Contents

Introduction to the Hard Processor System..... 1-1
Features of the HPS..... 1-3
HPS Block Diagram and System Integration..... 1-5
HPS Block Diagram..... 1-5
Cortex-A9 MPCore..... 1-6
HPS Interfaces..... 1-6
System Interconnect..... 1-7
On-Chip Memory..... 1-8
Flash Memory Controllers..... 1-9
Support Peripherals..... 1-10
Interface Peripherals..... 1-13
CoreSight Debug and Trace..... 1-16
Hard Processor System I/O Pin Multiplexing..... 1-16
Endian Support..... 1-16
Introduction to the Hard Processor System Address Map..... 1-17
HPS Address Spaces..... 1-17
HPS Peripheral Region Address Map..... 1-20
Document Revision History..... 1-23

Clock Manager..... 2-1
Features of the Clock Manager..... 2-1
Clock Manager Block Diagram and System Integration..... 2-3
L4 Peripheral Clocks..... 2-5
Boot Clock..... 2-6
Functional Description of the Clock Manager..... 2-7
Clock Manager Building Blocks..... 2-7
PLL Integration..... 2-9
Hardware-Managed and Software-Managed Clocks..... 2-11
Hardware Sequenced Clock Groups..... 2-11
Software Sequenced Clocks..... 2-14
Resets..... 2-16
Security..... 2-17
Interrupts..... 2-18
Clock Manager Address Map and Register Definitions..... 2-18
clkmgr_clkmgrp Address Map..... 2-18
clkmgr_mainpllgrp Address Map..... 2-39
clkmgr_perpllgrp Address Map..... 2-67
clkmgr_alteragrp Address Map..... 2-96
Document Revision History..... 2-99

Reset Manager..... 3-1

Reset Manager Block Diagram and System Integration..... 3-3
Reset Controller.....3-4
Security Reset Functions..... 3-8
Module Reset Signals..... 3-8
Slave Interface and Status Register..... 3-14
Functional Description of the Reset Manager..... 3-15
Reset Sequencing.....3-16
Reset Pins..... 3-20
Reset Effects..... 3-21
Reset Handshaking..... 3-21
Reset Manager Address Map and Register Definitions.....3-21
rst_mgr Address Map..... 3-21
Document Revision History.....3-73

FPGA Manager..... 4-1
Features of the FPGA Manager..... 4-1
FPGA Manager Block Diagram and System Integration.....4-2
Functional Description of the FPGA Manager..... 4-3
FPGA Configuration..... 4-3
FPGA Status.....4-4
Error Message Extraction.....4-4
Data AES Decryption..... 4-4
Boot Handshake..... 4-4
General Purpose I/O.....4-5
Clock..... 4-5
Reset..... 4-5
FPGA Manager Address Map and Register Definitions..... 4-5
fpga_mgr_fpgamgrdata Address Map.....4-6
fpga_mgr_fpgamgrregs Address Map..... 4-7
Document Revision History.....4-49

System Manager.....5-1
Features of the System Manager.....5-1
System Manager Block Diagram and System Integration..... 5-2
Functional Description of the System Manager.....5-3
Boot Configuration and System Information..... 5-3
Additional Module Control..... 5-3
Boot ROM Code.....5-6
FPGA Interface Enables..... 5-7
ECC and Parity Control..... 5-8
Preloader Handoff Information..... 5-8
Clocks..... 5-8
Resets..... 5-8
System Manager Address Map and Register Definitions.....5-9
sys_mgr_core Address Map.....5-9
sys_mgr_rom Address Map.....5-90
Document Revision History.....5-107

SoC Security....6-1
Security Manager....6-2
Security Manager Block Diagram....6-3
Functional Overview....6-4
Functional Description....6-4
Security System Extensions....6-21
TrustZone....6-21
Arria 10 HPS Secure Firewalls....6-24
Revision History....6-37

System Interconnect....7-1
About the System Interconnect....7-2
Features of the System Interconnect....7-2
System Interconnect Block Diagram and System Integration....7-2
Arria 10 HPS Secure Firewalls....7-7
About the Rate Adapters....7-8
About the SDRAM L3 Interconnect....7-8
About Quality of Service and Arbitration....7-11
About the Service Network....7-11
About the Observation Network....7-11
Functional Description of the System Interconnect....7-12
System Interconnect Address Spaces....7-13
Secure Transaction Protection....7-20
System Interconnect Master Properties....7-20
System Interconnect Slave Properties....7-22
System Interconnect Clocks....7-24
System Interconnect Resets....7-26
Functional Description of the Rate Adapters....7-26
Functional Description of the Firewalls....7-27
Functional Description of the SDRAM L3 Interconnect....7-28
Functional Description of the QoS Generators....7-34
Functional Description of the Arbitration Logic....7-39
Functional Description of the Observation Network....7-40
Configuring the System Interconnect....7-42
Configuring the Rate Adapters....7-42
Configuring the SDRAM Scheduler....7-42
Configuring the Hard Memory Controller....7-43
System Interconnect Address Map and Register Definitions....7-45
io48_hmc_mmr Address Map....7-45
ecc_hmc_ocp_slv_block Address Map....7-126
noc_l4_priv_l4_priv_filter Address Map....7-189
noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter Address Map....7-203
noc_mpu_m0_MPU_M0_rate_adResp_main_RateAdapter Address Map....7-208
noc_mpu_m0_L4_MP_rate_ad_main_RateAdapter Address Map....7-213
noc_mpu_m0_fpga2soc_rate_ad_main_RateAdapter Address Map....7-218
noc_mpu_m0_L3Tosoc2fpgaResp_main_RateAdapter Address Map....7-223

noc_mpu_m0_acp_rate_ad_main_RateAdapter Address Map 7-228
noc_mpu_m0_ddr_T_main_Probe Address Map 7-233
noc_mpu_m0_ddr_T_main_Scheduler Address Map 7-302
noc_fw_l4_per_l4_per_scr Address Map 7-312
noc_fw_l4_sys_l4_sys_scr Address Map 7-357
noc_fw_ocram_ocram_scr Address Map 7-411
noc_fw_ddr_mpu_fpga2sdram_ddr_scr Address Map 7-423
noc_fw_ddr_l3_ddr_scr Address Map 7-449
noc_fw_soc2fpga_soc2fpga_scr Address Map 7-464
noc_mpu_m0_Probe_SoC2FPGA_main_Probe Address Map 7-470
noc_mpu_m0_Probe_emacs_main_Probe Address Map 7-530
noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler Address Map 7-590
noc_mpu_m0_cs_obs_at_main_AtbEndPoint Address Map 7-603
noc_mpu_m0_cs_obs_at_main_ErrorLogger_0 Address Map 7-608
noc_mpu_m0_Probe_MPU_main_Probe Address Map 7-619
noc_mpu_m0_I_main_QosGenerator Address Map 7-663
noc_mpu_m1_I_main_QosGenerator Address Map 7-672
noc_mpu_fpga2soc_axi32_I_main_QosGenerator Address Map 7-681
noc_mpu_fpga2soc_axi64_I_main_QosGenerator Address Map 7-690
noc_mpu_fpga2soc_axi128_I_main_QosGenerator Address Map 7-699
noc_mpu_dma_I_main_QosGenerator Address Map 7-708
noc_mpu_emac0_m_I_main_QosGenerator Address Map 7-717
noc_mpu_emac1_m_I_main_QosGenerator Address Map 7-726
noc_mpu_emac2_m_I_main_QosGenerator Address Map 7-735
noc_mpu_usb0_m_I_main_QosGenerator Address Map 7-744
noc_mpu_usb1_m_I_main_QosGenerator Address Map 7-753
noc_mpu_nand_m_I_main_QosGenerator Address Map 7-762
noc_mpu_sdmmc_m_I_main_QosGenerator Address Map 7-771
noc_mpu_fpga2sdram0_axi32_I_main_QosGenerator Address Map 7-780
noc_mpu_fpga2sdram0_axi64_I_main_QosGenerator Address Map 7-789
noc_mpu_fpga2sdram0_axi128_I_main_QosGenerator Address Map 7-798
noc_mpu_fpga2sdram1_axi32_I_main_QosGenerator Address Map 7-807
noc_mpu_fpga2sdram1_axi64_I_main_QosGenerator Address Map 7-816
noc_mpu_fpga2sdram2_axi32_I_main_QosGenerator Address Map 7-825
noc_mpu_fpga2sdram2_axi64_I_main_QosGenerator Address Map 7-834
noc_mpu_fpga2sdram2_axi128_I_main_QosGenerator Address Map 7-843
noc_mpu_emac0_m_I_main_TransactionStatFilter Address Map 7-852
Document Revision History 7-864

HPS-FPGA Bridges 8-1
Features of the HPS-FPGA Bridges 8-1
Arria 10 HPS-FPGA Bridges Block Diagram and System Integration 8-3
Functional Description of the HPS-FPGA Bridges 8-3
Functional Description of the FPGA-to-HPS Bridge 8-3
Functional Description of the HPS-to-FPGA Bridge 8-7
Functional Description of the Lightweight HPS-to-FPGA Bridge 8-10
Clocks and Resets 8-14
Data Width Sizing 8-15

Ready Latency Support....8-15
HPS-FPGA Bridges Address Map and Register Definitions for Arria 10....8-15
fpga_bridge_soc2fpga128 Address Map....8-15
fpga_bridge_lwsoc2fpga Address Map....8-16
Document Revision History....8-16

Cortex-A9 Microprocessor Unit Subsystem....9-1
Features of the Cortex-A9 MPU Subsystem....9-1
Cortex-A9 MPU Subsystem Block Diagram and System Integration....9-2
Cortex-A9 MPU Subsystem with System Interconnect....9-2
Cortex-A9 MPU Subsystem Internals....9-3
Cortex-A9 MPCore....9-4
Functional Description....9-4
Implementation Details....9-5
Cortex-A9 Processor....9-6
Interactive Debugging Features....9-7
L1 Caches....9-7
Preload Engine....9-7
Floating Point Unit....9-8
NEON Multimedia Processing Engine....9-9
Memory Management Unit....9-10
Performance Monitoring Unit....9-12
ARM Cortex-A9 MPCore Timers....9-12
Generic Interrupt Controller....9-13
Global Timer....9-27
Snoop Control Unit....9-28
Accelerator Coherency Port....9-29
L2 Cache....9-34
Functional Description....9-34
CPU Prefetch....9-41
TrustZone....9-41
Secure Partitioning....9-42
Virtual Processor Operation....9-43
Secure Debug....9-44
Debugging Modules....9-44
Program Trace....9-44
Event Trace....9-45
Cross-Triggering....9-46
Clocks....9-46
Cortex-A9 MPU Subsystem Register Implementation....9-46
Cortex-A9 MPU Subsystem Address Map for Arria 10....9-47
L2 Cache Controller Address Map for Arria 10....9-48
Document Revision History....9-50

CoreSight Debug and Trace....10-1
Features of CoreSight Debug and Trace....10-2
ARM CoreSight Documentation....10-2

CoreSight Debug and Trace Block Diagram and System Integration....10-3
Functional Description of CoreSight Debug and Trace....10-4
Debug Access Port....10-4
System Trace Macrocell....10-5
Trace Funnel....10-5
CoreSight Trace Memory Controller....10-6
AMBA Trace Bus Replicator....10-7
Trace Port Interface Unit....10-7
Embedded Cross Trigger System....10-7
Program Trace Macrocell....10-12
HPS Debug APB Interface....10-12
FPGA Interface....10-12
Debug Clocks....10-16
Debug Resets....10-17
CoreSight Debug and Trace Programming Model....10-18
Coresight Component Address....10-18
STM Channels....10-19
CTI Trigger Connections to Outside the Debug System....10-21
Configuring Embedded Cross-Trigger Connections....10-22
CoreSight Debug and Trace Address Map and Register Definitions....10-24
Document Revision History....10-24

Error Checking and Correction Controller....11-1
ECC Controller Features....11-1
ECC Supported Memories....11-1
ECC Controller Block Diagram and System Integration....11-2
ECC Controller Functional Description....11-3
Overview....11-3
ECC Structure....11-3
Memory Data Initialization....11-5
Indirect Memory Access....11-6
Error Logging....11-11
ECC Controller Interrupts....11-13
ECC Controller Initialization and Configuration....11-16
ECC Controller Clocks....11-17
ECC Controller Reset....11-18
ECC Controller Address Map and Register Descriptions....11-18
emac_rx_ecc Address Map....11-18
emac_tx_ecc Address Map....11-63
nandecc_ecc Address Map....11-108
nandr_ecc Address Map....11-140
nandw_ecc Address Map....11-173
sdmmc_ecc Address Map....11-205
onchip_ram_ecc Address Map....11-241
dmac_ecc Address Map....11-274
qspi_ecc Address Map....11-306
usb_ecc Address Map....11-339
Revision History....11-377

On-Chip Memory..... 12-1
On-Chip RAM.....12-1
Features of the On-Chip RAM.....12-1
On-Chip RAM Block Diagram and System Integration.....12-2
Functional Description of the On-Chip RAM.....12-2
Boot ROM.....12-4
Features of the Boot ROM.....12-4
Boot ROM Block Diagram and System Integration.....12-5
Functional Description of the Boot ROM.....12-5
On-Chip Memory Address Map and Register Definitions.....12-6
onchip_ram_ecc Address Map.....12-6
ram_onchip_ram_block Address Map.....12-39
rom_onchip_rom_block Address Map.....12-39
Document Revision History.....12-39

NAND Flash Controller..... 13-1
NAND Flash Controller Features.....13-1
NAND Flash Controller Block Diagram and System Integration.....13-2
NAND Flash Controller Signal Descriptions.....13-2
Functional Description of the NAND Flash Controller.....13-4
Discovery and Initialization.....13-4
Bootstrap Interface.....13-5
Configuration by Host.....13-5
Local Memory Buffer.....13-6
Clocks.....13-7
Resets.....13-7
Indexed Addressing.....13-8
Command Mapping.....13-9
Data DMA.....13-14
ECC.....13-18
NAND Flash Controller Programming Model.....13-21
Basic Flash Programming.....13-22
Flash-Related Special Function Operations.....13-25
NAND Flash Controller Address Map and Register Definitions.....13-33
nandecc_ecc Address Map.....13-33
nandr_ecc Address Map.....13-66
nandw_ecc Address Map.....13-98
nand_config Address Map.....13-131
nand_param Address Map.....13-190
nand_status Address Map.....13-212
nand_ecc Address Map.....13-252
nand_dma Address Map.....13-256
nand_NANDDATA Address Map.....13-276
Document Revision History.....13-276

SD/MMC Controller.....14-1
Features of the SD/MMC Controller.....14-1
SD Card Support Matrix.....14-3
MMC Support Matrix.....14-3
SD/MMC Controller Block Diagram and System Integration.....14-4
SD/MMC Controller Signal Description.....14-4
Functional Description of the SD/MMC Controller.....14-5
SD/MMC/CE-ATA Protocol.....14-5
BIU.....14-6
CIU.....14-20
Clocks.....14-35
Resets.....14-36
Voltage Switching.....14-37
SD/MMC Controller Programming Model.....14-39
Software and Hardware Restrictions†.....14-39
Initialization†.....14-41
Controller/DMA/FIFO Buffer Reset Usage.....14-47
Non-Data Transfer Commands.....14-47
Data Transfer Commands.....14-49
Transfer Stop and Abort Commands.....14-56
Internal DMA Controller Operations.....14-57
Commands for SDIO Card Devices.....14-59
CE-ATA Data Transfer Commands.....14-62
Card Read Threshold.....14-69
Interrupt and Error Handling.....14-72
Booting Operation for eMMC and MMC.....14-74
SD/MMC Controller Address Map and Register Definitions.....14-84
sdmmc Address Map.....14-84
sdmmc_ecc Address Map.....14-180
Document Revision History.....14-216

Quad SPI Flash Controller.....15-1
Features of the Quad SPI Flash Controller.....15-1
Quad SPI Flash Controller Block Diagram and System Integration.....15-2
Quad SPI Flash Controller Signal Description.....15-3
Functional Description of the Quad SPI Flash Controller.....15-4
Overview.....15-4
Data Slave Interface.....15-4
SPI Legacy Mode.....15-8
Register Slave Interface.....15-8
Local Memory Buffer.....15-9
DMA Peripheral Request Controller.....15-10
Arbitration between Direct/Indirect Access Controller and STIG.....15-11
Configuring the Flash Device.....15-11
XIP Mode.....15-13
Write Protection.....15-13

Data Slave Sequential Access Detection 15-13
Clocks 15-13
Resets 15-14
Interrupts 15-14
Quad SPI Flash Controller Programming Model 15-16
Setting Up the Quad SPI Flash Controller 15-16
Indirect Read Operation with DMA Disabled 15-17
Indirect Read Operation with DMA Enabled 15-17
Indirect Write Operation with DMA Disabled 15-18
Indirect Write Operation with DMA Enabled 15-18
XIP Mode Operations 15-19
Quad SPI Flash Controller Address Map and Register Definitions 15-20
qspi_QSPIDATA Address Map 15-21
qspiregs Address Map 15-21
qspi_ecc Address Map 15-77
Document Revision History 15-110

DMA Controller 16-1
Features of the DMA Controller 16-1
DMA Controller Block Diagram and System Integration 16-3
Functional Description of the DMA Controller 16-4
AXI Characteristics for a DMA Transfer 16-5
Operating States 16-6
Initializing the DMAC 16-9
Using the Slave Interfaces 16-10
Peripheral Request Interface 16-11
Using Events and Interrupts 16-22
Aborts 16-24
Security Usage 16-27
Programming Restrictions 16-30
Constraints and Limitations of Use 16-34
DMA Controller Programming Model 16-35
Instruction Syntax Conventions 16-35
Instruction Set Summary 16-35
Instructions 16-37
Assembler Directives 16-52
MFIFO Buffer Usage Overview 16-54
DMA Controller Address Map and Register Definitions 16-62
DMA Controller Address Map and Register Definitions 16-63
Document Revision History 16-99

Ethernet Media Access Controller 17-1
Features of the Ethernet MAC 17-2
MAC 17-2
DMA 17-2
Management Interface 17-3
Acceleration 17-3

PHY Interface 17-3
EMAC Block Diagram and System Integration 17-4
EMAC Signal Description 17-5
HPS EMAC I/O Signals 17-6
FPGA EMAC I/O Signals 17-8
PHY Management Interface 17-11
EMAC Internal Interfaces 17-12
DMA Master Interface 17-12
Timestamp Interface 17-13
System Manager Configuration Interface 17-15
Functional Description of the EMAC 17-16
Transmit and Receive Data FIFO Buffers 17-17
DMA Controller 17-18
Descriptor Overview 17-31
IEEE 1588-2002 Timestamps 17-48
IEEE 1588-2008 Advanced Timestamps 17-54
IEEE 802.3az Energy Efficient Ethernet 17-57
Checksum Offload 17-58
Frame Filtering 17-58
Clocks and Resets 17-63
Interrupts 17-68
Ethernet MAC Programming Model 17-68
System Level EMAC Configuration Registers 17-69
EMAC FPGA Interface Initialization 17-71
EMAC HPS Interface Initialization 17-72
DMA Initialization 17-73
EMAC Initialization and Configuration 17-74
Performing Normal Receive and Transmit Operation 17-75
Stopping and Starting Transmission 17-75
Programming Guidelines for Energy Efficient Ethernet 17-75
Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output 17-77
Ethernet MAC Address Map and Register Definitions 17-78
emac Address Map 17-79
emac_rx_ecc Address Map 17-1224
emac_tx_ecc Address Map 17-1269
Document Revision History 17-1314

