is busy (actively transferring data) Note that it is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the DW_apb_uart has no data in the THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the DW_apb_uart. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled) the assertion of this bit will also be delayed by several cycles of the slower clock.	RO	0x0

Bit	Name	Description	Access	Reset
31:1	rsvd_srts_31to1	Reserved bits [31:1] - Read Only	RO	0x0

Bit	Name	Description	Access	Reset
0	srts	Shadow Request to Send. This is a shadow register for the RTS bit (MCR[1]), this can be used to remove the burden of having to performing a read modify write on the MCR. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFO's enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold) only when RTC Flow Trigger is disabled; otherwise it is gated by the receiver FIFO almost-full trigger, where almost full refers to two available slots in the FIFO (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. **Value** **Description** 0 LOGIC1 1 LOGIC0	RW	0x0

sbcr

Shadow Break Control Register.

Module Instance	Base Address	Register Address
i_uart_0_uart	0xFFC02000	0xFFC02090

General-Purpose I/O Interface 22

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides three general-purpose I/O (GPIO) interface modules. The GPIO modules are instances of the Synopsys® DesignWare® APB General Purpose Programming I/O (DW_apb_gpio) peripheral.† (55)

Features of the GPIO Interface

The GPIO interface offers the following features:

- Supports digital debounce
- Configurable interrupt mode
- Supports up to 62 I/O pins

(55) Portions © 2016 Synopsys, Inc. Used with permission. All rights reserved. Synopsys & DesignWare are registered trademarks of Synopsys, Inc. HPS_DEDICATED_Q3 [12:1]	GPIO 1 [11:0]	Input / Output

Pin Name	Mapped to GPIO Signal Name	Comments
HPS_DEDICATED_Q4 [12:1]	GPIO 1 [23:12]	Input / Output

Functional Description of the GPIO Interface

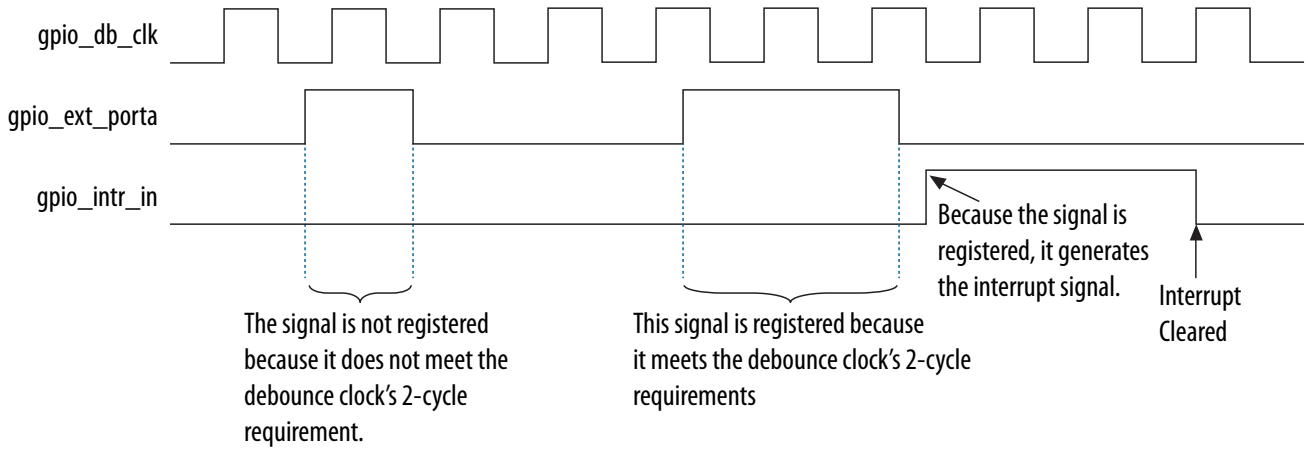
Debounce Operation

The GPIO modules provided in the HPS include optional debounce capabilities. The external signal can be debounced to remove any spurious glitches that are less than one period of the external debouncing clock, `gpio_db_clk`. †

When input signals are debounced using the `gpio_db_clk` debounce clock, the signals must be active for a minimum of two cycles of the debounce clock to guarantee that they are registered. Any input pulse widths less than a debounce clock period are filtered out. If the input signal pulse width is between one and two debounce clock widths, it may or may not be filtered out, depending on its phase relationship to the debounce clock. If the input pulse spans two rising edges of the debounce clock, it is registered. If it spans only one rising edge, it is not registered. †

The figure below shows a timing diagram of the debounce circuitry for both cases: a bounced input signal, and later, a propagated input signal.

Figure 22-2: Debounce Timing With Asychronous Reset Flip-Flops



Note: Enabling the debounce circuitry increases interrupt latency by two clock cycles of the debounce clock.

Pin Directions

All GPIO pins can be configured to be either input or output signals.

Taking the GPIO Interface Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

GPIO Interface Programming Model

Debounce capability for each of the input signals can be enabled or disabled under software control by setting the corresponding bits in the `gpio_debounce` register, accordingly. The debounce clock must be stable and operational before the debounce capability is enabled.

Under software control, the direction of the external I/O pad is controlled by a write to the `gpio_swportx_ddr` register. When configured as input mode, reading `gpio_ext_porta` would read the values on the signal of the external I/O pad. When configured as output mode, the data written to the `gpio_swporta_dr` register drives the output buffer of the I/O pad. The same pins are shared for both input and output modes, so they cannot be configured as input and output modes at the same time. †

General-Purpose I/O Interface Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

gpio Address Map

Module Instance	Base Address	End Address
i_gpio_0_gpio	0xFFC02900	0xFFC029FF
i_gpio_1_gpio	0xFFC02A00	0xFFC02AFF
i_gpio_2_gpio	0xFFC02B00	0xFFCF9FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Timer 23

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus.The timers optionally generate an interrupt when the 32-bit binary count-down timer reaches zero. The timers are instances of the Synopsys DesignWare APB Timers (DW_apb_timers) peripheral. (56)

Related Information

Cortex-A9 Microprocessor Unit Subsystem on page 9-1
The MPU subsystem provides additional timers. For more information about the timers in the MPU, refer to the *Cortex-A9 MPU* chapter.

Features of the Timer

- Supports interrupt generation
- Supports free-running mode
- Supports user-defined count mode

Timer Block Diagram and System Integration

Each timer includes a slave interface for control and status register (CSR) access, a register block, and a programmable 32-bit down counter that generates interrupts on reaching zero. The timer operates on a single clock domain driven by the clock manager.

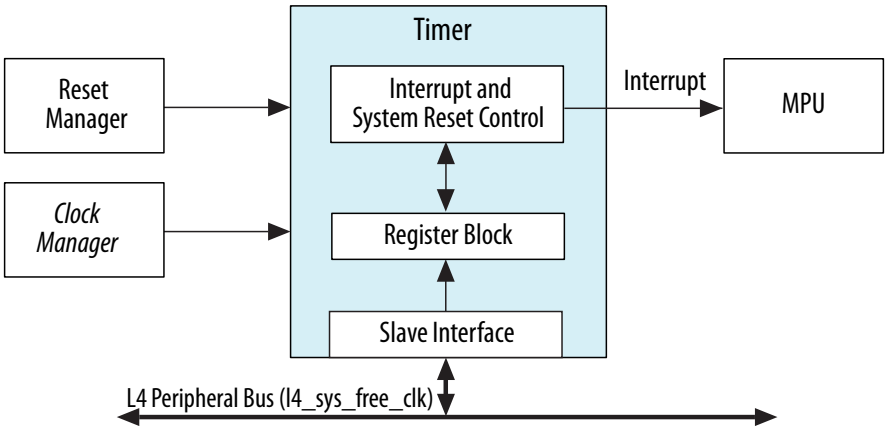
Figure 23-1: Timer Block Diagram



Functional Description of the Timer

The 32-bit timer counts down from a programmed value and generates an interrupt when the count reaches zero. The timer has an independent clock input connected to the system clock signal or to an external clock source. †

The timer supports the following modes of operation:

- Free-running mode—decrementing from the maximum value (0xFFFFFFFF). Reloads maximum value upon reaching zero.
- User-defined count mode—generates a periodic interrupt. Decrements from the user-defined count value loaded from the timer1 load count register (`timer1loadcount`). Reloads the user-defined count upon reaching zero.

The initial value for the timer (that is, the value from which it counts down) is loaded into the timer by the `timer1loadcount` register. The following events can cause a timer to load the initial count from the `timer1loadcount` register: †

- Timer is enabled after being reset or disabled
- Timer counts down to 0

Clocks

Table 23-1: Timer Clock Characteristics

Timer		System Clock	Notes
System timer 0	sys_timer0	l4_sys_free_clk	_
System timer 1	sys_timer1		
SP timer 0	sp_timer0	l4_sp_clk	Timer must be disabled if clock frequency changes
SP timer 1	sp_timer1		

The timers above are labeled according to the clock they receive. The system timers are connected to the L4_SYS bus and clocked by the l4_sys_free_clk. The SP timers are connected to the L4_SP bus and clocked by l4_sp_clk.

SP timer 0 and SP timer 1 must be disabled before l4_sp_clk is changed to another frequency. You can then re-enable the timer once the clock frequency change takes effect.

Related Information

Clock Manager on page 2-1
For more information about clock performance, refer to the *Clock Manager* chapter.

Resets

The timers are reset by a cold or warm reset. Resetting the timers produces the following results in the following order:

1. The timer is disabled.
2. The interrupt is enabled.
3. The timer enters free-running mode.
4. The timer count load register value is set to zero.

Interrupts

The timer1 interrupt status (timer1intstat) and timer1 end of interrupt (timer1eoi) registers handle the interrupts. The timer1intstat register allows you to read the status of the interrupt. Reading from the timer1eoi register clears the interrupt. †

The timer1 control register (timer1controlreg) contains the timer1 interrupt mask bit (timer1_interrupt_mask) to mask the interrupt. In both the free-running and user-defined count modes of operation, the timer generates an interrupt signal when the timer count reaches zero and the interrupt mask bit of the control register is high.

If the timer interrupt is set, then it is cleared when the timer is disabled.

Timer Programming Model

Initialization

To initialize the timer, perform the following steps: †

1. Initialize the timer through the `timer1controlreg` register: †
   - Disable the timer by writing a 0 to the timer1 enable bit (`timer1_enable`) of the `timer1controlreg` register. †

   Note: Before writing to a timer1 load count register (`timer1loadcount`), you must disable the timer by writing a 0 to the `timer1_enable` bit of the `timer1controlreg` register to avoid potential synchronization problems. †
   - Program the timer mode—user-defined count or free-running—by writing a 0 or 1, respectively, to the timer1 mode bit (`timer1_mode`) of the `timer1controlreg` register. †
   - Set the interrupt mask as either masked or not masked by writing a 1 or 0, respectively, to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †
2. Load the timer counter value into the `timer1loadcount` register. †
3. Enable the timer by writing a 1 to the `timer1_enable` bit of the `timer1controlreg` register. †

Enabling the Timer

When a timer transitions to the enabled state, the current value of `timer1loadcount` register is loaded into the timer counter. †

1. To enable the timer, write a 1 to the `timer1_enable` bit of the `timer1controlreg` register.

Disabling the Timer

When the timer enable bit is cleared to 0, the timer counter and any associated registers in the timer clock domain, are asynchronously reset. †

1. To disable the timer, write a 0 to the `timer1_enable` bit. †

Loading the Timer Countdown Value

When a timer counter is enabled after being reset or disabled, the count value is loaded from the `timer1loadcount` register; this occurs in both free-running and user-defined count modes. †

When a timer counts down to 0, it loads one of two values, depending on the timer operating mode: †

- User-defined count mode—timer loads the current value of the `timer1loadcount` register. Use this mode if you want a fixed, timed interrupt. Designate this mode by writing a 1 to the `timer1_mode` bit of the `timer1controlreg` register. †
- Free-running mode—timer loads the maximum value (0xFFFFFFFF). The timer max count value allows for a maximum amount of time to reprogram or disable the timer before another interrupt occurs. Use this mode if you want a single timed interrupt. Enable this mode by writing a 0 to the `timer1_mode` bit of the `timer1controlreg` register. †

Servicing Interrupts

Clearing the Interrupt

An active timer interrupt can be cleared in two ways.

1. If you clear the interrupt at the same time as the timer reaches 0, the interrupt remains asserted. This action happens because setting the timer interrupt takes precedence over clearing the interrupt. †
2. To clear an active timer interrupt, read the `timer1eoi` register or disable the timer. When the timer is enabled, its interrupt remains asserted until it is cleared by reading the `timer1eoi` register. †

Checking the Interrupt Status

You can query the interrupt status of the timer without clearing its interrupt.

1. To check the interrupt status, read the `timer1intstat` register. †

Masking the Interrupt

The timer interrupt can be masked using the `timer1controlreg` register.

To mask an interrupt, write a 1 to the `timer1_interrupt_mask` bit of the `timer1controlreg` register. †

Timer Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

timer_sys Address Map

Module Instance	Base Address	End Address
`i_timer_sys_0_timer`	`0xFFD00000`	`0xFFD000FF`
`i_timer_sys_1_timer`	`0xFFD00100`	`0xFFD001FF`

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Reserved															timersintstat RO 0x0

timersintstat Fields

Bit	Name	Description	Access	Reset
0	timersintstat	Contains the interrupt status of all timers in the component. If a bit of this register is 0, then the corresponding timer interrupt is not active and the corresponding interrupt could be on either the timer_intr bus or the timer_intr_n bus, depending on the interrupt polarity you have chosen. Similarly, if a bit of this register is 1, then the corresponding interrupt bit has been set in the relevant interrupt bus. In both cases, the status reported is the status after the interrupt mask has been applied. Reading from this register does not clear any active interrupts: 0 = either timer_intr or timer_intr_n is not active after masking 1 = either timer_intr or timer_intr_n is active after masking. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Watchdog Timer 24

2016.10.28

a10_5v4 Subscribe Send Feedback

The watchdog timers are peripherals you can use to recover from system lockup that might be caused by software or system related issues. The hard processor system (HPS) provides two programmable watchdog timers, which are connected to the level 4 (L4) peripheral bus. The watchdog timers are instances of the Synopsys DesignWare APB Watchdog Timer (DW_apb_wdt) peripheral. (57)

The microprocessor unit (MPU) subsystem provides two additional watchdog timers.

Related Information

For more information about the watchdog timers in the MPU, refer to *Cortex A9 Microprocessor Unit Subsystem* chapter.

Features of the Watchdog Timer

The following list describes the features of the watchdog timer:

- Programmable 32-bit timeout range
- Timer counts down from a preset value to zero, then performs one of the following user-configurable operations:
  - Generates a system reset †
  - Generates an interrupt, restarts the timer, and if the timer is not cleared before a second timeout occurs, generates a system reset
- Dual programmable timeout period, used when the time to wait after the first start is different than that required for subsequent restarts †
- Prevention of accidental restart of the watchdog counter †
- Prevention of accidental disabling of the watchdog counter †
- Pause mode for debugging

Watchdog Timer Block Diagram and System Integration

Each watchdog timer consists of a slave interface for control and status register (CSR) access, a register block, and a 32-bit down counter that operates on the slave interface clock (`l4_sys_free_clk`). A pause input, driven by the system manager, optionally pauses the counter when a CPU is being debugged.

The watchdog timer drives an interrupt request to the MPU and a reset request to the reset manager.

Functional Description of the Watchdog Timer

Watchdog Timer Counter

Each watchdog timer is a programmable, little-endian down counter that decrements by one on each clock cycle. The watchdog timer supports 16 fixed timeout period values, Software chooses which timeout periods are desired. A timeout period is 2<*n*> `l4_sys_free_clk` clock periods, where *n* is an integer from 16 to 31 inclusive.

Software must regularly restart the timer (which reloads the counter with the restart timeout period value) to indicate that the system is functioning normally. Software can reload the counter at any time by writing to the restart register. If the counter reaches zero, the watchdog timer has timed out, indicating an unrecoverable error has occurred and a system reset is needed.

Software configures the watchdog timer to one of the following output response modes:

- On timeout, generate a reset request.
- On timeout, assert an interrupt request and restart the watchdog timer. Software must service the interrupt and reset the watchdog timer before a second timeout occurs. Otherwise, generate a reset request.

If a restart occurs at the same time the watchdog counter reaches zero, an interrupt is not generated.

Note: After the watchdog timer reaches zero and generates a reset or interrupt, the counter resets and continues to count.

Watchdog Timer Pause Mode

The watchdog timers can be paused during debugging. The watchdog timer pause mode is controlled by the system manager. The following options are available:

- Pause the timer while either CPU0 or CPU1 is in debug mode
- Pause the timer while only CPU1 is in debug mode
- Pause the timer while only CPU0 is in debug mode
- Do not pause the timer

When pause mode is enabled, the system manager pauses the watchdog timer while debugging. When pause mode is disabled, the watchdog timer runs while debugging.

At reset, the watchdog pausing feature is enabled for both CPUs by default.

Related Information

Pausing a Watchdog Timer on page 24-5

Watchdog Timer Clocks

Each watchdog timer is connected to the `l4_sys_free_clk` clock so that timer operation is not dependent on the phase-locked loops (PLLs) in the clock manager and so that it is always running. This independence allows recovery from software that inadvertently programs the PLLs in the clock manager incorrectly.

Table 24-1: Watchdog Timer Clocks

Timer	System Clock
`watchdog0`	`l4_sys_free_clk`
`watchdog1`	`l4_sys_free_clk`

Table 24-2: Watchdog Timer Clocks

Timer	System Clock
watchdog0	l4_sys_free_clk
watchdog1	l4_sys_free_clk
watchdog2	l4_sys_free_clk
watchdog3	l4_sys_free_clk

Related Information

Clock Manager on page 2-1
For more information, refer to the *Clock Manager* chapter.

Watchdog Timer Resets

Watchdog timers are reset by a cold or warm reset from the reset manager, and are disabled when exiting reset. †

Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Taking the Watchdog Timer Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Watchdog Timer Programming Model

Setting the Timeout Period Values

The watchdog timers have a dual timeout period. The counter uses the initial start timeout period value the first the timer is started. All subsequent restarts use the restart timeout period. The valid values are $2^{(16+<i>)}$ – 1 clock cycles, where i is an integer from 0 to 15. To set the programmable timeout periods, perform the following actions in no specific order:

Note: Set the timeout values before enabling the timer.

- To set the initial start timeout period, write i to the timeout period for the initialization field (`top_init`) of the watchdog timeout range register (`wdt_torr`).
- To set the restart timeout period, write i to the timeout period field (`top`) of the `wdt_torr` register

Selecting the Output Response Mode

The watchdog timers have two output response modes. To select the desired mode, perform one of the following actions:

- To generate a system reset request when a timeout occurs, write 0 to the output response mode bit (`rmod`) of the watchdog timer control register (`wdt_cr`).
- To generate an interrupt and restart the timer when a timeout occurs, write 1 to the `rmod` field of the `wdt_cr` register.

If a restart occurs at the same time the watchdog counter reaches zero, a system reset is not generated. †

Related Information

Watchdog Timer Counter on page 24-2

Enabling and Initially Starting a Watchdog Timer

To enable and start a watchdog timer, write the value 1 to the watchdog timer enable bit (`wdt_en`) of the `wdt_cr` register.

Reloading a Watchdog Counter

To reload a watchdog counter, write the value 0x76 to the counter restart register (`wdt_crr`). This unique 8-bit value is used as a safety feature to prevent accidental restarts.

Pausing a Watchdog Timer

Pausing the watchdog timers is controlled by the L4 watchdog debug register (`wddbg`) in the system manager.

Related Information

Features of the System Manager on page 5-1
For more information, refer to the *System Manager* chapter.

Disabling and Stopping a Watchdog Timer

The watchdog timers are disabled and stopped by resetting them from the reset manager.

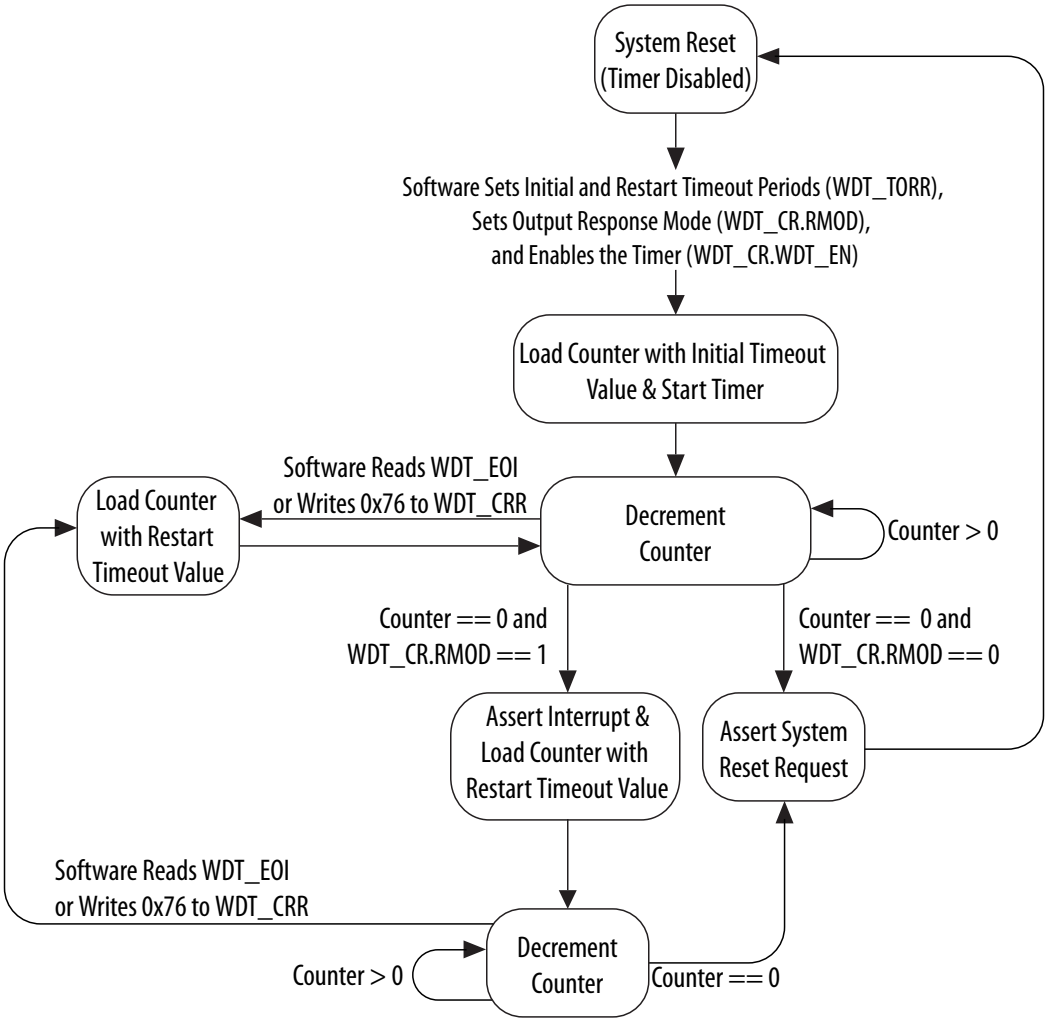
Related Information

Reset Manager on page 3-1
For more information, refer to the *Reset Manager* chapter.

Watchdog Timer State Machine

The following figure illustrates the behavior of the watchdog timer, including the behavior of both output response modes. Once initialized, the counter decrements at every clock cycle. The state machine remains in the Decrement Counter state until the counter reaches zero, or the watchdog timer is restarted. If software reads the interrupt clear register (`wdt_eoi`), or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to Decrement Counter.

Figure 24-2: Watchdog Timer State Machine



If the counter reaches zero, the state changes based on the value of the output response mode setting defined in the `rmod` bit of the `wdt_cr` register. If the `rmod` bit of the `wdt_cr` register is 0, the output response mode is to generate a system reset request. In this case, the state changes to Assert System Reset Request. In response, the reset manager resets and disables the watchdog timer, and gives software the opportunity to reinitialize the timer.

If the `rmod` bit of the `wdt_cr` register is 1, the output response mode is to generate an interrupt. In this case, the state changes to Assert Interrupt and Load Counter with Restart Timeout Value. An interrupt to the processor is generated, and the watchdog counter is reloaded with the restart timeout value. The state then changes to the second Decrement Counter state, and the counter resumes decrementing. If software reads the `wdt_eoi` register, or writes 0x76 to the `wdt_crr` register, the state changes from Decrement Counter to Load Counter with Restart Timeout Value. In this state, the watchdog counter gets reloaded with the restart timeout value, and then the state changes back to the first Decrement Counter state. If the counter again reaches zero, the state changes to Assert System Reset Request. In response, the reset manager resets the watchdog timer, and gives software the opportunity to reinitialize the timer.

Watchdog Timer Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

watchdog Address Map

wdt_torr Fields

Bit	Name	Description	Access	Reset
31:8	reserved	Reserved and read as 0.	RO	0x0
7:4	top_init	Timeout period for initialization. Used to select the timeout period that the watchdog counter restarts from for the first counter restart (kick) . This register should be written after reset and before the WDT is enabled. A change of the timeout period for initialization (TOP_INIT) is seen only once the WDT has been enabled, and any change after the first kick is not seen as subsequent kicks use the period specified by the TOP bits. If TOP_INIT is programmed to select a range that is greater than the counter width of 32, the timeout period is truncated to fit to the counter width. This	RW	0xF

Bit	Name	Description	Access	Reset
		affects only the non-user specified values as users are limited to these boundaries during configuration. **Value** **Description** 0xa TIMEOUT64M 0xb TIMEOUT128M 0xc TIMEOUT256M 0xd TIMEOUT512M 0xe TIMEOUT1G 0xf TIMEOUT2G 0x0 TIMEOUT64K 0x1 TIMEOUT128K 0x2 TIMEOUT256K 0x3 TIMEOUT512K 0x4 TIMEOUT1M 0x5 TIMEOUT2M 0x6 TIMEOUT4M 0x7 TIMEOUT8M 0x8 TIMEOUT16M 0x9 TIMEOUT32M		
3:0	top	Timeout period. This field is used to select the timeout period from which the watchdog counter restarts. A change of the timeout period takes effect only after the next counter restart (kick). If the time out period (TOP) is programmed to select a range that is greater than the counter width of 32, the timeout period is truncated to fit to the counter width. This affects only the non-user specified values as users are limited to these boundaries during configuration. **Value** **Description** 0xa TIMEOUT64M 0xb TIMEOUT128M 0xc TIMEOUT256M 0xd TIMEOUT512M 0xe TIMEOUT1G 0xf TIMEOUT2G	RW	0xF

Hard Processor System I/O Pin Multiplexing 25

2016.10.28

a10_5v4 Subscribe Send Feedback

The Arria 10 SoC has two banks of flexible I/O pins that are used for hard processor system (HPS) operation, external memory and external peripheral connection. Some of the pins are dedicated to the HPS, and others can be shared with the FPGA fabric. A pin multiplexing mechanism allows the SoC to use the flexible I/O pins in a wide range of configurations.

Features of the HPS I/O Block

The I/O block provides the following functionality and features:

- I/O pins
  - Dedicated I/O – 17 pins supporting clock, resets, boot devices, and other key peripherals.
  - Shared I/O – 48 pins available for HPS external memory and peripherals. Shared I/O pins can also be used by FPGA logic.

  Note: The HPS also interfaces with an SDRAM memory controller. This interface is separate from the dedicated and shared I/O pins discussed in this chapter.
- I/O multiplexing
  - Selects pins used by each HPS peripheral
  - Can assign shared I/O pins to FPGA logic
  - Can expose HPS peripheral interfaces to FPGA logic

  Note: When routed to the FPGA, some HPS peripherals require additional pipeline support in the connected soft logic. Refer to the relevant HPS peripheral chapter for details.

  I/O multiplexing is configured when you instantiate the HPS component.

Related Information

  For information about configuring the HPS I/O MUXes during system configuration, refer to the *Configuring Peripheral Pin Multiplexing* chapter.

HPS I/O Block Diagram and System Integration

The HPS I/O block consists of the following subblocks:

- Dedicated pin multiplexers (MUXes) – MUXes for the dedicated I/O bank
- Shared pin multiplexers – MUXes for the shared I/O bank
- FPGA access pin multiplexers – MUXes for HPS peripheral connections to the FPGA fabric
- Register slave interface – Provides access to control registers, which allow the bootloader to initialize I/O pins and HPS peripheral interfaces at system startup

Control Registers on page 25-5

Functional Description of the HPS I/O

Dedicated I/O Pins

The HPS has 17 dedicated I/O pins. Three are used as clock, cold reset and warm reset. The remaining 14 dedicated I/O pins are dedicated to boot devices and other commonly-used peripherals. The following HPS peripherals can be served by dedicated I/O pins:

- GPIO2
- NAND
- SD/MMC
- QSPI
- CM_PLL
- UART1
- SPI0
- EMAC0 MDIO interface
- EMAC1 MDIO interface
- EMAC2 MDIO interface

Each of these peripherals can alternatively be routed through the FPGA. You can configure this routing when you instantiate the HPS component.

Warm Reset Pin

The warm reset signal is a bidirectional signal; a warm reset event can drive into the HPS, or a warm reset event can be generated by the HPS and drive out of this pin.

Boot Pins

The following dedicated I/O pins convey boot source information:

- `HPS_DEDICATED_6/BOOTSEL2`
- `HPS_DEDICATED_10/BOOTSEL1`
- `HPS_DEDICATED_11/BOOTSEL0`

Typically, software samples these pins at cold reset.

Shared I/O Pins

There are 48 HPS peripheral pins that are shared with the FPGA core. They are divided into four quadrants of 12 signals per quadrant. Each quadrant can be assigned to the HPS or the FPGA fabric.

In each shared I/O quadrant, all 12 I/Os are assigned either to the FPGA or to the HPS. It is not possible to divide the I/Os in a quadrant between the FPGA and HPS.

When a quadrant is assigned to the FPGA fabric, you can connect FPGA soft logic to the shared I/O pins with the assignment editor, just as for any other FPGA I/O pins. Soft logic can use the shared I/O pins to interface to off-chip resources. However, pins in that quadrant are no longer directly available to HPS peripherals. Enabled HPS peripherals can be assigned to another quadrant, or else their interfaces can be routed to the FPGA fabric.

The following HPS peripherals can be assigned to shared I/O pins:

- EMAC0
- EMAC1
- EMAC2
- GPIO0
- GPIO1
- I2C0
- I2C1
- NAND
- QSPI
- SD/MMC
- SPI0
- SPI1
- TRACE
- UART0
- UART1
- USB0
- USB1

Each of these peripherals except USB0 and USB1 can alternatively be routed through the FPGA. You configure this routing when you instantiate the HPS component in Qsys.

Note: Although the shared I/O pins are configured through the control registers, software cannot reconfigure the shared I/O pins after I/O configuration is complete. There is no support for dynamically changing the pin MUX selections for shared pins.

FPGA Access

Most HPS peripheral interfaces can be connected into the FPGA fabric, instead of to the dedicated or shared I/O pins.

HPS peripherals connect to the FPGA fabric through the FPGA access pin MUX. When connected to the FPGA fabric, peripheral interfaces are exposed as ports of the HPS component.

Connecting HPS peripherals to the FPGA fabric can be a strategy to make optimal use of the I/O pins available to the HPS. For example, you can route HPS peripherals through the FPGA if your design requires more I/Os than the HPS I/O block provides.

All HPS peripherals except the USB 2.0 OTG controllers can interface to the FPGA fabric.

Related Information

Configuring HPS I/O Multiplexing on page 25-8
Information about configuring the HPS I/O MUXes

Control Registers

The HPS provides control registers that allow the system to initialize the following I/O parameters at system startup:

- Pins assigned to each HPS peripheral
- Shared I/O pins optionally assigned to FPGA logic
- HPS peripheral interfaces optionally exposed to FPGA logic
- I/O cell configuration

The HPS I/O control registers can only be accessed in secure mode.