USB 2.0 OTG Controller 18-1
Features of the USB OTG Controller 18-2
Supported PHYS 18-3
USB OTG Controller Block Diagram and System Integration 18-4
USB 2.0 ULPI PHY Signal Description 18-5
Functional Description of the USB OTG Controller 18-6
USB OTG Controller Block Description 18-6
Local Memory Buffer 18-10
Clocks 18-10
Resets 18-10
Interrupts 18-11

USB OTG Controller Programming Model....18-13
Enabling SPRAM ECCs....18-13
Host Operation....18-13
Device Operation....18-15
USB 2.0 OTG Controller Address Map and Register Definitions....18-16
usb_globgrp Address Map....18-17
usb_hostgrp Address Map....18-149
usb_devgrp Address Map....18-611
usb_pwrclkgrp Address Map....18-1393
usb_DWC_otg_DFIFO Address Map....18-1396
usb_DWC_otg_DFIFO_Direct_access Address Map....18-1398
Document Revision History....18-1398

SPI Controller....19-1
Features of the SPI Controller....19-1
SPI Block Diagram and System Integration....19-2
SPI Block Diagram....19-2
SPI Controller Signal Description....19-3
Interface to HPS I/O....19-3
FPGA Routing....19-3
Functional Description of the SPI Controller....19-5
Protocol Details and Standards Compliance....19-5
SPI Controller Overview....19-5
Transfer Modes....19-8
SPI Master....19-9
SPI Slave....19-12
Partner Connection Interfaces....19-16
DMA Controller Interface....19-21
Slave Interface....19-21
Clocks and Resets....19-22
SPI Programming Model....19-23
Master SPI and SSP Serial Transfers....19-24
Master Microwire Serial Transfers....19-26
Slave SPI and SSP Serial Transfers....19-28
Slave Microwire Serial Transfers....19-29
Software Control for Slave Selection....19-29
DMA Controller Operation....19-30
SPI Controller Address Map and Register Definitions....19-33
spim Address Map....19-33
spis Address Map....19-88
Document Revision History....19-132

I^2C Controller....20-1
Features of the I^2C Controller....20-1
I^2C Controller Block Diagram and System Integration....20-2
I^2C Controller Signal Description....20-3
Functional Description of the I^2C Controller....20-5

Feature Usage....20-5
Behavior....20-5
Protocol Details....20-7
Multiple Master Arbitration....20-11
Clock Frequency Configuration....20-13
SDA Hold Time....20-15
DMA Controller Interface....20-15
Clocks....20-15
Resets....20-15
I2C Controller Programming Model....20-16
Slave Mode Operation....20-16
Master Mode Operation....20-20
Disabling the I2C Controller....20-23
Abort Transfer....20-23
DMA Controller Operation....20-23
I 2 C Controller Address Map and Register Definitions....20-27
i2c Address Map....20-27
i2c_emac Address Map....20-121
Document Revision History....20-239

UART Controller....21-1
UART Controller Features....21-1
UART Controller Block Diagram and System Integration....21-2
UART Controller Signal Description....21-3
HPS I/O Pins....21-3
FPGA Routing....21-4
Functional Description of the UART Controller....21-4
FIFO Buffer Support....21-4
UART(RS232) Serial Protocol....21-5
Automatic Flow Control....21-6
Clocks....21-7
Resets....21-8
Interrupts....21-8
DMA Controller Operation....21-11
Transmit FIFO Underflow....21-12
Transmit Watermark Level....21-12
Transmit FIFO Overflow....21-13
Receive FIFO Overflow....21-14
Receive Watermark Level....21-14
Receive FIFO Underflow....21-14
UART Controller Address Map and Register Definitions....21-15
uart Address Map....21-15
Document Revision History....21-109

General-Purpose I/O Interface....22-1
Features of the GPIO Interface....22-1
GPIO Interface Block Diagram and System Integration....22-2

Functional Description of the GPIO Interface....22-3
Debounce Operation....22-3
Pin Directions....22-3
Taking the GPIO Interface Out of Reset....22-3
GPIO Interface Programming Model....22-4
General-Purpose I/O Interface Address Map and Register Definitions....22-4
gpio Address Map....22-4
Document Revision History....22-37

Timer....23-1
Features of the Timer....23-1
Timer Block Diagram and System Integration....23-1
Functional Description of the Timer....23-2
Clocks....23-3
Resets....23-3
Interrupts....23-3
Timer Programming Model....23-4
Initialization....23-4
Enabling the Timer....23-4
Disabling the Timer....23-4
Loading the Timer Countdown Value....23-4
Servicing Interrupts....23-5
Timer Address Map and Register Definitions....23-5
timer_sys Address Map....23-5
timer Address Map....23-20
Document Revision History....23-35

Watchdog Timer....24-1
Features of the Watchdog Timer....24-1
Watchdog Timer Block Diagram and System Integration....24-2
Functional Description of the Watchdog Timer....24-2
Watchdog Timer Counter....24-2
Watchdog Timer Pause Mode....24-3
Watchdog Timer Clocks....24-3
Watchdog Timer Resets....24-4
Watchdog Timer Programming Model....24-4
Setting the Timeout Period Values....24-4
Selecting the Output Response Mode....24-5
Enabling and Initially Starting a Watchdog Timer....24-5
Reloading a Watchdog Counter....24-5
Pausing a Watchdog Timer....24-5
Disabling and Stopping a Watchdog Timer....24-5
Watchdog Timer State Machine....24-5
Watchdog Timer Address Map and Register Definitions....24-7
watchdog Address Map....24-7
Document Revision History....24-27

Hard Processor System I/O Pin Multiplexing.....25-1
Features of the HPS I/O Block..... 25-1
HPS I/O Block Diagram and System Integration.....25-2
Functional Description of the HPS I/O..... 25-3
Dedicated I/O Pins.....25-3
Shared I/O Pins..... 25-4
FPGA Access.....25-5
Control Registers.....25-5
Configuring HPS I/O Multiplexing.....25-8
Test Considerations..... 25-9
I/O Pin MUX Address Map and Register Definitions for Arria 10.....25-9
Document Revision History.....25-10

Introduction to the HPS Component..... 26-1
MPU Subsystem..... 26-2
ARM CoreSight Debug Components.....26-2
Interconnect.....26-2
HPS-to-FPGA Interfaces.....26-2
Memory Controllers..... 26-3
HPS SDRAM Controller..... 26-3
Support Peripherals.....26-5

Introduction to the Hard Processor System

1

2016.10.28

a10_5v4 Subscribe Send Feedback

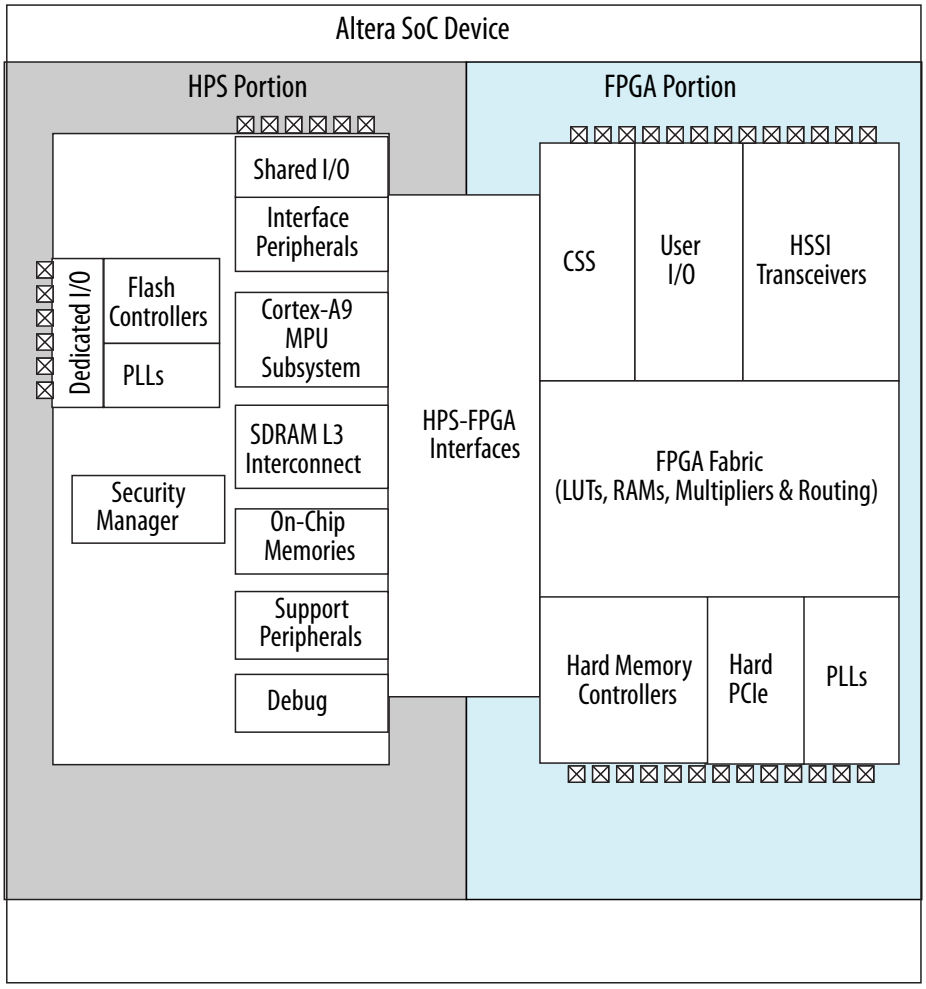
The Arria® 10 system-on-a-chip (SoC) is composed of two distinct portions- a dual-core ARM® Cortex™-A9 hard processor system (HPS) and an FPGA. The HPS architecture integrates a wide set of peripherals that reduce board size and increase performance within a system. A dedicated security manager within the HPS supports secure boot with the ability to authenticate, decrypt and provide tamper event response.

Figure 1-1 shows a high-level block diagram of the Altera® Arria 10 SoC device. Blocks connected to device pins have symbols (square with an X) adjacent to them in the figure.

The SoC features the following types of I/O pins:

- Dedicated I/O - I/O that is dedicated to an external non-volatile storage device (for boot ROM), HPS clock and resets.
- Shared I/O - I/O that can be assigned to peripherals in the HPS or FPGA logic.
- FPGA I/O - I/O that is dedicated to the FPGA fabric.

Figure 1-1: Altera SoC Device Block Diagram



The HPS consists of the following types of modules:

- Microprocessor unit (MPU) subsystem with a dual ARM Cortex-A9 MPCore® processors
- Flash memory controllers
- SDRAM L3 interconnect
- System interconnect
- On-chip memories
- Support peripherals
- Interface peripherals
- Debug components
- Phase-locked loops (PLLs)

The HPS incorporates third-party intellectual property (IP) from several vendors.

The dual-processor HPS supports symmetric (SMP) and asymmetric (AMP) multiprocessing.

The FPGA portion of the device contains:

- FPGA fabric
- Configuration sub-system (CSS)
- PLLs
- High-speed serial interface (HSSI) transceivers, depending on the device variant
- Hard PCI Express® (PCI-e) controllers
- Hard memory controllers

The HPS and FPGA communicate with each other through bus interfaces that bridge the two distinct portions. On a power-on reset, the HPS can boot from multiple sources, including the FPGA fabric and external flash. The FPGA can be configured through the HPS or an externally supported device.

The HPS and FPGA portions of the device each have their own pins. The HPS has dedicated I/O pins and can also share some FPGA I/O pins. Pin assignments are configured when the HPS component is instantiated in Qsys. At boot time, software executing on the HPS assigns the I/O pins to the available HPS modules and configures the I/O pins through I/O control registers. For more information, refer to the "Hard Processor System I/O Pin Multiplexing" chapter. The FPGA I/O pins are configured by an FPGA configuration image through the HPS or any external source supported by the device.

The FPGA fabric and the HPS must be powered at the same time. Once powered, the FPGA fabric and the HPS can be configured independently thus providing you with more design flexibility:

- You can boot the HPS independently. After the HPS is running, the HPS can fully or partially reconfigure the FPGA fabric at any time under software control. The HPS can also configure other FPGAs on the board through the FPGA configuration controller.
- You can configure the FPGA fabric first, and then boot the HPS from the memory accessible to the FPGA fabric.

Related Information

- **Hard Processor System I/O Pin Multiplexing** on page 25-1
  Information about I/O pin configuration. The FPGA I/O pins are configured by an FPGA configuration image through the HPS or any external source supported by the device.
- **Arria 10 Device Datasheet**

Features of the HPS

The main modules of the HPS are:

- MPU subsystem featuring a dual-core ARM Cortex-A9 MPCore processor
- System interconnect that includes three memory-mapped interfaces between the HPS and FPGA:
  - HPS-to-FPGA: 32-, 64-, or 128-bit wide AXI-4
  - Lightweight HPS-to-FPGA: 32-bit wide AXI-4
  - FPGA-to-HPS: 32-, 64-, or 128-bit wide ACE
- General-purpose direct memory access (DMA) controller
- Security manager
- Supports peripheral memories with single-error correction and double-error detection (SECDED)
- Three Ethernet media access controllers (EMACs)
- Two USB 2.0 on-the-go (OTG) controllers
- NAND flash controller
- Quad serial peripheral interface (QSPI) flash controller
- Secure digital/multimedia card (SD/MMC) controller
- Two serial peripheral interface (SPI) master controllers

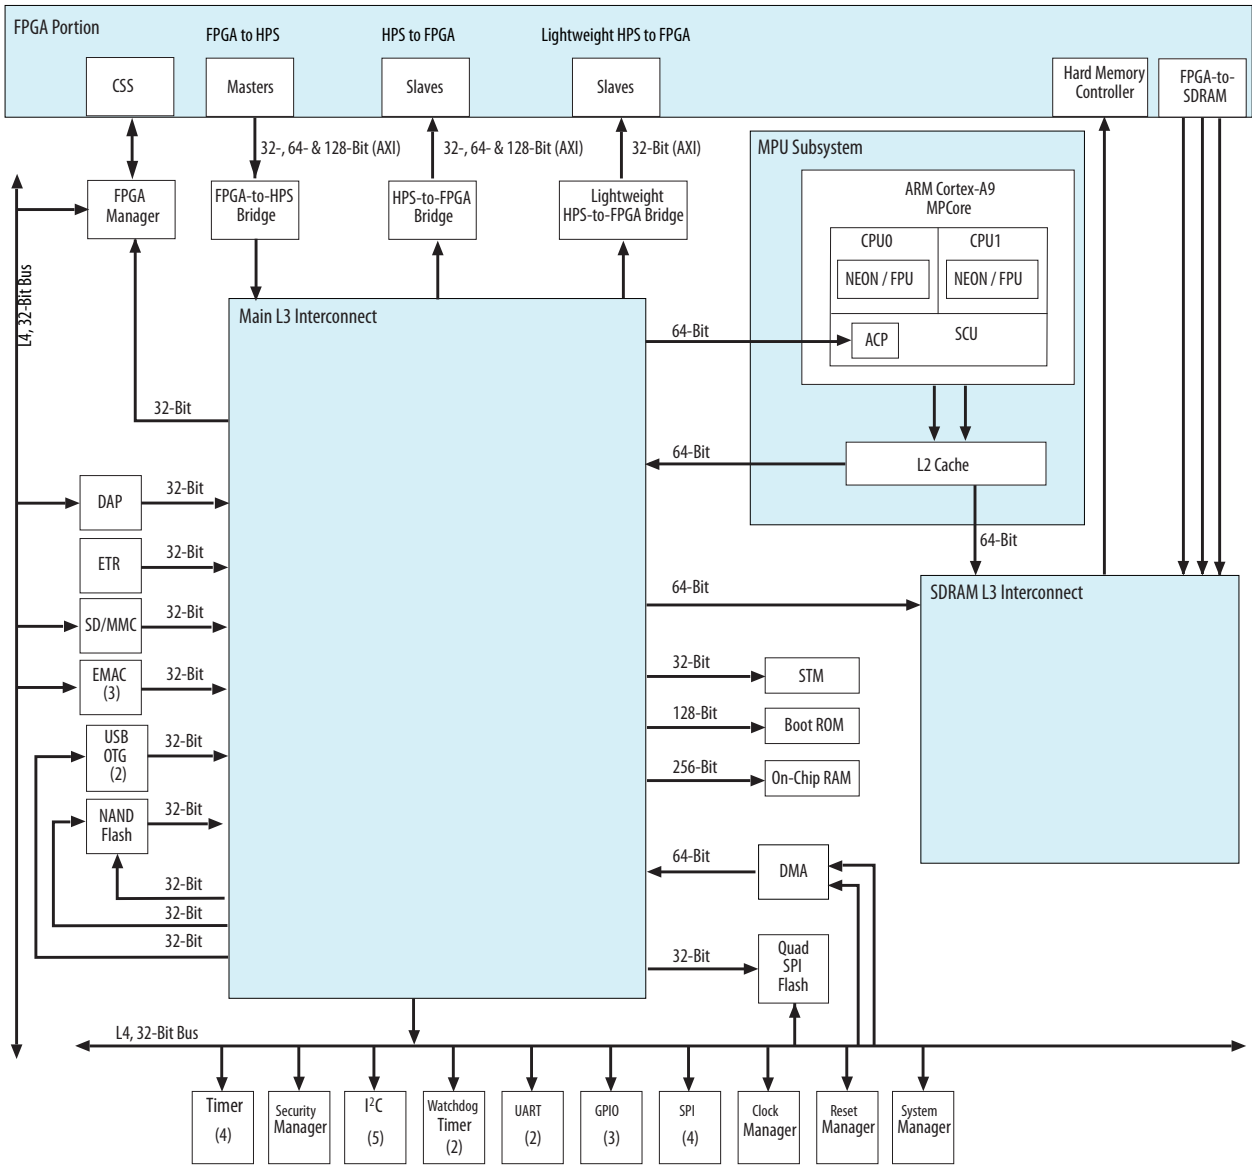
- Two SPI slave controllers
- Five inter-integrated circuit (I^2C) controllers(1)
- 256 KB on-chip RAM
- 128 KB on-chip boot ROM
- Two UARTs
- Four system timers
- Two watchdog timers
- Three general-purpose I/O (GPIO) interfaces
- ARM Coresight™ debug components:
  - Debug access port (DAP)
  - Trace port interface unit (TPIU)
  - System trace macrocell (STM)
  - Program trace macrocell (PTM)
  - Embedded trace router (ETR)
  - Embedded cross trigger (ECT)
- System manager
- Clock manager
- Reset manager
- FPGA manager

(1) Three of the five I^2Cs, can optionally be configured to provide PHY management support for each EMAC controller.

HPS Block Diagram and System Integration

HPS Block Diagram

Figure 1-2: HPS Block Diagram



Cortex-A9 MPCore

The MPU subsystem is a stand-alone, full-featured ARM Cortex-A9 MPCore dual-core 32-bit application processor. It provides the following functionality:

- ARM Cortex-A9 MPCore
  - Two ARM Cortex-A9 processors
  - NEON™ single instruction, multiple data (SIMD) coprocessor and vector floating-point v3 (VFPv3) per processor
  - Snoop control unit (SCU) to ensure coherency between processors
  - Accelerator coherency port (ACP) that accepts coherency memory access requests
  - Interrupt controller
  - One general-purpose timer and one watchdog timer per processor
  - Debug and trace features
  - 32 KB instruction and 32 KB data level 1 (L1) caches per processor
  - Memory management unit (MMU) per processor
- ARM L2-310 level 2 (L2) cache
  - Shared 512 KB L2 cache

As shown in the "HPS Block Diagram", the L2 cache has one 64-bit master port that is connected to the main L3 interconnect and one 64-bit master port connected to the SDRAM L3 interconnect. A programmable address filter in the L2 cache controls which portions of the 32-bit physical address space can be accessed by each master.

Related Information

HPS Block Diagram on page 1-5

HPS Interfaces

The Arria 10 device family provides multiple communication channels to the HPS.

HPS–FPGA Memory-Mapped Interfaces

The HPS–FPGA memory-mapped interfaces provide the major communication channels between the HPS and the FPGA fabric. The HPS–FPGA memory-mapped interfaces include:

- FPGA–to–HPS bridge—a high–performance bus with a configurable data width of 32, 64, or 128 bits, allowing the FPGA fabric to master transactions to the slaves in the HPS. This interface allows the FPGA fabric to have full visibility into the HPS address space. This interface also provides access to the coherent memory interface
- HPS–to–FPGA bridge—a high–performance interface with a configurable data width of 32, 64, or 128 bits, allowing the HPS to master transactions to slaves in the FPGA fabric
- Lightweight HPS–to–FPGA bridge—an interface with a 32–bit fixed data width, allowing the HPS to master transactions to slaves in the FPGA fabric

Related Information

HPS-FPGA Bridges on page 8-1

Other HPS Interfaces

- TPIU trace—sends trace data created in the HPS to the FPGA fabric
- FPGA System Trace Macrocell (STM)—an interface that allows the FPGA fabric to send hardware events to be stored in the HPS trace data
- FPGA cross–trigger—an interface that allows the CoreSight trigger system to send triggers to IP cores in the FPGA, and vise versa
- DMA peripheral interface—multiple peripheral–request channels
- FPGA manager interface—signals that communicate with the FPGA fabric for boot and configuration
- Interrupts—allow soft IP cores to supply interrupts directly to the MPU interrupt controller
- MPU standby and events—signals that notify the FPGA fabric that the MPU is in standby mode and signals that wake up Cortex–A9 processors from a wait for event (WFE) state
- HPS debug interface – an interface that allows the HPS debug control domain (debug APB) to extend into FPGA

Another HPS–FPGA communications channel is FPGA clocks and resets.

System Interconnect

The system interconnect consists of the main L3 interconnect, SDRAM L3 interconnect, and level 4 (L4) buses. The system interconnect is based on the Arteris™ FlexNoC® network-on-chip (NoC) interconnect module. The system interconnect incorporates configurable secure firewalls protecting each peripheral.

The L4 buses are each connected to a master in the main L3 interconnect. Each L4 bus is 32 bits wide and is connected to multiple slaves. Each L4 bus operates on a separate clock source.

The SDRAM L3 interconnect consists of the SDRAM adapter and the SDRAM scheduler. SDRAM is protected by firewalls in the SDRAM L3 interconnect.

Related Information

- **System Interconnect** on page 7-1
- **Arria 10 HPS Secure Firewalls** on page 6-24

You can use the system interconnect firewalls to enforce security policies for slave and memory regions in the system interconnect.

Arria 10 HPS SDRAM L3 Interconnect

The SDRAM L3 interconnect is part of the system interconnect and connects the HPS to the hard memory controller that is located in the FPGA fabric. The SDRAM L3 interconnect is composed of the SDRAM adapter and the SDRAM scheduler, which are secured by firewalls. It supports ARM Advanced Microcontroller Bus Architecture (AMBA®) Advanced eXtensible Interface (AXI™) quality of service (QoS) for the fabric interfaces

The hard memory controller implements the following high-level features:

- Support for double data rate 3 (DDR3) and DDR4 devices
- Software-configurable priority scheduling on individual SDRAM bursts
- Error correction code (ECC) support, including calculation, single-bit error correction and write-back, and error counters
- Fully-programmable timing parameter support for all JEDEC-specified timing parameters
- All ports support memory protection and mutual-exclusive accesses
- FPGA-to-SDRAM interface—a configurable interface to the SDRAM scheduler in the SDRAM L3 interconnect You can configure the following parameters:
  - Up to three bridges
  - Up to 288 bits across all three ports

Related Information

SDRAM L3 Interconnect Block Diagram and System Integration on page 7-9
For more information on the components of the SDRAM L3 Interconnect and how they interface to the hard memory controller in the FPGA, refer to this diagram.

SDRAM Adapter

The SDRAM adapter is responsible for bridging the hard memory controller in the FPGA fabric to the SDRAM scheduler. The adapter is also responsible for error correction code (ECC) generation and checking.

SDRAM Scheduler

The SDRAM scheduler accepts read and write requests from the processor, HPS peripheral masters, and soft logic in FPGA through the FPGA-to-SDRAM interface. It is programmed with memory timings, allowing it to opimize memory access.

On-Chip Memory

On-Chip RAM

The on-chip RAM offers the following features:

- 256 KB size
- 64-bit slave interface
- High performance for all burst lengths
- ECC support provides detection of single–bit and double–bit errors and correction for single-bit errors
- Can clear the on-chip RAM on reset

Related Information

On-Chip Memory on page 12-1

Boot ROM

The boot ROM offers the following features:

- 32-bit interface
- Capable of data transfers for every clock cycle
- 128 KB size
- Contains the code required to support both secure and non-secure HPS boot from cold or warm reset
- Used exclusively for booting the HPS

Related Information

- **On-Chip Memory** on page 12-1
- **Booting and Configuration** on page 30-1

Flash Memory Controllers

NAND Flash Controller

The NAND flash controller is based on the Cadence® Design IP® NAND Flash Memory Controller and offers the following functionality and features:

- Supports up to four chip selects. One chip select is connected to an HPS I/O pin and the rest can be connected to the FPGA I/O pins.
- Integrated descriptor-based DMA controller
- 8-bit and 16-bit ONFI 1.0 NAND flash devices
- Programmable page sizes of 512 bytes, 2 KB, 4 KB, and 8 KB
- Supports 32, 64, 128, 256, 384, and 512 pages per block
- Programmable hardware ECC for single-level cell (SLC) and multi-level cell (MLC) devices
- 512-byte ECC sector size with 4-, 8-, or 16-bit correction
- 1 KB ECC sector size with 24-bit correction

Related Information

NAND Flash Controller on page 13-1

Quad SPI Flash Controller

The quad SPI flash controller is used for access to serial NOR flash devices. It supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The Quad SPI flash controller is based on the Cadence Quad SPI Flash Controller and offers the following features:

- Supports SPIx1, SPIx2, or SPIx4 (Quad SPI) serial NOR flash devices
- Supports direct access and indirect access modes
- Supports single, dual, and quad I/O instructions
- Support up to four chip selects
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Support eXecute-In-Place (XIP) mode
- Programmable baud rate generator to generate device clocks

Related Information

Quad SPI Flash Controller on page 15-1

SD/MMC Controller

The Secure Digital (SD), Multimedia Card (MMC), (SD/MMC) and CE-ATA host controller is based on the Synopsys® DesignWare® Mobile Storage Host controller and offers the following features:

- Integrated descriptor-based DMA
- Supports CE-ATA digital protocol commands
- Supports single card
- Single data rate (SDR) mode only
- Programmable card width: 1-, 4-, and 8-bit
- Programmable card types: SD, SDIO, or MMC
- Up to 64 KB programmable block size
- Supports the following standards and card types:
  - SD, including eSD—version 3.0[(2)]
  - SDIO, including embedded SDIO (eSDIO)—version 3.0[(3)]
  - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41[(4)]
  - MMC: 1-bit data bus
  - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
  - MMCMobile: 1-bit data bus
- Supports embedded MMC (eMMC) version 4.5[(5)]
  - 1-bit, 4-bit, and 8-bit data bus

Note: For an inclusive list of the programmable card types and versions supported, refer to the *SD/MMC Controller* chapter.

Related Information

SD/MMC Controller on page 14-1

Support Peripherals

Clock Manager

The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. The clock manager offers the following features:

- Manages clocks for HPS
- Supports clock gating at the signal level
- Supports dynamic clock tuning

Related Information

Clock Manager on page 2-1

(2) Does not support SDR50, SDR104, and DDR50 modes.
(3) Does not support SDR50, SDR104, and DDR50 modes.
(4) Does not support DDR mode.
(5) Does not support DDR and HS200 mode.

Reset Manager

The reset domains and sequences support several security features. The security manager brings the reset manager out of reset only when device security is confirmed. Afterwards, the reset manager brings the rest of the HPS system out of reset. The reset manager performs the following functions:

- Manages resets for HPS
- Controls the resets for cold, warm, debug, and TAP reset domains
- Controls the RAM clearing domain separately

Related Information

- **Reset Manager** on page 3-1
- **SoC Security** on page 6-1

Security Manager

The security manager module is integrated in the HPS and provides the overall management of security within the SoC, including:

- Recognition of secure fuse configuration, preventing non-secure device startup
- State control and check of the security features
- Secure boot options
- Secure debug options
- Anti-tamper support

Related Information

SoC Security on page 6-1

System Manager

The system manager contains logic to control system functions and logic to control other modules that need external control signals provided as part of system integration. The system manager offers the following features:

- Provides combined ECC status and interrupts from other HPS modules with ECC-protected RAM
- Low-level control of peripheral features not accessible through the control and status registers (CSRs)

Related Information

System Manager on page 5-1

System Timers

The HPS provides four 32-bit general-purpose timers connected to the level 4 (L4) peripheral bus. The four system timers are based on the Synopsys DesignWare Advanced Peripheral Bus (APB) Timers peripheral and offer the following features:

- 32-bit timer resolution
- Free-running timer mode
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)
- Interrupt generation

Related Information

Timer on page 23-1

System Watchdog Timers

The two system watchdog timers are based on the Synopsys DesignWare APB Watchdog Timer peripheral and offer the following features:

- 32-bit timer resolution
- Interrupt request
- Reset request
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)

Note: Countdown can be paused when the MPU is in debug mode.

Related Information

Watchdog Timer on page 24-1

DMA Controller

The DMA controller provides high-bandwidth data transfers for modules without integrated DMA controllers. The DMA controller is based on the ARM Corelink™ DMA Controller (DMA-330) and offers the following features:

- Micro-coded to support flexible transfer types
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Scatter-gather
- Supports up to eight channels
- Supports flow control with 32 peripheral handshake interfaces

Related Information

DMA Controller on page 16-1

FPGA Manager

The FPGA manager manages and monitors the FPGA portion of the SoC device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

Related Information

FPGA Manager on page 4-1

Error Checking and Correction Controller

ECC controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the HPS.

The following peripherals have integrated ECC-protected memories:

- USB OTG 0 - 1
- SD/MMC Controller
- EMAC 0 - 2
- DMA controller
- NAND flash controller
- QSPI flash controller

Features of the ECC controller:

- Single-bit error detection and correction
- Double-bit error detection
- Interrupts generated on single- and double-bit errors

Related Information

Error Checking and Correction Controller on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Interface Peripherals

EMACs

The three EMACs are based on the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC and offer the following features:

- Supports 10, 100, and 1000 Mbps standard
- PHY interfaces supported through the HPS I/O pins:
  - Reduced media independent interface (RMII) and Reduced gigabit media independent interface (RGMII) through the HPS I/O pins
- PHY interfaces supported using adapter logic to route signals to the FPGA I/O pins:
  - Media independent interface (MII), Gigabit media independent interface (GMII), RMII, RGMII, and Serial gigabit media independent interface (SGMII) (with external conversion logic) through the FPGA pins
- Integrated DMA controller
- Supports IEEE 1588-2002 and IEEE 1588-2008 standards for precision networked clock synchronization
- IEEE 802.3-az, version D2.0 of Energy Efficient Ethernet
- Supports IEEE 802.1Q Virtual local area network (VLAN) tag detection for reception frames
- PHY Management control through Management data input/output (MDIO) interface or I^2C interface
- 4 KB TX FIFO and 16 KB RX FIFO RAM
- Supports a variety of address filtering modes

Related Information

Ethernet Media Access Controller on page 17-1

USB Controllers

The HPS provides two USB 2.0 Hi-Speed On-the-Go (OTG) controllers from Synopsys DesignWare. The USB controller signals cannot be routed to the FPGA like those of other peripherals; instead they are routed to the dedicated I/O.

Each of the USB controllers offers the following features:

- Complies with the following specifications:
  - USB OTG Revision 1.3
  - USB OTG Revision 2.0
  - Embedded Host Supplement to the USB Revision 2.0 Specification
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)

  Note: In host mode, all speeds are supported; however, in device mode, only high speed and full speed are supported.
- Local buffering with Error Correction Code (ECC) support

  Note: The USB 2.0 OTG controller does not support the following interface standards:
  - Enhanced Host Controller Interface (EHCI)
  - Open Host Controller Interface (OHCI)
  - Universal Host Controller Interface (UHCI)
- Supports USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) PHYs (SDR mode only)
- Supports up to 16 bidirectional endpoints, including control endpoint 0

  Note: Only seven periodic device IN endpoints are supported.
- Supports up to 16 host channels

  Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports generic root hub
- Supports automatic ping capability

Related Information

- **USB 2.0 OTG Controller** on page 18-1
- **Universal Serial Bus (USB) website**
  Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website.

I²C Controllers

The five I²C controllers are based on Synopsys DesignWare APB I²C controller which offer the following features:

- Three controllers optionally can be used as a control interface for Ethernet PHY communication

  Note: When an I²C controller is used for Ethernet, it will take the place of the MDIO pins.
- Support both 100 KBps and 400 KBps modes
- Support both 7-bit and 10-bit addressing modes
- Support master and slave operating mode
- Direct access for host processor
- DMA controller may be used for large transfers

Related Information

I2C Controller on page 20-1

UARTs

The HPS provides two UART controllers to provide asynchronous serial communications. The two UART modules are based on Synopsys DesignWare APB Universal Asynchronous Receiver/ Transmitter peripheral and offer the following features:

- 16550-compatible UART
- Support automatic flow control as specified in 16750 standard
- Programmable baud rate up to 6.25 MBaud (with 100MHz reference clock)
- Direct access for host processor
- DMA controller may be used for large transfers
- 128-byte transmit and receive FIFO buffers
- Separate thresholds for DMA request and handshake signals to maximize throughput

Related Information

UART Controller on page 21-1

SPI Master Controllers

The two SPI master controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and has a maximum bit rate of 60Mbps. The following features are offered:

- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Supports two chip selects connected to HPS I/O
- Supports four chip selects connected to the FPGA fabric
- Direct access for host processor
- DMA controller may be used for large transfers
- Programmable master serial bit rate
- Support for `rxd` sample delay
- Transmit and receive FIFO buffers are 256 words deep
- Choice of Motorola® SPI, Texas Instruments® Synchronous Serial Protocol or National Semiconductor® Microwire protocol

Related Information

SPI Controller on page 19-1

SPI Slave Controllers

The two SPI slave controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and has a maximum bit rate of 50 Mbps. The following features are offered:

- Programmable data frame size from 4 bits to 16 bits
- Supports full- and half-duplex modes
- Direct access for host processor
- DMA controller may be used for large transfers
- Transmit and receive FIFO buffers are 256 words deep

Related Information

SPI Controller on page 19-1

GPIO Interfaces

The HPS provides three GPIO interfaces that are based on Synopsys DesignWare APB General Purpose Programming I/O peripheral and offer the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 17 dedicated 1.8 V and 3.0 V HPS I/O pins used for clock, reset, and external flash devices
- Supports up to 48 shared 3.0 V I/O pins that can be used by either the HPS or the FPGA. These pins are useful for Ethernet, USB, and other communication functions

Related Information

General-Purpose I/O Interface on page 22-1

CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate PTM for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP cores to generate of triggers and system trace messages
- Custom message injection through STM into trace stream for delivery to host debugger
- Capability to route trace data to any slave accessible to the ETR master, which is connected to the level 3 (L3) interconnect

Related Information

CoreSight Debug and Trace on page 10-1

Hard Processor System I/O Pin Multiplexing

The Stratix® 10 SoC has a total of 48 dedicated I/O pins that are used for hard processor system (HPS) operation, external flash memories, and external peripheral communication. A pin multiplexing mechanism allows the SoC to use the flexible I/O pins in a wide range of configurations.

Endian Support

The HPS is natively a little–endian system. All HPS slaves are little endian.

The processor masters are software configurable to interpret data as little endian, big endian, or byte–invariant (BE8). All other masters, including the USB 2.0 interface, are little endian. Registers in the MPU and L2 cache are little endian regardless of the endian mode of the CPUs.

Note: Altera strongly recommends that you only use little endian.

The FPGA–to–HPS, HPS–to–FPGA, FPGA–to–SDRAM, and lightweight HPS–to–FPGA interfaces are little endian.

If a processor is set to BE8 mode, software must convert endianness for accesses to peripherals and DMA linked lists in memory. The processor provides instructions to swap byte lanes for various sizes of data.

The ARM Cortex–A9 MPU supports a single instruction to change the endianness of the processor and provides the REV and REV16 instructions to swap the endianness of bytes or half–words respectively. The MMU page tables are software configurable to be organized as little–endian or BE8.

The ARM DMA controller is software configurable to perform byte lane swapping during a transfer.

Introduction to the Hard Processor System Address Map

The address map specifies the addresses of slaves, such as memory and peripherals, as viewed by the MPU and other masters. The HPS has multiple address spaces, defined in the following section.

Related Information

MPU Address Space on page 7-17

HPS Address Spaces

The following table shows the HPS address spaces and their sizes.

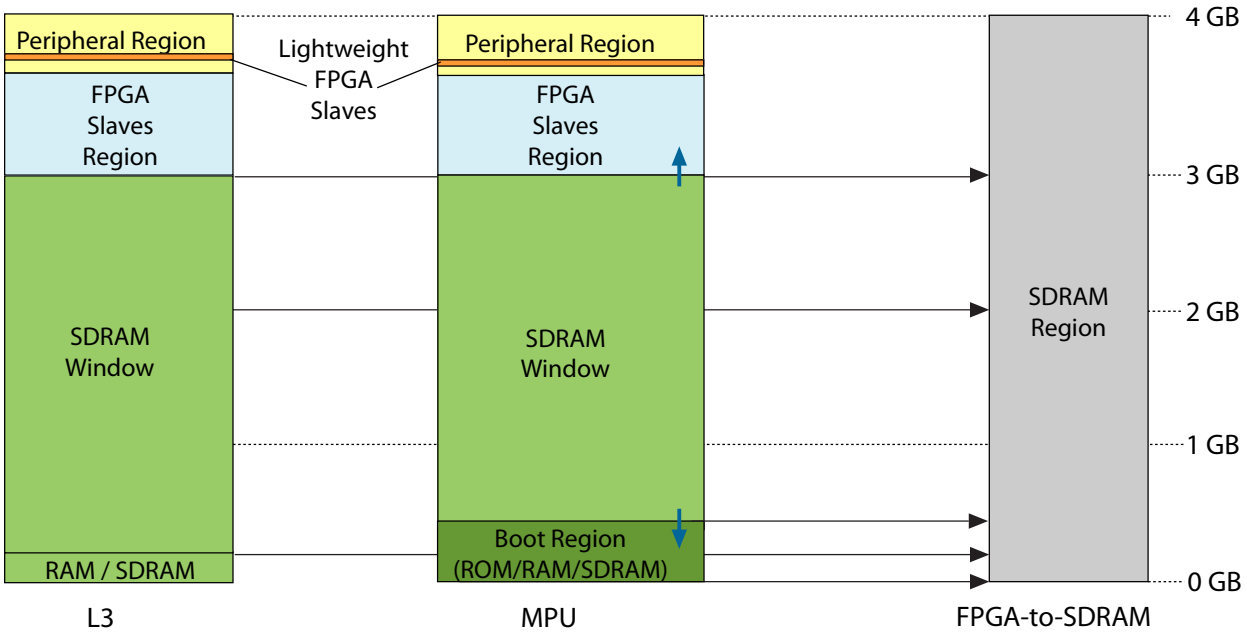
Table 1-1: HPS Address Spaces

Name	Description	Size
MPU	MPU subsystem	4 GB
L3	System interconnect	4 GB
SDRAM	SDRAM region	4 GB

Address spaces are divided into one or more nonoverlapping regions. For example, the MPU address space has the peripheral, FPGA slaves, SDRAM window, and boot regions.