Control registers can be divided into the following groups:

- Dedicated pin MUX registers
- Dedicated configuration registers
- Shared pin MUX registers
- FPGA access MUX registers

You set up the control registers when you instantiate the HPS component at the time of system generation. When you configure the HPS component, Qsys determines the correct register settings, and places them in the Quartus® Prime I/O programming file.

- **Configuring HPS I/O Multiplexing** on page 25-8
  Information about configuring the HPS I/O MUXes

Dedicated Pin MUX Registers

Dedicated pin MUX registers control the functions of the dedicated pins. One register is provided for each dedicated I/O pin.

The HPS provides pin MUX registers, `pinmux_dedicated_io_4` through `pinmux_dedicated_io_17`, for each of the dedicated pins HPS_DEDICATED_4 through HPS_DEDICATED_17. Each pin MUX register contains a 4-bit MUX select field to select the function of the dedicated pin. At a cold reset event these fields are reset to 15, selecting a general purpose I/O function. A warm reset event does not affect these registers.

The registers for dedicated I/O pins HPS_DEDICATED_1 through HPS_DEDICATED_3 provide no functionality, because these pins are always used as the HPS clock and reset pins.

Note: Although the dedicated I/O pins are configured through the control registers, Altera recommends against reconfiguring the dedicated I/O pins after I/O configuration is complete.

- **Arria 10 Hard Processor System Pin Information spreadsheet**
  Details of available HPS pin MUXing options
- **Pin-Out Files for Altera Devices**
  Pinout files for Arria 10 devices

Dedicated Configuration Registers

Configuration registers for each dedicated I/O pin allow software to control the corresponding I/O cell. These registers, `configuration_dedicated_io_1` through `configuration_dedicated_io_17`, allow software to set the following characteristics:

- Termination
- Slew rate
- Input buffer settings

These registers are not affected by a warm reset.

One configuration register, `configuration_dedicated_io_bank`, is also provided to select the I/O voltage for the dedicated I/O bank. At cold reset this register defaults to 0x2 (2.5-3.0 volt operation). This register is not affected by a warm reset.

Typically, the boot code programs this register when the system boots up. The boot code reads the BOOTSEL0, BOOTSEL1, and BOOTSEL2 pins and then sets the dedicated I/O bank to either 1.8 or 2.5-3.0 volt operation, depending on the pin status.

Note: Although the dedicated I/O pins are configured through the control registers, Altera recommends against reconfiguring the dedicated I/O pins after I/O configuration is complete.

...	...	...
pinmux_shared_io_q4_12	HPS_SHARED_IO_Q4_12	FPGA_SHARED_IO_Q4_12

Each shared pin MUX register contains a 4-bit MUX select field to select the function of the shared I/O pin. At a cold reset event these fields default to 15, selecting a general purpose I/O function. A warm reset event does not affect these registers.

Note: Although the shared I/O pins are configured through the control registers, software cannot reconfigure the shared I/O pins after I/O configuration is complete. There is no support for dynamically changing the pin MUX selections for shared pins.

FPGA Access MUX Registers

The FPGA access ("use FPGA") MUX registers select whether each HPS peripheral uses HPS I/O pins or is routed to the FPGA fabric.

All peripherals except the USBs can be routed to the FPGA. The following FPGA access registers are available:

- `pinmux_emac0_usefpga`
- `pinmux_emac1_usefpga`
- `pinmux_emac2_usefpga`
- `pinmux_i2c0_usefpga`
- `pinmux_i2c1_usefpga`
- `pinmux_i2c_emac0_usefpga`
- `pinmux_i2c_emac1_usefpga`
- `pinmux_i2c_emac2_usefpga`
- `pinmux_nand_usefpga`
- `pinmux_qspi_usefpga`
- `pinmux_sdmmc_usefpga`
- `pinmux_spim0_usefpga`
- `pinmux_spim1_usefpga`
- `pinmux_spis0_usefpga`
- `pinmux_spis1_usefpga`
- `pinmux_uart0_usefpga`
- `pinmux_uart1_usefpga`
- `pinmux_mdio0_usefpga`
- `pinmux_mdio1_usefpga`
- `pinmux_mdio2_usefpga`

At cold reset, the FPGA access registers default to 0, selecting the HPS I/O pins. These registers are not affected by a warm reset event.

Note: Although the FPGA access MUX is configured through the control registers, Altera recommends against reconfiguring the FPGA access MUX after I/O configuration is complete.

- **Configuring HPS I/O Multiplexing** on page 25-8
  Information about configuring the HPS I/O MUXes

Configuring HPS I/O Multiplexing

HPS I/O multiplexing is configured when the system is generated with Qsys.

Related Information

Configuring Peripheral Pin Multiplexing on page 27-14
For information about configuring the HPS I/O MUXes during system configuration, refer to the *Configuring Peripheral Pin Multiplexing* chapter.

Configuring Multiplexing at System Generation

There are 48 HPS peripheral pins that are shared with the FPGA core. They are divided into four quadrants of 12 signals per quadrant. Each quadrant can be configured with the Qsys system integration tool to be assigned to the HPS or the FPGA fabric.

The select for this multiplexer is in the I/O configuration shift registers (IOCSRs) which are configured by the Quartus Prime I/O programming file.

When you configure the HPS component, Qsys determines the correct register settings, and creates a device tree for the boot loader. When the system boots up, the boot loader configures the registers before configuring the I/O chain.

Configuring Multiplexing at Boot Time

Typically, the boot code programs the `configuration_dedicated_io_bank` register when the system boots up. The boot code reads the BOOTSEL0, BOOTSEL1, and BOOTSEL2 pins and then sets the dedicated I/O bank to either 1.8 V or 2.5-3.0 V operation, depending on the pin status.

Related Information

- **Control Registers** on page 25-5

Test Considerations

The dedicated I/O pins are chained into the full chip JTAG boundary scan chain. However, in some power modes the HPS can be off or disabled. The SoC device provides a bypass MUX to remove the dedicated I/O pins from the scan chain in this situation.

The boundary scan phase is not required to include I/O configuration shift register (IOCSR) configuration for the CONFIG_IO instruction. The only requirement is that no software be executing on the HPS during boundary scan.

If CONFIG_IO mode is active during the boundary scan phase, the HPS is in cold reset, preventing any software interference with the boundary scan. However, if the I/Os are configured in user mode, CONFIG_IO mode is not active during the scan phase, and you must implement safeguards to prevent software from executing during scan.

Introduction to the HPS Component 26

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) component is a wrapper that interfaces logic in the user design to the HPS hard logic, simulation models, BFMs, and software handoff files. It instantiates the HPS hard logic in the user design; and enables other soft components to interface with the HPS hard logic. The HPS component itself has a small footprint in the FPGA fabric, because its only purpose is to enable soft logic to connect to the extensive hard logic in the HPS. You can connect soft logic to the HPS.

After the soft logic is connected to the HPS, Qsys ensures the following features:

- Interoperability by adapting Avalon® Memory-Mapped (Avalon-MM) interfaces to AXI
- Handle data width mismatches
- Clock domain transfer crossing

This allows you to integrate IP from Altera, 3rd party IP cores, and custom IP cores to the HPS without having to create integration logic.

For a description of the HPS and its integration into the system on a chip (SoC), refer to the *Arria 10 Device Datasheet*.

For a description of the HPS system architecture and features, refer to the "Introduction to the Hard Processor" and the CoreSight Debug and Trace chapters in the *Arria 10 Device Handbook*.

For more information about instantiating the HPS component, refer to the *Instantiating the HPS Component* chapter in the *Hard Processor System Technical Reference Manual*.

ARM CoreSight Debug Components

The following lists the ARM CoreSight debug components:

- Debug Access Port (DAP)
- System Trace Macrocell (STM)
- Trace Funnel
- Embedded Trace FIFO (ETF)
- AMBA Trace Bus Replicator (Replicator)
- Embedded Trace Router (ETR)
- Trace Port Interface Unit (TPIU)
- Embedded Cross Trigger (ECT)
- Program Trace Macrocell (PTM)

Related Information

CoreSight Debug and Trace on page 10-1

Interconnect

The interconnect consists of the L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The L3 interconnect is an Arteris FlexNoC network-on-chip (NOC) interconnect module.

Related Information

System Interconnect on page 7-1

HPS-to-FPGA Interfaces

The HPS-to-FPGA interfaces provide a variety of communication channels between the HPS and the FPGA fabric. The HPS is highly integrated with the FPGA fabric, resulting in thousands of connecting signals. Some of the HPS-to-FPGA interfaces include:

- FPGA-to-HPS port
- HPS-to-FPGA port
- Lightweight HPS-to-FPGA port
- FPGA-to-SDRAM interface

Related Information

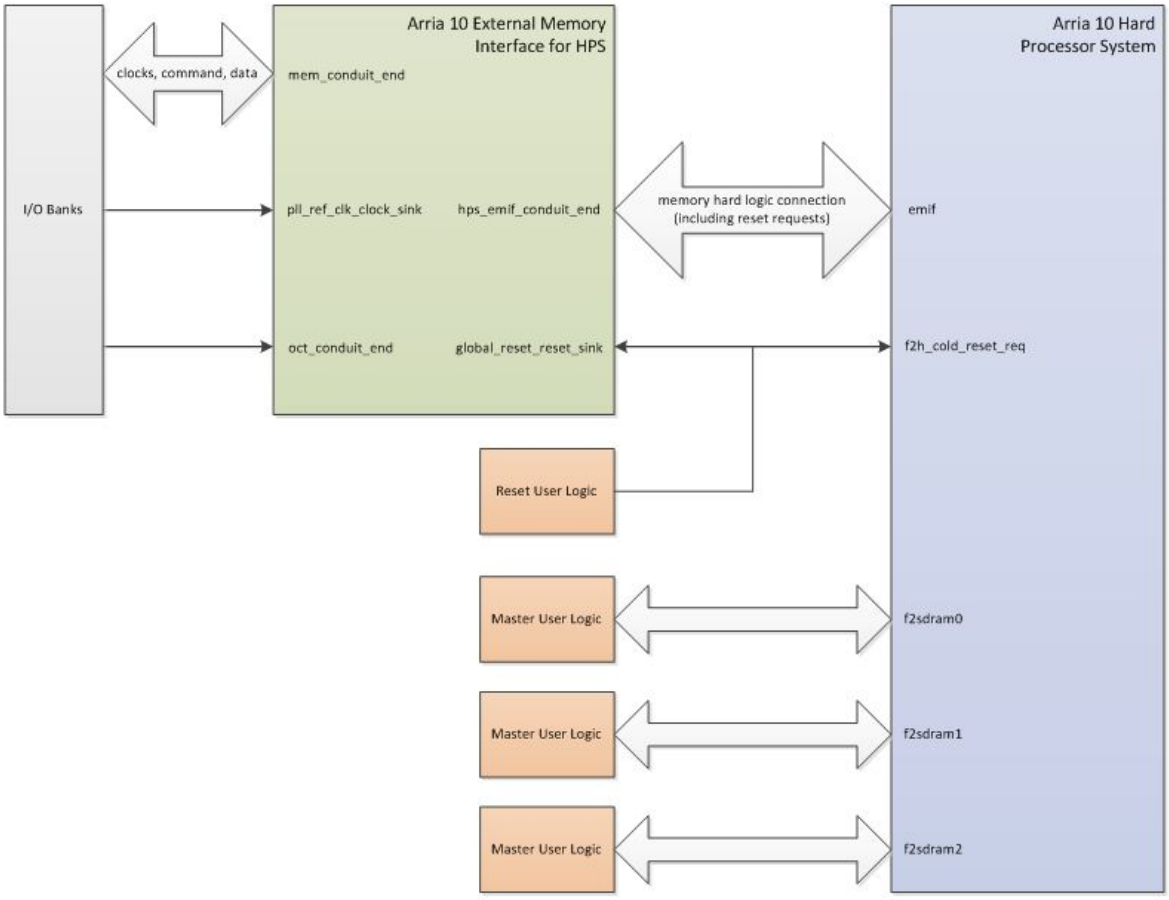
HPS SDRAM Controller

There are several memory interfaces connected, but only one connection to each interface is allowed at one time. You must instantiate a separate SDRAM controller and connect it to the HPS.

HMC and HPS Connectivity

The following figure shows that the HMC clock comes from the I/O itself, the HPS can reset the memory through the dedicated hard-logic connection between them, and any logic in the FPGA that resets the HMC must also be connected to the HPS.

Figure 26-1: HMC and HPS Connectivity



Clocks

You must connect the SDRAM controller to a reference clock that comes from the I/O column where the RAM controller is located.

Resets

There are two ways that the SDRAM controller can be connected to reset.

- One way - Reset and status connection is automatic by just connecting the SDRAM Hard Memory Controller (HMC) to the HPS. You access these wires in the reset manager so that you can reset the HMC and find out when the reset is complete.
- Second way - The HMC reset input from the FPGA fabric. This signal is called `global_reset_n` and is one of the signals exposed to the FPGA fabric from the HMC when you instantiate it in Qsys. The purpose of this signal is to reset the HMC from the FPGA side of the fabric. Before the FPGA fabric is configured, the memory controller ignores this signal which is why the memory controller can become live before the fabric is configured. This also means that the user design that gets configured into the fabric must drive it because once the fabric is configured, the HMC will use `global_reset_n` as an input source.

Note: You must connect the input source for `global_reset_n` to the cold reset input for the HPS. If you put the SDRAM into reset but that same reset source does not connect to the HPS, the memory is then wiped out while the HPS is still trying to access it. This causes the software to crash.

Instantiating the HPS Component 27

2016.10.28

a10_5v4 Subscribe Send Feedback

This chapter describes the parameters available in the hard processor system (HPS) component parameter editor, which opens when you add or edit an HPS component. You instantiate the HPS component in Qsys.

Related Information

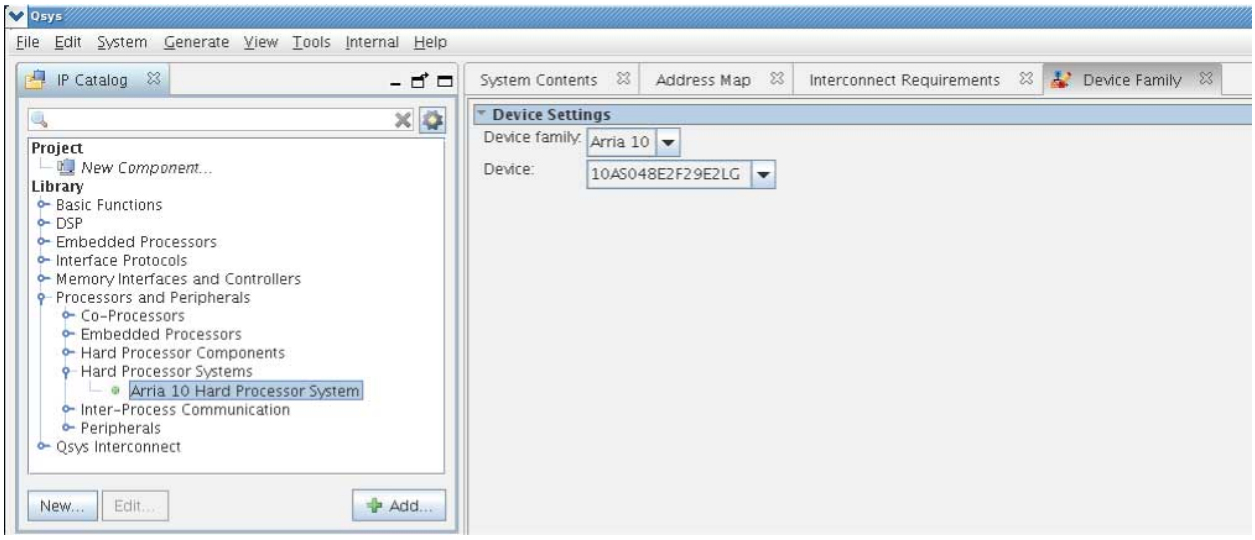
Arria 10 Device Datasheet

The HPS requires specific device targets. For a detailed list of supported devices, refer to the *Arria 10 Device Datasheet* .

Using the HPS Parameter Editor

1. Install the Arria 10 ACDS version 14.0.
2. Open the Quartus Prime software.
3. Open Qsys by selecting **Tools** > **Qsys**.
4. In the **Device Family** tab, select a 10ASxxx device from the **Device** pull-down menu.
5. In the **IP Catalog** tab, under Library, select **Processors and Peripherals** > **Hard Processor Systems** > **Arria 10 Hard Processor System**.

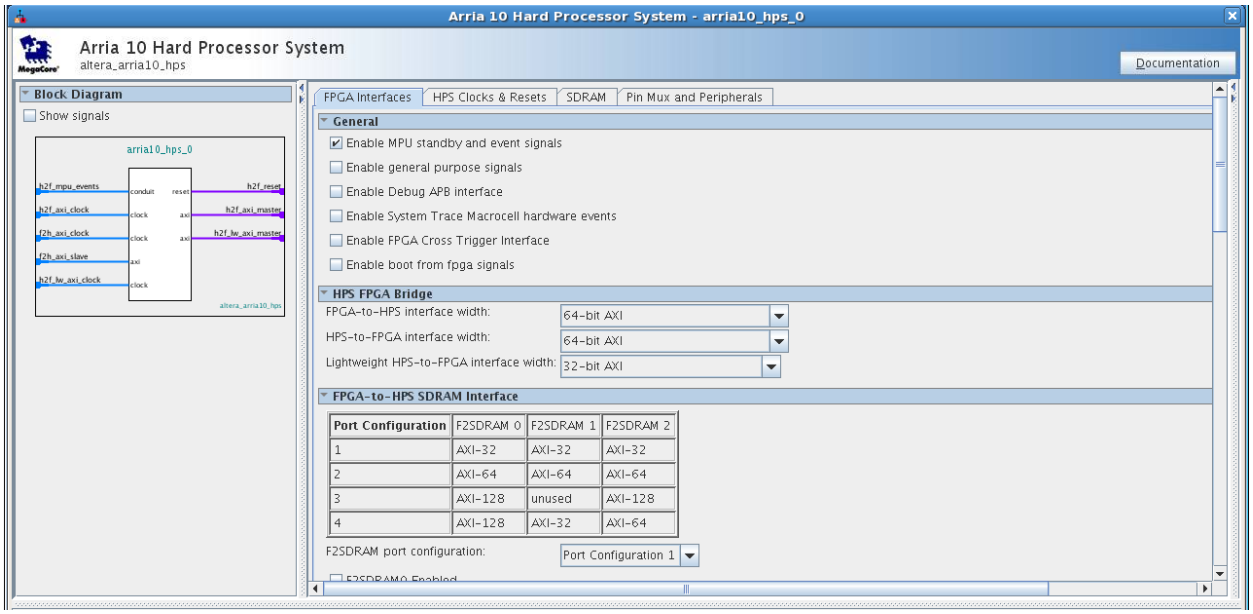
Figure 27-1: Qsys Device Family Tab



FPGA Interfaces

The **FPGA Interfaces** tab is one of four tabs on the HPS Component. This tab contains several groups with the parameters shown in the following figure.

Figure 27-2: FPGA Interfaces Tab



Related Information

Introduction to the HPS Component on page 26-1

General Interfaces

When enabled, the interfaces described in the following table become visible in the HPS component.

Table 27-1: General Parameters

Parameter Name	Parameter Description	Interface Name
Enable MPU standby and event signals	Enables interfaces that perform the following functions: • Notify the FPGA fabric that the microprocessor unit (MPU) is in standby mode. • Wake up an MPCore processor from a wait for event (WFE) state.	`h2f_mpu_events`
	Input for FPGA to signal events to both processors. This signal must be asserted high for at least two MPU clock cycles to be visible to either Cortex-A9 processor core. This signal is used to wake either processor core from standby mode.	`h2f_mpu_eventi`
	Output event from either processor sent to the FPGA. The output event is a multiple cycle pulse so logic in the FPGA should detect it using a rising edge detector circuit to detect the occurrence of the event. This signal is asserted each time either processor executes the SEV instruction.	`h2f_mpu_evento`
	Output per processor that indicates if the processor is in WFE standby mode. When high the processor is in WFE standby mode.	`h2f_mpu_standbywfe [1..0]`
	Output per processor that indicates if the processor is in WFI standby mode. When high the processor is in WFI standby mode.	`h2f_mpu_standbywfi [1..0]`
Enable general purpose signals	Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA fabric and the FPGA manager in the HPS portion of the SoC device.	`h2f_gp` • `h2f_gp_in [31..0]` • `h2f_gp_out [31..0]`

Parameter Name	Parameter Description	Interface Name

Enable Debug APB interface	Enables debug interface to the FPGA, allowing access to debug components in the HPS. For more information, refer to the *CoreSight Debug and Trace* chapter.	`h2f_debug_apb`
		• `h2f_dbg_apb_PADDR [17..0]`
		• `h2f_dbg_apb_PADDR31`
		• `h2f_dbg_apb_PENABLE`
		• `h2f_dbg_apb_PRDATA [31..0]`
		• `h2f_dbg_apb_PREADY`
		• `h2f_dbg_apb_PSEL`
		• `h2f_dbg_apb_PSLVERB`
		• `h2f_dbg_apb_PWDATA [31..0]`
		• `h2f_dbg_apb_PWRITE`
		`h2f_debug_apb_sideband`
		• `h2f_debug_apb_PCLKEN`
		• `h2f_debug_apb_DBG_APB_DISABLE`
		`h2f_debug_apb_clock`
		• `h2f_abg_apb_clk`
		`h2f_debug_apb_reset`
		• `h2f_dbg_apb_rst_n`

Enable System Trace Macrocell hardware events	Enables system trace macrocell (STM) hardware events, allowing logic inside the FPGA to insert messages into the trace stream. For more information, refer to the *CoreSight Debug and Trace* chapter.	`f2h_stm_hw_events` • `f2h_stm_hwevents [27..0]`
Enable FPGA Cross Trigger interface	Enables the cross trigger interface (CTI), which allows trigger sources and sinks to interface with the embedded cross trigger (ECT). For more information, refer to the *CoreSight Debug and Trace* chapter. If this interface has to be connected to a SignalTap II instance in the FPGA fabric, then it has to be left disabled in Qsys.	`h2f_cti` • `h2f_cti_trig_in [7..0]` • `h2f_cti_trig_out_ack [7..0]` • `h2f_cti_trig_out [7..0]` • `h2f_cti_trig_in_ack [7..0]`

Parameter Name	Parameter Description	Interface Name
Enable boot from FPGA signals	Enables an input to the HPS indicating whether a preloader is available in the on-chip memory of the FPGA. This option also enables a separate input to the HPS indicating a fallback preloader is available in the FPGA memory. A fallback preloader is used when there is no valid preloader image found in flash memory. For more information, refer to *Appendix A: Booting and Configuration*.	`f2h_boot_from_fpga`
	This is an active high signal which the Boot ROM polls to determine when the FPGA is configured and the memory located at offset 0x0 from the FPGA to HPS bridge is ready to be written to. When the FPGA is not configured the hardware will drive this signal low. You will need to drive this signal high when the memory in the FPGA is ready to accept memory mapped transactions. The `f2h_boot_from_fpga_ready` signal is used by the Boot ROM when accessing the public key stored in the FPGA. The Boot ROM will only use the signal if asserted to boot with the public key. For more information, refer to *Appendix A: Booting and Configuration*.	`f2h_boot_from_fpga_ready`
	This is an active high signal which the Boot ROM polls when all the preloaders fail to load. This signal is driven low when the FPGA is not configured. You will need to drive the signal high in your design. The Boot ROM will continuously poll both **f2h_boot_from_fpga** signals until both are set. For more information, refer to *Appendix A: Booting and Configuration*.	`f2h_boot_from_fpga_on_failure`

Related Information

- **CoreSight Debug and Trace** on page 10-1
  Enabling the TPIU exposes trace signals to the device pins. Refer to the *CoreSight Debug and Trace* for more information.
- **Booting and Configuration** on page 30-1
  For detailed information about the HPS boot sequence, refer to the *Booting and Configuration*.

FPGA-to-HPS SDRAM Interface

In the FPGA-to-HPS SDRAM interface table, use the F2SDRAM port configuration pull-down menu to choose bus widths for each SDRAM. You can add one to three SDRAM ports that make the HPS SDRAM subsystem accessible to the FPGA fabric.

The following table shows the width options for the SDRAM ports in Qsys.

Table 27-2: FPGA-to-HPS SDRAM Port and Interface Names

Port configuration	F2SDRAM 0	F2SDRAM 1	F2SDRAM 2
1	AXI-32	AXI-32	AXI-32
2	AXI-64	AXI-64	AXI-64
3	AXI-128	unused	AXI-128
4	AXI-128	AXI-32	AXI-64

Table 27-3: FPGA-to-HPS SDRAM Port and Interface Names

Port Name	Interface Name
F2SDRAM 0	`f2sdram0_data` `f2sdram0_clock`
F2SDRAM 1	`f2sdram1_data` `f2sdram1_clock`
F2SDRAM 2	`f2sdram2_data` `f2sdram2_clock`

Note: You can configure the slave interface to a data width of 32-, 64-, 128-bits. To facilitate accessing this slave from a memory-mapped master with a smaller address width, you can use the *Altera Address Span Extender*.

Related Information

Using the Address Span Extender Component on page 27-17
Address span extender details

DMA Peripheral Request

You can enable each direct memory access (DMA) controller peripheral request ID individually. Each request ID enables an interface for FPGA soft logic to request one of eight logical DMA channels to the FPGA.

Related Information

DMA Controller on page 16-1
For more information, refer to the *DMA Controller* chapter in the *Arria 10 Hard Processor System Technical Reference Manual* .

Security Manager

Table 27-4: Anti Tamper signals

Interface Name	Description	Associated Signal
`h2f_security`	The security manager anti-tamper interface provides communication between the anti-tamper logic in the FPGA and the HPS security manager.	`f2h_security_anti_tamper_in` `f2h_security_anti_tamper_out`

Related Information

SoC Security on page 6-1

Interrupts

Table 27-5: FPGA-to-HPS Interrupts Interface

Parameter Name	Parameter Description	Interface Name
Enable FPGA-to-HPS Interrupts	Enables interface for FPGA interrupt signals to the MPU (in the HPS).	f2h_irq0 f2h_irq1

You can enable the interfaces for each HPS peripheral interrupt to the FPGA.

Table 27-6: HPS-to-FPGA Interrupts Interface

The following table lists the available HPS to FPGA interrupt interfaces and the corresponding parameters to enable them.

Parameter Name	Parameter Description	Interface Name
Enable Clock Peripheral Interrupts	Enables interface for HPS clock manager and MPU wake-up interrupt signals to the FPGA	`h2f_clkmgr_interrupt` `h2f_mpuwakeup_interrupt`

Parameter Name	Parameter Description	Interface Name
Enable CTI Interrupts	Enables interface for HPS cross-trigger interrupt signals to the FPGA	h2f_ncti_interrupt0 h2f_ncti_interrupt1
Enable DMA Interrupts	Enables interface for HPS DMA channels interrupt and DMA abort interrupt to the FPGA	h2f_dma_interrupt0 h2f_dma_interrupt1 h2f_dma_interrupt2 h2f_dma_interrupt3 h2f_dma_interrupt4 h2f_dma_interrupt5 h2f_dma_interrupt6 h2f_dma_interrupt7 h2f_dma_abort_interrupt
Enable EMAC Interrupts	Enables interface for HPS Ethernet MAC controller interrupt to the FPGA. EMAC must be enabled in Pin Mux Tab before enabling interrupt.	h2f_emac0_interrupt h2f_emac1_interrupt h2f_emac2_interrupt
Enable FPGA manager Interrupts	Enables interface for the HPS FPGA manager interrupt to the FPGA	h2f_fpga_man_interrupt
Enable GPIO Interrupts	Enables interface for the HPS general purpose IO (GPIO) interrupt to the FPGA	h2f_gpio0_interrupt h2f_gpio1_interrupt h2f_gpio2_interrupt
Enable HMC Interrupts	Enable the HPS peripheral interrupt for HMC to be driven into the FPGA fabric.	h2f_hmc_interrupt
Enable I2C-EMAC Interrupts	Enable the HPS peripheral interrupt for I2CEMAC to be driven into the FPGA fabric	h2f_i2c_emac0_interrupt h2f_i2c_emac1_interrupt h2f_i2c_emac2_interrupt
Enable I2C Peripherals Interrupts	Enable the HPS peripheral interrupt for I2C0 to be driven into the FPGA fabric. The I2C must be enabled in the Pin Mux Tab before enabling interrupt.	h2f_i2c0_interrupt h2f_i2c1_interrupt

Parameter Name	Parameter Description	Interface Name
Enable L4 Timer Interrupts	Enables the HPS peripheral interrupt for L4TIMER to be driven into the FPGA fabric.	`h2f_timer_l4sp_0_interrupt` `h2f_timer_l4sp_1_interrupt`
Enable NAND Interrupts	Enables interface for the HPS NAND controller interrupt to the FPGA. The NAND IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_nand_interrupt`
Enable Quad SPI Interrupts	Enables interface for the HPS QSPI controller interrupt to the FPGA. The Quad SPI IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_qspi_interrupt`
Enable SYS Timer Interrupts	Enables the HPS peripheral interrupt for SYSTIMER to be driven into the FPGA fabric.	`h2f_timer_sys_0_interrupt` `h2f_timer_sys_1_interrupt`
Enable SD/MMC Interrupts	Enables interface for the HPS SD/MMC controller interrupt to the FPGA. The SD/MMC IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_sdmmc_interrupt`
Enable SPI Master Interrupts	Enables interface for the HPS SPI master controller interrupt to the FPGA. The SPI Master IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_spim0_interrupt` `h2f_spim1_interrupt`
Enable SPI Slave Interrupts	Enables interface for the HPS SPI slave controller interrupt to the FPGA. The SPI IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_spis0_interrupt` `h2f_spis1_interrupt`

Enable ECC/Parity_L1 Interrupts	Enables the HPS peripheral interrupt for ECC single and double bit error and L1 parity error to be driven into the FPGA fabric.	`h2f_ecc_serr_interrupt`
		`h2f_ecc_derr_interrupt`
		`h2f_parity_l1_interrupt`

Parameter Name	Parameter Description	Interface Name
Enable UART Interrupts	Enables interface for the HPS UART controller interrupt to the FPGA. The UART IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_uart0_interrupt` `h2f_uart1_interrupt`
Enable USB Interrupts	Enables interface for the HPS USB controller interrupt to the FPGA. The USB IP Block must be enabled in Pin Mux Tab before enabling interrupt.	`h2f_usb0_interrupt` `s2f_usb1_interrupt`
Enable Watchdog Interrupts	Enables interface for the HPS watchdog interrupt to the FPGA	`h2f_wdog0_interrupt` `h2f_wdog1_interrupt`

AXI Bridges

Table 27-7: Bridge Parameters

Parameter Name	Parameter Description	Interface Name
FPGA-to-HPS interface width	Enable or disable the FPGA-to-HPS interface; if enabled, set the data width to 32, 64, or 128 bits.	`f2h_axi_slave` `f2h_axi_clock`
HPS-to-FPGA interface width	Enable or disable the HPS-to-FPGA interface; if enabled, set the data width to 32, 64, or 128 bits.	`h2f_axi_master` `h2f_axi_clock`
Lightweight HPS-to-FPGA interface width	Enable or disable the lightweight HPS-to-FPGA interface. When enabled, the data width is 32 bits.	`h2f_lw_axi_master` `h2f_lw_axi_clock`

Note: To facilitate accessing these slaves from a memory-mapped master with a smaller address width, you can use the Altera Address Span Extender.