The following figure shows the relationships between the HPS address spaces. The figure is not to scale.

Figure 1-3: HPS Address Space Relationships



The SDRAM window in the MPU address space can grow and shrink at the top and bottom (short, blue vertical arrows) at the expense of the FPGA slaves and boot regions. For specific details, refer to "MPU Address Space".

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

Table 1-2: Common Address Space Regions

Region Name	Base Address	Size
FPGA slaves	0xC0000000	960 MB
Peripheral	0xFC000000	64 MB
Lightweight FPGA slaves	0xFF200000	2 MB

SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces can be configured at runtime.

There are cacheable and non-cacheable views into the SDRAM space. When a master of the L3 SDRAM interconnect performs a cacheable access to the SDRAM, the transaction is performed through the ACP port of the MPU subsystem. When a master of the SDRAM L3 interconnect performs a non-cacheable

access to the SDRAM, the transaction is performed through the 64-bit L3 interconnect master of the SDRAM L3 interconnect.

Related Information

System Interconnect on page 7-1
For more information about how to configure SDRAM address space.

MPU Address Space

The MPU address space is 4 GB and applies to addresses generated inside the MPU.

The MPU address space contains the following regions:

- The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space.

The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries. The boundaries are megabyte-aligned. Addresses within the boundaries route to the SDRAM master. Addresses outside the boundaries route to the system interconnect master.

FPGA Slaves Address Space

The FPGA Slaves address space is located in the FPGA core and accessed from the HPS through the HPS2FPGA AXI Bridge. The FPGA Slaves address space in the FPGA core is of unlimited size (soft logic in the FPGA performs address decoding). The L3 and MPU regions provide a window of nearly 1GB (actually 1GB less 64MB) into the FPGA Slaves address space. The base address of the FPGA Slaves Window is mapped to address 0x0 in the FPGA Slaves address space.

The HPS is able to boot from offset 0x0 into the FPGA Slaves address space (BSELselection).

LWFPGA Slaves Address Space

The Lightweight (LW) FPGA Slaves address space is located in the FPGA core and accessed from the HPS through the LWHPS2FPGA Bridge. The LWFPGA Slaves address space in the FPGA core is of unlimited size (soft logic in the FPGA performs address decoding). A portion of the Peripheral region provides a window of 2MB into the LWFPGA Slaves address space. The base address of the LWFPGA Slaves window is mapped to address 0x0 in the LWFPGA Slaves address space.

The HPS is not able to boot from the LWFPGA Slaves address space.

L3 Address Space

The L3 address space is 4 GB and applies to all L3 masters except the MPU. The L3 address space has more configuration options than the other address spaces.

Related Information

System Interconnect on page 7-1
For more information about configuring the L3 address space, refer to the System Interconnect chapter.

HPS Peripheral Region Address Map

Each peripheral slave interface has a dedicated address range in the peripheral region. The table below lists the base address and address range size for each slave.

Table 1-3: Peripheral Region Address Map

Slave Identifier	Description	Base Address	Size
STM	STM module	0xFC000000	48 MB

Document Revision History

Table 1-4: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Renamed MPU Subsystem to Cortex-A9 MPCore
May 2016	2016.05.27	Corrected the HPS-FPGA powering scheme.
May 2016	2016.05.03	Removed low-power double data rate 3 (LPDDR3) as a supported device.
November 2015	2015.11.02	Updated the link to the Memory Maps.
May 2015	2015.05.04	Corrected HPS-FPGA powering scheme.
December 2014	2014.12.15	Maintenance release
August 2014	2014.08.18	Initial release

Clock Manager 2

2016.10.28

a10_5v4

The hard processor system (HPS) clock generation is centralized in the clock manager. The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. Clocks are organized in clock groups. A clock group is a set of clock signals that originate from the same clock source. A phase-locked loop (PLL) clock group is a clock group where the clock source is a common PLL voltage-controlled oscillator (VCO).

Features of the Clock Manager

The *Clock Manager* offers the following features:

- Generates and manages clocks in the HPS
- Contains the following clock groups:
  - Main—contains clocks for the Cortex-A9 microprocessor unit (MPU) subsystem, level 3 (L3) interconnect, level 4 (L4) peripheral bus, and debug
  - Peripheral—contains clocks for PLL-driven peripherals
- Contains two identical 16-output PLL blocks:
  - PLL 0
  - PLL 1
- Generates clock gate controls for enabling and disabling most clocks
- Initializes and sequences clocks
- Allows software to program clock characteristics, such as the following items discussed later in this chapter:
  - Input clock source for the two PLLs
  - Multiplier range, divider range, and 16 post-scale counters for each PLL
  - VCO enable for each PLL
  - Bypass modes for each PLL
  - Gate of individual clocks in all PLL clock groups
  - Clear loss of lock status for each PLL
  - Boot mode for hardware-managed clocks
  - General-purpose I/O (GPIO) debounce clock divide

- Allows software to observe the status of all writable registers
- Supports interrupting the MPU subsystem on PLL-lock and loss-of-lock
- Supports clock gating at the signal level

The clock manager is **not** responsible for the following functional behaviors:

- Selection or management of the clocks for the FPGA-to-HPS and HPS-to-FPGA interfaces. The FPGA logic designer is responsible for selecting and managing these clocks.
- Software must not program the clock manager with illegal values. If it does, the behavior of the clock manager is undefined and could stop the operation of the HPS. The only guaranteed means for recovery from an illegal clock setting is a cold reset.
- When re-programming clock settings, there are no automatic glitch-free clock transitions. Software must follow a specific sequence to ensure glitch-free clock transitions. Refer to *Hardware-Managed and Software-Managed Clocks* section of this chapter.

Clock Manager Block Diagram and System Integration

Figure 2-1: Clock Manager Block Diagram

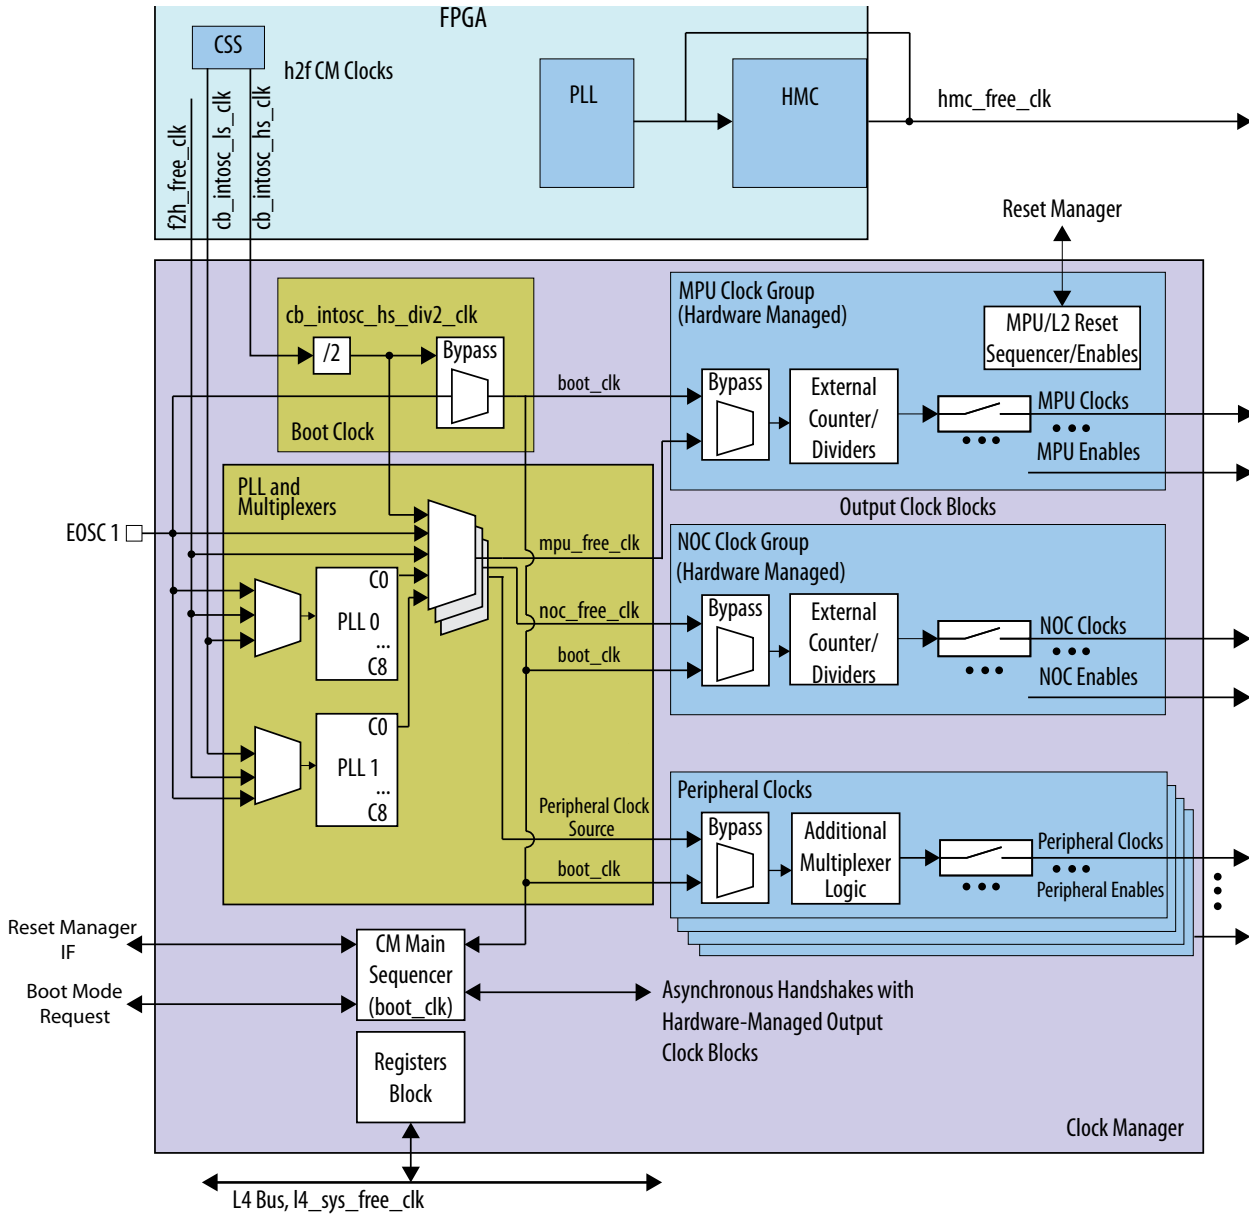

Table 2-1: Arria 10 Top Level Clocks

Clock Name	Source/Destination	Description
`mpu_free_clk`	Clock manager To MPU complex	Source clock from clock manager for both MPU clock groups.
`mpu_clk`	Internal to MPU complex	MPU main clock

Clock Name	Source/Destination	Description
mpu_l2ram_clk	Internal to MPU complex and HMC switch in NOC.	MPU L2 RAM clock and HMC switch in NOC. Fixed at ½ mpu_clk.
mpu_periph_clk	Internal to MPU complex	MPU peripherals clock for interrupts, timers, and watchdogs. Fixed at ¼ mpu_clk.
l3_main_free_clk	Clock manager to NOC/ Peripherals	Interconnect L3 main switch clock. Always free running.
l4_sys_free_clk	Clock manager to NOC/ Peripherals	Interconnect L4 system clock. Always free running.
l4_main_clk	Clock manager to NOC/ Peripherals	L4 Interconnect clock for fast peripherals including DMA, SPIM, SPIS and TCM.
l4_mp_clk	Clock manager to NOC/ Peripherals	Interconnect L4 peripheral clock.
l4_sp_clk	Clock manager to NOC/ Peripherals	Interconnect L4 slow peripheral clock.
cs_at_clk	Clock manager to CoreSight/ NOC	CoreSight Trace clock and debug time stamp clock.
cs_pdbg_clk	Clock manager to CoreSight	CoreSight bus clock
cs_trace_clk	Clock manager to CoreSight	CoreSight Trace I/O clock. This will be independent and defaults to a low frequency (25 MHz) for lower speed debuggers. Not required to be sync. to other clocks (but keep in clock group as hardware managed)
cs_timer_clk	Clock manager to CoreSight/ NOC	CoreSight timer clock. Same as cs_at_clk with different software enable to ensure MPU clock running. Not required to be sync. to other clocks (but still hardware managed).
fpga2soc_clk	FPGA fabric to NOC	FPGA to SoC interface clock from the FPGA.
soc2fpga_clk	FPGA fabric to NOC	SoC to FPGA interface clock from the FPGA.
lws2f_clk	FPGA fabric to NOC	LWHPS to FPGA interface clock from FPGA.
hmc_free_clk	From HMC to HMC switch in NOC	HMC interface clock from HMC (Hard Memory Controller) in FPGA.

Clock Name	Source/Destination	Description
f2h_sdram0_clk f2s_sdram1_clk f2h_sdram2_clk	FPGA fabric to HMC switch in NOC	FPGA fabric SDRAM write interfaces clocks.
f2h_pclkdbg	FPGA fabric to CoreSight bridge	CoreSight FPGA fabric APB debug port clock
usb[0,1]_ulpi_clk	I/O to USB	ULPI clock for PHY.

L4 Peripheral Clocks

The L4 peripheral clocks, denoted by l4_mp_clk, range up to 200 MHz.

Table 2-2: Clock List

Peripheral	Clock Name	Description
USB OTG 0/1(6)	hclk	AHB clock
	pmu_hclk	PMU AHB clock. pmu_hclk is the scan clock for the PMU's AHB domain. **Note:** Select it as a test clock.
	utmi_clk	Always used as the PHY domain clock during DFT Scan mode. **Note:** Select utmi_clk as a test clock even when the core is configured for a non-UTMI PHY.
Quad SPI Flash Controller(6)	pclk	APB clock
	hclk	AHB clock
NAND Flash Controller (Locally gated nand_mp_clk.)(6)	ACLK	AHB Data port clock
	mACLK	AXI Master port clock
	regACLK	AHB Register port clock
	ecc_clk	ECC circuitry clock
	clk_x	Bus Interface Clock
EMAC 0/1/2	aclk	Application clock for DMA AXI bus and CSR APB bus.
SD/MMC Controller	sdmmc_clk	All registers reside in the BIU clock domain.

For more information about the specific peripheral clocks, refer to their respective chapters.

Boot Clock

The Boot Clock (`boot_clk`) is used as the default clock for both cold or warm reset (Boot Mode), the Hardware Sequencer local clock and the external bypass clock reference.

The `boot_clk` is generated from the secure `cb_intosc_hs_div2_clk` or the unsecure external oscillator. `boot_clk` is only updated coming out of cold reset or a warm reset (boot mode request) and is not sampled at any other time.

The source of every output clock block comes from the following:

- Bypass source: `boot_clock` configured through fuses and security manager: registers at cold or warm reset
- Non-External Bypass: Each Clock may come from 1 of 5 sources:

Table 2-3: Non-External Bypass Sources of clocks

Source	Description
`OSC1`	Pin for external oscillator
`f2h_free_clk`	FPGA fabric PLL clock reference
`cb_intosc_hs_div2_clk`	FPGA CSS (Control Block) high speed internal oscillator divided by 2 (200 MHz maximum)
PLL0 Counter Output	Main PLL counter outputs 0 to 8
PLL1 Counter Output	Peripheral PLL counter outputs 0 to 8

Clock Output Blocks have the following features:

- Each clock output block contains an external bypass multiplexer
- Some clock output blocks contain additional dividers
- Clock gates controlled by either hardware or software are used to disable the clocks
- The MPU and NOC (includes debug clocks) blocks contain enable outputs to define clock frequency ratios to the MPU, NOC and CoreSight logic

The CSR Register logic uses an independent clock, `l4_sys_free_clk`, to allow the clock to be changed by software.

(6) Clock manager provides CSR bits for software enables to some peripherals. These enables are defaulted to enable. In boot mode, these enables are automatically active to ensure all clocks are active if RAM is cleared for security.

Updating PLL Settings without a System Reset

Updating the PLL settings wihtout a system reset will not reset the clock manager. All clocks will transition gracefully to their boot safe dividers. You can go in and out of boot mode and force the PLLs into bypass without doing a system reset. Software may reset the PLLs and reconfigure the VCO and bring it out of reset. By doing this you can safely update the PLL settings.

MPU Clock Scaling

You can dynamically slow down the MPU clock without touching the PLL by modifying the MPU external counter register (`MAINPLLGRP.MPUCLK.CNT`) to slow down the MPU frequency.

Related Information

Clock Manager Address Map and Register Definitions on page 2-18

Functional Description of the Clock Manager

Clock Manager Building Blocks

PLLs

The two PLLs in the clock manager generate the majority of clocks in the HPS. There is no phase control between the clocks generated by the two PLLs.

Each PLL has the following features:

- Phase detector and output lock signal generation
- Registers to set VCO frequency
  - Multiplier range is 1 to 4096
  - Divider range is 1 to 64
- 16 post-scale counters (C0-C8) with a range of 1 to 2048 to further subdivide the clock
- A PLL can be enabled to bypass all outputs to the input clock for glitch-free transitions

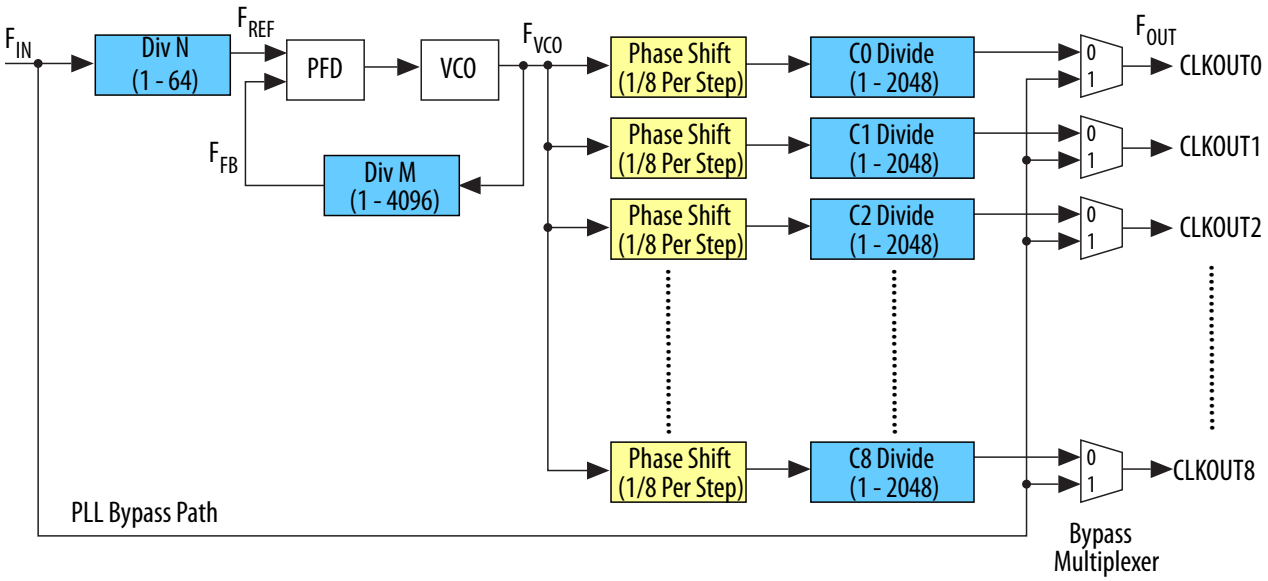
FREF, FVCO, and FOUT Equations

Figure 2-2: PLL Block Diagram

Values listed for M, N, and C are actually one greater than the values stored in the CSRs.



$$F_{REF} = F_{IN} / N$$
$$F_{VCO} = F_{REF} \times M = F_{IN} \times M/N$$
$$F_{OUT} = F_{VCO} /C_i = F_{REF} \times M/C_i = (F_{IN} \times M)/ (N \times C_i)$$

where:

- FVCO = VCO frequency
- FIN = input frequency
- FREF = reference frequency
- FOUT = output frequency
- M = numerator, part of the clock feedback path
- N = denominator, part of the input clock reference path
- Ci = post-scale counter, where *i* is 0-8

The Ci dividers are used to derive lower frequencies from the PLLs. The M and N dividers can be dynamically updated without losing the PLL lock if the VCO frequency changes less than 20%. If changes greater than 20% are needed, iteratively changing the frequency in increments of less than 20% allows a slow ramp of the VCO frequency without loss of clock.