Address span extender details

Configuring HPS Clocks and Resets

The **HPS Clocks and Reset** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

Alternate Clock Source from FPGA on page 27-11

User Clocks on page 27-11

Reset Interfaces on page 27-12

Peripheral FPGA Clocks on page 27-13

Alternate Clock Source from FPGA

Table 27-8: Alternate Clock Source Parameters

Parameter Name	Parameter Description	Clock Interface Name
Enable Alternate Clock Source from FPGA	Drives the HPS Clock source to originate from the FPGA fabric instead of the dedicated HPS input clock pin.	`f2h_free_clk`

User Clocks

When you enable a HPS-to-FPGA user clock, you must manually enter its maximum frequency for timing analysis. The TimeQuest Timing Analyzer has no other information about how software running on the HPS configures the phase-locked loop (PLL) outputs. Each possible clock, including clocks that are available from peripherals, has its own parameter for describing the clock frequency.

User Clock Parameters

The frequencies that you provide are the maximum expected frequencies. The actual clock frequencies can be modified through the register interface, for example by software running on the microprocessor unit (MPU). For further details, refer to *Selecting PLL Output Frequency and Phase*.

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 0 clock	Enable main PLL from HPS-to-FPGA	`h2f_user0_clock`
User 0 clock frequency	Specify the maximum expected frequency for the main PLL	

Parameter Name	Parameter Description	Clock Interface Name
Enable HPS-to-FPGA user 1 clock	Enable peripheral PLL from HPS-to-FPGA	h2f_user1_clock
User 1 clock frequency	Specify the maximum expected frequency for the peripheral PLL	

Clock Frequency Usage

The clock frequencies you provide are reported in a Synopsys Design Constraints File (**.sdc**) generated by Qsys. The **.sdc** file will be referenced in the system **.qip** file when the system is generated.

Clock Manager on page 2-1
For general information about clock signals, refer to the *Clock Manager* chapter in the *Arria 10 Hard Processor System Technical Reference Manual* .

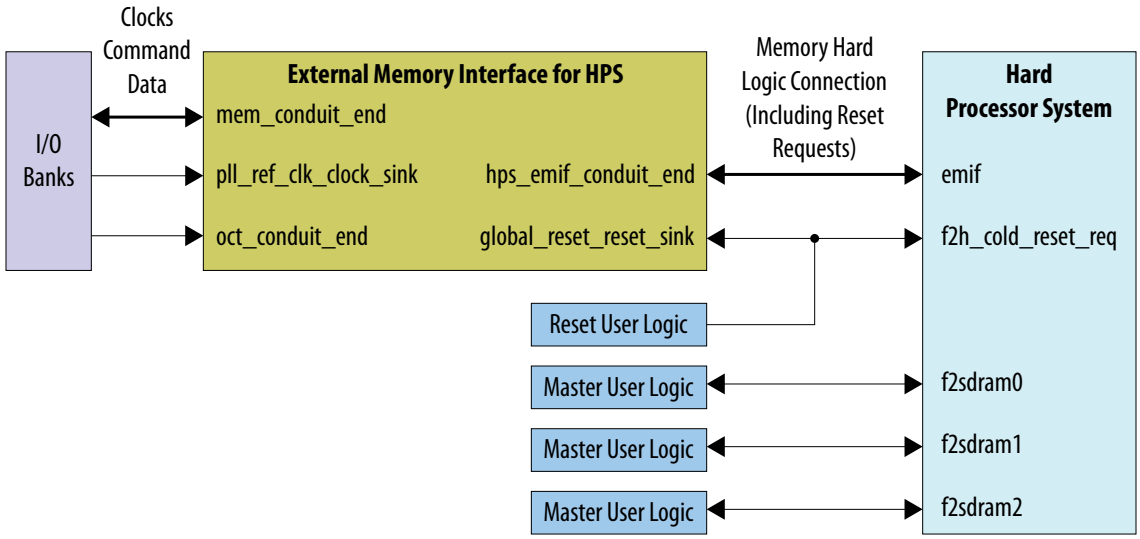
Reset Interfaces

You can enable the resets on an individual basis through the **HPS Clocks and resets** tab under the **Resets** sub tab.

Table 27-9: Reset Parameters

Parameter Name	Parameter Description	Interface Name
Enable HPS-to-FPGA cold reset output	Enable interface for HPS-to-FPGA cold reset output	h2f_cold_reset
Enable HPS warm reset handshake signals	Enable an additional pair of reset handshake signals allowing soft logic to notify the HPS when it is safe to initiate a warm reset in the FPGA fabric.	h2f_warm_reset_handshake
Enable FPGA-to-HPS debug reset request	Enable interface for FPGA-to-HPS debug reset request	f2h_debug_reset_req
Enable FPGA-to-HPS warm reset request	Enable interface for FPGA-to-HPS warm reset request	f2h_warm_reset_req
Enable FPGA-to-HPS cold reset request	Enable interface for FPGA-to-HPS cold reset request	f2h_cold_reset_req

Figure 27-3: Recommended SDRAM Reset Connections



The SDRAM reset relies on the `f2h_cold_reset_req`to be enabled. The reset can be enabled through the Qsys **Resets** tab.

Note: SDRAM and the EMIF conduit can be enabled through the Qsys **FPGA Interface** and **SDRAM** tab.

Peripheral FPGA Clocks

Parameter Name	Parameter Description
EMAC 0 (emac0_md_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 MDIO clock frequency
EMAC 0 (emac0_gtx_clk clock frequency)	If EMAC 0 peripheral is routed to FPGA, use the input field to specify EMAC 0 transmit clock frequency
EMAC 1 (emac1_md_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 MDIO clock frequency
EMAC 1 (emac1_gtx_clk clock frequency)	If EMAC 1 peripheral is routed to FPGA, use the input field to specify EMAC 1 transmit clock frequency
EMAC 2 (emac2_md_clk clock frequency)	If EMAC 2 peripheral is routed to FPGA, use the input field to specify EMAC 2 MDIO clock frequency

Parameter Name	Parameter Description
EMAC 2 (emac2_gtx_clk clock frequency)	If EMAC 2 peripheral is routed to FPGA, use the input field to specify EMAC 2 transmit clock frequency
QSPI (qspi_sclk_out clock frequency)	If QSPI peripheral is routed to FPGA, use the input field to specify QSPI serial clock frequency
SDMMC (sdmmc_cclk)	If this peripheral pin multiplexing is configured to route to FPGA fabric, use the input field to specify the SDMMC sdmmc_cclk clock frequency
SPIM 0 (spim0_sclk_out clock frequency)	If SPI master 0 peripheral is routed to FPGA, use the input field to specify SPI master 0 output clock frequency
SPIM 1 (spim1_sclk_out clock frequency)	If SPI master 1 peripheral is routed to FPGA, use the input field to specify SPI master 1 output clock frequency
I^2C0 (i2c0_clk clock frequency)	If I^2C 0 peripheral is routed to FPGA, use the input field to specify I^2C 0 output clock frequency
I^2C1 (i2c1_clk clock frequency)	If I^2C 1 peripheral is routed to FPGA, use the input field to specify I^2C 1 output clock frequency
I2CEMAC0 (i2cemac0_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC0 i2cemac0_clk clock frequency
I2CEMAC1 (i2cemac1_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC1 i2cemac1_clk clock frequency
I2CEMAC2 (i2cemac2_clk)	If this peripheral pin multiplexing is configured to route to the FPGA fabric, use the input field to specify the I2CEMAC2 i2cemac2_clk clock frequency

Configuring Peripheral Pin Multiplexing

The **Pin Mux and Peripherals** tab is one of four tabs on the HPS Component. This tab contains several groups with the following parameters:

Configuring Peripherals on page 27-14

Connecting Unassigned Pins to GPIO on page 27-16

Peripheral Signals Routed to FPGA on page 27-16

Configuring Peripherals

The **Pin MUX and Peripherals** tab contains three sub tabs **IP Selection**, **Advanced Pin Placement**, and **Advanced FPGA Placement**. The **IP Selection** tab contains a list of peripherals that can be enabled and

either routed to the HPS I/Os or to the FPGA. You can enable one or more instances of each peripheral type by using the drop down menu next to each peripheral. When enabled, some peripherals also have mode settings specific to their functions.

Note: Once you have selected a peripheral, you must click the **Apply Selections** button in order to enable the selected peripherals.

Under the the **IP Selection** tab, Qsys allows you to boot from the following flash device sources if selected.

- NAND
- SD/MMC
- QSPI

In the **Advanced Pin Placement** tab you can be more specific about the placement of each peripheral in the HPS dedicated I/O and HPS shared I/O quadrant space. Each location has a pull down IP selection menu where you can select a peripheral for the location.

Pin placement for peripherals cannot span both dedicated I/O and HPS shared I/O, except for the following situations:

- QSPI signals `qspi_ss_o[2]` and `qspi_ss_o[3]` are available to the HPS shared I/O and can be routed to any quadrant selected.
- If the SD/MMC signals are routed to the HPS shared I/O, and the `SDMMC_PWR_ENA` pin is required, then it is only available to the HPS dedicated I/O.
- If the signals for all three EMACs are routed to the HPS shared I/O, the MDIO signals for all three EMACs can be routed to the HPS dedicated I/Os.
- If the NAND Flash Controller pins are routed to the HPS dedicated I/O, `NAND_WP_N` is only available to the HPS shared I/O.

In addition, peripheral pins cannot span multiple quadrants within the HPS shared I/O. All pins of an instance must be self-contained in one quadrant, except for NANDx16 and the GPIO modules because of the number of pins required for these peripherals. For example, NANDx16 may be routed to either quadrant 1 and quadrant 2 or quadrant 3 and quadrant 4.

The **Advanced FPGA Placement** tab allows you to route peripherals to the FPGA. Aside from the **IP Selection** tab this tab allows you to focus on the FPGA routing only. There are also SDMMC and NAND Bit-width options. You can select the EMAC interface and PHY options on this tab if peripheral is selected.

Note: Changes in the **IP Selection** tab carry over to the **Advanced Pin Placement** tab, **Advanced FPGA Placement** tab, and vise versa.

You can enable the following types of peripherals:

Boot Source

Under the **IP Selection** tab you have the option to choose a nonvolatile flash-based memory to be the boot source. The following flash controller peripherals under the IP block list in the **IP Selection** tab have a **Boot** enable button beside them where you can make this selection.

- NAND
- SD/MMC
- QSPI

Related Information

Booting and Configuration on page 30-1
For detailed information about the HPS boot sequence, refer to the *Booting and Configuration*.

Connecting Unassigned Pins to GPIO

For pins that are not assigned to any peripherals, you can assign them to the GPIO peripheral by clicking on the corresponding GPIO push button in the table. Click on the selected push button to remove GPIO pin assignment. The table also shows the GPIO bit number that correlates to the I/O pins.

Peripheral Signals Routed to FPGA

You can route the peripheral signals to the FPGA fabric and assign them to the FPGA I/O pins.

The following steps show you how to enable the peripheral signals:

1. Select a peripheral in the IP Selection list.
2. Choose the To FPGA drop-down box next to the IP you have selected and choose the amount of instances for the peripheral
3. Click the Apply Selections button at the bottom of the peripherals list.

Configuring the External Memory Interface

The **SDRAM** tab is one of four tabs on the HPS component. Enable the conduit to connect to the Arria 10 External Memory Interface. This option enables a conduit interface for the HPS to talk to the Arria 10 External Memory interfaces for the HPS.

The HPS supports one memory interface implementing double data rate 3 (DDR3), double data rate 3 Low Voltage (DDR3L), and double data rate 4 (DDR4) protocols.

External Memory Interface In Arria 10 Devices
For more information on the A10 External Memory Interface, refer to the External Memory Interfaces in Arria 10 Devices in the Arria 10 Core Fabric and General Purpose I/O Handbook.

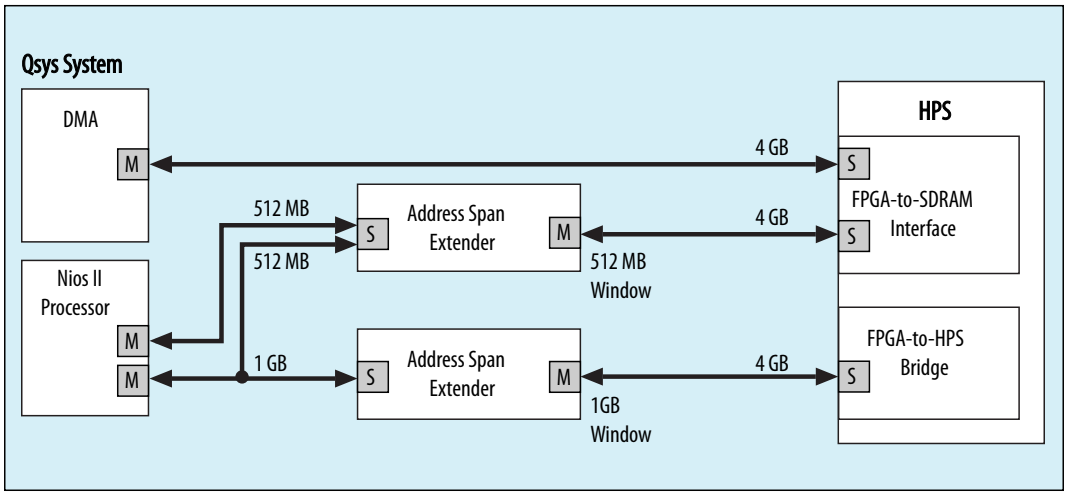
Using the Address Span Extender Component

The FPGA-to-HPS bridge and FPGA-to-HPS SDRAM memory-mapped interfaces expose their entire 4-GB address spaces to the FPGA fabric. The address span extender component provides a memory-mapped window into the address space that it masters. Using the address span extender, you can expose portions of the HPS memory space without needing to expose the entire 4 GB address space.

You can use the address span extender between a soft logic master and an FPGA-to-HPS bridge or FPGA-to-HPS SDRAM interface. This component reduces the number of address bits required for a master to address a memory-mapped slave interface located in the HPS.

Figure 27-4: Address Span Extender Components

Two address span extender components used in a system with the HPS.



You can also use the address span extender in the HPS-to-FPGA direction, for slave interfaces in the FPGA. In this case, the HPS-to-FPGA bridge exposes a limited, variable address space in the FPGA, which can be paged in using the address span extender.

For example, suppose that the HPS-to-FPGA bridge has a 1-GB span, and the HPS needs to access three independent 1-GB memories in the FPGA portion of the device. To achieve this, the HPS programs the address span extender to access one SDRAM (1-GB) in the FPGA at a time. This technique is commonly called paging or windowing.

Related Information

Qsys System Design Components

For more information about the Altera Span Extender, refer to the Address Span Exdenter section in the Qsys System Design Components chapter of the Qsys Design Handbook.

Generating and Compiling the HPS Component

The process of generating and compiling an HPS design is very similar to the process for any other Qsys project. Perform the following steps:

1. Generate the design with Qsys. The generated files include an **.sdc** file containing clock timing constraints. If simulation is enabled, simulation files are also generated.
2. Add *<qsys_system_name>.qip* to the Quartus Prime project. *<qsys_system_name>.qip* is the Quartus Prime IP File for the HPS component, generated by Qsys.

   Note: Qsys generates pin assignments in the **qip** file.
3. Perform analysis and synthesis with the Quartus Prime software.
4. Compile the design with the Quartus Prime software.
5. Optionally back-annotate the SDRAM pin assignments, to eliminate pin assignment warnings the next time you compile the design.

Document Revision History

Table 27-10: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release.
May 2016	2016.05.27	Removed *FPGA EMAC Switch Interface* section. The application interface (also called the switch interface) is not supported.
May 2016	2016.05.03	Maintenance release.
November 2015	2015.11.02	Added content regarding peripheral pin placmement in HPS shared and dedicated I/O to the "Configuring Peripherals" section.
May 2015	2015.05.04	• Updated "Reset Interfaces" section. • Updated "General Interfaces" section.
December 2014	2014.12.15	Initial release.

HPS Component Interfaces 28

2016.10.28

a10_5v4

This chapter describes the interfaces, including clocks and resets, implemented by the hard processor system (HPS) component.

The majority of the resets can be enabled on an individual basis. The exception is the `h2f_reset` interface, which is always enabled.

You must declare the clock frequency of each HPS-to-FPGA clock for timing purposes. Each possible clock, including ones that are available from peripherals, has its own parameter for describing the clock frequency. Declaring the clock frequency for HPS-to-FPGA clocks specifies how you plan to configure the PLLs and peripherals, to enable TimeQuest to accurately estimate system timing. It has no effect on PLL settings.

Related Information

  For Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) protocol timing, refer to the AMBA AXI Protocol Specification v1.0, which you can download from the ARM info center website.

Memory-Mapped Interfaces

FPGA-to-HPS Bridge

Interface Name	Description	Associated Clock Interface
`f2h_axi_slave`	FPGA-to-HPS AXI slave interface	`f2h_axi_clock`

The FPGA-to-HPS interface is a configurable data width AXI slave allowing FPGA masters to issue transactions to the HPS. This interface allows the FPGA fabric to access the majority of the HPS slaves. This interface also provides a coherent memory interface.

Other interface standards in the FPGA fabric, such as connecting to Avalon® Memory-Mapped (Avalon-MM) interfaces, can be supported through the use of soft logic adapters. The Qsys system integration tool automatically generates adapter logic to connect AXI to Avalon-MM interfaces.

The FPGA-to-HPS interface is an AXI-3 compliant interface with the following features:

- Configurable data width: 32, 64, or 128 bits
- Ready latency support data widths: 32, 64, or 128 bits

Related Information

- **Clocks** on page 28-4

HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges

Table 28-1: HPS-to-FPGA and Lightweight HPS-to-FPGA Bridges and Clocks

Interface Name	Description	Associated Clock Interface
`h2f_axi_master`	HPS-to-FPGA AXI master interface	`h2f_axi_clock`
`h2f_lw_axi_master`	HPS-to-FPGA lightweight AXI master interface	`h2f_lw_axi_clock`

The HPS-to-FPGA interface is a configurable data width AXI master (32-, 64-, or 128-bit) that allows HPS masters to issue transactions to the FPGA fabric.

The lightweight HPS-to-FPGA interface is a 32-bit AXI master that allows HPS masters to issue transactions to the FPGA fabric.

Other interface standards in the FPGA fabric, such as connecting to Avalon-MM interfaces, can be supported through the use of soft logic adaptors. The Qsys system integration tool automatically generates adaptor logic to connect AXI to Avalon-MM interfaces.

Each AXI bridge accepts a clock input from the FPGA fabric and performs clock domain crossing internally. The exposed AXI interface operates on the same clock domain as the clock supplied by the FPGA fabric.

Latency Support for (32-,64, or 128-bit)

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface is a direct connection between the FPGA fabric and the HPS SDRAM controller. The interface is highly configurable, allowing a mix between the four port configurations and the port width. The FPGA-to-HPS SDRAM interface supports AMBA AXI interface standards.

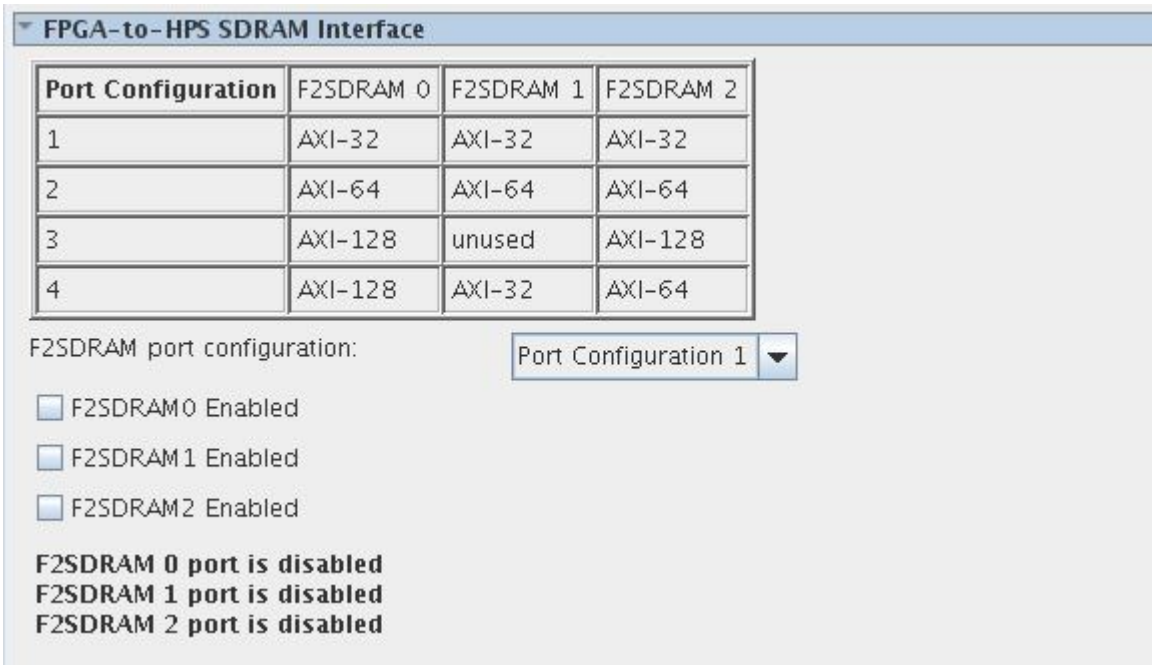
Table 28-2: FPGA-to-HPS SDRAM Interfaces and Clocks

Interface Name	Associated Data Interface	Associated Clock Interface
F2SDRAM0	f2sdram0_data	f2sdram0_clock
F2SDRAM1	f2sdram1_data	f2sdram1_clock
F2SDRAM2	f2sdram2_data	f2sdram2_clcok

The FPGA-to-HPS SDRAM interface is a configurable interface to the multi-port SDRAM controller. There are four port configurations that are a combination of the SDRAM ports 0 - 2 that you are able to select. Once a port configuration is selected, you can choose to enable the ports that you need.

The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction. The HPS SDRAM controller supports up to 3 masters (command ports), 3x 64-bit read data ports and 3x 64-bit write data ports.

Figure 28-1: FPGA-to-HPS SDRAM Qsys Interface



Related Information

- Clocks on page 28-4

- **HPS Component Interfaces** on page 28-1
  For information about the address span extender, refer to "Using the Address Span Extender Component" in the *Instantiating the HPS Component* chapter.

EMIF Conduit

Under the SDRAM tab in Qsys, the EMIF conduit can be enabled. This enables the HPS dedicated conduit to the Arria 10 External Interface for the HPS. This conduit cannot connect to any other External Memory Interface (EMIF). Only IP generated by the Arria 10 External Memory Interface for HPS Qsys library should be used.

Clocks

The HPS-to-FPGA clock interface supplies physical clocks to the FPGA. These clocks and resets are generated in the HPS.

Alternative Clock Inputs to HPS PLLs

This section lists alternative clock inputs to HPS PLLs.

- `f2h_free_clk`—FPGA-to-HPS free clock. Drives the HPS clock source to originate from the FPGA fabric instead of the dedicated HPS input clock pin.

User Clocks

A user clock is a PLL output that is connected to the FPGA fabric rather than the HPS. You can connect a user clock to logic that you instantiate in the FPGA fabric.

- `h2f_user0_clock`—HPS-to_FPGA user clock, driven from main PLL
- `h2f_user1_clock`—HPS-to-FPGA user clock, driven from peripheral PLL

AXI Bridge FPGA Interface Clocks

The AXI interface has an asynchronous clock crossing in the FPGA-to-HPS bridge. The FPGA-to-HPS and HPS-to-FPGA interfaces are synchronized to clocks generated in the FPGA fabric. These interfaces can be asynchronous to one another.

- `f2h_axi_clock`—AXI slave clock for FPGA-to-HPS bridge, generated in FPGA fabric
- `h2f_axi_clock`—AXI master clock for HPS-to-FPGA bridge, generated in FPGA fabric
- `h2f_lw_axi_clock`—AXI master clock for lightweight HPS-to-FPGA bridge, generated in FPGA fabric

SDRAM Clocks

You can configure the HPS component with up to three FPGA-to-HPS SDRAM clocks.

Each command channel to the SDRAM controller has an individual clock source from the FPGA fabric. The interface clock is always supplied by the FPGA fabric, with clock crossing occurring on the HPS side of the boundary.

The FPGA-to-HPS SDRAM clocks are driven by soft logic in the FPGA fabric.

- f2h_sdram0_clock—SDRAM clock for port 0
- f2h_sdram1_clock—SDRAM clock for port 1
- f2h_sdram2_clock—SDRAM clock for port 2

Peripheral FPGA Clocks

Table 28-3: Peripheral FPGA Clocks

Clock Name	Description
emac_md_clk	Ethernet PHY management interface clock
emac_gtx_clk	Ethernet transmit clock that is used by the PHY in GMII mode
emac_rx_clk_in	Ethernet MAC reference clock from the PHY
emac_tx_clk_in	Ethernet MAC uses this clock input for TX reference
emac_ptp_ref_clock	Ethernet timestamp precision time protocol (PTP) reference clock
qspi_sclk_out	QSPI master clock output
qspi_s2f_clk	QSPI serial clock output (connects to the FPGA clock network)
sdmmc_clk_in	Clock for SD/MMC controller
sdmmc_cclk	Generated output clock for card
spim_sclk_out	SPI master serial clock output
spis_sclk_in	SPI slave serial clock input
i2c_clk	I^2C outgoing clock (part of the SCL bidirectional pin signals)
i2c_scl_in	I^2C incoming clock (part of the SCL bidirectional pin signals)
i2cemac_clk	I^2C EMAC outgoing clock

Note: The Peripheral FPGA Clocks can only be accessed once the corresponding IP Block has been selected and routed to the FPGA through the Pin Mux and Peripherals tab.

Resets

This section describes the reset interfaces to the HPS component.

Related Information

Reset Manager on page 3-1
For details about the HPS reset sequences, refer to the *Functional Description of the Reset Manager* in the *Reset Manager* chapter .

HPS-to-FPGA Reset Interfaces

The following interfaces allow the HPS to reset soft logic in the FPGA fabric:

- `h2f_reset`—HPS-to-FPGA warm reset
- `h2f_cold_reset`—HPS-to-FPGA cold reset
- `h2f_warm_reset_handshake`—Warm reset request and acknowledge interface between HPS and FPGA

HPS External Reset Request

The following interfaces allow soft logic in the FPGA fabric to request for different types of HPS resets:

- `f2h_cold_reset_req`—FPGA-to-HPS cold reset request
- `f2h_warm_reset_req`—FPGA-to-HPS warm reset request
- `f2h_dbg_reset_req`—FPGA-to-HPS debug reset request

Peripheral Reset Interfaces

The following are Ethernet reset interfaces, that can be used when the Ethernet is routed to the FPGA:

- `emac_tx_reset`— Ethernet transmit clock reset output used to reset external PHY TX clock domain logic
- `emac_rx_reset`— Ethernet receive clock reset output used to reset external PHY RX clock domain logic

Debug and Trace Interfaces

FPGA System Trace Macrocell Events Interface

The system trace macrocell (STM) hardware events allow logic in the FPGA to insert messages into the trace stream.

- `f2h_stm_hw_events`

FPGA Cross Trigger Interface

The cross trigger interface (CTI) allows trigger sources and sinks to interface with the embedded cross trigger (ECT).

- `h2f_cti`

Debug APB Interface

The debug Advanced Peripheral Bus (APB™) interface allows debug components in the FPGA fabric to debug components on the CoreSight™ debug APB.

- `h2f_debug_apb`
- `h2f_debug_apb_sideband`
- `h2f_debug_apb_reset`
- `h2f_debug_apb_clock`

Peripheral Signal Interfaces

Qsys Peripheral Port Interface Mapping

For many of the HPS component peripherals, the Qsys ports can be routed to the HPS pins, FPGA pins or both. The following tables show the available mappings.

NAND Flash Controller Interface

Table 28-4: NAND Flash Controller Interface Qsys Port Mappings

Qsys Port Name	Routed to FPGA	Routed to HPS I/O	HPS Pin Name
`nand_adq_i[15:0]`	Yes	Yes	`NAND_ADQ[15:0]`
`nand_adq_oe`	Yes	Yes	
`nand_adq_o[15:0]`	Yes	Yes	
`nand_ale_o`	Yes	Yes	`NAND_ALE`
`nand_ce_o[3:0]`	Yes, 4 chip enables	Yes, 1 chip enable	`NAND_CE_N`
`nand_cle_o`	Yes	Yes	`NAND_CLE`
`nand_re_o`	Yes	Yes	`NAND_RE_N`
`nand_rdy_busy_i[3:0]`	Yes, 4 ready/busy signals	Yes, 1 ready/busy signal	`NAND_RB`
`nand_we_o`	Yes	Yes	`NAND_WE_N`
`nand_wp_o`	Yes	Yes	`NAND_WP_N`

DMA Controller Interface

The DMA controller interface allows soft IP in the FPGA fabric to communicate with the DMA controller in the HPS. You can configure up to eight separate interface channels.

- f2h_dma0—FPGA DMA controller peripheral request interface 0
- f2h_dma1—FPGA DMA controller peripheral request interface 1
- f2h_dma2—FPGA DMA controller peripheral request interface 2
- f2h_dma3—FPGA DMA controller peripheral request interface 3
- f2h_dma4—FPGA DMA controller peripheral request interface 4

- f2h_dma5—FPGA DMA controller peripheral request interface 5
- f2h_dma6—FPGA DMA controller peripheral request interface 6
- f2h_dma7—FPGA DMA controller peripheral request interface 7

Each of the DMA peripheral request interface contains the following three signals:

- f2h_dma_req—This signal is used to request burst transfer using the DMA
- f2h_dma_single—This signal is used to request single word transfer using the DMA
- f2h_dma_ack—This signal indicates the DMA acknowledgment upon requests from the FPGA

Related Information

DMA Controller on page 16-1
For details about the DMA Controller, refer to *DMA controller* chapter.

Other Interfaces

Related Information

For more information, refer to *Cortex-A9 MPU Subsystem* .

MPU Standby and Event Interfaces

MPU standby signals are notification signals to the FPGA fabric that the MPU is in standby. Event signals are used to wake up the Cortex-A9 processors from a wait for event (WFE) state. The following shows the signals in the interface:

- h2f_mpu_eventi—Sends an event from logic in the FPGA fabric to the MPU. This FPGA-to-HPS signal is used to wake up a processor that is in a Wait For Event state. Asserting this signal has the same effect as executing the SEV instruction in the Cortex-A9. This signal must be de-asserted until the FPGA fabric is powered-up and configured.
- h2f_mpu_evento—Sends an event from the MPU to logic in the FPGA fabric. This HPS-to-FPGA signal is asserted when an SEV instruction is executed by one of the Cortex-A9 processors.
- h2f_mpu_standbywfe[1:0]—Indicates which Cortex-A9 processor is in the WFE state
- h2f_mpu_standbywfi[1:0]—Indicates which Cortex-A9 processor is in the wait for interrupt (WFI) state

The MPU provides signals to indicate when it is in a standby state. These signals are available to custom hardware designs in the FPGA fabric.

Related Information

Cortex-A9 MPCore on page 9-4
For more information, refer to *Cortex-A9 MPU Subsystem* .

General Purpose Signals

Table 28-12: General Purpose Interfaces

Signal	Description	Associated Signal
h2f_gp	General purpose interface. Enables a pair of 32-bit unidirectional general-purpose interfaces between the FPGA manager in HPS and the FPGA fabric.	h2f_gp_in h2f_gp_out

FPGA-to-HPS Interrupts

You can configure the HPS component to provide 64 general purpose FPGA-to-HPS interrupts, allowing soft IP in the FPGA fabric to trigger interrupts to the MPU's generic interrupt controller (GIC). The interrupts are implemented through the following 32-bit interfaces:

- f2h_irq0—FPGA-to-HPS interrupts 0 through 31
- f2h_irq1—FPGA-to-HPS interrupts 32 through 63

The FPGA-to-HPS interrupts are asynchronous on the FPGA interface. Inside the HPS, the interrupts are synchronized to the MPU's internal peripheral clock (periphclk).

Related Information

HPS Component Interfaces on page 28-1
There are various HPS peripherals to FPGA interrupt interfaces that you can configure. To learn the complete list of interfaces, refer to the *Instantiating the HPS Component* chapter.

Boot from FPGA Interface

You can enable the boot from FPGA interface to indicate the availability of preloader software in the FPGA memory. This interface is used to indicate the availability of a fallback preloader software in FPGA memory as well. The fallback preloader is used when there is no valid preloader image found in HPS flash memories.

Simulating the HPS Component 29

2016.10.28

a10_5v4 Subscribe Send Feedback

This section describes the simulation support for the hard processor system (HPS) component. The HPS simulation models provide bus functional models of the HPS and FPGA fabric and a simulation model of the interface to SDRAM memory.

The HPS simulation support does not include modules implemented in the HPS, such as the ARM Cortex-A9 MPCore processor.

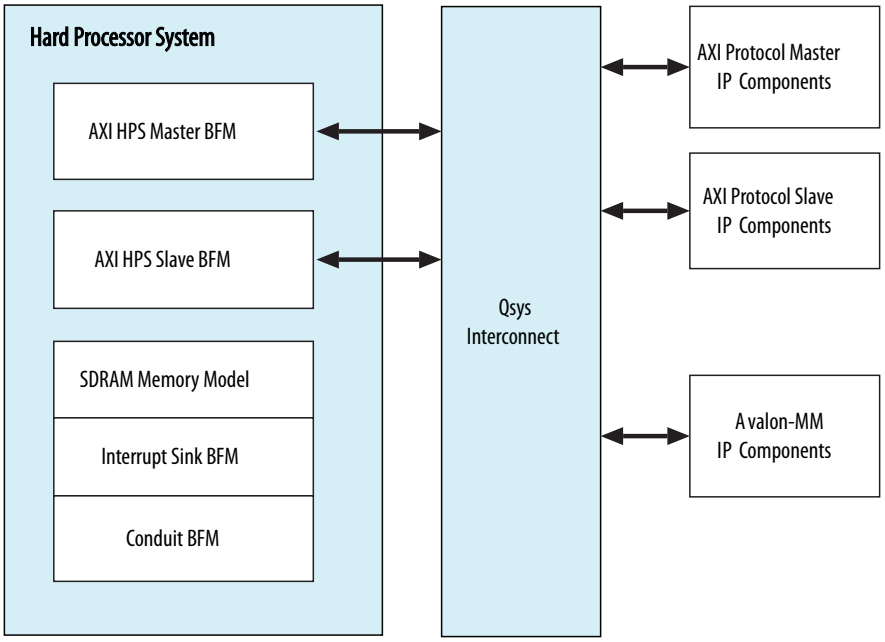
The simulation support files are specified when the HPS component is instantiated in the Qsys system integration tool. When you enable a particular HPS-FPGA interface, Qsys provides the corresponding model during the generation process.

The HPS simulation support enables you to develop and verify your own FPGA user logic or intellectual property (IP) that interfaces to the HPS component.

The simulation model supports the following interfaces:

- Clock and reset interfaces
- FPGA-to-HPS Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) slave interface
- HPS-to-FPGA AXI master interface
- Lightweight HPS-to-FPGA AXI master interface
- Microprocessor unit (MPU) general-purpose I/O (GPIO) interface
- MPU standby and event interface
- Interrupts interface
- Direct memory access (DMA) controller peripheral request interface
- Debug Advanced Peripheral Bus (APB) interface
- System Trace Macrocell (STM) hardware event
- FPGA cross trigger interface (CTI)
- FPGA trace port interface unit (TPIU)
- Boot from FPGA interface

Figure 29-1: HPS BFM Block Diagram



The HPS BFMs use standard function calls from the Altera BFM application programming interface (API), as detailed in the remainder of this chapter.

HPS simulation supports only Verilog HDL or SystemVerilog simulation environments. Users with VHDL Custom IP can run BFM simulations so long as a mixed-language simulation license is available on their chosen simulator.

Simulation Flows

Altera provides a functional register transfer level (RTL) simulation and a post–fitter gate–level simulation flow. Both simulation flows involve the following major steps, which is defined in the following sections:

1. Setting up the HPS component for simulation.
2. Generating the HPS simulation model in Qsys.
3. Running the simulation.

Related Information

Simulating Altera Designs
For general information about simulation, refer to the *Simulating Altera Designs* chapter in volume 3 of the *Quartus Prime Handbook*.

Setting Up the HPS Component for Simulation

The following steps outline how to set up the HPS component for simulation.

1. Add the HPS component from the Qsys Component Library.
2. Configure the component based on your application needs by selecting or deselecting the HPS-FPGA interfaces.
3. Connect the appropriate HPS interfaces to other components in the system. For example, connect the FPGA-to-HPS AXI slave interface to an AXI or Avalon-MM master interface in another component in the system.

When you create your component, make sure the conduit interfaces have the correct role names and widths. Also make sure the conduit interfaces are opposite in direction to what is shown in the HPS Conduit Interfaces table.

Generating the HPS Simulation Model in Qsys

The following steps outline how to generate the simulation model:

1. In Qsys, click **Generate HDL** under the Generate menu.
2. Choose between RTL and post–fit simulation

   For RTL simulation, perform the following steps:

   a. Set **Create simulation model** to Verilog.
   b. Click **Generate**.[58]

   For post–fit simulation, perform the following steps:

   a. Turn on the **Create HDL design files for synthesis** option.
   b. Turn on the **Create block symbol file (.bsf)** option.[59][60]
3. Click **Generate**.

Related Information

- **Instantiating the HPS Component** on page 27-1
- **Creating a System with Qsys**
  For more information about Qsys simulation, refer to "Simulating a Qsys System" in the *Creating a System with Qsys* chapter in volume 1 of the *Quartus Prime Handbook*.

Running the Simulations

The steps to run a simulation depend on whether you are running an RTL simulation or a post-fit simulation.

[58] VHDL is supported for HPS simulation and it requires a mix language simulator. However, the BFMs always need to be in verilog. Custom components can be in VHDL.
[59] A **.bsf** file is only needed for schematic entry.
[60] This is not a requirement for simulation or implementation unless a schematic is used.

Running HPS RTL Simulation

Qsys generates scripts for several simulators that you can use to complete the simulation process, as listed in the following table.

Table 29-10: Qsys-Generated Scripts for Supported Simulators

Simulator	Script Name	Directory
Mentor Graphics® Modelsim Altera Edition	**msim_setup.tcl**	*<project directory>*/*<Qsys design name>*/**simulation/mentor**
Cadence NC-Sim	**ncsim_setup.sh**	*<project directory>*/*<Qsys design name>*/**simulation/cadence**
Synopsys VCS	**vcs_setup.sh**	*<project directory>*/*<Qsys design name>*/**simulation/synopsys/vcs**
Synopsys VCS-MX	**vcsmx_setup.sh**	*<project directory>*/*<Qsys design name>*/**simulation/synopsys/vcsmx**

Running HPS Post-Fit Simulation

To run HPS post-fit simulation after successful Qsys generation, perform the following steps:

1. Add the generated synthesis file set to your Quartus Prime project by performing the following steps:
   a. In the Quartus Prime software, click **Settings** in the Assignments menu.
   b. In the **Settings** *<your Qsys system name>* dialog box, on the **Files** tab, browse to *<your project directory>*/*<your Qsys system name>*/**synthesis/** and select *<your Qsys system name>*.**qip**.
   c. Click **Open**. The **Select File** dialog box closes.
   d. Click **OK**. The **Settings** dialog box closes.
2. Optionally instantiate your HPS system as the top-level entity in your Quartus Prime project.
3. Compile the design by clicking **Start Compilation** in the Processing menu.
4. Change the EDA Netlist Writer settings, if necessary, by performing the following steps:
   a. Click **Settings** in the Assignment menu.
   b. On the **Simulation** tab, under the **EDA Tool Settings** tab, you can specify the following EDA Netlist Writer settings:

- **Tool name**—The name of the simulation tool
- **Format for output netlist**
- **Output directory**

c. Click **OK**.

5. To create the post-fitter simulation model with Quartus Prime EDA Netlist Writer, perform the following steps:

a. Click **Start** in the Processing menu.
b. Click **Start EDA Netlist Writer**.

Related Information

Quartus Prime Help

Post-Fit Simulation Files

Post-fit simulation is the simulation of the netlist generated from the original RTL design after it has been mapped, synthesized, and fit. The netlist represents the actual hardware and its connections as they appear in the FPGA. Quartus Prime generates the netlist and can generate a Standard Delay Format (**.sdf**) file with the timing information for all connections. The simulation can be functional only (without the timing information) where all wires and gates take zero time, or it can be a timing simulation where the time for all transitions is based on the SDF information.

Post-fit simulation can serve a number of different purposes. It can be used to perform a dynamic verification of the timing of the design, or it can be used to verify the functional correctness of either the design, the compilation flow (in particular, the fitter), or both.

This table uses the following symbols:

BFM API Hierarchy Format

For post-fit simulation, you must call the BFM API in your test program with a specific hierarchy. The hierarchy format is:

```
<DUT>.\<HPS>|fpga_interfaces|<interface><space>.<BFM>.<API function>
```

Where:

- <*DUT*> is the instance name of the design under test that you instantiated in your test bench . The design under test is the HPS component.
- <*HPS*> is the HPS component instance name that you use in your Qsys system.
- <*interface*> is the instance name of a specific FPGA-to-HPS or HPS-to-FPGA interface. This name can be found in the **fpga_interfaces.sv** file located in <*project directory*>/<*Qsys design name*>/**synthesis/submodules**.
- <*space*>—You must insert one space character after the interface instance name.
- <*BFM*> is the BFM instance name. To identify the BFM instance name, in <*ACDS install*>/**ip/altera/hps/postfitter_simulation**, find the SystemVerilog file corresponding to the interface type that you are using. This SystemVerilog file contains the BFM instance name.

For example, a path for the Lightweight HPS-to-FPGA master interface hierarchy could be formed as follows:

```
top.dut.\my_hps_component|fpga_interface|hps2fpga_light_weight .h2f_lw_axi_master
```

Notice the space after `hps2fpga_light_weight`. Omitting this space would cause simulation failure because the instance name `hps2fpga_light_weight` , including the space, is the name used in the post-fit simulation model generated by the Quartus Prime software.

Clock and Reset Interfaces

Clock Interface

Qsys generates the clock source BFM for the FPGA-to-HPS alternate clock source.

Table 29-12: HPS Clock Input Interface Simulation Model

The Altera clock source BFM application programming interface (API) applies to the BFM listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
`f2h_free_clk`	`f2h_free_clock_inst`

Qsys generates the clock source BFM for each clock output interface from the HPS component. For HPS-to-FPGA user clocks, specify the BFM clock rate in the **User clock frequency field** in the **HPS Clocks** page when instantiating the HPS component in Qsys.

The HPS-to-FPGA debug APB interface generates a clock output to the FPGA, named `h2f_debug_apb_clock`. In simulation, the clock source BFM also represents this clock output's behavior.

Table 29-13: HPS Clock Output Interface Simulation Model

The Altera clock source BFM application programming interface (API) applies to all the BFMs listed in this table. Your Verilog interfaces use the same API.

Interface Name	BFM Instance Name
h2f_user0_clock	h2f_user0_clock_inst
h2f_user1_clock	h2f_user1_clock_inst
h2f_user2_clock	h2f_user2_clock_inst

Reset Interface

The HPS reset request and handshake interfaces are connected to Altera conduit BFMs for simulation.

Table 29-14: HPS Reset Input Interface Simulation Model

You can monitor the reset request interface state changes or set the interface by using the API listed.

Interface Name	BFM Instance Name	API Function Names
f2h_cold_reset_req	f2h_cold_reset_req_inst	get_f2h_cold_rst_req_n()
f2h_debug_reset_req	f2h_debug_reset_req_inst	get_f2h_dbg_rst_req_n()
f2h_warm_reset_req	f2h_warm_reset_req_inst	get_f2h_warm_rst_req_n()
h2f_warm_reset_handshake	h2f_warm_reset_handshake_inst	set_h2f_pending_rst_req_n() get_f2h_pending_rst_ack_n()

Table 29-15: HPS Reset Output Interface Simulation Model

The Altera reset source BFM application programming interface applies to all the BFMs listed.

Interface Name	BFM Instance Name
h2f_reset	h2f_reset_inst
h2f_cold_reset	h2f_cold_reset_inst
h2f_debug_apb_reset	h2f_debug_apb_reset_inst

Table 29-16: Configuration of Reset Source BFM for HPS Reset Output Interface

The HPS reset output interface is connected to a reset source BFM. Qsys configures the BFM as shown in the following table. The parameter value of the instantiated BFM is configured for HPS simulation.

Parameter	BFM Value	Meaning
Assert reset high	Off	This parameter is off, specifying an active-low reset signal from the BFM.

Parameter	BFM Value	Meaning
Cycles of initial reset	0	This parameter is 0, specifying that the BFM does not assert the reset signal automatically.

FPGA-to-HPS AXI Slave Interface

The FPGA-to-HPS AXI slave interface, `f2h_axi_slave`, is connected to a Mentor Graphics AXI slave BFM for simulation with an instance name of `f2h_axi_slave_inst`. Qsys configures the BFM as shown in the following table. The BFM clock input is connected to `f2h_axi_clock` clock.

Table 29-17: Configuration of FPGA-to-HPS AXI Slave BFM

Parameter	Value
AXI Address Width	32
AXI Read Data Width	32, 64, or 128
AXI Write Data Width	32, 64, or 128
AXI ID Width	8

You control and monitor the AXI slave BFM by using the BFM API.

HPS-to-FPGA AXI Master Interface

The HPS-to-FPGA AXI master interface, `h2f_axi_master`, is connected to a Mentor Graphics AXI master BFM for simulation with an instance name of `h2f_axi_master_inst`. In Qsys, you can configure the HPS-to-FPGA interface with the following address, data, and ID widths. The BFM clock input is connected to `h2f_axi_clock` clock.

Table 29-18: Configuration of HPS-to-FPGA AXI Master BFM

Parameter	Value
AXI Address Width	30
AXI Read and Write Data Width	32, 64, or 128
AXI ID Width	12

You control and monitor the AXI master BFM by using the BFM API.

HPS-to-FPGA Debug APB Interface

The HPS-to-FPGA debug APB interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-23: HPS-to-FPGA Debug APB Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
h2f_debug_apb	h2f_debug_apb	set_h2f_dbg_apb_PADDR() set_h2f_dbg_apb_PADDR_31() set_h2f_dbg_apb_PENABLE() get_h2f_dbg_apb_PRDATA() get_h2f_dbg_apb_PREADY() set_h2f_dbg_apb_PSEL() get_h2f_dbg_apb_PSLVERR() set_h2f_dbg_apb_PWDATA() set_h2f_dbg_apb_PWRITE()	set_PADDR() set_PADDR_31() set_PENABLE() get_PRDATA() get_PREADY() set_PSEL() get_PSLVERR() set_PWDATA() set_PWRITE()
h2f_debug_apb_sideband	h2f_debug_apb_sideband	get_h2f_dbg_apb_PCLKEN() get_h2f_dbg_apb_DBG_APB_DISABLE()	get_PCLKEN() get_DBG_APB_DISABLE()

FPGA-to-HPS System Trace Macrocell Hardware Event Interface

The FPGA-to-HPS STM hardware event interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with the API function name for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-24: FPGA-to-HPS STM Hardware Event Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Name	Post-Fit Simulation API Function Name
f2h_stm_hw_events	f2h_stm_hw_events_inst	get_f2h_stm_hwevents()	get_stm_events()

HPS-to-FPGA Cross-Trigger Interface

The HPS-to-FPGA cross-trigger interface is connected to an Altera conduit BFM for simulation. The following table lists the name of each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API functions listed.

Table 29-25: HPS-to-FPGA Cross-Trigger Interface Simulation Model

Interface Name	BFM Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
h2f_cti	h2f_cti_inst	get_h2f_cti_trig_in()	get_trig_in()
		set_h2f_cti_trig_in_ack()	set_trig_inack()
		set_h2f_cti_trig_out()	set_trig_out()
		get_h2f_cti_trig_out_ack()	get_trig_outack()
		get_h2f_cti_fpga_clk_en()	get_clk_en()

FPGA-to-HPS DMA Handshake Interface

The FPGA-to-HPS DMA handshake interface is connected to an Altera conduit BFM for simulation. The following table lists the name for each interface, along with API function names for each type of simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 29-26: FPGA-to-HPS DMA Handshake Interface Simulation Model

The usage of conduit `get_*()` and `set_*()` API functions is the same as with the general Avalon conduit BFM.

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
f2h_dma0	f2h_dma0_inst	get_f2h_dma0_req() get_f2h_dma0_single() set_f2h_dma0_ack()	get_channel0_req() get_channel0_single() set_channel0_xx_ack()
f2h_dma1	f2h_dma1_inst	get_f2h_dma1_req() get_f2h_dma1_single() set_f2h_dma1_ack()	get_channel1_req() get_channel1_single() set_channel1_xx_ack()

Interface Name	BFM Instance Name	RTL Simulation API Function Names	Post-Fit Simulation API Function Names
f2h_dma2	f2h_dma2_inst	get_f2h_dma2_req() get_f2h_dma2_single() set_f2h_dma2_ack()	get_channel2_req() get_channel2_single() set_channel2_xx_ack()
f2h_dma3	f2h_dma3_inst	get_f2h_dma3_req() get_f2h_dma3_single() set_f2h_dma3_ack()	get_channel3_req() get_channel3_single() set_channel3_xx_ack()
f2h_dma4	f2h_dma4_inst	get_f2h_dma4_req() get_f2h_dma4_single() set_f2h_dma4_ack()	get_channel4_req() get_channel4_single() set_channel4_xx_ack()
f2h_dma5	f2h_dma5_inst	get_f2h_dma5_req() get_f2h_dma5_single() set_f2h_dma5_ack()	get_channel5_req() get_channel5_single() set_channel5_xx_ack()
f2h_dma6	f2h_dma6_inst	get_f2h_dma6_req() get_f2h_dma6_single() set_f2h_dma6_ack()	get_channel6_req() get_channel6_single() set_channel6_xx_ack()
f2h_dma7	f2h_dma7_inst	get_f2h_dma7_req() get_f2h_dma7_single() set_f2h_dma7_ack()	get_channel7_req() get_channel7_single() set_channel7_xx_ack()

Boot from FPGA Interface

The boot from FPGA interface is connected to an Altera conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API functions in the table below.

Table 29-27: Boot from FPGA Interface Simulation Model

Interface Name	BFM Name	RTL simulation API Function Names	Post-fit Simulation API Function Names
f2h_boot_from_fpga	f2h_boot_from_fpga_inst	get_f2h_boot_from_fpga_ready() get_f2h_boot_from_fpga_on_failure()	get_boot_fpga_ready() get_boot_from_fpga_on_failure()

Security Manager Anti-Tamper Signals Interface

The security manager anti-tamper signals interface is connected to an Altera conduit BFM for simulation. You can monitor the interface state changes or set the interface by using the API listed.

Table 29-28: Security Manager Anti-Tamper Signals Interface Simulation Model

Interface Name	BFM Instance Name	RTL Simulation API Function Names
h2f_security	h2f_security_inst	get_f2h_security_anti_tamper_in set_h2f_security_anti_tamper_out

EMIF Conduit

Enables the HPS dedicated conduit to the Arria 10 External memory Interface for HPS. This conduit cannot connect to any other External memory Interface (EMIF). Only IP generated by the Arria 10 External memory Interface for HPS QSYS library should be used.

Table 29-29: EMIF Conduit Interface Simulation Model

Interface Name	BFM Instance Name	RTL Simulation API Function Names
emif	emif_inst	emif_emif_to_hps emif_hps_to_emif

Pin MUX and Peripherals

Under Pin MUX and Peripherals, the **Pin Mux GUI** has three folder tabs with the following functions:

- IP Selection
- Advanced Pin Placement
- Advanced FPGA Placement

The **IP Selection** tab contains two sub-windows. In the left sub-window, you are able to select the following:

- Boot source — SD/MMC, NAND, and QSPI
- Pin routing decisions between:
  - IP and HPS I/O—where your selections are reflected on the **Advanced Pin Placement**
  - IP and FPGA—where your selections are reflected on the **Advanced FPGA Placement**
- NAND bit-width when the NAND IP is selected
- SD/MMC bit-width and SD/MMC Power Enable when the SD/MMC IP is selected
- RGMII and PHY Options for each of the EMACs when the EMAC IP is selected
- Additional QSPI Slave Selects when the QSPI IP is selected

After you have made your selection, you must click on the **Apply Selections** button and select "Show signals" so that you can see your selection reflected in the right sub-window. Depending on if you are routing to the HPS I/O or the FPGA, your selection is reflected on the **Advanced Pin Placement** or **Advanced FPGA Placement** tab, respectively.

Document Revision History

Table 29-51: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
May 2016	2016.05.27	Removed *FPGA EMAC Switch Interface* section. The application interface (also called the switch interface) is not supported.
May 2016	2016.05.03	Removed references to FPGA to HPS SDRAM simulation.
November 2015	2015.11.02	Added information about the signals on the "Advanced FPGA Placement" tab.
May 2015	2015.05.04	Maintenance release.
December 2014	2014.12.15	Maintenance release.
August 2014	2014.08.15	Initial release.

Booting and Configuration

A

a10_5v4 Subscribe Send Feedback

The Altera system-on-a-chip (SoC) device provides a variety of ways to boot the hard processor system (HPS) and configure the FPGA portion.

Boot Overview

The boot flow of the HPS is a multi-stage process. Each stage is responsible for loading the next stage.

The first stage is the boot ROM execution. The boot ROM code, located in the HPS, brings the processor out of reset, puts the processor into a known and stable state, finds the second-stage boot loader and passes control to the next stage. The boot ROM code is only aware of the second-stage boot loader and not aware of any potential subsequent software stages. During this time, the boot ROM also seamlessly handles any error conditions that may occur.

The next stage is when control passes to the second-stage boot loader. The second-stage boot loader is located external to the HPS, either in off-chip flash memory or within the FPGA. If the FPGA is used, the second stage boot loader can execute directly from the FPGA without the need to copy it to on-chip RAM. The second stage-boot loader locates and loads the next stage software and so on.

Before the control is passed to the second stage boot loader, it can be decrypted and/or authenticated if a secure boot is enabled.

After a warm reset, the user can program the HPS to instruct the boot ROM to find an image in the on-chip RAM and execute directly from that. In this case, the image that resides in RAM is unauthenticated and clear text, although it may have been imported into on-chip RAM as authenticated code initially.

The figure below illustrates the typical boot flow. However, there may be more or less software stages in the user software than shown and the roles of the software stages may vary.

Figure A-1: Typical Boot Flow

FPGA Configuration Overview

After power is applied to the FPGA and HPS portion of the SoC, configuration may begin. The FPGA may be configured through a variety of ways, such as through the HPS, JTAG, or an external host.

The Configuration Subsystem (CSS) in the FPGA portion of the device is responsible for obtaining an FPGA configuration image and configuring the FPGA fabric, as well as the IOCSRs (I/O Configuration and Status Registers). The I/O configuration file programs the following in the IOCSRs:

- FPGA I/O
- Shared I/O
- Hard memory controller I/O
- Hard memory controller settings, such as memory type, frequency and timings
- FPGA PLL settings
- Transceiver settings

The FPGA configuration ends when the configuration image has been fully loaded and the FPGA enters user mode. The FPGA configuration image is typically stored in external non-volatile flash-based memory. The FPGA Configuration Subsystem can obtain a configuration image from the HPS through the FPGA Manager or from any of the sources supported by the Arria 10 FPGA family.

Related Information

- **FPGA Manager** on page 4-1
  For more information regarding programming the FPGA through the HPS, refer to the *FPGA Manager* chapter.
- **Configuration, Design Security, and Remote System Upgrades in Arria 10 Devices**

Booting and Configuration Options

SoC initialization includes the booting of the HPS and the configuration of the FPGA fabric and I/O.

The I/O provided in the SoC are:

- HPS dedicated I/O that are configured by the HPS
- Shared I/O used by the HPS or FPGA and configured by the Quartus Prime I/O configuration file.
- FPGA I/O configured by the Quartus Prime I/O configuration file.
- Hard memory controller I/O shared by the HPS and FPGA and configured by the Quartus Prime I/O configuration file.

Depending on the initialization option you choose, the I/O configuration is handled differently. You can choose one of the three initialization options:

- The HPS boot and FPGA configuration occur separately.
- The HPS boots first and then configures the FPGA.
- The HPS boots from the FPGA after the FPGA is configured.

Note: The HPS and FPGA fabric must be powered at the same time. You must not power-down the HPS or FPGA independently in the middle of device operation.

The following three figures illustrate the possible HPS boot and FPGA configuration schemes. The arrows in the figures denote the data flow direction.

Figure A-2: Separate FPGA Configuration and HPS Booting

In the figure below, the FPGA configuration and HPS boot can occur separately. The FPGA obtains its configuration image from a non-HPS source. The source is sent to the CSS block which configures the FPGA fabric, FPGA I/O, shared I/O, hard memory controller I/O and other settings. If the hard memory controller or shared I/O are required by the HPS, then the FPGA fabric and I/O (FPGA, shared and hard memory controller) configuration must be complete before the HPS can boot.

The HPS boot ROM obtains its second-stage boot loader from a non-FPGA fabric source. The second-stage boot loader should contain the configuration for the HPS dedicated I/O.

For more information about FPGA configuration, refer to the "FPGA Configuration" section.

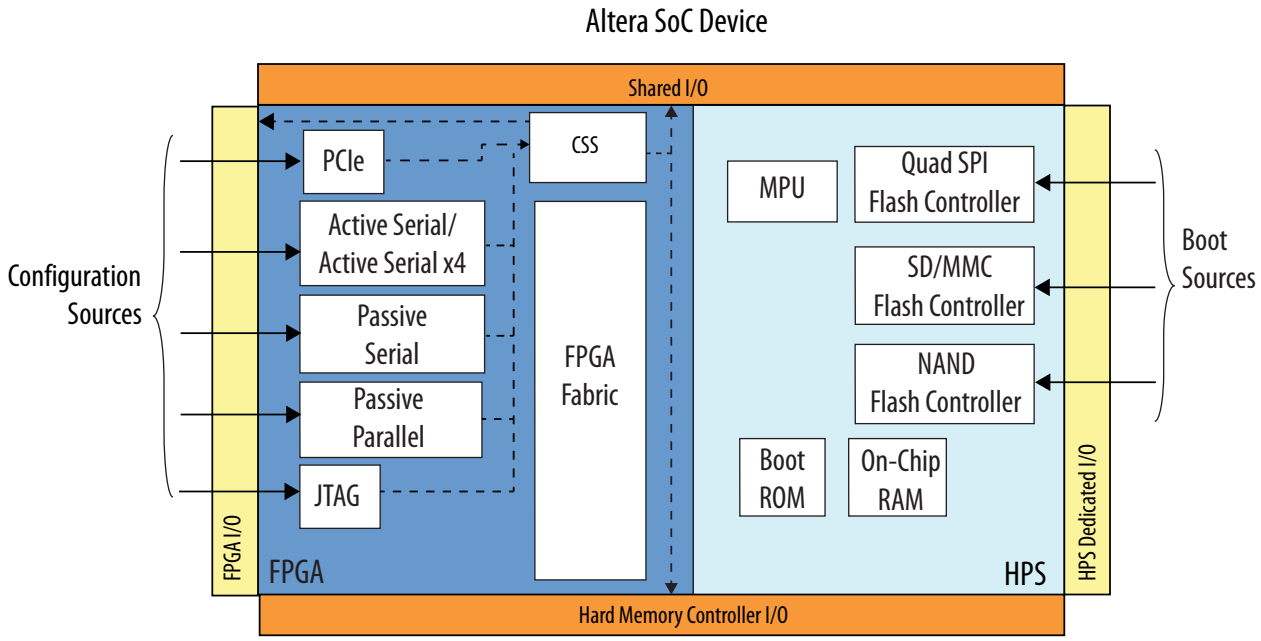

Figure A-3: HPS Boots First and then Configures the FPGA

In the figure below, the HPS boots first through one of its non-FPGA fabric boot sources. If the hard memory controller or shared I/O are required by the HPS during booting then you can either execute a full FPGA configuration flow or an early I/O release configuration flow. The FPGA must be in a power-on state for the HPS to reset properly and for the second stage boot loader to initiate configuration through the FPGA Manager. The software executing on the HPS obtains the FPGA configuration image from any of its flash memory devices. For more information about full FPGA configuration or early I/O release configuration after HPS booting, refer to the "FPGA Configuration" section.

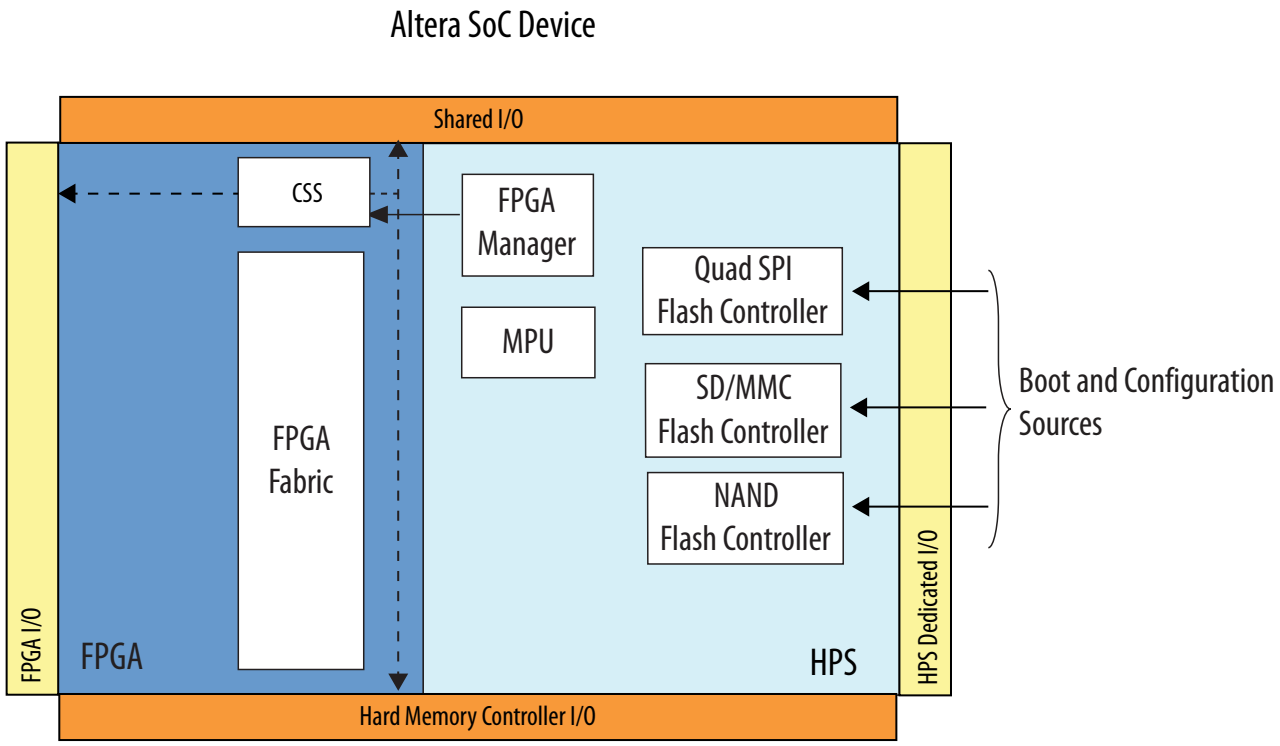

Figure A-4: HPS Boots From FPGA

In the figure below, the FPGA is configured first through one of its non-HPS configuration sources. The CSS block configures the FPGA fabric as well as the FPGA I/O, shared I/O and hard memory controller I/O. The HPS executes the second-stage boot loader from the FPGA. In this situation, the HPS should not be released from reset until the FPGA is powered on and programmed. Once the FPGA is in user mode and the HPS has been released from reset, the boot ROM code begins executing. The HPS boot ROM code executes the second-stage boot loader from the FPGA fabric over the HPS-to-FPGA bridge.