To minimize jitter, use the following guidelines:

- The VCO should be as close to maximum as possible
- It is better to use the Ci dividers than the N divider. The N divider should be kept as small as possible.
- The M divider should be minimized, but should be greater than 32.

When making any changes that affect the VCO frequency, software must put the PLL into external bypass. After changing the VCO frequency, software must wait for the PLL lock, as indicated by the `intrs` register or enabled interrupt, before taking the PLL out of bypass.

As shown in the "Hardware Clock Groups" and "Peripheral Clocks" figures, every clock has five possible sources. When switching between clock sources:

- Put PLL into bypass mode
- Change the mux select
- Switch back out of bypass mode

Note: The new clock source must be active and locked before exiting bypass mode.

As shown in the "PLL Integration in Clock Manager" figure, each PLL has multiple input sources. If the input source is changed, the PLL loses VCO lock and all output clocks are not reliable. Before switching the PLL input source, software must select the `boot_clk` bypass for all PLL0 and PLL1 clocks. After the PLL output clocks are bypassed, software can change the PLL source and reinitialize the PLL.

Unused clock outputs should be set to a safe frequency such as 50 MHz to reduce power consumption and improve system stability.

Clock Gating

Clock gating enables and disables clock signals. Refer to the Peripheral PLL Group Enable Register (`en`) for more information on what clocks can be gated.

Related Information

Clock Manager Address Map and Register Definitions on page 2-18

PLL Integration

The two PLLs contain exactly the same set of output clocks. PLL0 is intended to be used for the MPU and the NOC clocks. PLL1 is intended to be used as the 250 MHz Ethernet clock reference.

Figure 2-3: PLL Integration in Clock Manager

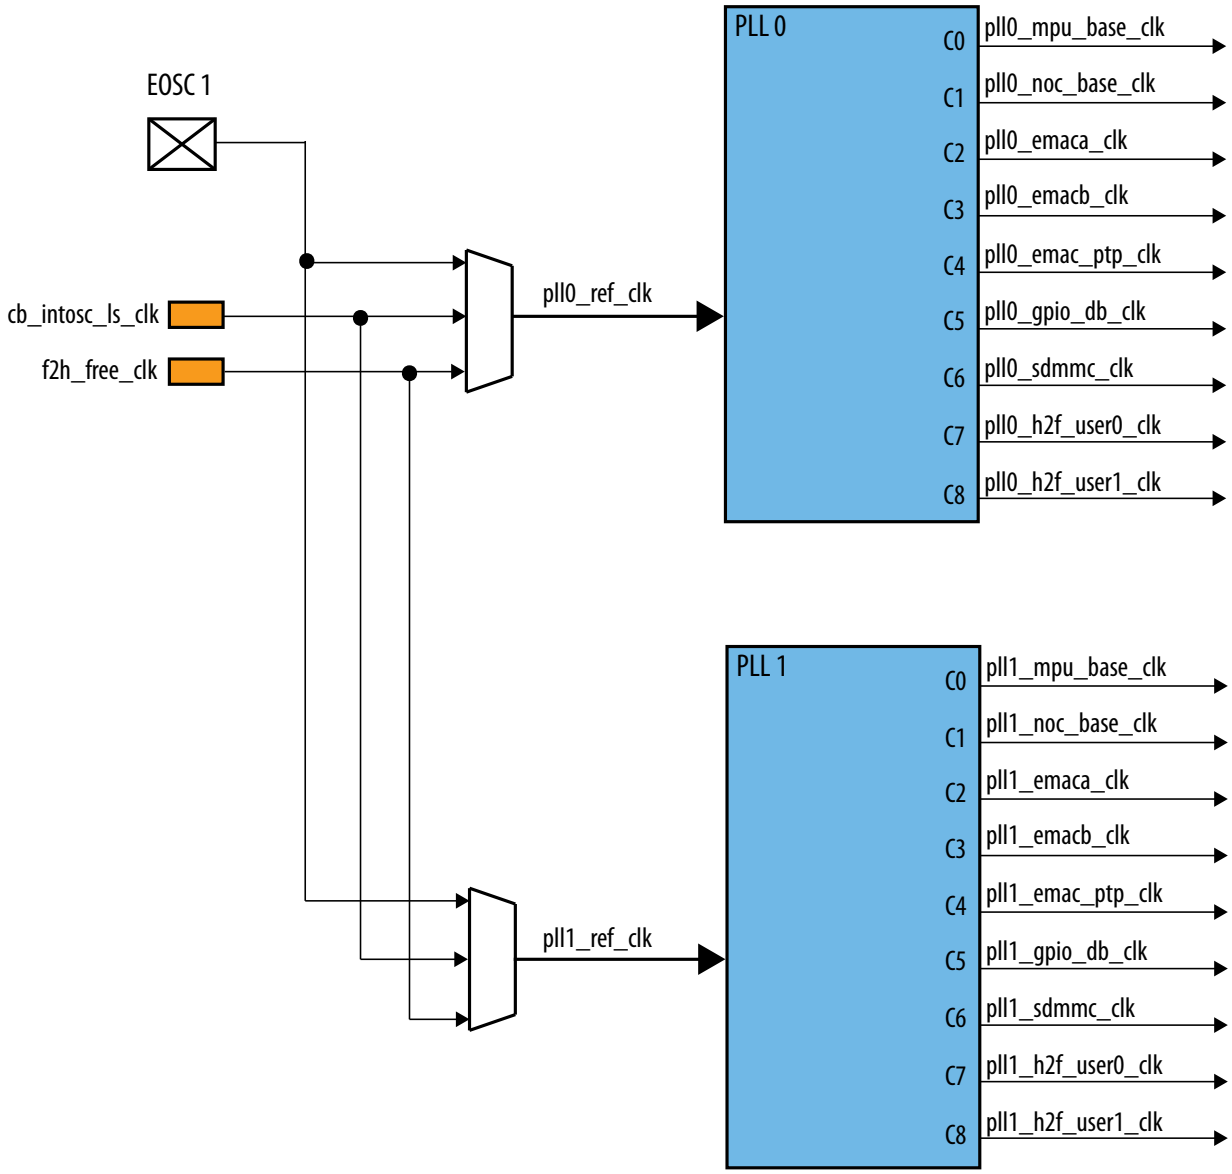


Table 2-4: PLL Output Clock Characteristics

Output Counter	Clock Name	Frequency	Boot Frequency
C0	`mpu_base_clk`	Up to varies	10 MHz to 200 MHz
C1	`noc_base_clk`	Up to C0/3	10 MHz to 200 MHz

(7) Frequency depends on device, refer to device datasheet for more information.

Output Counter	Clock Name	Frequency	Boot Frequency
C2	emaca_clk	50 to 250 MHz	10 MHz to 200 MHz
C3	emacb_clk	50 to 250 MHz	10 MHz to 200 MHz
C4	emac_ptp_clk	Up to 100 MHz	10 MHz to 200 MHz
C5	gpio_db_clk	Up to 200 MHz	10 MHz to 200 MHz
C6	sdmmc_clk	Up to 200 MHz	10 MHz to 200 MHz
C7	h2f_user0_clk	Up to 400 MHz	10 MHz to 200 MHz
C8	h2f_user1_clk	Up to 400 MHz	10 MHz to 200 MHz

Hardware-Managed and Software-Managed Clocks

When changing values on clocks, the terms hardware-managed and software-managed define how clock transitions are implemented. When changing a software-managed clock, software is responsible for gating off the clock, waiting for a PLL lock if required, and gating the clock back on. Clocks that are hardware-managed are automatically transitioned by the hardware to ensure glitch-free operation.

- mpu_periph_clk
- mpu_l2_ram_clk
- mpu_clk

- l3_main_free_clk
- l4_sys_free_clk
- l4_sys_free_div4_clk
- l4_main_clk
- l4_mp_clk
- l4_sp_clk

- cs_timer_clk
- cs_at_clk
- cs_pdbg_clk
- cs_trace_clk

All other clocks in the HPS are software-managed clocks.

Hardware Sequenced Clock Groups

The hardware sequenced clock groups consists of the MPU clocks and the NOC clocks. The following diagram shows the external bypass muxes, hardware-managed external counters and dividers, and clock gates. For hardware-managed clocks, the group of clocks has only one software enable for the clock gate. As a result, the group of clocks are all enabled or disabled together. The slight exception is the NOC has two software enables, one for the l3/l4 clocks and one for the CoreSight clocks.

Figure 2-4: Hardware Clock Groups

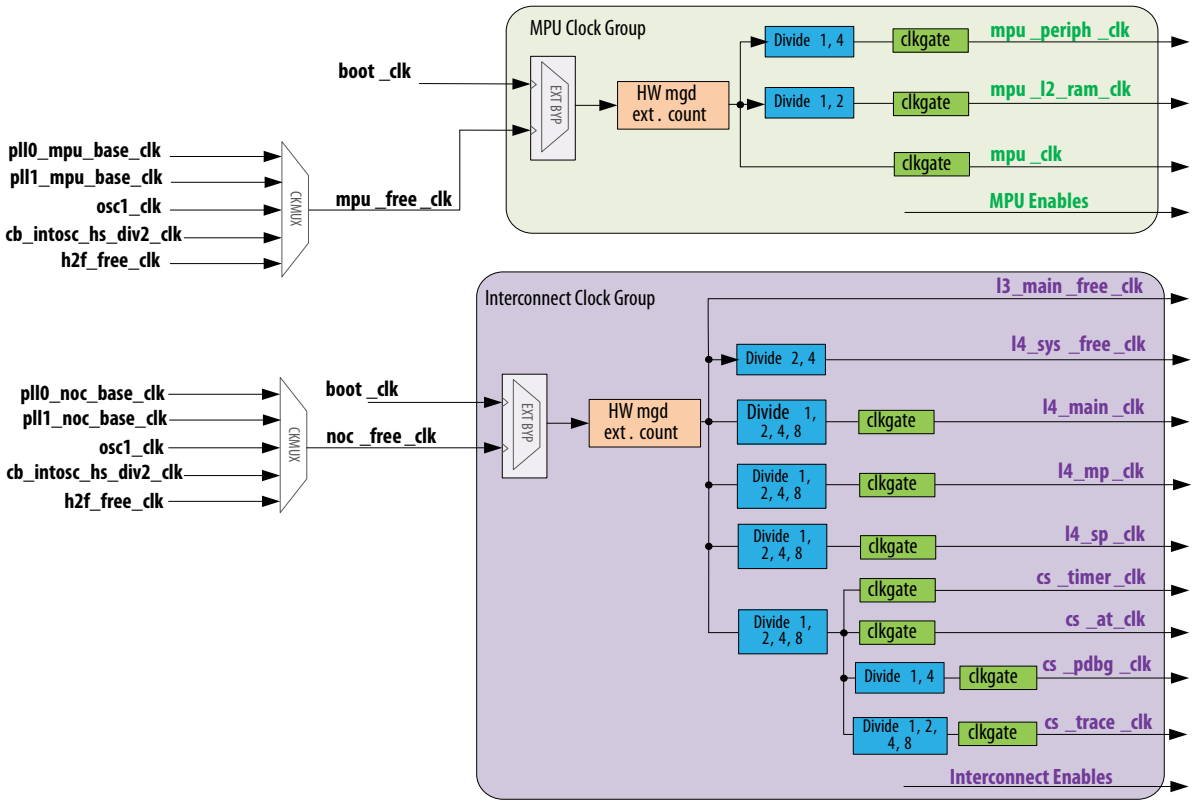

Table 2-5: The Hardware Sequenced Clocks Feature Summary

Clock Output Group	System Clock Name	Frequency	Boot Frequency	Uses
MPU	mpu_clk	PLL C0	boot_clk	MPU subsystem, including CPU0 and CPU1
	mpu_I2_ram_clk	mpu_clk/2	boot_clk	MPU level 2 (L2) RAM
	mpu_periph_clk	mpu_clk/4	boot_clk	MPU snoop control unit (SCU) peripherals, such as the general interrupt controller (GIC)

Clock Output Group	System Clock Name	Frequency	Boot Frequency	Uses
NOC	l3_main_free_clk	PLL C1	boot_clk	L3 interconnect
	l4_sys_free_clk	l3_main_free_clk/4	boot_clk/2	L4 interconnect
	l4_sys_free_div4_clk	l4_sys_free_clk/4	l4_sys_free_clk/4	L4 interconnect timer reference
	l4_main_clk	l3_main_free_clk/{1,2,4,8}	boot_clk	L4 main bus

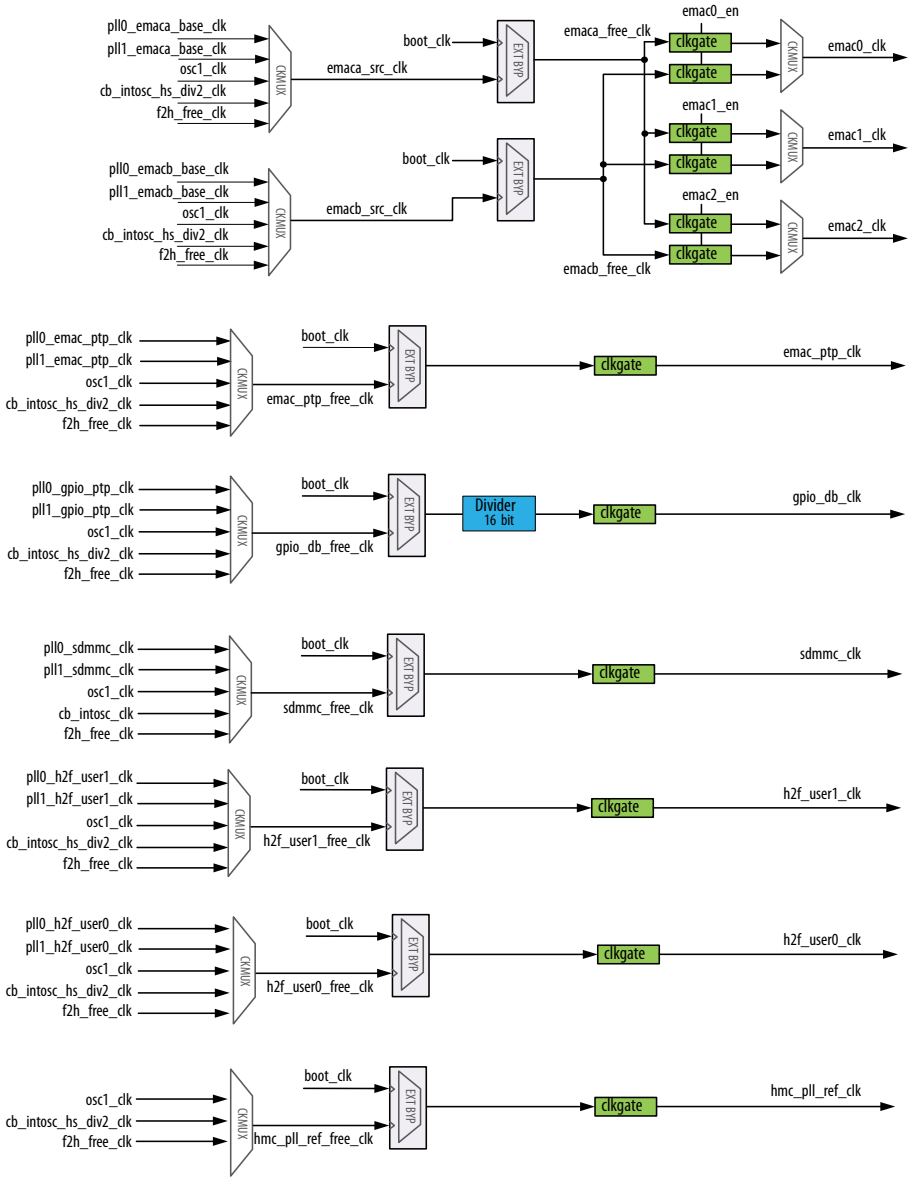
Software Sequenced Clocks

The software sequenced clock groups include additional clocks for peripherals not covered by the NOC clocks. The main purpose is to have a second PLL for the Ethernet 250 MHz clock reference. The following diagram shows the external bypass muxes, hardware-managed external counters and dividers, and clock gates.

Figure 2-5: Peripheral Clocks



There are 3 EMAC cores that have a very strict requirement of either a 250 MHz or 50 MHz clock reference. If the PLL0 frequency is a multiple of 250 MHz (for example 1.5 GHz), driving the EMAC clocks from PLL0 provides PLL1 with more flexibility in VCO clock frequency. In addition, to minimize the PLL clock outputs required, `emac_clka` can be 250 MHz and `emac_clkb` can be 50 MHz, allowing each EMAC core to be software configured to select 250 MHz or 50 MHz.

Table 2-6: Software Sequenced Clocks Feature Summary

System Clock Name	Frequency	Boot Frequency	Descriptions
emac{0,1,2}_clk	PLL C2 or PLL C3	boot_clk	Clock for EMAC. Fixed at 250 MHz or 250 MHz emac_clk and 50 MHz emacb_clk
emac_ptp_clk	PLL C4	boot_clk	Clock for EMAC PTP timestamp clock
gpio_db_clk	125 Hz to PLL C5	boot_clk	Clock for GPIO debounce clock
sdmmc_clk	PLL C6	boot_clk	Clock for SDMMC
h2f_user0_clk	PLL C7	boot_clk	Clock reference for FPGA
h2f_user1_clk	PLL C8	boot_clk	Clock reference for FPGA

Resets

Power-On-Reset (POR) Reset

The security manager handles clocking during POR. Depending on the status of one of the security fuses, the device is initially clocked using either the secure cb_intosc_hs_div2_clk or the unsecure external oscillator.

Cold Reset

The reset manager brings the clock manager out of cold reset first in order to provide clocks to the rest of the blocks. After POR is de-asserted, clock manager enables boot_clk to the rest of the system before the module resets are de-asserted.

Warm Reset

During a Warm Rest, the clock manager module is not reset. The following steps are taken during a warm reset:

1. Reset manager puts all modules affected by Warm Reset into reset. Reset manager issues a Boot Mode request to clock manager.
2. Based on the status of the hps_clk_f fuse during POR, security manager indicates if the boot clock should be secure.
   a. If secure clocks are enabled, boot_clk transitions gracefully to cb_intosc_hs_div2_clk.
   b. If secure clocks are not enabled, boot_clk transitions gracefully to EOSC1.

   Note: The security fuse is only sampled during cold reset and warm reset. The security fuse HPS CLK allows the user to enable secure clocks. If clearing RAM on a Cold or Warm reset, the user should enable secure clocks (cb_intosc_hs_clk divide by 2).
3. The *Clock Manager* gracefully transitions Hardware-Managed and Software Managed clocks into Boot Mode as follows:
   a. Disable all output clocks including Hardware and Software-Managed clocks.
   b. Wait for all clocks to be disabled, and do the following two things:

   a. Bypass all external Hardware and Software-Managed clocks.
   b. Update Hardware-Managed external counters/dividers to Boot Mode settings.
c. Wait for all bypasses to switch, and then synchronously reset the CSR registers.
d. Enable all clocks.

4. After Hardware Managed Clocks have transitioned, the *Clock Manager* acknowledges the *Reset Manager*.
5. *Reset Manager* continues with Warm Reset de-assertion sequence.

Security

The clock manager creates a boot clock as the clock reference for boot mode and external bypass. The clock configuration is based on security features in the security manager.

Security Input Clocks

The following table defines the boot clock sources.

Table 2-7: Security Input Clocks

Clock Name	Max	Min	Source/Dest	Description
`EOSC1`	50	10	Pin	External Oscillator Clock Reference. Non-secure clock reference.
`cb_intosc_hs_clk`	400	120	FPGA Control Block	Control Block high speed internal ring oscillator. This clock has wide variation across process/temperature. This clock is used as the secure reference for Boot Mode. Because the range/jitter of the clock is low quality, the clock is divided by 2.

Clock Name	Max	Min	Source/Dest	Description
cb_intosc_ls_clk	100	30	FPGA Control Block	Control Block low speed internal ring oscillator. This clock has wide variation across process/ temperature. This clock is used by *Security Manager* as the Power on Reset Domain secure clock. This clock is also provided as an input to the *Clock Manager* PLLs. However, because of the low quality of the clock, it is not recommended to use this clock as the PLL reference.

Boot Clock

The status of the hps_clk_f security fuse in the *Security Manager* determines if boot_clk should be secure:

- If set, then boot_clk is cb_intosc_hs_clk divided by 2.
- If clear, then boot_clk is EOSC1.

The above setting is reported by the security manager before the chip is brought out of cold reset. Also the security status may be updated by security option registers in the security manager.

Related Information

SoC Security on page 6-1

Interrupts

The clock manager provides one interrupt output, which is enabled through the interrupt enable register (intren). The interrupt can be programmed to trigger twhen either the PLL achieves or loses its lock.

Clock Manager Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

ctrl

Contains fields that control the entire Clock Manager.

Bit	Name	Description	Access	Reset
9	swctrlbtclksel	This bit is only used if swctrlbtclken is set. If 1, boot_clk source will be from cb_intosc_hs_clk divided by 2. If 0, boot_clk source will be from the external oscillator (EOSC1). This bit is cleared on a cold reset. Warm reset has no affect on this bit.	RW	0x0
8	swctrlbtclken	If set, then Software will take control of the boot_clk mux select. If set, then swctrlbtclksel will determine the mux setting. If not set, the security features will determine the fuse settings. This bit is cleared on a cold reset. Warm reset has no affect on this bit.	RW	0x0

Bit	Name	Description	Access	Reset
0	bootmode	When set the Clock Manager is in Boot Mode. In Boot Mode Clock Manager register settings defining clock behavior are ignored and clocks are set to their Boot Mode settings. All clocks will be bypassed and external HW managed counters and dividers will be set to divide by 1. This bit should only be cleared when clocks have been correctly configured. This field is set on a cold reset and optionally on a warm reset. SW may set this bit to force the clocks into Boot Mode. SW exits Boot Mode by clearing this bit.	RW	0x1

intr

Contains interrupt fields for Clock Manager

Bit	Name	Description	Access	Reset

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved														bootclksrc RO 0x0	bootmode RO 0x1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						perpllocked RO 0x0	mainplllocked RO 0x0	Reserved							busy RO 0x0

stat Fields

Bit	Name	Description	Access	Reset
17	bootclksrc	If 1, the source of boot_clk is cb_intosc_hs_div2_clk. . If 0, the boot_clk source is the external oscillator (EOSC1). This is a read only status.	RO	0x0
16	bootmode	If 1, the clocks are currently in Boot Mode. If 0, the clocks are not in Boot Mode. This is a read only status. For SW to exit Boot Mode, SW must clear the RW bit CTRL.BOOTMODE.	RO	0x1
9	perplllocked	If 1, the Peripheral PLL is currently locked. If 0, the Peripheral PLL is currently not locked.	RO	0x0
8	mainplllocked	If 1, the Main PLL is currently locked. If 0, the Main PLL is currently not locked.	RO	0x0

Bit	Name	Description	Access	Reset
0	busy	This read only bit indicates that the Hardware Managed clock's state machine is active. If the state machine is active, then the clocks are in transition. Software should poll this bit after changing the source of internal clocks when changing the state of CTRL.BOOTMODE, MAINPLLGRP.BYPASS.MPU or MAINPLLGRP.BYPASS.NOC register bits. Immediately following writes to any of these registers, SW should wait 0.5 usecs and then poll this BUSY bit until it is IDLE before proceeding with any other register writes in the Clock Manager. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit. **Value** **Description** 0 IDLE 1 BUSY	RO	0x0

testioctrl

Contains fields setting the IO output select for Test Clock and Debug outputs. The dedicated IO outputs includes two outputs for the Main PLL clock outputs (PLL_CLK0 and PLL_CLK1), two outputs for the Peripheral PLL clock outputs (PLL_CLK2 and PLL_CLK3), and one output for miscelaneous debug for the Main and Peripheral PLL (PLL_CLK4).

The Test Clock and Debug outputs will only propagate to the dedicated IO based on the IO pinmux configuration. If Test Clocks are selected in the pinmux, then the selects in this register determine which PLL clocks and PLL debug signals will propagate to the IOs.

Module Instance	Base Address	Register Address

vco0 Fields

Bit	Name	Description	Access	Reset
28	bwadjen	If set to 1, the Loop Bandwidth Adjust value comes from the Loop Bandwidth Adjust field. If set to 0, the Loop Bandwidth Adjust value equals the M field divided by 2 value of the VCO Control Register. The M divided by 2 is the upper 12 bits (12:1) of the M field in the VCO register.	RW	0x0
27:16	bwadj	Provides Loop Bandwidth Adjust value.	RW	0x1
9:8	psrc	Controls the VCO input clock source. **Value** — **Description** 0 — EOSC1 (external oscillator) 1 — cb_intosc_ls_clk (internal low speed oscillator) 2 — f2h_free_clk (FPGA fabric PLL clock reference)	RW	0x0
6	saten	Enables saturation behavior.	RW	0x1
5	fasten	Enables fast locking circuit.	RW	0x0
4	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is slected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulater once the PLL becomes enabled. Software should simulate-ously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

Bit	Name	Description	Access	Reset
3	outresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0
2	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
1	pwrdn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
0	bgpwrdn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

vco1

Contains settings that control the Main PLL VCO. The VCO1 register contains the numerator and denominator counter settings.

Module Instance	Base Address	Register Address

4	csclken	Enables Debug Clock outputs (cs_at_clk, cs_pdbg_clk and cs_trace_clk)	RW	0x1
3	l4spclken	Enables clock l4_sp_clk output	RW	0x1
2	l4mpclken	Enables clock l4_mp_clk output	RW	0x1
1	l4mainclken	Enables clock l4_main_clk output	RW	0x1
0	mpuclken	Enable for MPU Clock Group (mpu_clk, mpu_l2ram_clk and mpu_periph_clk).	RW	0x1

bypass

Contains fields that control bypass for clocks derived from the Main PLL.
1: The clock is bypassed to boot_clk.
0: The clock is derived from the 5:1 active mux.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD04054

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

outrst

Contains settings to assert individual Outreset for all Main PLL Counters.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD040A0

Offset: 0x60

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
outreset RW 0x0															

outrst Fields

Bit	Name	Description	Access	Reset
15:0	outreset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the Output Counter Reset Register 'Output Counter Reset' bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective Output Counter Reset bit. LSB 'outreset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

outrststat

Contains Output Clock Counter Reset acknowledge status.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD040A4

Offset: 0x64

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
outresetack RO 0x0															

outrststat Fields

Bit	Name	Description	Access	Reset
15:0	outresetack	These read only bits per PLL output indicate that the PLL has received the Output Reset Counter request and has gracefully stopped the respective PLL output clock. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the Output Counter Reset Register 'Output Counter Reset' bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective Output Counter Reset bit. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit. **Value** **Description** 0 IDLE 1 ACK_RECEIVED	RO	0x0

nocdiv

Contains fields that control clock dividers for NoC Clocks.

Module Instance	Base Address	Register Address
i_clk_mgr_mainpllgrp	0xFFD04040	0xFFD040A8

Offset: 0x68

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

vco0

Contains settings that control the Peripheral PLL VCO. VCO0 register contains signals required for PLL reset and power down.

Module Instance	Base Address	Register Address
i_clk_mgr_perpllgrp	0xFFD040C0	0xFFD040C0

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved			bwadjen RW 0x0	bwadj RW 0x1											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						psrc RW 0x0		Reserved	saten RW 0x1	fasten RW 0x0	regextsel RW 0x0	outresetall RW 0x0	en RW 0x0	pwrdn RW 0x1	bgpwrdn RW 0x1

vco0 Fields

Bit	Name	Description	Access	Reset
28	bwadjen	If set to 1, the Loop Bandwidth Adjust value comes from the Loop Bandwidth Adjust field. If set to 0, the Loop Bandwidth Adjust value equals the M field divided by 2 value of the VCO Control Register. The M divided by 2 is the upper 12 bits (12:1) of the M field in the VCO register.	RW	0x0
27:16	bwadj	Provides Loop Bandwidth Adjust value.	RW	0x1
9:8	psrc	Controls the VCO input clock source. Value: Description 0: EOSC1 1: INTOSC 2: F2S 3: MAIN	RW	0x0
6	saten	Enables saturation behavior.	RW	0x1
5	fasten	Enables fast locking circuit.	RW	0x0
4	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is slected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulater once the PLL becomes enabled. Software should simulate-ously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

Bit	Name	Description	Access	Reset
3	outresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0
2	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
1	pwrdn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
0	bgpwrdn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

vco1

Contains settings that control the Peripheral PLL VCO. The VCO1 register contains the numerator and denominator counter settings.

Module Instance	Base Address	Register Address
i_clk_mgr_perpllgrp	0xFFD040C0	0xFFD040C4

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Reserved										denom RW 0x1					
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			numer RW 0x1												

vco1 Fields

Bit	Name	Description	Access	Reset
21:16	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
12:0	numer	Numerator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1

en

Contains fields that control clock enables for clocks derived from the Peripheral PLL.
1: The clock is enabled.
0: The clock is disabled.

outreset RW 0x0															

outrst Fields

Bit	Name	Description	Access	Reset
15:0	outreset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the Output Counter Reset Register 'Output Counter Reset' bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective Output Counter Reset bit. LSB 'outreset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0

outrststat

Contains Output Clock Counter Reset acknowledge status.

Document Revision History

Table 2-8: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	• Added `mpuclk` register (offset 0x0) to i_clk_mgr_alteragrp
May 2016	2016.05.27	• Removed references to `f2h_emac*_ap_clk` in the *Arria 10 Top Level Clocks* table. The Ethernet application interface (also called the switch interface) is not supported. • Removed `clk9cntr` (offset 0x44) and `clk15cntr` (offset 0x5C) registers from the i_clk_mgr_mainpllgrp • Removed `clk9cntr` register (offset 0x44) from the i_clk_mgr_perpllgrp • Clarified the `src` fields of the `clk*cntr` registers in the i_clk_mgr_mainpllgrp and i_clk_mgr_perpllgrp Removed references to PLL counter outputs C9-C15 from the following topics: • Boot Clock • PLLs • FREF, FVCO, and FOUT Equations
May 2016	2016.05.03	Added a section titled "L4 Peripheral Clocks".
November 2015	2015.11.02	Updated Sections: • Clock Manager Block Diagram and System Integration • PLL Integration • Software Sequenced Clocks • Clock Gating • Boot Clock Added Sections: • Updating PLL Settings without a System Reset • MPU Clock Scaling Updates: • Removed references to PLL output C9 used as HMC PLL reference clock.
May 2015	2015.05.04	• Updated Block Diagram with HMC block • Added Arria 10 Top Level Clocks table • Updated PLL Integration in Clock Manager figure • Added Address Map and Register Descriptions

Date	Version	Changes
December 2014	2014.12.15	Clock Manager Block Diagram. Updated mux output route. NOC clock added. Peripheral Clocks block update C15 input for PLL1 has been removed throughout document.
August 2014	2014.08.18	Initial release.

Reset Manager 3

2016.10.28

a10_5v4 Subscribe Send Feedback

The reset manager generates module reset signals based on reset requests from the various sources in the HPS and FPGA fabric, and software writing to the module-reset control registers. The reset manager ensures that a reset request from the FPGA fabric can occur only after the FPGA portion of the system-on-a-chip (SoC) device is configured.

The HPS contains multiple reset domains. Each reset domain can be reset independently. A reset may be initiated externally, internally or through software.

The Reset domains and sequences include security features. The security manager works with Power On Reset (POR) and brings the reset manager out of reset only when the secure fuses have been loaded and validated. Once this process is complete, the reset manager brings the rest of the HPS out of reset.

Table 3-1: HPS Reset Domains

Domain Name	Domain Logic	Module Master	Description
POR	Power on Reset. The entire HPS is reset.	Security Manager	After POR, the security manager comes out of reset and validates the security fuses. After validation, the reset manager is released from reset and proceeds to perform a cold reset on the HPS.
System Cold	Cold Reset. All of the HPS except security manager and POR fuse logic.	Reset Manager	Using the known security state, the HPS is placed in the default state, allowing software to boot. Cold reset is triggered by POR as well as other sources.

Domain Name	Domain Logic	Module Master	Description
System Warm	System Warm (SW) is a warm reset. All of the HPS except security manager, POR, Fuse Logic, and test access port (TAP), and Debug domains are reset.	Reset Manager	Used to recover system from a non-responsive condition. Resets a subset of the HPS state reset by a cold reset. Only affects the system reset domain, which allows debugging (including trace) to operate through the warm reset. It is possible to mask a warm reset for some modules such that they are not affected.
Debug	All debug logic including most of the DAP, CoreSight™ components connected to the debug peripheral bus, trace, the microprocessor unit (MPU) subsystem, and the FPGA fabric.	Reset Manager	May be asserted by cold reset, the debugger or software. Used to recover debug logic from a non-responsive condition.
TAP	JTAG test access port (TAP) controller, which is used by the debug access port (DAP).	Reset Manager	Asserted by cold reset or by Software.
RAM Clear	The on-chip memories are cleared	Reset Manager	Memories may be cleared on cold or warm as indicated by the corresponding bits in the `ramstat` register.

The HPS supports the following reset types:

- System cold reset
  - Used to ensure the HPS is placed in a default state sufficient for software to boot
  - Triggered by a power-on reset and other sources
  - Resets all HPS logic that can be reset
  - Affects all reset domains
- System warm reset
  - Used to recover system from a non-responsive condition
  - Does not reset the Debug or TAP reset domain, allowing debug functions including trace to operate through out a warm reset
  - Masks allow software to exclude modules from warm reset. Exceptions for masks:
    - To maintain security, there is no mask for security manager
    - The MPU cannot be masked
  - RAM Clearing domain (if not masked) logic is reset
- Debug reset
  - Used to recover debug logic from a non-responsive condition
  - Only affects the debug reset domain
- TAP Reset
  - JTAG TAP controller is reset
  - Software may trigger TAP reset

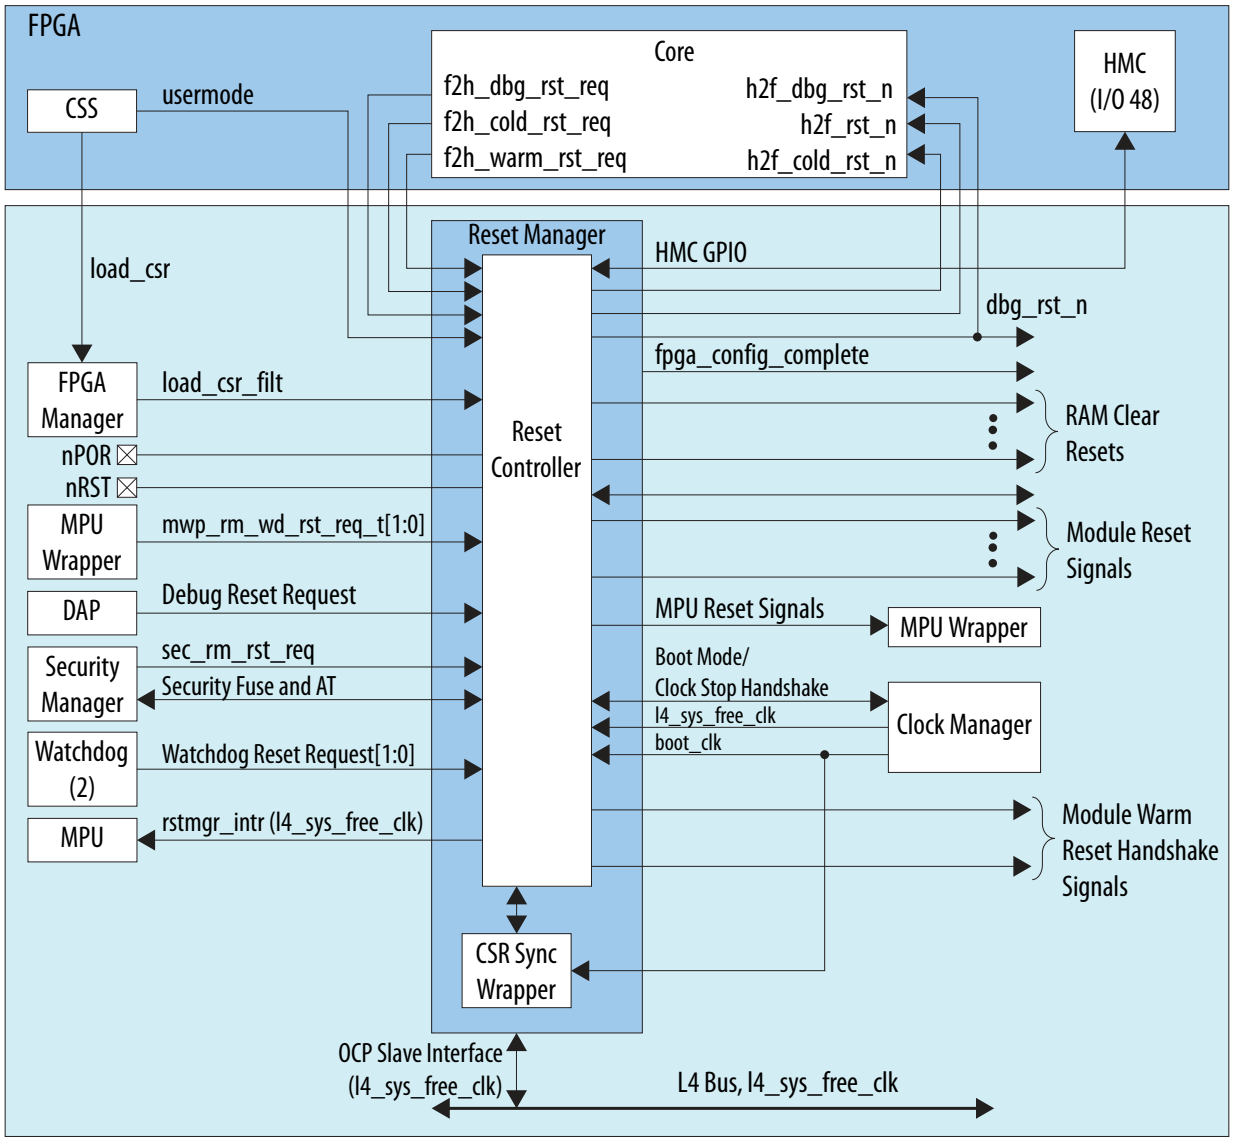
SoC Security on page 6-1

Reset Manager Block Diagram and System Integration

The reset manager accepts reset requests from the security manager, FPGA control block, FPGA core, modules in the HPS, and reset pins and generates module reset signals. The reset manager receives security status from the security manager. The reset manager also has warm reset handshaking signals to support system reset behavior, clock manager interfaces, and the Anti-Tamper interface with security manager. The Boot clock (`boot_clk`) is used as the default clock for both cold or warm reset. When the device is configured to operate in secure mode, `boot_clk` is `cb_intosc_hs_div2_clk`. When the device is not in secure mode, `boot_clk` is EOSC1.