You can select a boot from FPGA by setting the BSEL value to 0x1. If the fpga_boot_f fuse is blown then the FPGA is always selected as the boot source. In both cases, when the FPGA is selected as the boot source, the CSEL fuses are ignored and clock configuration is controlled through the second-stage boot loader code in the FPGA.

Boot Definitions

The following sections contain basic terms and definitions that are part of the boot process.

Reset

Reset precedes the boot stages and is an important part of device initialization. There are two different reset types: cold reset and warm reset.

The FPGA portion of the SoC can trigger a warm or cold reset on completion of configuration.

The boot process begins when CPU0 in the MPU exits from the reset state. When CPU0 exits from reset, it starts executing code at the reset exception address where the boot ROM code is located. CPU1 remains in reset during this time and is brought out of reset by user software.

With warm reset, some software registers are preserved and the boot process may skip some steps depending on software settings. In addition, on a warm reset, the second-stage boot loader has the ability to be executed from on-chip RAM.

Boot ROM

The boot ROM code is 128 KB in size and located in on-chip ROM at address range 0xFFFC0000 to 0xFFFDFFFF. The function of the boot ROM code is to determine the boot source, initialize the HPS after a reset, and jump to the second-stage boot loader. In the case of indirect execution, the boot ROM code loads the second-stage boot loader image from the flash memory to on-chip RAM. The boot ROM performs the following actions to initialize the HPS:

- Enable instruction cache, branch predictor, floating point unit, NEON vector unit of CPU0
- Sets up the level 4 (L4) watchdog 0 timer
- Initializes the flash controller to default settings
- Configures HPS dedicated I/O

When booting from flash memory, the boot ROM code uses the top 32 KB of the on-chip RAM as data workspace. This area is reserved for the boot ROM code after a reset until the boot ROM code passes software control to second-stage boot loader. The maximum second-stage boot loader size is 208 KB with authentication and 224 KB without. For a warm reset or cold reset with a boot from FPGA, the boot ROM code does not reserve the top 32 KB of the on-chip RAM, and the user may place user data in this area without being overwritten by the boot ROM.

The boot process begins when CPU0 exits from the reset state. The boot ROM code only executes on CPU0. CPU1 is held in reset while boot ROM executes on CPU0. When a CPU0 exits from reset, it starts executing code at the reset exception address.

During boot ROM execution, the clock control fuse information is automatically sent to the Clock Manager, the memory control fuse information is automatically sent to the Reset Manager and all other fuse functions (authentication, encryption, private and public key source, hash functions) are stored in a memory-mapped location for boot code to read. In normal operation, the boot ROM is mapped at the reset exception address so code starts executing in the boot ROM.

When CPU0 exits the boot ROM code and starts executing user software, the boot ROM access is disabled. The user software in CPU0 must map the user software exception vectors at 0x0 (which is previously mapped to boot ROM exception vectors). The user software also has the option of releasing CPU1 from reset. If CPU1 is released from reset, CPU1 executes the user software exception instead of boot ROM.

Boot Select

The boot select (BSEL) pins offer multiple methods to obtain the second-stage boot image. On a cold reset, the boot source is determined by a combination of secure boot fuses and BSEL pins. These fuse values and BSEL pin values are sent to the Security Manager module of the HPS when the cold reset occurs. When the HPS is released from reset, the boot ROM reads the `bootinfo` register of the System Manager to determine the source of the boot.

Note: If the fpga_boot_f fuse is blown, the BSEL pins are bypassed and the HPS can only boot from the FPGA. Additionally, the clock select (CSEL) fuse values are ignored and clock configuration is controlled through the FPGA. This configuration allows the HPS to boot from encrypted user code in the FPGA. If the boot source is the FPGA, the boot ROM code does not configure any of the

boot-specific HPS I/Os for booting from flash memory. If the fpga_boot_f fuse is not blown, then the boot source is determined according to the BSEL pins. If the BSEL pins are used for determining the boot source, then the following table shows the flash devices assigned to each encoding.

Note: If a boot from FPGA is required (BSEL[2:0]=0x1), then you must ensure that the HPS is not released from reset until after the FPGA has been fully programmed. Otherwise, the `bootinfo` register to determine the boot source might be read incorrectly by the boot ROM. FPGA readiness is indicated by handshake signals, `f2h_boot_from_fpga_ready` and `f2h_boot_from_fpga_on_failure`, from the FPGA to the HPS. The `f2h_boot_from_fpga_ready` signal must be pulled up to indicate readiness. Refer to the "Instantiating the HPS Component" chapter for more information about FPGA boot handshake signals.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

Table A-1: BSEL Values for Boot Source Selection

BSEL[2:0] Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.0 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.0 V SD/MMC flash memory with internal transceiver
0x6	1.8 V quad SPI flash memory
0x7	3.0 V quad SPI flash memory

Note: If the BSEL value is set to 0x4 or 0x5, an external translation transceiver may be required to supply level-shifting and isolation if the SD cards interfacing to the SD/MMC controller must operate at a different voltage than the controller interface. Please refer to the *SD/MMC Controller* chapter for more information.

The typical boot flow is for the boot ROM code to find the second-stage boot loader image on a flash device, load that into on-chip RAM and execute it. After a warm reset, the boot ROM code can be instructed to find the image in RAM and execute that.

The HPS flash sources can store various file types, such as:

- FPGA programming files
- Second-stage boot loader binary file (up to four copies)
- Operating system binary files
- Application file system

The second-stage boot loader image in flash can be authenticated and decrypted by the HPS. A boot directly from the HPS on-chip RAM is always unauthenticated and in clear text, although it may have an optional CRC if required.

When the BSEL value is 0x1, the FPGA is selected as the boot source for that boot. This selection is not permanent as it is when the fpga_boot_f fuse is enabled. In both cases, the CSEL fuses are also ignored and the HPS must be held in reset until the FPGA is powered on and programmed to prevent the boot ROM from misinterpreting the boot source.

If an HPS flash interface has been selected to load the boot image, then the boot ROM enables and configures that interface before loading the boot image into on-chip RAM, verifying it and passing software control to the second-stage boot loader.

If the FPGA fabric is the boot source, the boot ROM code waits until the FPGA portion of the device is in user mode, and is ready to execute code and then passes software control to the second-stage boot loader in the FPGA RAM.

Boot Source I/O Pins

The HPS has 17 dedicated I/O pins. Three are used as a clock, cold reset and warm reset pin. The warm reset signal is a bidirectional signal; a warm reset event can drive into the HPS, or a warm reset event can be generated by the HPS and drive out of this pin.

The remaining 14 dedicated I/O pins are used for boot devices as well as other peripherals. Three of these 14 dedicated I/O pins are sampled by software at either cold or warm reset and convey boot source information. The following table identifies the pin mux values for the boot source options.

Table A-2: Boot Source MUX Selects

This table identifies the dedicated HPS signals that are mapped to each boot interface and the mux select value each boot interface signal requires. Note that Clock Manager clock inputs are also assigned to MUX select 4 and are documented here for thoroughness.

Signal	MUX Select

Boot Fuses

During boot ROM execution, the boot ROM reads user-programmed fuses that configure the boot state of the HPS.

These fuse values are read by the Configuration Subsystem (CSS) after power-up and to the Security Manager where they are read by the boot ROM. The following list describes the basic fuses that affect the state of the HPS:

- Clock select fuses: Determine the clock frequencies of the MPU clock, the interconnect clocks and the peripheral clocks.
- Debug fuses: Determine the state of debug during the boot process and during hand-off to the second-stage boot loader.
- RAM fuses: Determine whether or not the various peripheral RAMs are cleared during a warm reset and how they are cleared (series or parallel).
- Boot fuses: Determines whether the second-stage boot loader is from on-chip RAM, whether an internal or external clock is used for booting and whether the boot source is solely from FPGA.
- Security fuses: Determines whether the second-stage boot loader is authenticated or decrypted. If authentication is used, then there are fuses that are read by the boot ROM to determine where the key authorization key (KAK) resides and what its length is.
- User fuses: The user fuses may either hold proprietary user information or may hold the value of the KAK.

Table A-4: `HPS_fusesec` Register Description

Bits	Name	Description
31:27	`Reserved`	Bit values in this field are undefined.
26:23	`csel_f`	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the *Clock Configuration* section for more information on CSEL encodings.
22	`dbg_access_f`	This fuse determines the initial state of the debug access domains.
21	`dbg_lock_JTAG`	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. • 0x0= HPS JTAG access level can be changed through the `sec_jtagdbg` register. • 0x1= HPS JTAG access level cannot be changed (locked).
20	`dbg_lock_DAP`	This field indicates if the DAP access level can be changed through software when the HPS is released from reset. • 0x0= The DAP access level can be changed through the `sec_dapdbg` register. • 0x1= The DAP access level cannot be changed (locked).

Bits	Name	Description
19	dbg_lock_CPU0	This field indicates if the CPU0 debug access level can be changed through software when the HPS is released from reset. • 0x0= CPU0 debug access level can be changed through the sec_cpu0dbg register. • 0x1= CPU0 debug access level cannot be changed (locked).
18	dbg_lock_CPU1	This field indicates if the CPU1 debug access level can be changed through software when the HPS is released from reset. • 0x0= The CPU1 debug access level can be changed through the sec_cpu1dbg register. • 0x1= The CPU1 debug access level cannot be changed (locked).
17	dbg_lock_CS	This field indicates if the CoreSight debug access level can be changed through software when the HPS is released from reset. • 0x0= The CoreSight debug access level can be changed through the sec_csdbg register. • 0x1= The CoreSight debug access level cannot be changed (locked).
16	dbg_lock_FPGA	This field indicates if the FPGA debug access level can be changed through software when the HPS is released from reset. • 0x0= The FPGA debug access level can be changed through the sec_fpgadbg register. • 0x1= The FPGA debug access level cannot be changed (locked).
15:12	Reserved	Bit values in this field are undefined.
11	clr_ram_order_f	This fuse value determines how RAMs are cleared during a tamper event. • 0x0= All RAMs are cleared in parallel. • 0x1= All RAMs are cleared in series.

Bits	Name	Description
10	clr_ram_cold_f	This fuse value indicates what happens to the RAM on a cold reset. • 0x0= All RAMs are not cleared on a cold reset. • 0x1= All RAMs are cleared on a cold reset.
9	clr_ram_warm_f	This fuse value indicates what happens to the RAMs on a warm reset. • 0x0= All RAMs are not cleared on a warm reset. • 0x1= All RAMs are cleared on a warm reset.
8	oc_boot_f	This fuse value determines if the second-stage boot code is allowed to boot from on-chip RAM. • 0x0= Second-stage boot can be from on-chip RAM if enabled by the System Manager. • 0x1= Second-stage boot is not from on-chip RAM.
7	hps_clk_f	This fuse value selects the clock used for the boot process and in the case of a tamper event, memory scrambling. • 0x0= The external oscillator, EOSC1, is used for boot. • 0x1= The internal oscillator, cb_intosc_ls_clk, is used for boot.
6	fpga_boot_f	If blown, this fuse value allows the FPGA to configure independently and allows the HPS to boot from an encrypted next-stage boot source that was decrypted into the FPGA. • 0x0= Booting is dependent on the BSEL pins. • 0x1= HPS only boots from the FPGA; BSEL options are ignored and CSEL fuse options are ignored.

Bits	Name	Description
5	aes_en_f	This fuse value indicates if a decryption of the flash image is always performed. • 0x0= An AES decryption of the flash image is determined from the second stage boot loader header. • 0x1= An AES decryption of the flash image is always performed.
4:2	kak_src_f	This bit field indicates the source of the Key Authorization Key (KAK) which can be in: • Proprietary ROM • FPGA logic elements • User fuses
1	kak_len_f	This fuse value indicates the Key Authorization Key (KAK) length: • 0x0= 256 bits • 0x1= 384 bits
0	authen_en_f	This fuse value determines whether authentication of flash images is required prior to execution. • 0x0= No authentication of the flash image is required prior to execution. • 0x1= HPS authentication of all flash images is required prior to execution.

For more information about the fuses and how they work, refer to the *SoC Security* chapter.

Flash Memory Devices for Booting

The memory controllers and devices that contain the boot loader image have configuration requirements for proper boot from flash.

On all flash devices, there is an area of memory, called the boot area that contains up to four second-stage boot loader images. For the QSPI and SD/MMC devices, the boot area is 1 MB in size. For NAND devices the boot area is four device blocks in size and may be larger than 1 MB if the NAND erase block is larger than 256 KB.

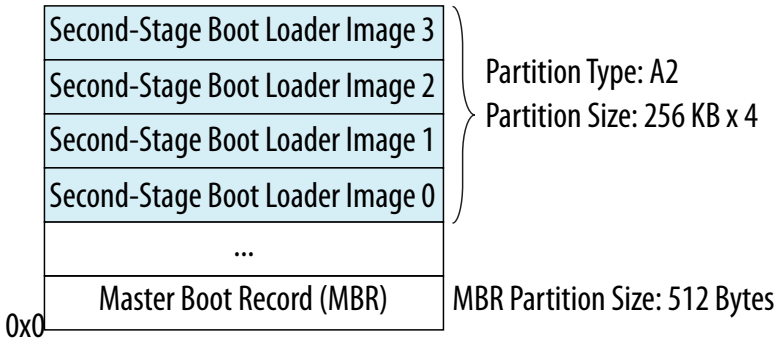
The SD/MMC, Quad SPI and NAND flash devices all support raw and MBR (partition) mode. In raw mode, the boot image is located at the start of the flash memory device, at offset 0x0. In MBR mode:

- The boot image is read from a custom partition (0xA2)
- The first image is located at the beginning of the partition, at offset 0x0
- Start address = partition start address

SD/MMC Flash Devices

The following figure shows an SD/MMC flash image layout example for boot. The master boot record (MBR) is located in the first 512 bytes of the memory. The MBR contains information about the partitions (address and size of partition). The second-stage boot loader image is stored in partition A2. Partition A2 is a custom raw partition with no file system.

Figure A-5: SD/MMC Flash Image Layout



The SD/MMC controller supports two booting modes:

- MBR (partition) mode
  - The boot image is read from a custom partition (0xA2)
  - The first image is located at the beginning of the partition, at offset 0x0
  - Start address = partition start address
- Raw mode
  - If the MBR signature is not found, SD/MMC driver assumes it is in raw mode
  - The boot image data is read directly from sectors in the user area and is located at the first sector of the SD/MMC
  - The first image is located at the start of the memory card, at offset 0x0
  - Start address = 0x0

The MBR contains the partition table, which is always located in the first sector (LBA0) with a memory size of 512 bytes. The MBR consists of executable code, four partition entries, and the MBR signature. A MBR can be created by specific tools like the FDISK program.

Table A-5: MBR Structure

Offset	Size (In Bytes)	Description
0x000	446	Code area
0x1BE	16	Partition entry for partition 1
0x1CE	16	Partition entry for partition 2
0x1DE	16	Partition entry for partition 3
0x1EE	16	Partition entry for partition 4
0x1FE	2	MBR signature: 0xAA55

The standard MBR structure contains a partition with four 16-byte entries. Thus, memory cards using this standard table cannot have more than four primary partitions or up to three primary partitions and one extended partition.

Each partition type is defined by the partition entry. The boot images are stored in a primary partition with custom partition type (0xA2). The SD/MMC flash driver does not support a file system, so the boot images are located in partition A2 at fixed locations.

Table A-6: Partition Entry

Offset	Size (In Bytes)	Description
0x0	1	Boot indicator. 0x80 indicates that it is bootable.
0x1	3	Starting CHS value
0x4	1	Partition type
0x5	3	Ending CHS value
0x8	4	LBA of first sector in partition
0xB	4	Number of sectors in partition

The boot ROM code configures the SD/MMC controller to default settings for the supported SD/MMC flash memory.

Default Settings of the SD/MMC Controller

Table A-7: SD/MMC Controller Default Settings

Parameter		Default	Register Value
Card type		1 bit	The card type register (`ctype`) in the SD/MMC controller registers (`sdmmc`) = 0x0
Bus mode		—	SD/MMC[63]
Timeout		Maximum	The timeout register (`tmout`) = 0xFFFFFFFF
FIFO threshold RX watermark level		1	The RX watermark level field (`rx_wmark`) of the FIFO threshold watermark register (`fifoth`) = 0x1
Clock source		0	The clock source register (`clksrc`) = 0x0
Block size		512	The block size register (`blksiz`) = 0x200
Clock divider	Identification mode	32	The clock divider register (`clkdiv`)= 0x10 (2*16=32)
	Data transfer mode	Bypass	The clock divider register (`clkdiv`)= 0x00

(63) SPI cards are not supported for boot.

Parameter	Default	Register Value
External Device Power enable	Disabled (Power Off)	The `power_enable` bit in the `pwren` register is programmed to 0x0 out of reset. In Arria 10, the SD/MMC power enable is inverted. To compensate for this active low polarity, you can implement one of three options: • Force the power enable high on the board. • Use a GPIO to control the power enable. • Invert the power enable line on the board so that when software disables the power (`SDMMC_PWR_ENA_HPS` is high), the board inverts the signal to turn off the card.

CSEL Settings for the SD/MMC Controller

Table A-8: SD/MMC Controller Clock Options Based on CSEL and HPS_CLK fuse settings

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	Controller Clock	Controller Clock Frequency	ID Mode: Baud Rate Divisor	ID Mode: Device Clock	Data Transfer Mode: Baud Rate Divisor	Data Transfer Mode: Device Clock	PLL Status
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure Bypass)	`cb_intosc_hs_clk/4`	15-50 MHz	128	29-97.75 KHz	4	937.5 KHz-3.125 MHz	Bypass
0x2	1	30-100 MHz (Secure PLL)	`cb_intosc_ls_clk/8`	2.75-12.5 MHz	32	29-97.75 KHz	1 (Bypass)	687.5 KHz-3.125 MHz	Locked
0x1	0	10-50 MHz (Untouched PLL)	`osc1_clk/4` (`EOSC1` pin)	2.5-12.5 MHz	32	19.5-97.75 KHz	1 (Bypass)	625 KHz-3.125 MHz	Untouched

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	Controller Clock	Controller Clock Frequency	ID Mode: Baud Rate Divisor	ID Mode: Device Clock	Data Transfer Mode: Baud Rate Divisor	Data Transfer Mode: Device Clock	PLL Status
0x0 and 0x2-0x6	0	10-50 MHz (PLL Bypass)	osc1_clk/4 (EOSC1 pin)	2.5-12.5 MHz	32	19.5-97.75 KHz	1 (Bypass)	625 KHz-3.125 MHz	Bypass
0x7	0	10-15 MHz	osc1_clk*0.8333	8.333-12.5 MHz	32	65-97.75 KHz	1 (Bypass)	2.08-3.125 MHz	Locked
0x8	0	15-20 MHz	osc1_clk*0.625	9.375-12.5 MHz	32	73-97.75 KHz	1 (Bypass)	2.34-3.125 MHz	Locked
0x9	0	20-25 MHz	osc1_clk/2	10-12.5 MHz	32	78.13-97.75 KHz	1 (Bypass)	2.5-3.125 MHz	Locked
0xA	0	25-30 MHz	osc1_clk*0.4166	10.4175-12.5 MHz	32	81.25-97.75 KHz	1 (Bypass)	2.60-3.125 MHz	Locked
0xB	0	30-35 MHz	osc1_clk*0.3571	10.715-12.5 MHz	32	83.5-97.75 KHz	1 (Bypass)	2.68-3.125 MHz	Locked
0xC	0	35-40 MHz	osc1_clk*0.3125	10.9375-12.5 MHz	32	85.25-97.75 KHz	1 (Bypass)	2.75-3.125 MHz	Locked
0xD	0	40-45 MHz	osc1_clk*0.2777	11.111-12.5 MHz	32	86.75-97.75 KHz	1 (Bypass)	2.78-3.125 MHz	Locked
0xE	0	45-50 MHz	osc1_clk/4	11.25-12.5 MHz	32	87.75-97.75 KHz	1 (Bypass)	2.81-3.125 MHz	Locked

NAND Flash Devices

The NAND subsystem reserves at least the first 1 MB on the NAND device. If the NAND flash device has blocks greater than 256 KB, then the NAND subsystem reserves the first four blocks on the device. For a NAND device with less than 256 KB block size, the second-stage boot loader image must be placed in multiple blocks. The NAND subsystem expects to find up to four second-stage boot loader images on the NAND device. You may have less than four images if required. The second-stage boot loader image should always be at the start of a physical page. Because a block is the smallest area used for erase operation, any update to a particular image does not affect other images.

NAND Flash Driver Features Supported in the Boot ROM Code

Table A-9: NAND Flash Support Features

Feature	Driver Support
Device	Open NAND Flash Interface (ONFI) 1.0 raw NAND or electronic signature devices, single layer cell (SLC) and multiple layer cell (MLC)
Chip select	CS0 only. Only CS0 is available to the HPS, the other three chip selects are routed out to the FPGA portion of the device
Bus width	8-bit only
Page size	2 KB, 4 KB, or 8 KB
Page per block	32, 64, 128
ECC	512-bytes with 8-bit correction

CSEL Settings for the NAND Controller

Table A-10: NAND Controller Clock Options Based on CSEL and HPS_CLK fuse settings

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	l4_mp_clk	l4_mp_clk Frequency	nand_clk	PLL Status
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure bypass)	cb_intosc_hs_clk	60-200 MHz	15-50 MHz	Bypassed
0x2	1	30-100 MHz (Secure PLL)	cb_intosc_ls_clk*2	60-200 MHz	15-50 MHz	Locked
0x1	0	10-50 MHz (Untouched PLL)	osc1_clk (EOSC1 pin)	10-50 MHz	2.50-12.5 MHz	Untouched
0x0 and 0x2-0x6	0	10-50 MHz (PLL bypass)	osc1_clk (EOSC1 pin)	10-50 MHz	2.50-12.5 MHz	Bypassed
0x7	0	10-15 MHz	osc1_clk*13.33	133.33-200 MHz	33.33-50 MHz	Locked

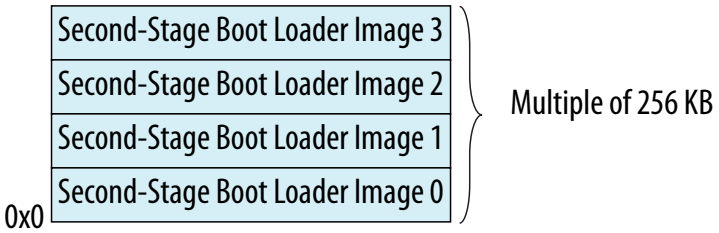
Quad SPI Flash Devices

The figure below shows the quad SPI flash image layout. The second-stage boot loader image is always located at offsets that are multiples of 256 KB.

Figure A-7: Quad SPI Flash Image Layout



The boot ROM code configures the quad SPI controller to default settings for the supported SPI or quad SPI flash memory.

Related Information

Quad SPI Flash Controller on page 15-1
Refer to the *Quad SPI Flash Controller* chapter for more information regarding features and functionality.

Quad SPI Controller Default Settings

Table A-11: Quad SPI Controller Default Settings

Parameter	Default Setting	Register Value
SPI baud rate	Divide by 4	The master mode baud rate divisor field (`bauddiv`) of the quad SPI configuration register (`cfg`) in the quad SPI controller registers (`qspiregs`) = 1.
Read opcode	Refer to the "QSPI Controller Clock Options Based on CSEL and HPS_CLK Fuse Settings" table to determine the correct configuration of the HPS_CLK and CSEL fuses for Normal or Fast Reads.	The read opcode in non-XIP mode field (`rdopcode`) in the device read instruction register (`devrd`) = 0x3 (for normal read) and 0xB (for fast read).
Instruction type	Single I/O (1 bit wide)	The address transfer width field (`addrwidth`) and data transfer width field (`datawidth`) of the `devrd` register = 0.

Parameter	Default Setting	Register Value
Number of address bytes	3 bytes	The number of address bytes field (`numaddrbytes`) of the device size register (`devsz`) = 2. **Note:** Before a reset, you must ensure that the QSPI flash device is configured to 3 byte address mode for the boot ROM to function properly.
Delay in terms of `l4_main_clk` for the length that the master mode chip select outputs are deasserted between words when the clock phase is zero	The default setting in clock cycles must equal 200 ns	The clock delay for chip select deassert (field `nss` in the quad SPI device delay register (`delay`)). Refer to `delay[31:24]` in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Delay in terms of `l4_main_clk` clock cycles between one chip select being deactivated and the activation of another. This delay ensures a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty	The default setting is 0 clock cycles.	The clock delay for chip select deactivation (field `btwn` in the `delay` register = 0x0).
Delay in terms of `l4_main_clk` clock cycles between the last bit of the current transaction and the first bit of the next transaction. If the clock phase is zero, the first bit of the next transaction refers to the cycle in which the chip select is deselected	The default setting in clock cycles must equal 20 ns.	The clock delay for last transaction bit (field `after` in the `delay` register). Refer to `delay[15:8]` in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.
Added delay in terms of `l4_main_clk` clock cycles between setting `qspi_n_ss_out` low and first bit transfer	The default setting in clock cycles must equal 20 ns.	The clock delay of `qspi_n_ss_out` (field `init` in the `delay` register). Refer to `delay[7:0]` in the "Quad SPI Flash Delay Configuration" table in the "Quad SPI Flash Delay Configuration" section for calculations.

Quad SPI Flash Delay Configuration

The `delay` register in the quad SPI controller configures relative delay of the generation of the master output signals. All timings are defined in cycles of `l4_main_clk`.

The quad SPI flash memory must meet the following timing requirements:

- T_{SLCH}: 20 ns
  - T_{SLCH} is used to calculate the `init` field (`delay[7:0]`) in the `delay` register. The `init` field represents the delay in `l4_main_clk` clocks between pulling the device chip select (`qspi_n_ss_out`) low and the first bit transfer.
- T_{CHSH}: 20 ns
  - T_{CHSH} is used to calculate the `after` field (`delay[15:8]`) in the `delay` register. The `after` field represents the delay in the `l4_main_clk` clocks between last bit of the current transaction and the deassertion of the device chip select (`qspi_n_ss_out`).
- T_{SHSL}: 200 ns
  - T_{SHSL} is used to calculate the `nss` (`delay[31:24]`) field in the `delay` register and is the delay in the `l4_main_clk` clocks for the length that the master mode chip select outputs are deasserted between transactions.
- $T_{qspi\_ref\_clk}$ is the master reference clock/external clock, `l4_main_clk`.

The formulas to calculate the fields in the `delay` register are:

`delay[7:0]`= `init` = $T_{SLCH}/T_{qspi\_ref\_clk}$

`delay[15:8]`= `after` = $T_{CHSH}/T_{qspi\_ref\_clk}$

`delay[31:24]`= `nss` = $(T_{SHSL} - T_{qspi\_clk})/T_{qspi\_ref\_clk}$

Table A-12: Quad SPI Flash Delay Configuration for Device Delay (`delay`) Register

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Input Clock Range	$T_{qspi\_ref\_clk}$ (ns)	T_{qspi_clk} (ns)	`delay[7:0]` (init)	`delay[15:8]` (after)	`delay[31:24]` (nss)
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure Bypass)	5	20	4	4	36
0x2	1	30-100 MHz (Secure PLL)	2.5	10	8	8	76
0x1	0	10-50 MHz (Untouched PLL)	20	80	1	1	6
0x0 and 0x2-0x6, 0xF	0	10-50 MHz (PLL Bypass)	20	80	1	1	6
0x7	0	10-15 MHz	2.5	10	8	8	76
0x8	0	15-20 MHz	2.5	10	8	8	76
0x9	0	20-25 MHz	2.5	10	8	8	76
0xA	0	25-30 MHz	2.5	10	8	8	76
0xB	0	30-35 MHz	2.5	10	8	8	76

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Input Clock Range	$T_{qspi\_ref\_clk}$ (ns)	T_{qspi_clk} (ns)	delay[7:0] (init)	delay[15:8] (after)	delay[31:24] (nss)
0xC	0	35-40 MHz	2.5	10	8	8	76
0xD	0	40-45 MHz	2.5	10	8	8	76
0xE	0	45-50 MHz	2.5	10	8	8	76

Read data capture delay is also configured when booting from QSPI. Depending on the CSEL and HPS_CLK fuse values, the Boot ROM configures the `delay` field of the `rddatacap` register in the QSPI differently. When you configure the CSEL and HPS_CLK fuses to enable the PLL, the boot ROM calibrates the interface by reading the QSPI signal for all delay values of the `rddatacap` register. The Boot ROM analyzes all of the delay values that return a valid signature and uses the delay value in the middle of the valid window as the value it programs into the `delay` field of the `rddatacap` register. If the PLL is not enabled, then the Boot ROM leaves the `rddatacap` register untouched.

Quad SPI Controller CSEL Settings

Table A-13: QSPI Controller Clock Options Based on CSEL and HPS_CLK Fuse Settings

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	Controller clock	Controller Clock Frequency (l4_main_clock)	Baud Rate Divisor	External Device Clock (Divided down reference clock)	Default Flash Read Instruction	PLL Status
0x0-0x1 and 0x3-0xF	1	60-200 MHz (Secure Bypass)	cb_intosc_hs_clk	60-200 MHz	16	3.75-12 MHz	READ	Bypassed
0x2	1	30-100 MHz (Secure PLL)	cb_intosc_ls_clk*4	120-400 MHz	8	15-50 MHz	FAST_READ	Locked
0x1	0	10-50 MHz (Untouched PLL)	osc1_clk (EOSC1 pin)	10-50 MHz	4	2.50-12.5 MHz	READ	Untouched
0x0-0x6, 0xF	0	10-50 MHz (PLL Bypass)	osc1_clk (EOSC1 pin)	10-50 MHz	4	2.50-12.5 MHz	READ	Bypassed
0x7	0	10-15 MHz	osc1_clk*26.75	266.67-400 MHz	8	33.33-50 MHz	FAST_READ	Locked
0x8	0	15-20 MHz	osc1_clk*20	300-400 MHz	8	37.50-50 MHz	FAST_READ	Locked

CSEL [3:0] Fuse Values	HPS CLK Fuse Value	Required Input Clock Range	Controller clock	Controller Clock Frequency (l4_main_clock)	Baud Rate Divisor	External Device Clock (Divided down reference clock)	Default Flash Read Instruction	PLL Status
0x9	0	20-25 MHz	osc1_clk*16	320-400 MHz	8	40-50 MHz	FAST_READ	Locked
0xA	0	25-30 MHz	osc1_clk*13.33	333.33-400 MHz	8	41.66-50 MHz	FAST_READ	Locked
0xB	0	30-35 MHz	osc1_clk*11.42	42.85-50 MHz	8	42.85-50 MHz	FAST_READ	Locked

0xD	0	40-45 MHz	osc1_clk*8.88	355.55-400 MHz	8	44.45-50 MHz	FAST_READ	Locked
0xE	0	45-50 MHz	osc1_clk*3	360-400 MHz	8	45-50 MHz	FAST_READ	Locked

Clock Select

The boot ROM reads the clock select values to determine what frequency has been selected for the CPU clock and any interface clock during boot.