The following figure shows a block diagram of the reset manager in the SoC device. For clarity, reset-related handshaking signals to other HPS modules and to the clock manager module are omitted.

Figure 3-1: Reset Manager Block Diagram



Reset Controller

In secure mode, all signals are synchronous to `boot_clk`. In non-secure mode, all signals are synchronous to `osc1_clk`. The following table lists the reset sources external to the HPS.

Table 3-2: HPS External Reset Sources

Source	Description
`f2h_cold_rst_req_n`	Cold reset request from FPGA fabric (active low)
`f2h_warm_rst_req_n`	Warm reset request from FPGA fabric (active low)

Source	Description
f2h_dbg_rst_req_n	Debug reset request from FPGA fabric (active low)
load_csr_filt	Cold-only reset from FPGA control block (CB)
nPOR	Power-on reset pin (active low)
nRST	Warm reset pin (active low)

Table 3-3: HPS External Reset Outputs

Source	Description
h2f_cold_rst_n	Cold-only reset to FPGA fabric (active low)
h2f_rst_n	Cold or warm reset to FPGA fabric (active low)
h2f_dbg_rst_n	Debug reset (dbg_rst_n) to FPGA fabric (active low)

The reset controller performs the following functions:

- Accepts reset requests from the FPGA control block (CB), FPGA fabric, modules in the HPS, and reset pins
- Generates an individual reset signal for each module instance for all modules in the HPS
- Provides reset handshaking signals to support system reset behavior

The reset controller generates module reset signals from external reset requests and internal reset requests. External reset requests originate from sources external to the reset manager. Internal reset requests originate from control registers in the reset manager.

The reset controller supports the following cold reset requests:

- Security manager reset
- Cold reset request pin (nPOR)
- FPGA fabric
- FPGA CB
- Software cold reset request bit (swcoldrstreq) of the control register (ctrl)

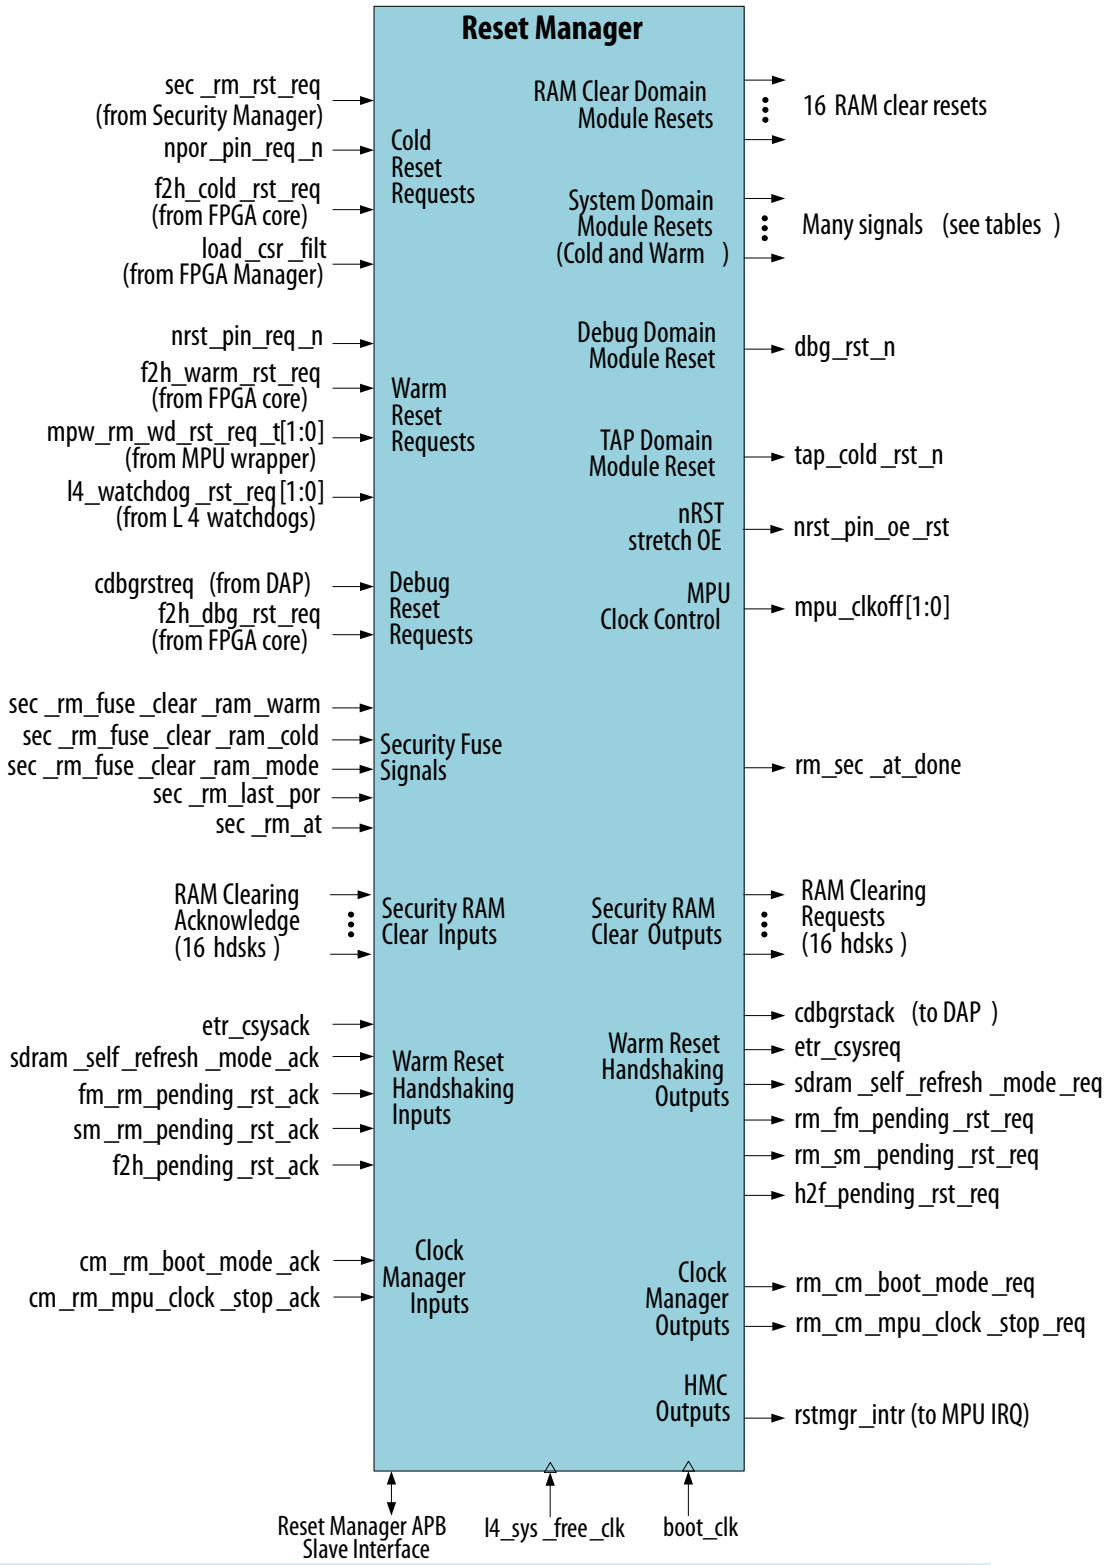
The reset controller supports the following warm reset requests:

- Warm reset request pin (nRST)
- FPGA fabric
- Software warm reset request bit (swwarmrstreq) of the ctrl register
- MPU watchdog reset requests for CPU0 and CPU1
- System watchdog timer 0 and 1 reset requests

The reset controller supports the following debug reset requests:

- CDBGRSTREQ from DAP
- FPGA fabric

Figure 3-2: Reset Controller Signals



Security Reset Functions

When secure mode is enabled on the device, reset manager performs some additional functions. To avoid unsecure snooping of existing RAM contents, the HPS can be configured to clear all RAM, both general-purpose RAM and dedicated RAM that is integrated into modules. The list of RAMs on the HPS is:

- Onchip RAM
- USB0
- USB1
- SDMMC
- EMAC0 - EMAC2 RX and TX buffers
- DMA
- NAND Read, Write and ECC RAMs
- QSPI
- MPU RAM

RAMs can be cleared on cold reset, warm reset or both as there are separate fuses that control behavior for cold and warm resets. When the corresponding fuse is blown, all RAMs are cleared for the indicated reset type. If an additional fuse is blown, the various RAM contents are cleared sequentially; otherwise, the contents of all of the RAMs are cleared simultaneously. Even if all security RAM clearing is disabled, the reset manager always invalidates the MPU L1 Cache.

The HPS also supports an Anti-Tamper interface from the FPGA fabric to security manager. If an Anti-Tamper event occurs, the HPS clears all RAMs and becomes unresponsive. The HPS only recovers from this state by a POR. Anti-Tamper logic, such as voltage detection, may reside in the FPGA.

Module Reset Signals

The following tables list the module reset signals. The module reset signals are organized in groups for the MPU, peripherals, bridges.

In the following tables, columns marked for Cold Reset, Warm Reset, and Debug Reset denote reset signals asserted by each type of reset. For example, writing a 1 to the `swwarmrstreq` bit in the `ctrl` register resets all the modules that have a checkmark in the Warm Reset column.

Note: For warm resets, software can set the warmmask registers to prevent the assertion of module reset signals to peripheral modules.

The column marked for Software Deassert denotes reset signals that are left asserted by the reset manager.

Table 3-4: MPU Group, Generated Module Resets

Module Reset Signal	Description	Reset Domain	Cold Reset	Warm Reset	Debug Reset	Software Deassert
`mpu_cpu_rst_n[0]`	Resets each processor in the MPU	System	X	X

Modules Requiring Software Deassert

The reset manager leaves the reset signal asserted on certain modules even after the rest of the HPS has come out of reset. These modules are likely to require software configuration before they can safely be taken out of reset.

When a module that has been held in reset is ready to start running, software can deassert the reset signal by writing to the appropriate register, shown in the following table.

Table 3-11: Module Reset Signals and Registers

HPS Peripheral	Reset Register	Module Reset Signal	Reset Group

Slave Interface and Status Register

The reset manager slave interface is used to control and monitor the reset states.

The status register (`stat`) in the reset manager contains the status of the reset requester. The register contains a bit for each monitored reset request. The `stat` register captures all reset requests that have occurred. Software is responsible for clearing the bits.

During the boot process, the Boot ROM copies the `stat` register value into memory before clearing it. After booting, you can read the value of the reset status register at memory address (`r0` + 0x0038). For more information, refer to the "HPS State on Entry to the Second-Stage Boot Loader" section of the *Booting and Configuration* appendix.

Related Information

HPS State on Entry to the Second-Stage Boot Loader on page 30-43

Functional Description of the Reset Manager

The reset manager generates reset signals to modules in the HPS and to the FPGA fabric. The following actions generate reset signals:

- Software writing a 1 to the `swcoldrstreq` or `swwarmrstreq` bits in the `ctrl` register. Writing either bit causes the reset controller to perform a reset sequence.
- Software writing to the `mpumodrst`, `per0modrst`, `per1modrst`, `brgmodrst`, `sysmodrst`, `coldmodrst`, `nrstmodrst` or `dbgmodrst` module reset control registers.
- Asserting reset request signals triggers the reset controller. All external reset requests cause the reset controller to perform a reset sequence.

Multiple reset requests can be driven to the reset manager at the same time. Cold reset requests take priority over warm and debug reset requests. Higher priority reset requests preempt lower priority reset requests. There is no priority difference among reset requests within the same domain.

If a cold reset request is issued while another cold reset is already underway, the reset manager extends the reset period for all the module reset outputs until all cold reset requests are removed. If a cold reset request is issued while the reset manager is removing other modules out of the reset state, the reset manager returns those modules back to the reset state.

If a warm reset request is issued while another warm reset is already underway, the first warm reset completes before the second warm reset begins. If the second warm reset request is removed before the first warm reset completes, the warm first reset is extended to meet the timing requirements of the second warm reset request.

The `nPOR` pin can be used to extend the cold reset beyond what the POR voltage monitor automatically provides. The use of the `nPOR` pin is optional and can be tied high when it is not required.

The nRST pin can be used to extend a warm reset. The nRST pin is tri-stated, and the Reset Manager stretches a warm reset by the count programed in the CSR (RSTMGR.COUNTS.NRSTCNT) [doc however you usually do registers and bits] After the count has elapsed, 256 additional clocks cycles elapse before the nRST input is sampled again.

The reset manager contains the stat register that indicates which reset source caused a reset as well as the `ramstat` register that indicates which RAM modules were cleared during the last reset. After a cold reset is complete, all bits are cleared except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the bit corresponding to the source that de-asserts its request last is set. If more than one source is de-asserted in the same cycle, the value of the bit corresponding to each source is set.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any bits in the stat register, so bits corresponding to any reset source that has caused a warm reset since the last cold reset or since the bits were last cleared are set. Any bit can be manually cleared by writing a 1 to it.

If RAM memory is cleared during a Cold or Warm reset, then the `ramstat` register indicates which RAMs during the reset. Bits are cleared manually by writing a 1.

The hard memory controller (HMC) in the FPGA is reset by the reset manager using a GPIO. The HMC is reset only through software; resetting the HMC is not part of the operation of any reset sources.

Related Information

Arria 10 Device Datasheet

For information about the required duration of reset request signal assertion, refer to the Arria 10 Device Datasheet.

Reset Sequencing

The reset controller sequences resets without software assistance. Module reset signals are asserted asynchronously and synchronously. The reset manager deasserts the module reset signals synchronous to the `boot_clk` clock. Module reset signals are deasserted in groups in a fixed sequence. All module reset signals in a group are deasserted at the same time.

The reset manager sends a request to the clock manager to put the clocks in boot mode, which creates a fixed and known relationship between the `boot_clk` clock and all other clocks generated by the clock manager.

After the reset manager releases the MPU subsystem from reset, CPU1 is left in reset and CPU0 begins executing code from the reset vector address. Software is responsible for deasserting CPU1 and other resets, as shown in MPU Group, Generated Module Resets Table. Software deasserts resets by writing the `mpumodrst`, `per0modrst`, `per1modrst`, `brgmodrst`, `sysmodrst`, `coldmodrst`, `nrstmodrst`, and `dbgmodrst` module-reset control registers.

Software can also bypass the reset controller and generate reset signals directly through the module-reset control registers. In this case, software is responsible for asserting module reset signals, driving them for the appropriate duration, and deasserting them in the correct order. The clock manager is not typically in boot mode during this time, so software is responsible for knowing the relationship between the clocks generated by the clock manager. Software must not assert a module reset signal that would prevent software from deasserting the module reset signal. For example, software should not assert the module reset to the processor executing the software.