If the FPGA boot fuse is not blown, the clock select (CSEL) fuses are used to configure the main PLL and peripheral PLL. The Clock Manager samples the clock configuration on a cold and warm reset. If the hps_clk_f fuse is blown, the internal oscillator divided by 2, `cb_intosc_hs_div2_clk`, is used as the boot clock. If the fuse is not blown, an external oscillator is used. During boot ROM execution, the boot code configures the device clock based on the CSEL fuse settings or software code. The `cb_intosc_hs_div2_clk` can be considered the secure reference clock option.

Note: The terms CSEL and CLKSEL are used interchangeably in Altera documentation to refer to clock select.

The CSEL settings are not used to configure the PLLs for the following conditions:

- A boot from RAM (warm reset)
- A boot from FPGA
- The clock select is set to 0x1, indicating the clocks should not be touched.

If a bypass condition is encountered, the boot ROM checks to make sure that the boot clock has a proper source according to the security level set and if it does not, the boot ROM stalls. ROM code bypasses the PLLs at warm or cold reset under the following conditions:

- The hps_clk_f fuse is not blown and the CSEL fuse value is 0xF. This setting is an unsecure bypass that uses the external oscillator (EOSC1) as the clock source.
- The hps_clk_f fuse is not blown and the CSEL fuses values are not 0xF, 0x1 or one of the values from 0x7 to 0xE that indicates PLL use. These are mapped to unsecure bypass using the external oscillator (`EOSC1`) as the clock source.
- The hps_clk fuse is set to secure clock, but the CSEL fuse value is not 0x2. This setting is considered secure bypass, using the internal oscillator as the clock source.

CSEL Fuse Encodings During Boot

The intent of the CSEL fuses is to give the user more control over the CPU clock in both non-secure and secure mode. For example, if you select CSEL=0x0 (the default) in non-secure mode, then the boot ROM configures all the clocks back to their default bypass (boot) mode and the MPU is clocked by the `EOSC1` (10-50 MHz). However, if you have a 10 MHz external oscillator (`EOSC1`) and want to operate faster, then the CSEL fuses can be programmed to 0x7 for a MPU clock of 553 MHz. Similarly, if the input clock is 25 MHz and the CSEL fuses are programmed to 0x9 then the MPU clock is 800 MHz (25 * 32). If CSEL=0xA is chosen, then the same clock gives a MPU clock of 650 MHz (25 * 26). Finally, if some set of CSEL fuses have been blown, you can return to the default bypass state (CSEL=0x0) by blowing all the fuses (CSEL=0xF).

The following tables represent the clock frequencies that are available during the boot process according the boot clock that is selected. As noted previously, when the internal secure clock, `cb_intosc_ls_clk`, is used as the boot clock, the meaning of the CSEL fuses is slightly different.

To configure the clock speeds for second-stage boot loader execution, you need to select the clock speeds in the HPS component of Qsys. The tables below only apply to the boot process.

Table A-14: CSEL Encodings for hps_clk_f = 0 (Non-secure Operation)

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	When no fuses are blown, the boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (`EOSC1`), which must be in the range of 10 to 50 MHz. No PLL is enabled.	External Oscillator, `EOSC1` (10 to 50 MHz)
0x1	All the clock codes are bypassed and the clock source is user selected.	User-selected clock source
0x2	Reserved	External Oscillator, `EOSC1` (10 to 50 MHz)
0x3	Reserved	External Oscillator, `EOSC1` (10 to 50 MHz)
0x4	Reserved	External Oscillator, `EOSC1` (10 to 50 MHz)
0x5	Reserved	External Oscillator, `EOSC1` (10 to 50 MHz)
0x6	Reserved	External Oscillator, `EOSC1` (10 to 50 MHz)

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x7	External oscillator input clock, EOSC1, is in the range of 10 to 15 MHz	533 to 800 MHz
0x8	External oscillator input clock, EOSC1, is in the range 15 to 20 MHz.	600 to 800 Mhz
0x9	External oscillator input clock, EOSC1, is in the range 20 to 25 MHz.	640 to 800 Mhz
0xA	External oscillator input clock, EOSC1, is in the range 25 to 30 MHz.	666 to 800 Mhz
0xB	External oscillator input clock, EOSC1, is in the range 30 to 35 MHz.	685 to 800 Mhz
0xC	External oscillator input clock, EOSC1, is in the range 35 to 40 MHz.	700 to 800 Mhz
0xD	External oscillator input clock, EOSC1, is in the range 40 to 45 MHz.	711 to 800 Mhz
0xE	External oscillator input clock, EOSC1, is in the range 45 to 50 MHz.	720 to 800 Mhz
0xF	The boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (EOSC1). No PLL is enabled.	External Oscillator (10 to 50 MHz)

Table A-15: CSEL Encodings for hps_clk_f = 1 (Secure Operation)

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	Bypass mode; in this mode all clocks are reset and boot mode is ensured active; cb_intosc_hs_div2_clk (cb_intosc_hs clock divided by 2) is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x1	All the clock codes are bypassed and the clock is user selected.	User-selected clock source
0x2	PLL is used with the internal oscillator (30 to 100 MHz)	120 to 800 MHz

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x3	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x4	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x5	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x6	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x7	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x8	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0x9	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xA	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xB	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xC	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xD	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xE	Reserved	cb_intosc_hs_div2_clk (60 to 200 MHz)
0xF	Bypass mode; reset all clocks and ensure boot mode is active; cb_intosc_hs_div2_clk is used.	cb_intosc_hs_div2_clk (60 to 200 MHz)

I/O Configuration

The flash devices needed for booting must be connected to specific I/Os. The Boot ROM configures these I/Os depending on the flash device selected by boot select setting. To configure the I/Os, the boot ROM performs pin muxing and pin configuration on these I/Os.

The boot ROM is allocated 14 dedicated HPS I/Os. There are three separate I/O tables in the boot ROM, one for each flash device.

On cold reset, the boot ROM always configures the pin muxes and pin configuration. On warm reset, the user has the capability to specify whether or not the boot ROM code configures the I/Os and pin muxes for boot pins after a warm reset. This configuration on warm reset is enabled by programming the romcode_ctrl register in the System Manager.

Refer to the "Boot Source I/O Pins" section for detail on mux select values.

Related Information

- **Hard Processor System I/O Pin Multiplexing** on page 25-1
  Refer to the *Hard Processor Subsystem I/O Multiplexing* chapter for more information regarding booting I/O options and configuration.

L4 Watchdog 0 Timer

The boot ROM enables the L4 Watchdog 0 Timer early in the boot process.

This watchdog is reserved for the boot ROM until the second-stage boot loader indicates that it has started correctly and taken control of the exception vectors. The timeout is at least one second, depending on the

clock select setting. Because the watchdog is reset just before the control passes to second-stage boot loader, the second-stage boot loader must reset the watchdog when it begins execution.

The L4 watchdog 0 timer is reserved for boot ROM use. While booting, if a watchdog reset happens before software control passes to the second-stage boot loader, the boot ROM code attempts to load the last valid second-stage boot loader image, identified by the `initswlastld` register in the System Manager.

If the watchdog reset happens after the second-stage boot loader has started executing but before it writes a valid value to `initswstate` register, the boot ROM increments `initswlastld` and attempts to load that image. If the watchdog reset happens after the second-stage boot loader writes a valid value to `initswstate` register, the boot ROM code attempts to load the image indicated by `initswlastld` register.

Second-Stage Boot Loader

The function of the second-stage boot loader is user-defined. The Altera-provided second-stage boot loader is a combination of initialization, configuration and U-Boot code and contains features such as:

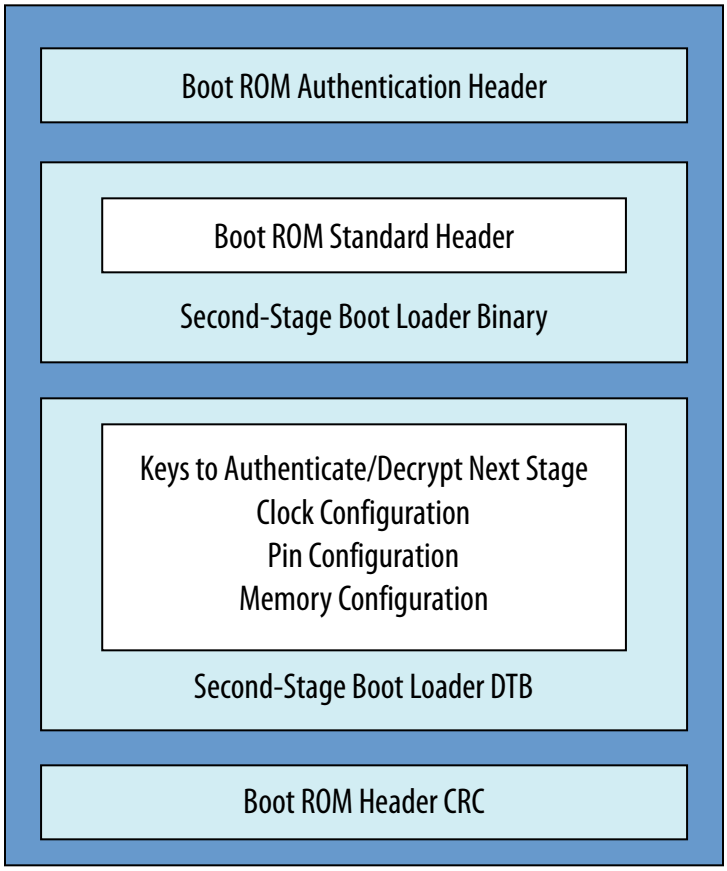
- SD/MMC controller driver
- QSPI controller driver
- Ethernet driver plus protocol support
- Drivers for system-level IP, such as Clock Manager, System Manager, and FPGA Manager
- Cache memory drivers
- UART, timer and watchdog drivers
- FAT file system support
- Flat Image Tree (FIT) image processing
- U-Boot console support including basic essential debug commands
- Cryptographic library
- Flattened device tree (FDT) processing library
- System and memory firewall configuration
- Initialization code for the HPS and FPGA I/O and the interface that loads the next stage of software

If a secure boot is required, the second-stage boot loader can be used to increase the level of security and to authenticate and initiate decryption of the next boot image if necessary.

If the hard memory controller I/O in the SoC device have been configured through the FPGA or HPS and the SDRAM firewall access has been lowered, the second-stage boot loader can be used to load the next stage of the boot software into SDRAM. The maximum length for a second-stage boot loader to fit into on-chip RAM is 208 KB with authentication and 224 KB without authentication. A typical next software stage is loading the application OS software. The second-stage boot loader is allowed to load the next stage boot software from any device available to the HPS. Typical sources include the same flash device that contains the second stage boot loader, a different flash device, or a communication interface such as an EMAC.

If the second-stage boot loader must be authenticated, it must store a public key. Below is a figure which depicts the second-stage boot loader image presented to the boot ROM, during a secure, authenticated boot.

Figure A-8: High-Level Diagram of Second-Stage Boot Loader Image



Secure Boot

The boot ROM supports both non-secure and secure boot.

Secure boot allows the HPS to release from reset into a known state and then validate the authenticity and integrity of the second-stage boot loader code prior to executing it. Secure boot can ensure that only authorized code is executed on the system. In addition, the system has the option to configure the FPGA from the HPS, which provides a secure boot mechanism for the FPGA portion of the SoC. In this mode, the HPS boot code can authenticate the FPGA POF prior to loading it.

The boot ROM determines the security level based on user fuse values that are stored in the Security Manager during initialization. The second-stage boot loader may provide a security header to indicate authentication or decryption for the image. Based on the merged data from security manager and the security header, the boot ROM can load the following images:

- Clear text: No authentication or decryption is required
- Secure, Authenticated - Authentication but no decryption is required on the image
- Secure, Encrypted - Decryption, but no authentication is required. During the decryption process, the boot ROM looks for an encrypted image on the flash device and decrypts it into the on-chip RAM
- Full Secure - Both authentication and decryption are required

The authentication process is independent of the decryption process. However, if authentication and decryption are both required, authentication is done before the decryption process.

For more information regarding Secure Boot, please refer to the *SoC Security* Chapter.

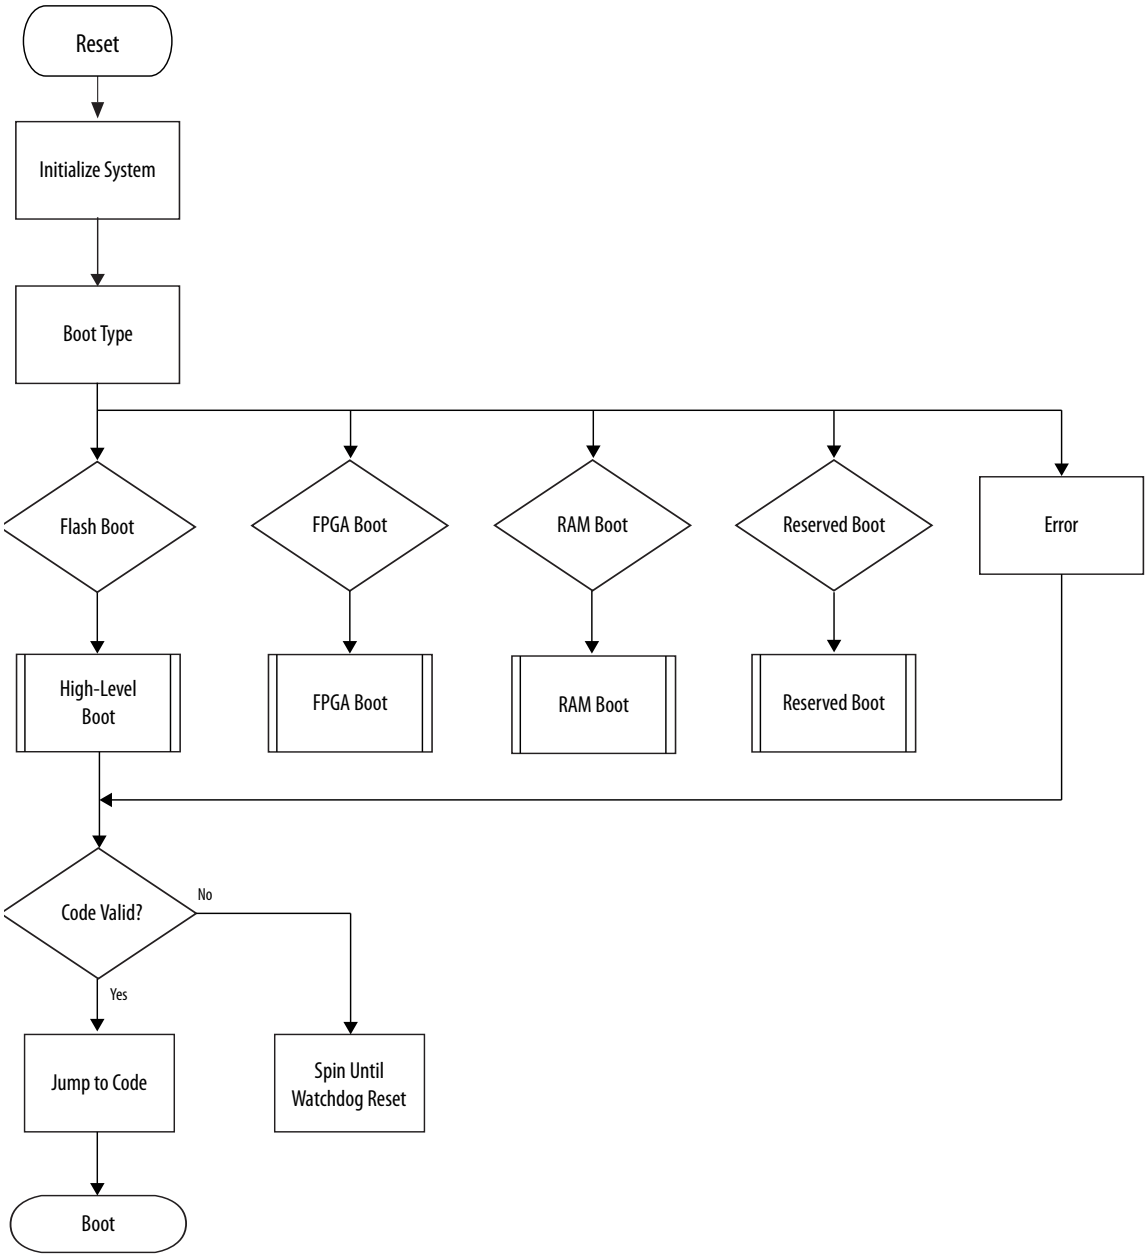
Boot ROM Flow

On a cold reset, the HPS boot process starts when CPU0 is released from reset (for example, on a power up) and executes code in the internal boot ROM at the reset exception address, 0x00000000. The boot ROM code brings the HPS out of reset and into a known state. After boot ROM code is exited, control passes to the next stage of the boot software, referred to as the second-stage boot loader. The second-stage boot loader can be customized and is typically stored external to the HPS in a nonvolatile flash-based memory or in on-chip RAM within the FPGA. The second-stage boot loader can then load an OS, BareMetal application or potentially a third-stage boot loader.

This section describes the software flow from reset until the boot ROM code passes software control to the second-stage boot loader.

The code starts, initializes the system and then depending on the type of boot requested, it may attempt to load the code into the on-chip RAM. An on-chip RAM boot can only occur on a warm reset. Warm boot from on-chip RAM has the highest priority to execute if the `warmram_*` registers in the system manager has been configured to support booting from on-chip RAM on a warm reset. If the `warmram_enable` register in the system manager is set to 0xAE9EFEBC, then the boot ROM code attempts to boot from on-chip RAM on a warm reset and the boot ROM does not configure boot I/Os, pin-muxes or clocks. The `warmram_datastart` and `warmram_length` registers in System Manager allow you to program the offset of the beginning of code and the length of the region of on-chip RAM for CRC validation. If the `warmram_length` register is clear, then the boot ROM does not perform a CRC calculation in the on-chip RAM. If the `warmram_length` register is non-zero, then CRC checking is performed. If CRC checking is successful, then the boot ROM jumps to global address programmed in the `warmram_execution` register. If for three subsequent load attempts, the boot ROM fails to find code or the CRC check fails, the boot ROM spins, waiting for a watchdog reset.

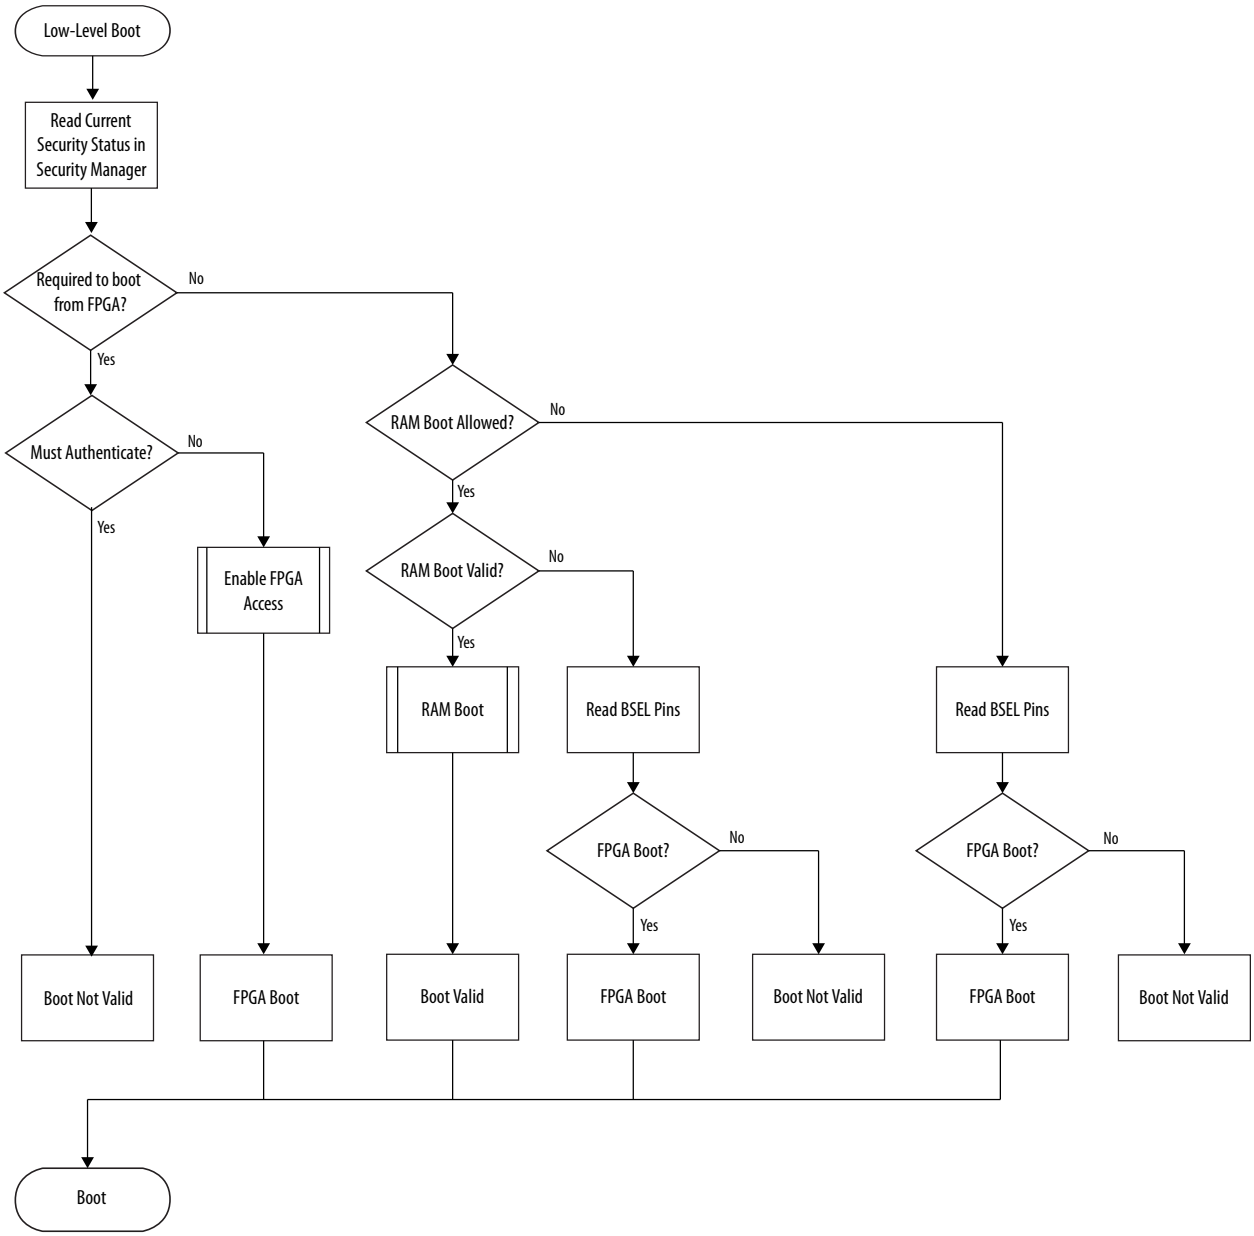
Figure A-9: Main Boot ROM Flow



The boot ROM always executes on CPU0. CPU1 is always held in reset while the main boot ROM code is executing and is only released when required by system software.

As part of determining the boot type, the boot ROM executes a low-level boot flow. The boot ROM code reads the security fuse to determine if the source of the second-stage boot is forced to be the FPGA. If a non-authenticated FPGA boot or a non-CRC on-chip RAM boot is requested or the boot is invalid, it is processed within the low-level boot flow. All other boot types are processed within the high-level boot flow.

Figure A-10: Low-Level Boot Flow

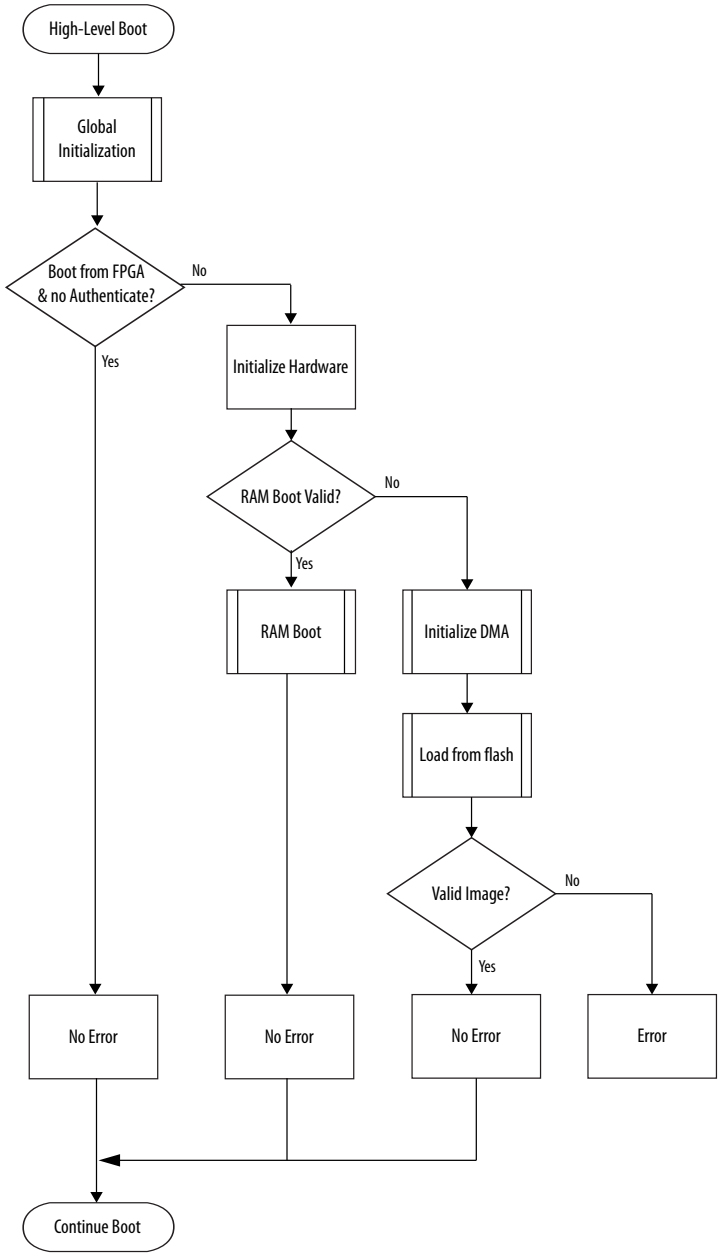


During the low-level portion of the boot ROM flow, the boot ROM reads the security fuses to determine if an FPGA-only boot is required. If so, then the boot ROM must also determine if the fuses indicate that authentication of the POF is needed. If no authentication is required, then a standard FPGA configuration occurs.

If an FPGA-only boot is not required, then the boot ROM checks if an on-chip RAM boot is allowed. If it is, then the boot ROM checks to see if the code is valid. If the code is invalid, the boot ROM reads the BSEL pins to determine if it indicated an FPGA boot.

If the secure fuses indicate that authentication is required for the boot image, then a high-level boot (executed in C code) must be performed.

Figure A-11: High-Level Boot Flow



During the boot process, authentication and decryption can be performed on the boot image. Authentication is independent of decryption; however, if both authentication and decryption are required, then authentication always occurs first. If an authenticated boot is required, then the boot ROM must have a root key to start the authentication process. This key can be implemented in the user fuses, in the FPGA logic elements or as part of the second-stage boot image header. The device configuration fuses determine the source of the key.

During a cold boot from flash memory, the boot ROM code attempts to load the first second-stage boot loader image from flash memory to on-chip RAM and pass control to the second-stage boot loader. If this initial image is invalid, the boot ROM code indexes the `romcode_initswlastld` register and attempts to load the next stored image. The boot ROM will attempt three subsequent loads after the initial one. If there is still no valid image found after the subsequent loads, the boot ROM code checks the FPGA portion of the device for a fallback image.

Note: During the boot process, the boot ROM enables all of the caches (L1 data and instruction caches and L2 cache). If the second-stage boot loader is not loaded from a boot flash device (SD/MMC, QSPI, NAND) properly, the caches may be left on when the boot ROM checks the FPGA portion the device for a fallback image. This situation can lead to issues of coherency when loading code, so caches must be flushed and disabled in the fallback image.

If the warm RAM boot has failed or if a cold reset has occurred, then the boot ROM reads the BSEL value in the `bootinfo` register of the System Manager. If the FPGA is selected as the boot source, then the boot ROM code attempts to execute code at address 0xC0000000 across the HPS-to-FPGA bridge (offset 0x00000000 from bridge). No error conditions are generated if the FPGA does not initialize properly and the watchdog is not enabled for time-out. Instead, the boot ROM continues to wait until the FPGA is available.

If the BSEL bits indicate a boot from external flash, then the boot ROM code attempts to load an image from a flash device into the on-chip RAM, verify and execute it. If the BSEL is invalid or the boot ROM code cannot find a valid image in the flash, then the boot ROM code checks if there is a fallback image in the FPGA. If there is, then the boot ROM executes the fallback image. If there is no fallback image then the boot ROM performs a post-mortem dump of information into the on-chip RAM and awaits a reset.

Note: The acronyms BSEL and BOOTSEL are used interchangeably to define the boot select pins.

The boot ROM code verifies the second-stage boot loader in several ways to ensure a corrupted image is not executed. The first test is of the image header, which identifies the magic number, version, block length, and CRC of the image that protects the block. If any of these are invalid, an error occurs.

Second-Stage Boot Flow

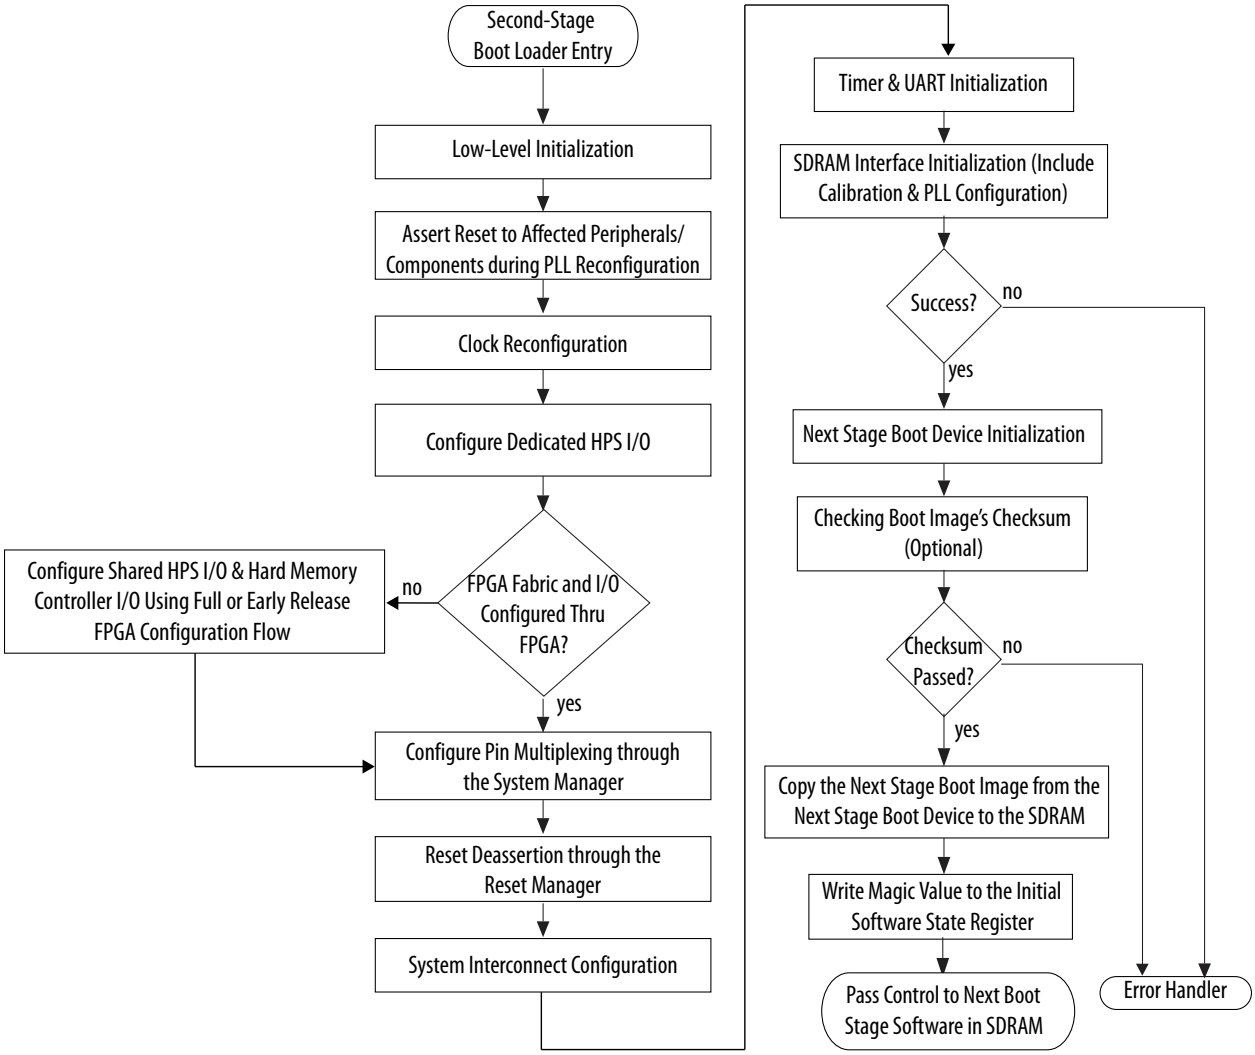
The second stage boot loader has the capability of supporting the following types of boot:

- Non-secure clear text boot
- Secure boot with:
  - Authentication only (also called verified boot)
  - Decryption only
  - Authentication and decryption

Typical Boot Flow (Non-Secure)

A non-secure second-stage boot process typically follows a flow as in the following figure.

Figure A-12: Typical Second-Stage Boot Loader Flow (Non-Secure)



Low-level initialization steps include reconfiguring or disabling the L4 watchdog 0 timer, invalidating the instruction cache and branch predictor, remapping the on-chip RAM to the lowest memory region, and setting up the data area.

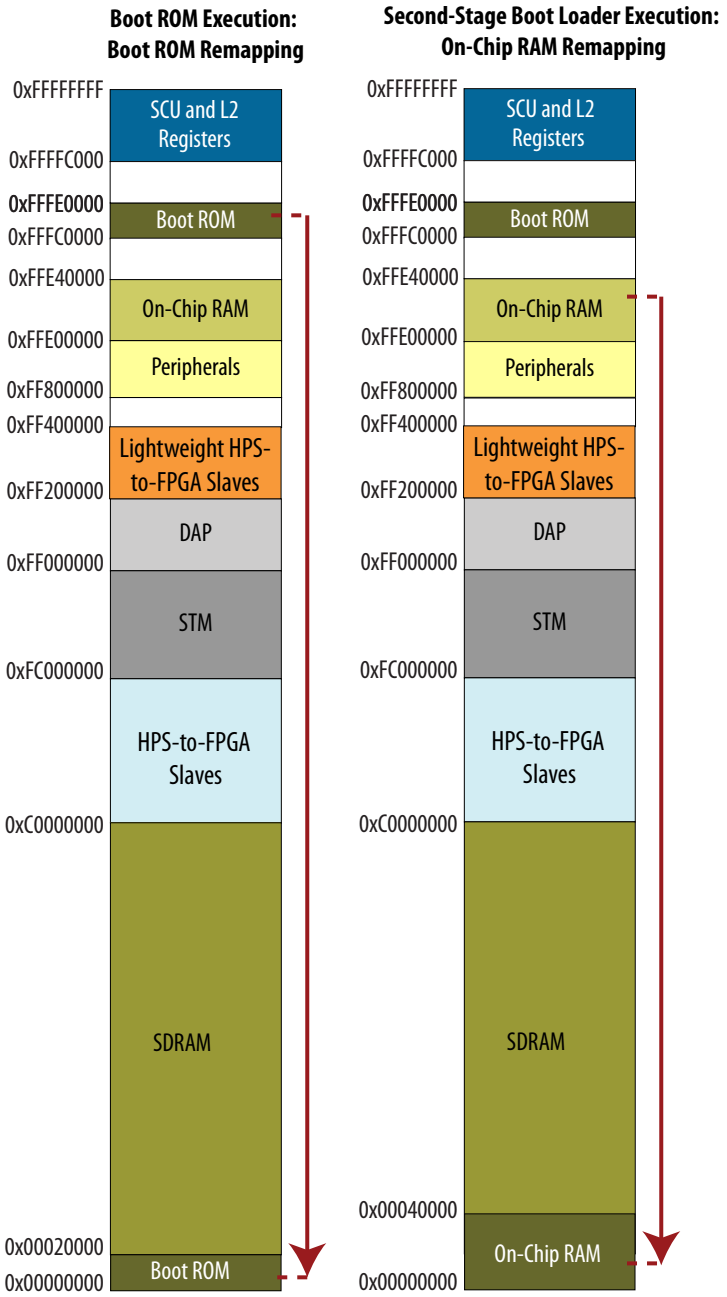
Upon entering the second-stage boot loader, the L4 watchdog 0 timer is active. The second stage boot loader can disable, reconfigure, or leave the watchdog timer unchanged. Once enabled after reset, the watchdog timer cannot be disabled, only paused or reset.

The instruction cache and branch predictor, which were previously enabled by the boot ROM code, must be invalidated. If the second-stage boot loader enables and uses the data cache, it must initialize all levels of the data cache before enabling.

The second-stage boot loader must remap the exception vector table because the exception vectors are still pointing to the exception handler in the boot ROM when it starts executing. By setting the system interconnect remap bit 0 to one, the on-chip RAM mirrors to the lowest region of the memory map. After this remap, the exception vectors use the exception handlers in the boot loader image.

The figure below shows the memory map before and after remap. The first mapping depicts boot ROM execution. The second mapping shows the remap of the on-chip RAM when the remap bit is set during second-stage boot loader execution.

Figure A-13: Remapping the On-Chip RAM



The second-stage boot loader can reconfigure all HPS clocks. During clock reconfiguration, the boot loader asserts reset to the peripherals in the HPS affected by the clock changes.

The I/O assignments for the HPS are configured as part of the IOCSR configuration in the second-stage boot loader. Effectively, a bitstream containing the I/O assignments is sent to the device as part of the

initialization code in the second-stage boot loader. If the FPGA fabric and I/O have not yet been configured through the FPGA and the HPS needs to access SDRAM, you should program the HPS to use the full or early I/O release configuration method to configure the shared and hard memory controller I/O. Refer to "FPGA Configuration" section of the "Booting and Configuration" appendix in the *Arria 10 Hard Processor System Technical Reference Manual* for details on full and early I/O release configuration.

The second-stage boot loader looks for a valid next-stage boot image in the next-stage boot device by checking the boot image validation data and checksum in the mirror image. Once validated, the second-stage boot loader copies the next-stage boot image (OS or application image) from the next-stage boot device to the SDRAM.

Before software passes control to the next-stage boot software, the second-stage boot loader can write a valid value (0x49535756) to the `romcode_initswstate` register in the System Manager. This value indicates that there is a valid boot image in the on-chip RAM. The `romcode_initiswlastld` register holds the index of the last second-stage boot loader software image loaded by the Boot ROM from the boot device. When a warm reset occurs, the Boot ROM loads the image indicated by the `romcode_initswlastld` register if the BSEL value is the same as the last boot.

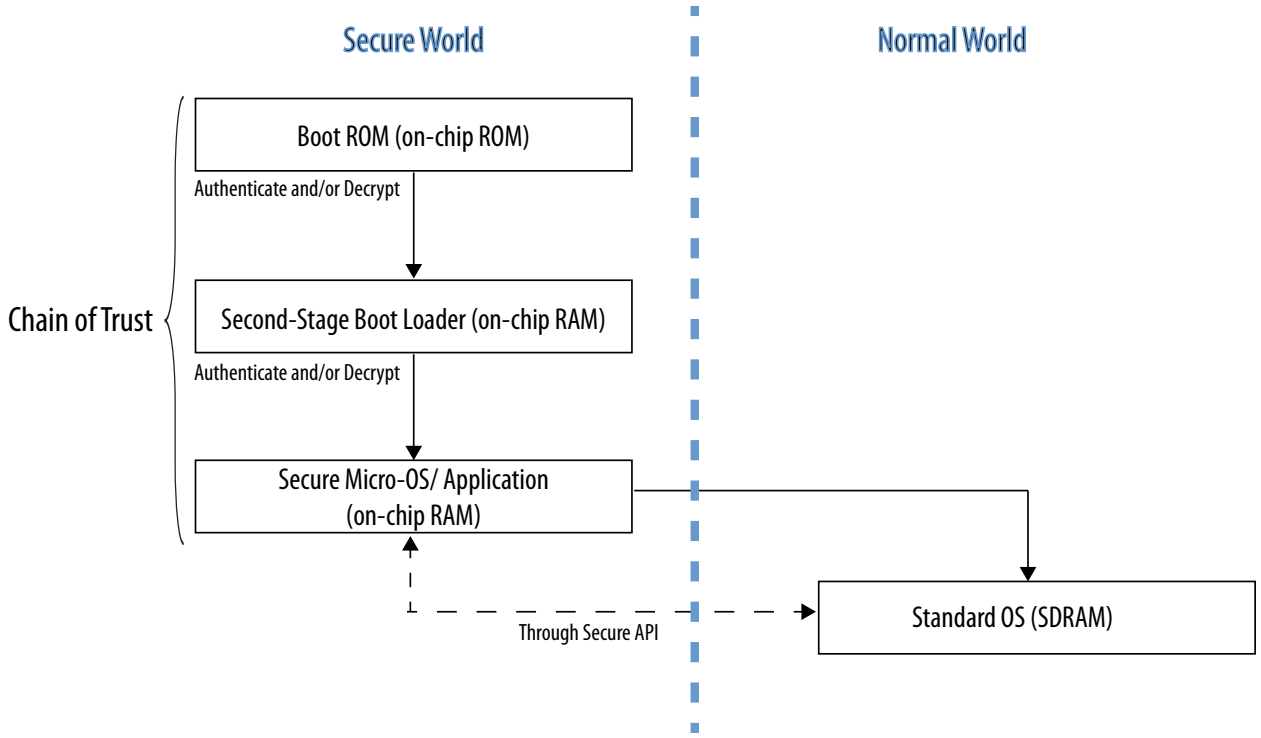
Secure Boot Flow

The main purpose of secure boot is to pass the chain of trust to the subsequent boot software. During a secure boot, the second-stage boot loader may authenticate or decrypt the subsequent boot image, depending on the current state registers in the Security Manager. In addition, the second-stage boot loader

must ensure that the subsequent boot image is executed from secure memory such as on-chip RAM. The second-stage boot loader fits into the chain of trust as such:

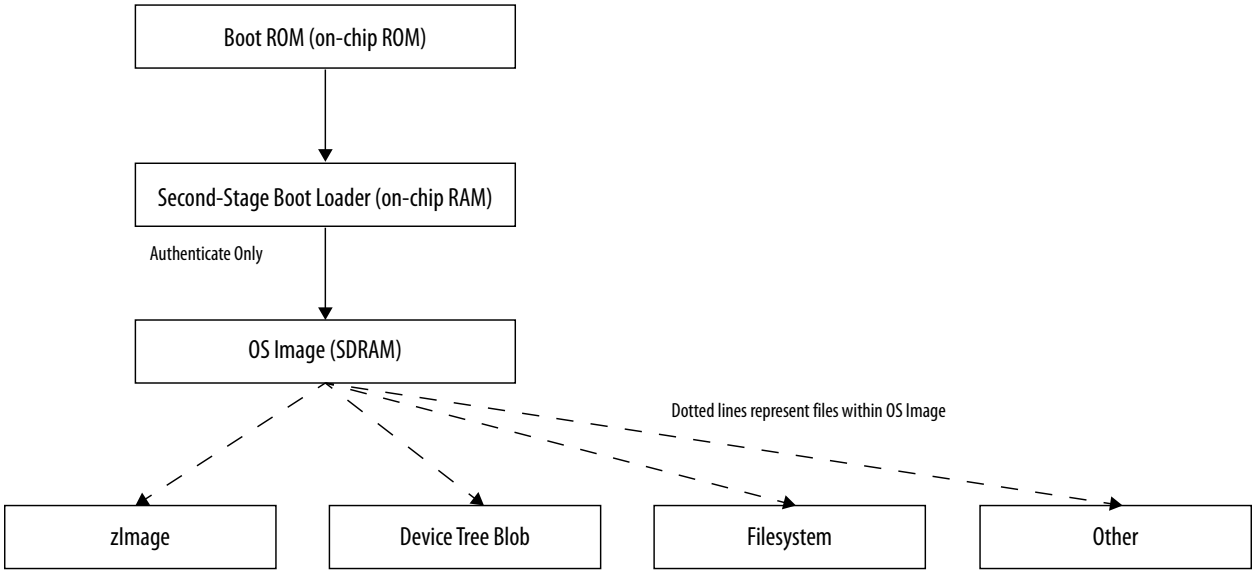
Figure A-14: Secure Boot Flow



The micro OS provides secure APIs to allow the application in the normal world OS to establish trusted services.

During a verified boot, the second-stage boot loader only authenticates the OS image and other images required by the OS. A flow for a verified boot is shown below.

Figure A-15: Verified (Authenticated) Boot Flow



For both the secure and verified boot, the subsequent boot image must be executed in on-chip RAM while the second-stage boot loader is still executing from on-chip RAM. In order to accommodate this requirement, the authentication and decryption process might follow the following steps depicted in the next three diagrams, depending on the type of secure boot chosen.

Figure A-16: Second-Stage Boot Loader Authentication Process

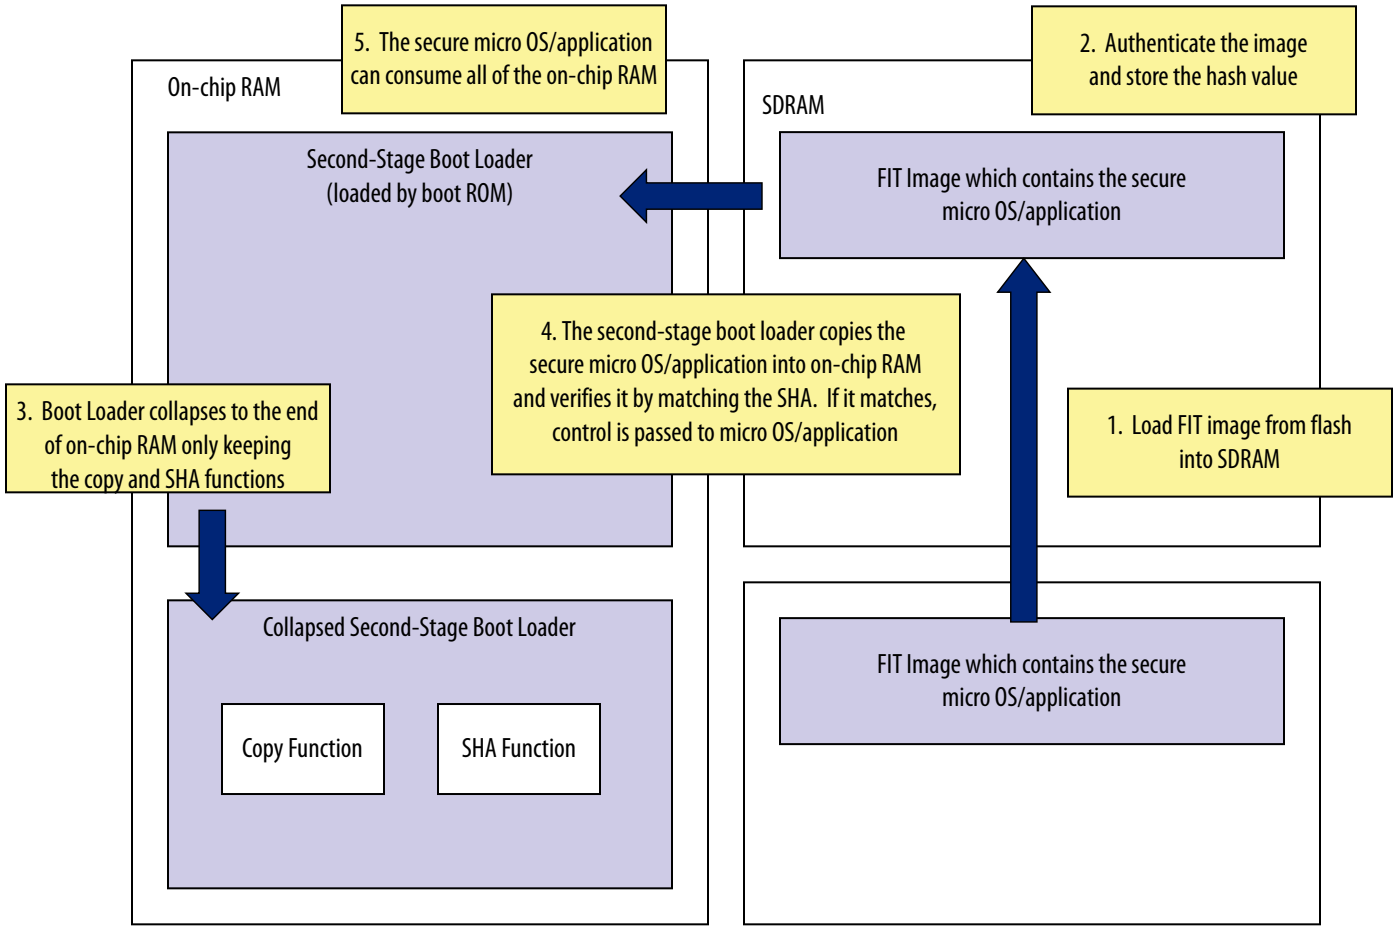


Figure A-17: Second-Stage Boot Loader Decryption Process

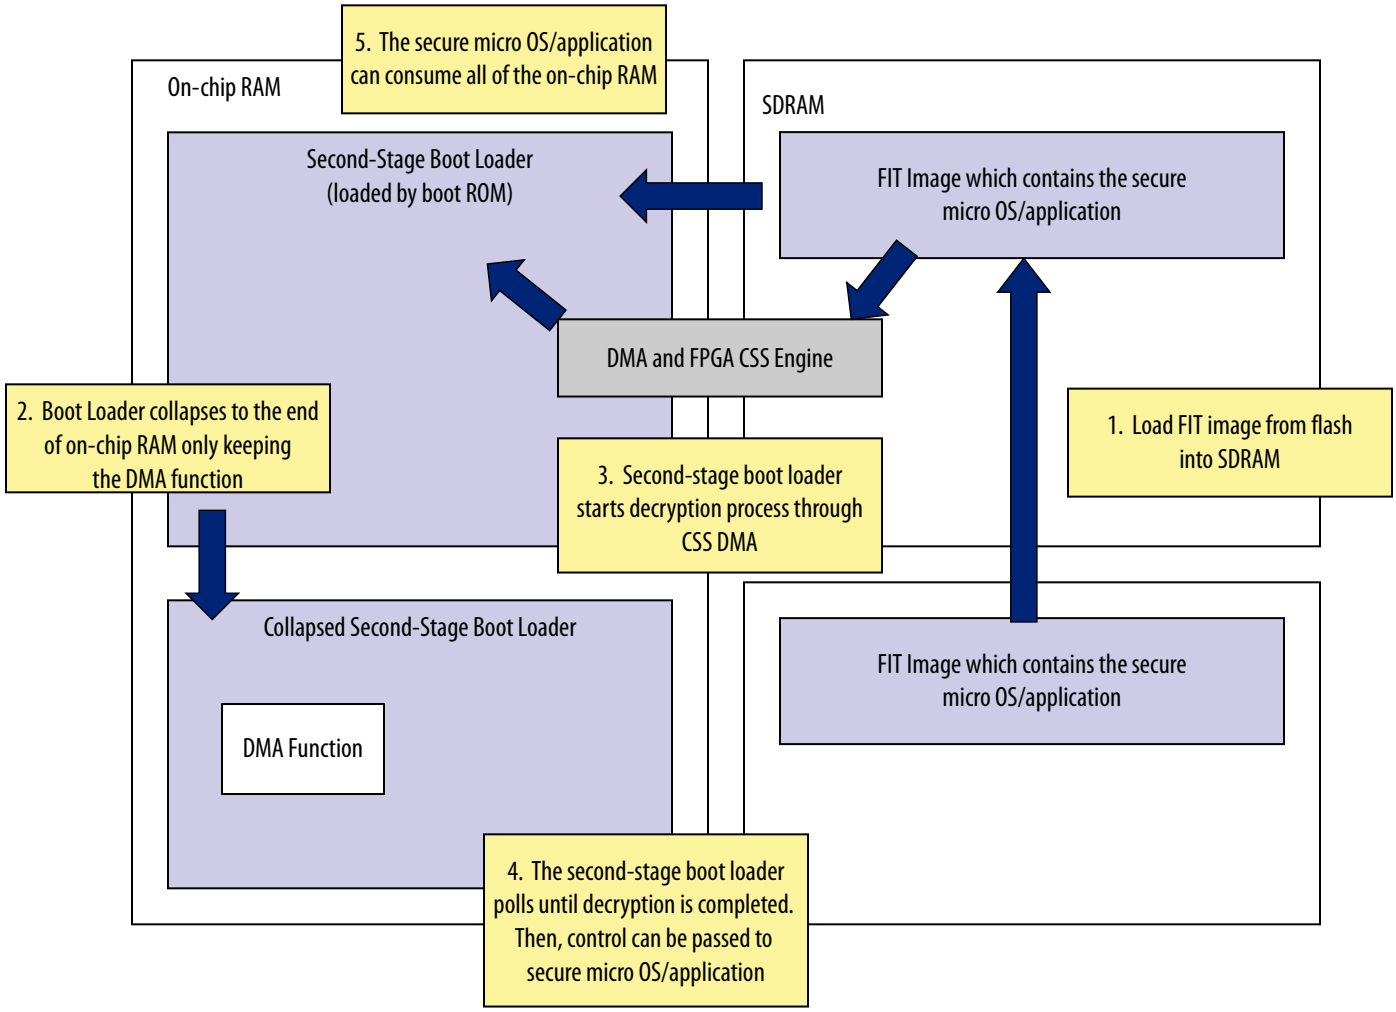
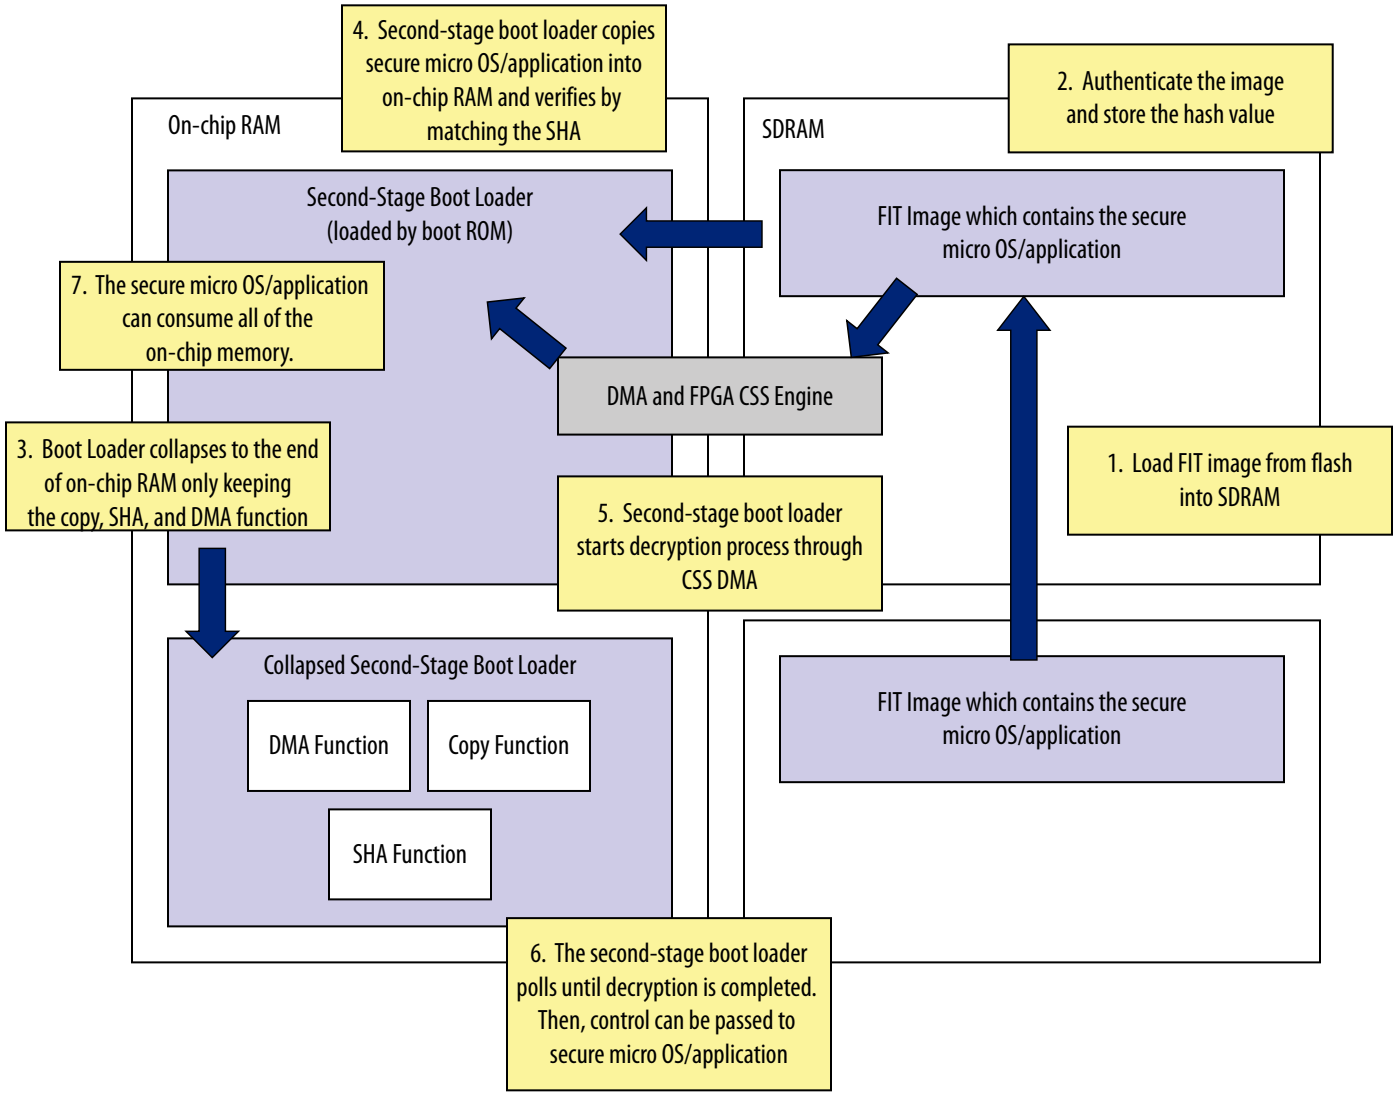


Decryption is optional and is not required for secure boot. Upon entry into the second-stage boot loader, the CSS engine is enabled. The second-stage boot loader decrypts the subsequent boot image and disables the CSS engine upon exit.

Figure A-18: Second-Stage Boot Loader Authentication and Decryption Process



HPS State on Entry to the Second-Stage Boot Loader

When the boot ROM code is ready to pass control to the second-stage boot loader, the processor (CPU0) is in the following state:

- Instruction cache is enabled
- Branch predictor is enabled
- Data cache is disabled
- MMU is disabled
- Floating point unit is enabled
- NEON vector unit is enabled
- Processor is in ARM secure supervisor mode

The boot ROM code sets the ARM Cortex-A9 MPCore registers to the following values:

- r0—contains the pointer to the shared memory block, which is used to pass information from the boot ROM code to the second-stage boot loader. The shared memory block is located in the top 4 KB of on-chip RAM.
- r1—contains the length of the shared memory.
- r2—unused and set to 0x0.
- r3—points to the version block.

All other MPCore registers are undefined.

Note: When booting CPU0 using the FPGA boot, or when booting CPU1 using any boot source, all MPCore registers, caches, the MMU, the floating point unit, and the NEON vector unit are undefined. HPS subsystems and the PLLs are undefined.

When the boot ROM code passes control to the second-stage boot loader, the following conditions also exist:

- CPU0 is in a secure system mode.
- The boot ROM is still mapped to address 0x0.
- The L4 watchdog 0 timer is active and has been toggled.
- The shared L2 cache is left in an uninitialized state.

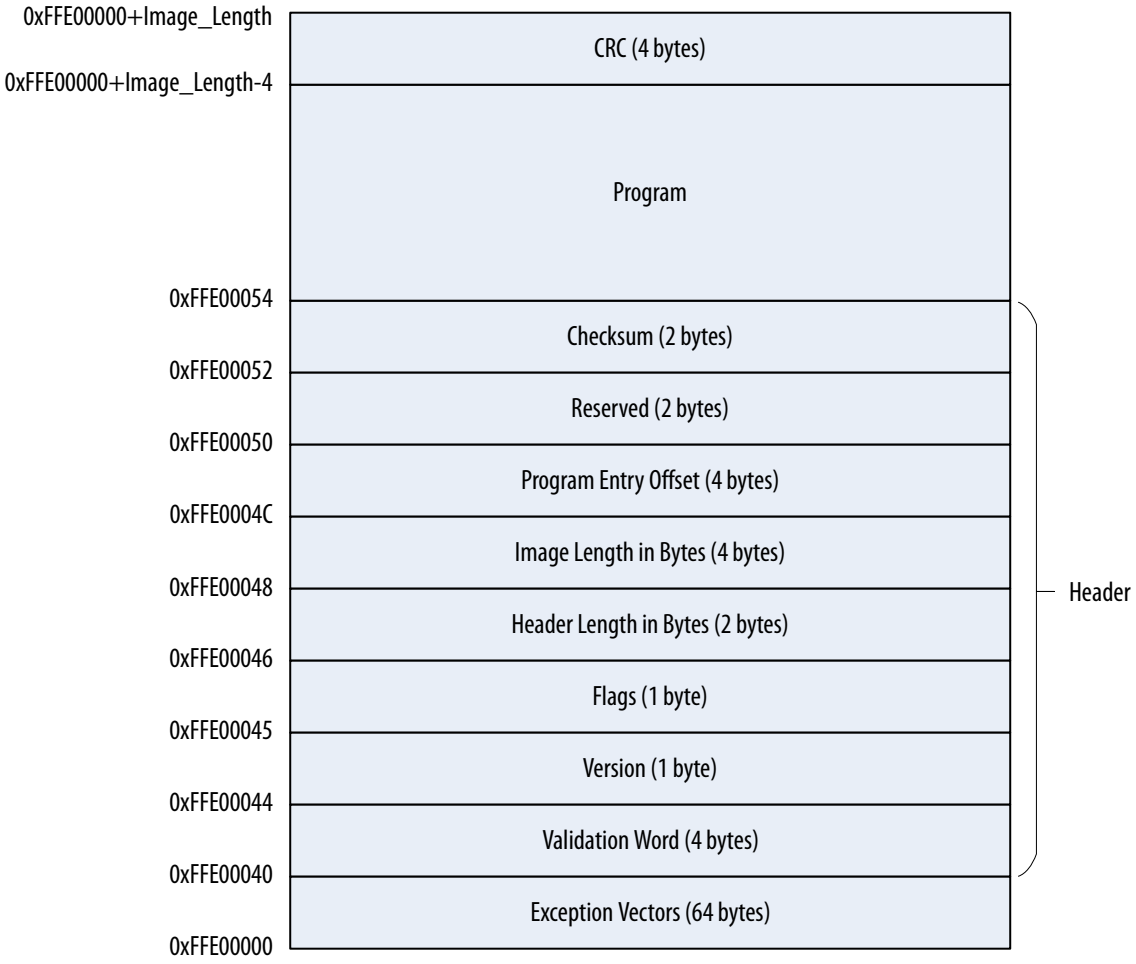
The boot ROM also saves the state of the reset cause in the `stat` register of the Reset Manager, and this information is available for the Second-Stage Boot Loader to read.

Loading the Second-Stage Boot Loader Image

The boot ROM code loads the image from flash memory into the on-chip RAM and passes control to the second-stage boot loader. The boot ROM code checks for a valid image by verifying the header and cyclic redundancy check (CRC) in the second-stage boot loader image.

The maximum second-stage boot loader size is 208 KB with authentication and 224 KB without. This size is limited by the on-chip RAM size of 256 KB, where 48KB or 32 KB is reserved as a workspace for the boot ROM data and stack depending on whether authentication is enabled or not. The second-stage boot loader can use this reserved region (for its stack and data, for example) after the boot ROM code passes control to the second-stage boot loader. This reserved region is overwritten by the boot ROM code on a subsequent reset. The following figure shows the second-stage boot loader image layout in the on-chip RAM after being loaded from the boot ROM.

Figure A-19: Second-Stage Boot Loader Image



- **Exception vectors**—Exception vectors are located at the start of the on-chip RAM. Typically, the second-stage boot loader remaps the lowest region of the memory map to the on-chip RAM (from the boot ROM) to create easier access to the exception vectors.
- **Header**—contains information such as validation word, version, flags, program length, security settings,and checksum for the boot ROM code to validate the second-stage boot loader image before passing control to the second-stage boot loader.
- **Version**—This byte describes the version and layout of the program header. This value must be 0x1.
- **Entry point**—After the boot ROM code validates the header, the boot ROM code jumps to this address.
- **Flags**— Not used.
- **Header length**— The length of the header in bytes.
- **Image length** — The total length of the image (including the exception vectors and the CRC field)
- **Program entry offset**— The boot ROM jumps to this offset. The offset value is in bytes from the start of the program header (0xFFE00040).
- **Reserved** —Not used. Must be set to 0x0.

- **Checksum**— A simple checksum of all the bytes from 0xFFE00040 to 0xFFE00051, inclusive
- **Program** — Program contents which typically includes U-Boot binary and U-Boot Device Tree Blob (DTB).
- **CRC**—There is a CRC value for the entire image. The CRC consists of data located from address 0xFFFE0000 to 0xFFFE0000+(Image Length)–0x0004. The polynomial used to validate the image is:

  $$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

  There is no reflection of the bits. The initial value of the remainder is 0xFFFFFFFF and the final value is XORed with 0xFFFFFFFF.

FPGA Configuration

You can configure the FPGA portion of the SoC device with non-HPS sources or by utilizing the HPS.

When the HPS handles the initial FPGA configuration, software executing on the HPS writes the configuration image to the FPGA Manager in the HPS. Software can control the configuration process and monitor the FPGA status by accessing the control and status register (CSR) interface in the FPGA Manager.

For the HPS to configure the FPGA, the mode select (MSEL) pins must be set to passive mode (fast or slow). The following table shows the pin encodings for MSEL[2:0] that are available to the HPS. Refer to the *Configuration, Design Security, and Remote System Upgrades in Arria 10 Devices* document for a comprehensive list of MSEL encodings.

Table A-16: MSEL Pin Settings Options for FPGA Configuration through HPS

Configuration Scheme allowed through HPS	Power-On Reset (POR) Delay	Valid MSEL[2:0]
FPP (x16, and x32)	Fast	000
	Standard	001

Note: You must also select the configuration scheme in the **Configuration** page of the **Device and Pin Options** dialog box in the Quartus Prime software. Based on your selection, the option bit in the programming file is set accordingly.

There are two types of initial FPGA configuration flows you can choose from when using the HPS to configure the FPGA.

- Full FPGA configuration flow: In this flow, the FPGA fabric, the shared I/O and hard memory controller I/O are configured. After full configuration is complete, the hard memory controller I/O, shared I/O and FPGA I/O are available to the HPS.
- Early I/O release configuration flow: In this flow, all I/O are configured and the HPS shared I/O and hard memory controller I/O are released so that the HPS has immediate access to them. At a later time, the FPGA fabric is configured and the FPGA I/O are released and available to the user design.

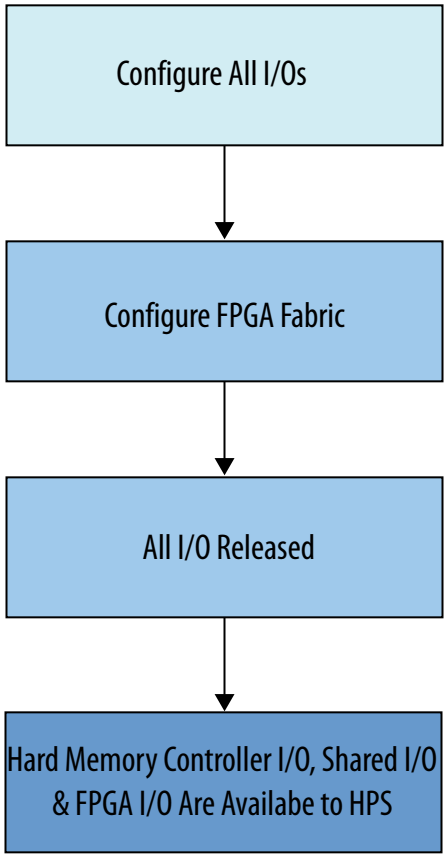
Related Information

- **FPGA Manager** on page 4-1
  For more information regarding programming the FPGA through the HPS, refer to the *FPGA Manager* chapter.
- **Configuration, Design Security, and Remote System Upgrades in Arria 10 Devices**

Full FPGA Configuration Flow Through HPS

Figure A-20: Full FPGA Configuration Flow Through HPS

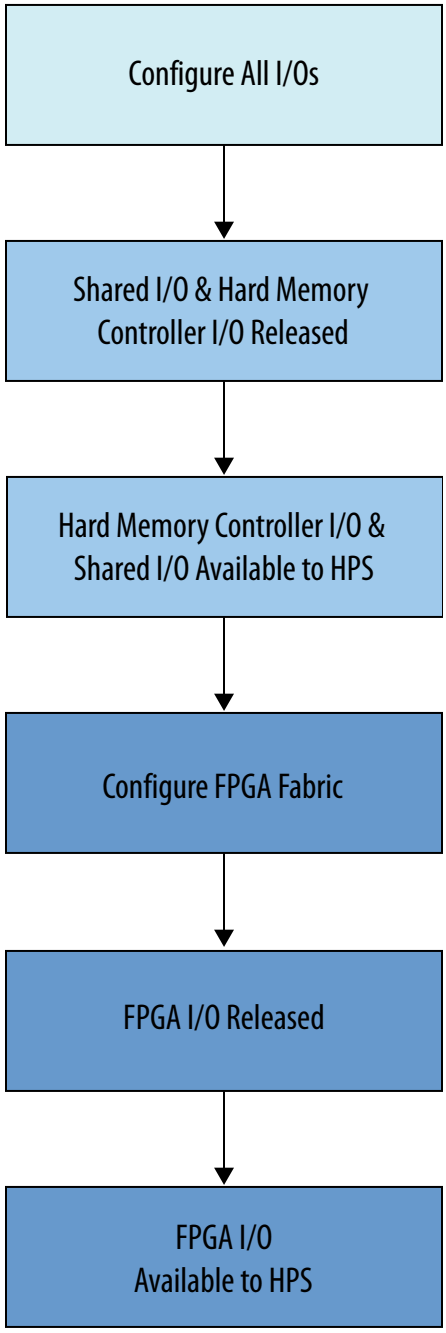
The FPGA fabric and the all I/Os are configured first and then all the I/O are released for use by the HPS.



Early I/O Release FPGA Configuration Flow Through HPS

Figure A-21: Early I/O Release FPGA Configuration Flow Through HPS

The I/Os are configured and the shared and hard memory controller I/Os are released so that the HPS has immediate access to them. The FPGA fabric configuration follows at a later time.

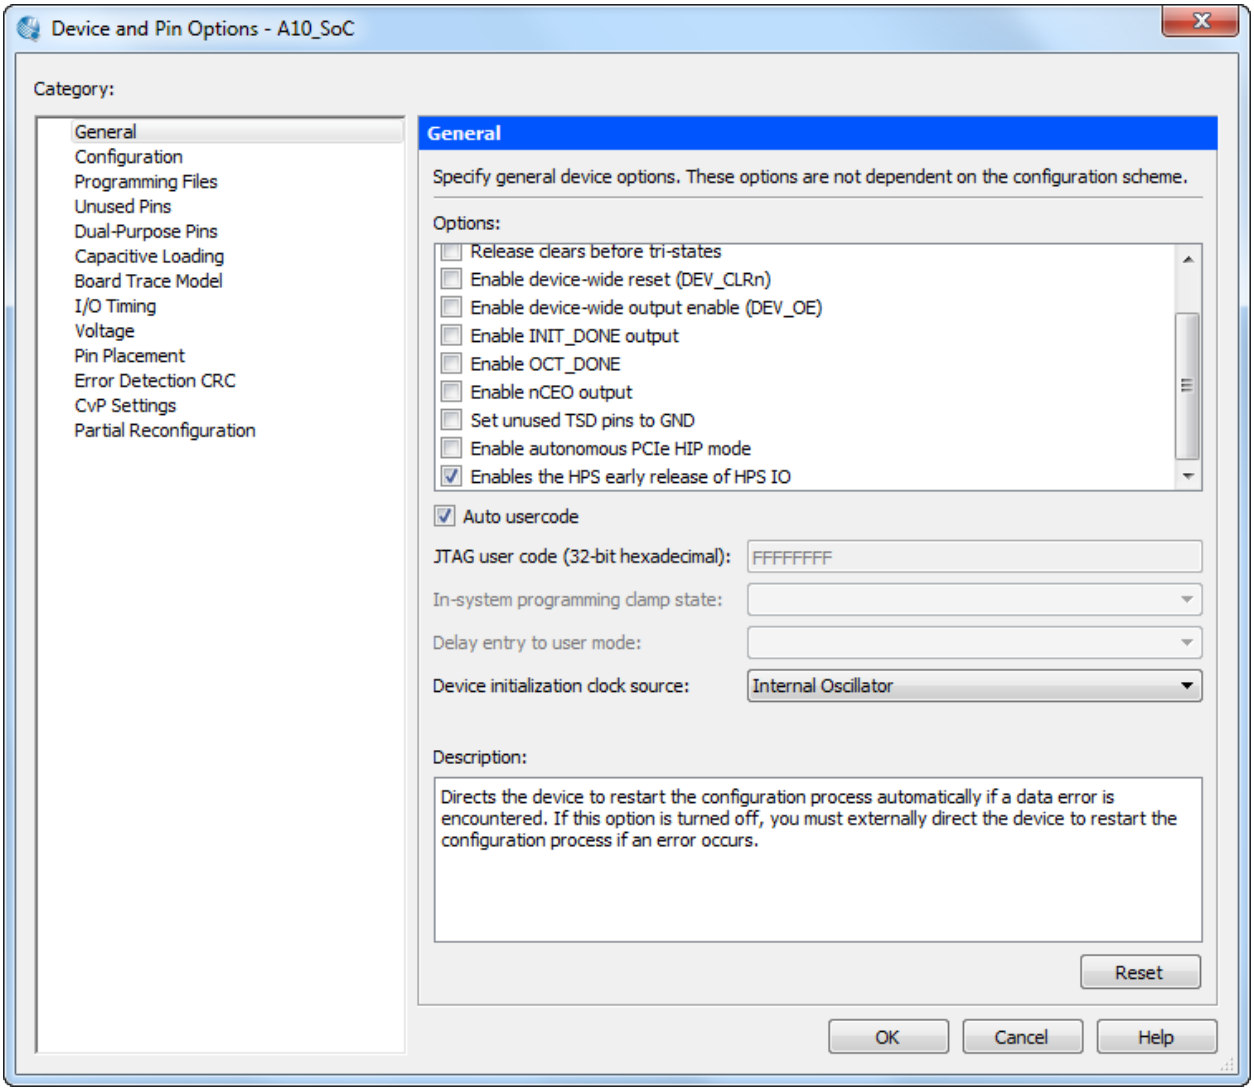


Note: The FPGA fabric is not required to be programmed immediately after the first I/O configuration. You can also program the I/Os, re-program the I/Os and then program the FPGA fabric as long as the early I/O release configuration option is enabled in each I/O configuration file.

You can enable early I/O configuration in Quartus Prime:

1. Click on the the **Assignments** menu and select **Device**.
2. When the **Device settings** window opens, click the **Device and Pin Options** button.
3. In the **General** category, click on the option labeled "Enables the HPS early release of HPS IO".

Figure A-22: Quartus Prime Early I/O Release Setting



Handling an FPGA Configuration Failure after Early I/O Release

If an FPGA configuration failure occurs after early I/O release, the HPS shared I/O and hard memory controller I/O enter input tri-state mode. In this situation, any accesses to peripherals or memory interfacing these I/O will fail. HPS dedicated I/O are not affected by FPGA configuration failures.

If you are using early I/O release and issuing an HPS-initiated FPGA configuration afterward, you must ensure that your software routine includes a way to avoid FPGA configuration failure or a recovery mechanism that does not rely on the HPS shared I/O or hard memory controller I/O.

You must implement one of the following solutions in software.

- To prevent FPGA configuration failure, load the FPGA core configuration file into SDRAM and perform an FPGA integrity check before initiating configuration. For example, you can run a custom integrity check, such as a CRC, on the `.rbf` file to validate that there are no errors in the file. Altera also recommends that you enable ECC capabilities to avoid bit-stream corruption issues.
- To recover from an FPGA configuration failure, execute the HPS-initiated configuration from on-chip RAM. If the HPS is executing entirely from on-chip RAM, you can recover your application by reconfiguring the peripheral `.rbf` file to reenable the HPS shared I/O and hard memory controller I/O. After these I/O are recovered, your application can either attempt to configure the same FPGA image that caused the original failure or use a fallback core `.rbf` file to prevent the same failure from occurring repeatedly.

Note: If you are using full FPGA configuration, you do not need to make any of the adjustments listed above. For full FPGA configuration, the .rbf file contains both the core and peripheral configuration and your application can only access the HPS I/O after the device is successfully configured.

Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager

The FPGA Manager in the HPS has the capability to execute an initial FPGA configuration using the full or early I/O release flow.

The steps below detail the programming of the FPGA Manager to initiate configuration.

1. Read the `f2s_msel[2:0]` field in the `imgcfg_stat` register to verify that the configuration mode is the passive fast (000) or passive slow (001).
2. Write the `cfgwidth` bit of the `imgcfg_ctrl_02` register in the FPGA manager to match the characteristics of the configuration image. For full, standard configuration, the `cfgwidth` bit must be set to 1. You can only initiate a full, standard configuration in 32-bit passive parallel mode.
3. Configure the `cdratio` field. The `cdratio` is a function of the datawidth and whether the POF in encrypted or compressed. This information should be provided through the Quartus Prime configuration. For example,if `cfgwidth` is 32-bits and the POF is compressed, you must program the `cdratio` field to 0x8. If the POF is encrypted, then program the `cdratio` to 0x4.
4. Ensure there are no other external devices interfering with the FPGA programming. Poll the `f2s_nconfig_pin` and `f2s_nstatus_pin` bits from the `imgcfg_stat` register until they are both 1.
5. Program the following bits to deassert signal drives from the HPS before overriding the signals.
   - `s2f_nce` =1 in the `imgcfg_ctrl_01` register
   - `s2f_pr_request`= 0 in the `imgcfg_ctrl_01` register
   - `en_cfg_ctrl`= 0 in the `imgcfg_ctrl_02` register
   - `s2_nconfig` = 1 in the `imgcfg_ctrl_00` register
   - `s2f_nstatus_oe` = 0 in the `imgcfg_ctrl_00` register
   - `s2f_condone_oe` = 0 `imgcfg_ctrl_00` register
6. Enable overrides for the `DATA`, `DCLK`, `nCE`, `PR_REQUEST` and `nCONFIG` signals.
   - `s2f_nenable_config` = 0 in the `imgcfg_ctrl_01` register
   - `s2f_nenable_nconfig` = 0 in the `imgcfg_ctrl_00` register
7. Disable overrides for the `nSTATUS` and `CONF_DONE` signals.

- s2f_nenable_nstatus = 1 in the imgcfg_ctrl_00 register
- s2f_nenable_condone = 1 in the imgcfg_ctrl_00 register

8. Assert the chip select signal.
   - s2f_nce=0 in the imgcfg_ctrl_01 register
9. Repeat step 4. Ensure there are no other external devices interfering with the FPGA programming. Poll the f2s_nconfig_pin and f2s_nstatus_pin bits from the imgcfg_stat register until they are both 1.
10. Reset the configuration.
    a. Write a 0 to the s2f_nconfig bit in the imgcfg_ctrl_00 register.
    b. Poll the f2s_nstatus_pin bit in the imgcfg_stat register until it is clear.
    c. Write a 1 to the s2f_nconfig bit in the imgcfg_ctrl_00 register.
    d. Poll the f2s_nstatus_pin bit in the imgcfg_stat register until it is set. In addition, read and confirm the f2s_condone_pin is clear and the f2s_condone_oe is set in the imgcfg_stat register.
11. Enable DCLK and the DATA path by setting the en_cfg_ctrl bit in the imgcfg_ctrl_02 register.
12. Write the bitstream data to the img_data_w register. When sending the bitstream data, you can periodically read and confirm that the f2s_nstatus_pin bit is set in the imgcfg_stat register. If it is not set, configuration has failed and you must restart with step 1.
13. When you have completed writing the data, continuously poll the f2s_condone_pin bit in the imgcfg_stat register until it reads as 1. When this bit is 1, it indicates configuration has completed. If the routine times out with f2s_nstatus_pin=0, configuration has failed and you must restart from step 1.
14. Write the dclkcnt register with 0xF and continuously poll until the dclkcntstat register reads as 0x0. A minimum of 2 DCLK cycles are needed after the CONFIG_DONE assertion for initialization to start.
15. Wait for the initialization sequence to complete. Poll the f2s_usermode bit in the imgcfg_stat register until it reads as 1.
16. Disable the DATA path and DCLK by clearing the en_cfg_ctrl bit in the imgcfg_ctrl_02 register.
17. Disable the chip select. Set the s2f_nce bit in the imgcfg_ctrl_01 register.
18. Disable overrides to the nCONFIG, DATA and DCLK signals.
    - s2f_nenable_config=1
    - s2f_nenable_nconfig=1
19. Check that user mode is enabled and the configuration is done by checking that the bits below have the following values:
    - f2s_usermode=1 in the imgcfg_stat register
    - f2s_nstatus_pin=1 in the imgcfg_stat register
    - f2s_condone_pin=1 in the imgcfg_stat register

FPGA Reconfiguration

The FPGA Manager also supports FPGA reconfiguration through two methods: full or partial reconfiguration.

Full FPGA Reconfiguration

A full FPGA reconfiguration requires a system reboot. The following table details the supported reconfiguration options:

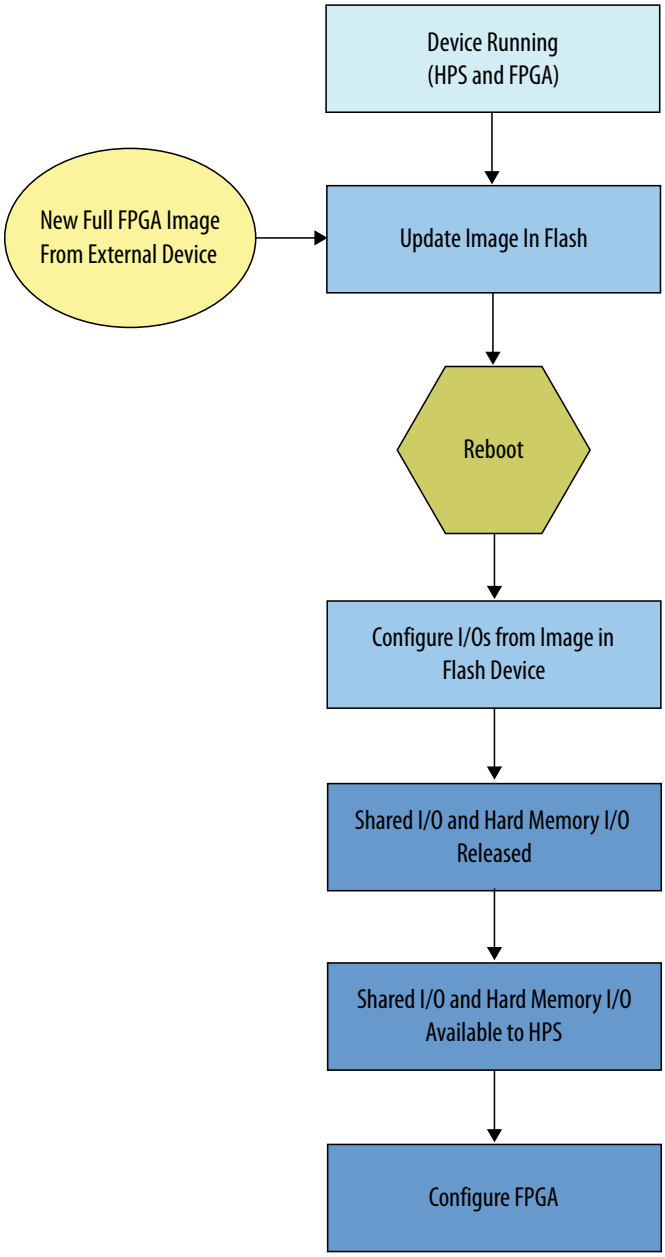
Table A-17: Supported Reconfiguration Options

Reconfiguration Option	Configuration Method	HPS Reboot Required
FPGA Core Only	Partial Reconfiguration	No
FPGA and/or HPS Shared I/O[64]	Full Reconfiguration	Yes
FPGA Core + FPGA I/O + HPS Shared I/O[64]	Full Reconfiguration	Yes

If a new FPGA fabric image is required and performing a system reboot is acceptable, then you can update the FPGA image in flash and perform a full system reboot of both hardware and software before following the steps found in the "Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager."

[64] HPS dedicated I/O are not affected by full reconfiguration.

Figure A-23: Full FPGA Fabric Reconfiguration with System Reboot



If a new FPGA fabric image is required and performing a system reboot is unacceptable because the hard memory controller or shared I/O are being used by the HPS, then you can perform a reconfiguration using the available partial reconfiguration support. For the partial reconfiguration sequence, follow the steps found in the "Arria 10 SoC FPGA Partial Reconfiguration Sequence Through FPGA Manager" section.

Figure A-24: Full FPGA Fabric Reconfiguration without System Reboot

Arria 10 SoC FPGA Partial Reconfiguration Sequence Through FPGA Manager

Partial reconfiguration allows you to reconfigure part of the device while other sections remain running. This implementation divides the design in to a static region and a partial reconfiguration region.

- Static Region: Comprised of hard memory controller I/O, shared I/O, FPGA I/O and a portion of your FPGA design
- Dynamic Region: Remaining portion of FPGA design

The HPS performs partial reconfiguration while the FPGA portion of the device is in user mode. The following sequence suggests one way for software to perform a partial configuration:

- If the `f2s_pr_ready` bit in the `imgcfg_stat` register of the FPGA Manager is set, continue to step 7.
- If `f2s_pr_ready` bit in the `imgcfg_stat` register of the FPGA Manager is clear, then go back and repeat step 5. Note that a minimum of 16 `DCLK` pulses are required.

If an HPS warm reset occurs in the middle of a partial reconfiguration, software must repeat the steps for partial configuration. After an HPS cold reset, software must repeat the steps for **Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager** on page 30-50.

1. Read the `f2s_usermode` bit of the `imgcfg_stat` register in FPGA Manager to ensure that the FPGA is in user mode.
2. Read the `f2s_msel[2:0]` field in the `imgcfg_stat` register to verify that the configuration mode is the passive fast (000) or passive slow (001). The FPGA manager only supports passive parallel programming.
3. Set the `cdratio` bit of the `imgcfg_ctrl_02` register to match the characteristics of the partial reconfiguration image and configure the `cfgwidth` bit of the `imgcfg_ctrl_02` register to 0. Partial reconfiguration only supports 16-bit passive parallel programming.
4. Prepare for partial reconfiguration. Set the `en_cfg_ctrl` bit of the `imgcfg_ctrl_02` register to give the FPGA manager control of the configuration input signals.
   a. Read and confirm that `s2f_pr_request=0` in the `imgcfg_ctrl_01` register and `s2f_nconfig=1` in the `imgcfg_ctrl_00` register.
   b. Drive the chip select signal by clearing the s2f_nce bit in the `imgcfg_ctrl_01` register.
   c. Enable overrides for configuration data and control by setting the `en_cfg_ctrl` bit in the `imgcfg_ctrl_02` to 1.
   d. Disable overrides that are not used for partial reconfiguration by programming the following bits in the `imgcfg_ctrl_00` register:
      - `s2f_condone_oe` = 0
      - `s2f_nstatus_oe` = 0
      - `s2_nconfig` = 1
      - `s2f_nenable_condone` = 1
      - `s2f_nenable_nstatus` = 1
      - `s2f_nenable_nconfig` = 0
5. Enable HPS to override the `DATA`, `DCLK`, `nCE` and `PR_REQUEST` signals to the CSS by clearing the `s2f_nenable_config` bit in the `imgcfg_ctrl_01` register.
6. Run `DCLK` to clear any errors. Write a value of 0x100 to the `dclkcnt` register to generate 256 `DCLK` cycles. Poll the `dclkstat` register until `dcntdone=1`. You must implement a timeout in your software loop that either exits with an error or restarts at step 1 if `dcntdone` is not set after a period of time.
7. Initiate a partial reconfiguration request.
   a. Set the `s2f_pr_request` bit of the `imgcfg_ctrl_01` register to assert `PR_REQUEST`
   b. Write 0x7FF to the `dclkcnt` register.
   c. Poll the `dclkstat` register until `dcntdone=1` .Again, you must implement a timeout in your software loop that either exits with an error or restarts at step 1 if `dcntdone` is not set after a period of time.
8. Poll the `f2s_pr_ready` bit and the `f2s_pr_error` bit in the `imgcfg_stat` register. When `f2s_pr_ready=1`, the `PR_READY` signal is asserted. Alternately, the FPGA Manager can be configured to generate an interrupt when the `PR_READY` signal is asserted. If `f2s_pr_error=1`, you cannot continue with partial reconfiguration because security is preventing the software from updating the configuration. Altera recommends that your software routine implement an exit with a timeout error when `f2s_pr_ready` and `f2s_pr_error` continue to read as 0 after ten register reads.

9. When the PR_READY signal is asserted, write the partial reconfiguration image to the img_data_w register in the FPGA Manager. You can also choose to use a DMA to transfer the configuration image from a peripheral device to the FPGA manager.
10. Poll the imgcfg_stat register to observe the f2s_pr_done and f2s_pr_error bits. When the f2s_pr_done bit is set, partial FPGA reconfiguration is complete. If f2s_pr_done or f2s_pr_error is not set to 1 after reading the imgcfg_stat register ten times, generate a timeout error and continue on to the next step.
11. Clear the s2f_pr_request bit of the imgcfg_ctrl_01 register to deassert PR_REQUEST.
12. Poll the dcntdone bit of the dclkstat register until it reads as 1, which indicates that all the DCLKs have been sent.
13. Write a 1 to the dcntdone bit of the dclkstat register to clear the completed status flag.
14. Disable the DATA path and DCLK by clearing the en_cfg_ctrl bit of the imgcfg_ctrl_02 register.
15. Disable the chip select. Set the s2f_nce bit in the imgcfg_ctrl_01 register.
16. Disable overrides to the nCONFIG, DATA and DCLK signals by setting the s2f_nenable_config in the imgcfg_ctrl_01 register.
17. Check that user mode is enabled and the configuration is done by checking that the bits below have the following values:
    - f2s_usermode=1 in the imgcfg_stat register
    - f2s_nstatus_pin=1 in the imgcfg_stat register
    - f2s_condone_pin=1 in the imgcfg_stat register

Document Revision History

Table A-18: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Modified the "Remapping the On-Chip RAM" diagram in the "Typical Boot Flow (Non-secure)" section
May 2016	2016.05.27	• Added *Handling an FPGA Configuration Failure after Early I/O Release* section. • Updated "Second-stage Boot Loader Image Layout" figure in the *Loading the Second-Stage Boot Loader Image* section. • Changed the name of the internal QSPI reference clock from qspi_clk to qspi_ref_clk; and the external QSPI output clock, from sclk_out to qspi_clk.

Date	Version	Changes
May 2016	2016.05.03	• Updated SD/MMC device clock values in the *CSEL Settings for SD/MMC Controller* section. • Updated configuration sequence steps in the *Arria 10 SoC FPGA Configuration Sequence Through FPGA Manager* section. • Updated the reconfiguration sequence steps in the *Arria 10 SoC FPGA Partial Reconfiguration Sequence Through FPGA Manager* section. • Added bus mode to the "SD/MMC Controller Default Settings" table in the *Default Settings of the SD/MMC Controller* section.
December 2015	2015.12.11	Updated the Full FPGA Reconfiguration section with the supported reconfiguration options.
November 2015	2015.11.02	Added Quartus Prime setting information to "Early I/O Release FPGA Configuration Through HPS" section
June 2015	2015.06.12	• Updated "Typical Second-Stage Loader Flow (Non-Secure)" figure in "Typical Boot Flow (Non-Secure)" section • Added content to "FPGA Overview" • Described I/O types and added details to booting option figures in "Booting and Configuration Options" • Added table to "Boot Fuses" section • Updated the CSEL setting tables in the "CSEL Settings for NAND Controller" section • Updated the "Quad SPI Controller Default Settings" table in the "Quad SPI Controller Default Settings" section • Updated the CSEL setting tables in the "Quad SPI Controller CSEL settings" section • Updated "Low-Level Boot Flow" figure in the "Typical Boot Flow (Non-Secure)" section • Added content regarding configuration flows in "FPGA Configuration" section • Added "Full FPGA Configuration Flow Through HPS" section • Added "Early I/O Release FPGA Configuration Flow Through HPS" section • Added "FPGA Reconfiguration" section with "Full FPGA Reconfiguration Section"

Date	Version	Changes
May 2015	2015.05.04	• Added more detail in the "FPGA Configures First" table of the "Booting and Configuration Options" section. • Added alternate "Boot Source Mux Selects" table in "Boot Source I/O Pins" section and "I/O Configuration" section. • Added more detail regarding booting from FPGA in the "Boot Select" section. • Added note in the "Boot ROM Flow" section about caches being enabled by the Boot ROM.

December 2014	2014.12.15	• Removed "Boot Stages" section.
		• The following sections were added:
		  • "Boot ROM Flow"
		  • "Typical Second-Stage Boot Flow"
		  • "HPS State on Entry to the Preloader"
		  • "Loading the Second-Stage Boot Image"
		  • "FPGA Configuration" section with "Arria 10 SoC FPGA Full Configuration" and "Arria 10 SoC FPGA Partial Reconfiguration"
		• In the "Boot Definitions" section, "Boot Source I/O Pins", "Boot Fuses", and "Flash Memory Device" subsections were added.

August 2014	2014.08.18	Initial release