Table 3-12: Minimum Pulse Width

Reset Type	Value
Warm Reset	200 ns
Cold Reset	6 `osc1_clk` cycles

Figure 3-3: Cold Reset Timing Diagram

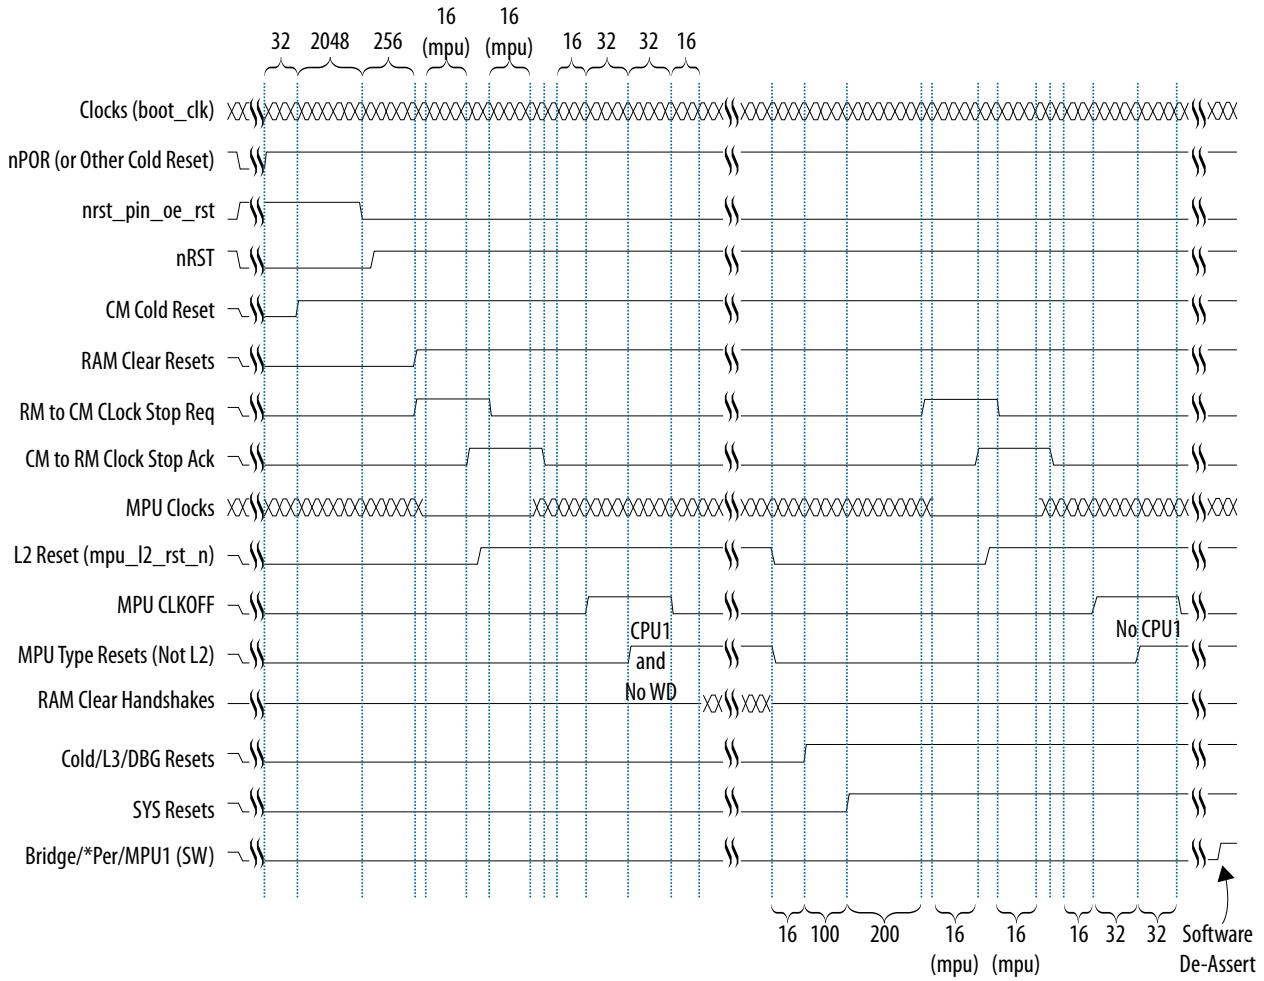

Figure 3-4: Warm Reset Timing Diagram

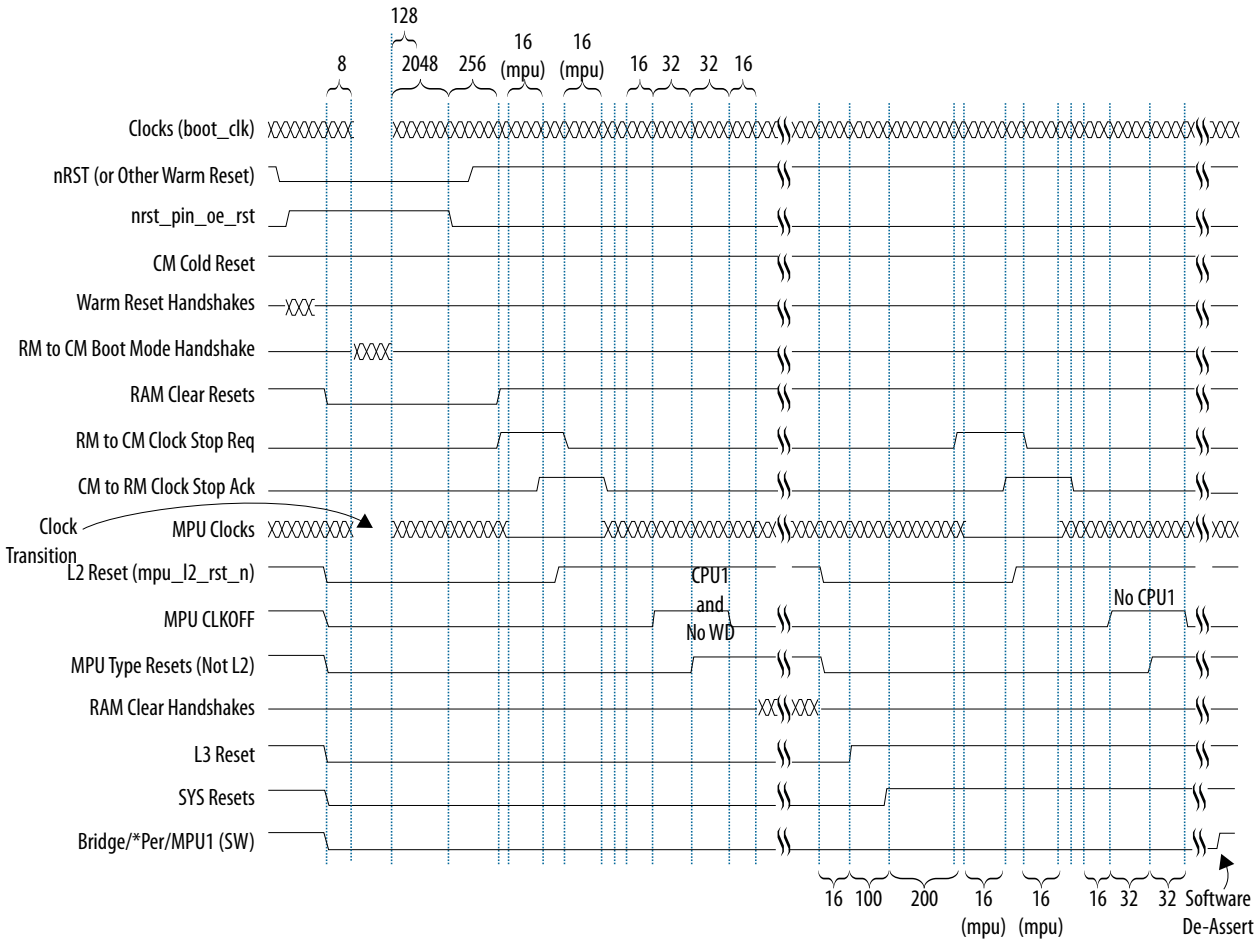

The cold and warm reset sequences consist of different reset assertion sequences and the same deassertion sequence. The following sections describe the sequences.

Note: Cold and warm reset affect only the `cpu0`, and by default cpu1 is held in reset until the software running in the `cpu0` releases it.

  For more information about safe mode, refer to the *Clock Manager* chapter.

Cold Reset Assertion Sequence

The following list describes the assertion steps for cold reset shown in the Cold Reset timing diagram:

1. Assert all module resets.
2. Wait for level cold reset requests to de-assert
3. Wait for 32 cycles, de-asserts clock manager cold reset
4. Wait the nRST count (default is 2048). De-assert NRST Output Enable.

5. Wait 256 clocks to allow the nRST pin to stabilize. Start sampling nRST input pin.
6. Wait for level warm reset requests to all de-assert.
7. Go to de-assertion sequence.

Related Information

Cold and Warm Reset Deassertion Sequence on page 3-19

Warm Reset Assertion Sequence

The following list describes the assertion steps for warm reset shown in the Warm Reset Timing Diagram:

1. Reset manager performs optional handshake configured by SW with debug ETR. Wait for acknowledge.
2. Reset manager performs optional handshake configured by SW handshake with FPGA core. Wait for acknowledge.
3. Reset manager performs optional handshakes configured by SW with SDRAM and FPGA manager. Wait for acknowledges.
4. Reset manager asserts module resets except for MPU watchdogs if the watchdogs were the source of the warm reset.
5. Wait for 8 cycles, then reset manger sends `rm_cm_boot_mode_req` to clock manager. Wait until the Clock Manager acknowledges.
6. Start nRST count if non-zero and a fixed counter to 128 (COUNTS.WARMRSCYCLES).
7. If nRST count non-zero, start 256 stretch counter after nRST count is done to allow the nRST pin to stabilize. After 256 clocks, sample input pin nRST.
8. Wait for level warm reset requests to de-assert, the nRST count to be zero and the fixed 128 count to be zero.
9. Go to de-assertion sequence.

Related Information

Cold and Warm Reset Deassertion Sequence on page 3-19

Cold and Warm Reset Deassertion Sequence

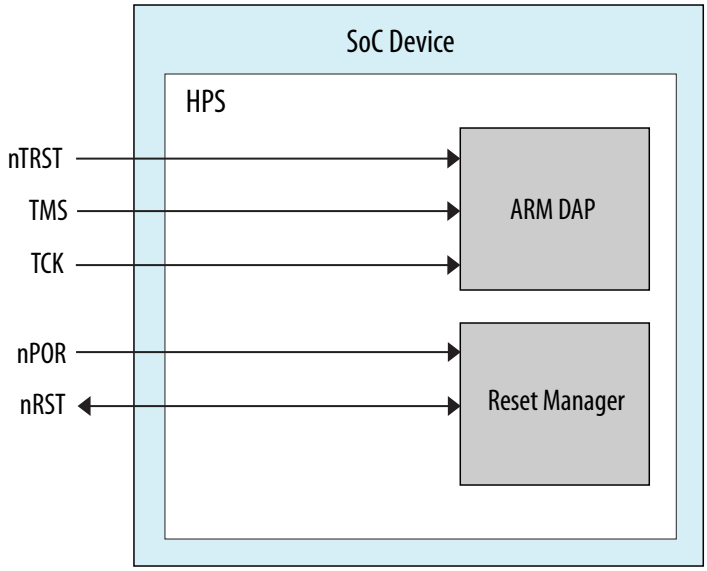
The following list describes the deassertion steps for both cold and warm reset shown in the Cold Reset Timing Diagram and Warm Reset Timing Diagram:

1. De-assert all RAM CLEAR resets. Reset Manager Initiates Clock Manager MPU clocks stop request.
2. Clock manager stops the MPU clocks and then waits 16 MPU clocks.
3. Clock manager asserts Clock stop acknowledge to Reset Manager.
4. Reset manager sees acknowledge and de-asserts L2 (mpu_l2_rst_n) reset only. Reset Manager de-asserts MPU stop request.
5. Clock manger sees request de-asserted. Wait 16 MPU clocks. Start MPU clocks, and Clock Manager de-asserts Clock stop acknowledge.
6. Reset manager sees de-assertion of acknowledge. Wait 16 cycles.
7. Reset manager asserts CPU0/1 CLKOFF signals and waits 32 cycles.
8. Reset manager de-asserts CPU0, CPU1, and SCU MPU resets (not WD). Wait 32 additional cycles.
9. De-assert CPU0/1 CLKOFF signals. Wait 16 cycles
10. Reset manager checks the Security fuse setting, and if the appropriate cold or warm reset fuse is set, do full RAM clearing sequence. Otherwise, clear only the MPU L1 RAM.
11. Wait for Security RAM Sequence to complete.
12. Assert again the CPU0, CPU1 and SCU MPU resets. Wait 16 cycles.
13. De-assert L3 reset, and if Cold Reset, de-assert DBG and COLD groups of resets. Wait for 100 cycles

14. De-assert SYS group module resets. Wait for 200 cycles.
15. Reset manager Initiates Clock Manager MPU clocks stop request.
16. Clock manager stops the MPU clocks and then waits 16 MPU clocks.
17. Clock manager asserts Clock stop acknowledge to Reset Manager.
18. Reset manager sees acknowledge and de-asserts L2 (mpu_l2_rst_n) reset only. Reset Manager de-asserts MPU stop request.
19. Clock manger sees request de-asserted. Wait 16 MPU clocks. Start MPU clocks, and Clock Manager de-asserts Clock stop acknowledge.
20. Reset manager sees de-assertion of acknowledge. Wait 16 cycles.
21. Reset manager asserts CPU0 CLKOFF signal(s) and waits 32 cycles.
22. Reset manager de-asserts remaining CPU0, SCU, and WD resets (no CPU1). Wait 32 additional cycles.
23. De-assert CPU0 CLKOFF signal(s). De-assertion sequence is finished.
24. Now SW should start running. SW to de-assert FPER/PER/SPER/BRIDGE/MPU2 resets.

Reset Pins

Figure 3-5: Reset Pins



The test reset (nTRST), test mode select (TMS), and test clock (TCK) pins are associated with the TAP reset domain and are used to reset the TAP controller in the DAP. These pins are not connected to the reset manager.

The nPOR and nRST pins are used to request cold and warm resets respectively. The nRST pin is an output as well. Any warm reset request causes the reset manager to drive the rst_pin_oe_rst output enable high, which drives the nRST pin low. The amount of time the reset manager pulls nRST low is controlled by the nRST pin count field (nrstcnt) of the reset cycles count register (counts); the default is 2048 clocks. This technique can be used to reset external devices (such as external memories) connected to the HPS.

Reset Effects

The following list describes how reset affects HPS logic:

- In the security manager domain, some status bits are cleared differently for cold and warm reset.
- The TAP reset domain ignores warm reset
- The Debug reset domain ignores warm reset
- The Clock Manager module is reset only by cold reset. After warm reset, the Clock Manager is put into Boot Mode.
- Each peripheral module and System Manager define reset behavior differently. See the appropriate control register for details.
- In the MPU module, the Watchdog Reset Status Registers are reset if an MPU Watchdog triggered the warm reset
- The Pin MUX is reset only by cold reset.

Reset Handshaking

The reset manager participates in several reset handshaking protocols to ensure other modules are safely reset.

Before issuing a warm reset, the reset manager performs a handshake with several modules to allow them to prepare for a warm reset. The handshake logic ensures the following conditions:

- Optionally the ETR master has no pending master transactions to the L3 interconnect
- Optionally preserve SDRAM contents during warm reset by issuing self-refresh mode request
- FPGA manager stops generating configuration clock
- Warns the FPGA fabric of the forthcoming warm reset

Similarly, the handshake logic associated with ETR also occurs during the debug reset to ensure that the ETR master has no pending master transactions to the L3 interconnect before the debug reset is issued. This action ensures that when ETR undergoes a debug reset, the reset has no adverse effects on the system domain portion of the ETR.

Reset Manager Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

stat

The STAT register contains bits that indicate the reset source. For reset sources, a field is 1 if its associated reset requester caused the reset.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any of the bits in the STAT register; these bits must be cleared by software writing the STAT register.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

ramstat

The RAMSTAT register contains bits that indicate the security RAM clearing event during cold or warm reset for each RAM.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

For MPU, there are seperate bits for L1 invalidate only or full security clearing.

There is another bit for L1 invalidate timeout error only. The security RAM clearing does not have a timeout.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

miscstat

The MISCSTAT register contains bits that indicate the timeout event. For timeout events, a field is 1 if its associated timeout occured as part of a hardware sequenced warm/debug reset.

Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored.

After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset

request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0.

After a warm reset is complete, the bit(s) that indicate the source of the warm reset are set to 1. A warm reset doesn't clear any of the bits in the MISCSTAT register; these bits must be cleared by software writing the STAT register.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												etrstallen RW 0x0	fpgahsen RW 0x0	fpgamgrhsen RW 0x0	sdrselfrefen RW 0x0

hdsken Fields

Bit	Name	Description	Access	Reset
3	etrstallen	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0
2	fpgahsen	This field controls whether to perform handshake with FPGA before asserting warm reset. If set to 1, the Reset Manager makes a request to the FPGAbefore asserting warm reset signals. However if FPGA is already in warm reset state, the handshake is not performed. If set to 0, the handshake is not performed	RW	0x0
1	fpgamgrhsen	Enables a handshake between the Reset Manager and FPGA Manager before a warm reset. The handshake is used to warn the FPGA Manager that a warm reset it coming so it can prepare for it. When the FPGA Manager receives a warm reset handshake, the FPGA Manager drives its output clock to a quiescent state to avoid glitches. If set to 1, the Manager makes a request to the FPGA Managerbefore asserting warm reset signals. However if the FPGA Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0

Bit	Name	Description	Access	Reset
0	sdrselfrefen	This field controls whether the contents of SDRAM devices survive a hardware sequenced warm reset. If set to 1, the Reset Manager makes a request to the SDRAM Controller Subsystem to put the SDRAM devices into self-refresh mode before asserting warm reset signals. However, if SDRAM is already in warm reset, Handshake with SDRAM is not performed.	RW	0x0

hdskreq

The CTRL register is used by software to control reset behavior.It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform software handshake. The software handshake sequence must match the hardware sequence. Software mustde-assert the handshake request after asserting warm reset and before de-assert the warm reset.

Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

hdskreq Fields

Bit	Name	Description	Access	Reset
3	etrstallreq	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0
2	fpgahsreq	Software writes this field 1 to initiate handshake request to FPGA . Software waits for the FPGAHSACK to be active and then writes this field to 0. Note that it is possible for the FPGA to never assert FPGAHSACK so software should timeout in this case.	RW	0x0
1	fpgamgrhsreq	Software writes this field 1 to request to the FPGA Manager to idle its output clock. Software waits for the FPGAMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the FPGA Manager to never assert FPGAMGRHSACK so software should timeout in this case.	RW	0x0
0	sdrselfrefreq	Software writes this field 1 to request to the SDRAM Controller Subsystem that it puts the SDRAM devices into self-refresh mode. This is done to preserve SDRAM contents across a software warm reset. Software waits for the SDRSELFREFACK to be 1 and then writes this field to 0. Note that it is possible for the SDRAM Controller Subsystem to never assert SDRSELFREFACK so software should timeout if SDRSELFREFACK is never asserted.	RW	0x0

hdskack

The CTRL register is used by software to control reset behavior.It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform software handshake. The software handshake sequence must match the hardware sequence. Software mustde-assert the handshake request after asserting warm reset and before de-assert the warm reset.

Fields are only reset by a cold reset.

Module Instance	Base Address	Register Address

counts Fields

Bit	Name	Description	Access	Reset
31:24	warmrstcycles	On a warm reset, the Reset Manager releases the reset to the Clock Manager, and then waits for the number of cycles specified in this register before releasing the rest of the hardware controlled resets.	RW	0x80
19:0	nrstcnt	The Reset Manager pulls down the nRST pin on a warm reset for the number of cycles specified in this register. A value of 0x0 is reserved. nRST assertion on a warm reset may be disabled by clearing NRSTWARMMASK.NRSTPINOE.	RW	0x800

mpumodrst

The MPUMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software.

Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal.

All fields except CPU1 are only reset by a cold reset. The CPU1 field is reset by a cold reset. The CPU1 field is also reset by a warm reset if not masked by the corresponding MPUWARMMASK field.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Reserved												scuper RW 0x0	wds RW 0x0	cpu1 RW 0x1	cpu0 RW 0x0

mpumodrst Fields

Bit	Name	Description	Access	Reset
3	scuper	Resets SCU and peripherals. Peripherals consist of the interrupt controller, global timer, both per-CPU private timers, and both per-CPU watchdogs (except for the Watchdog Reset Status registers).	RW	0x0
2	wds	Resets both per-CPU Watchdog Reset Status registers in MPU.	RW	0x0

Bit	Name	Description	Access	Reset
1	cpu1	Resets Cortex-A9 CPU1 in MPU. It is reset to 1 on a cold or warm reset. This holds CPU1 in reset until software is ready to release CPU1 from reset by writing 0 to this field. On single-core devices, writes to this field are ignored.On dual-core devices, writes to this field trigger the same sequence as writes to the CPU0 field (except the sequence is performed on CPU1).	RW	0x1
0	cpu0	Resets Cortex-A9 CPU0 in MPU. Whe software changes this field from 0 to 1, ittriggers the following sequence: 1. CPU0 reset is asserted. cpu0 clkoff is de-asserted 2. after 32 osc1_clk cycles, cpu0 clkoff is asserted. When software changes this field from 1 to 0, it triggers the following sequence: 1.CPU0 reset is de-asserted. 2. after 32 cycles, cpu0 clkoff is de-asserted. Software needs to wait for at least 64 osc1_clk cycles between each change of this field to keep the proper reset/clkoff sequence.	RW	0x0

per0modrst

The PER0MODRST register is used by software to trigger module resets for Peripheral Group and Fast Peripheral Group. Regular Peripheral Group resets are in the lower 2 bytes, and Fast Pheripheral Group resets are in the upper 2 bytes. Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software.

Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal.

All fields are reset by a cold reset.All fields are also reset by a warm reset if not masked by the corresponding PERWARMMASK field. The reset value of all fields is 1. This holds the corresponding

module in reset until software is ready to release the module from reset by writing 0 to its field.

0	dbg	Resets logic located only in the debug domain.	RW	0x0

mpuwarmmask

The MPUWARMMASK register is used by software to mask the assertion of module reset signals for hardware sequenced warm resets. There is a writeable bit for each module reset signal that is asserted by default on a hardware sequenced warm reset. If the bit is 1, the module reset signal is asserted by a hardware sequenced warm reset. If the bit is 0, the module reset signal is not changed by a hardware sequenced warm reset. The bit assignments of the *WARMMASK registers match the corresponding *MODRST registers. Any module reset signals that are never asserted by a warm reset have reserved bit offsets and are tied to 0 (read as 0, writes are ignored).

All fields are only reset by a cold reset.

0	wds	Masks hardware sequenced warm reset for both per-CPU Watchdog Reset Status registers in MPU	RW	0x1

per0warmmask

The PER0WARMMASK register is used by software to mask the assertion of Peripheral and Fast Peripheral reset signals for hardware sequenced warm resets. There is a writeable bit for each module reset signal that is asserted by default on a hardware sequenced warm reset. If the bit is 1, the module reset signal is asserted by a hardware sequenced warm reset. If the bit is 0, the module reset signal is not changed by a hardware sequenced warm reset. The bit assignments of the *WARMMASK registers match the corresponding *MODRST registers. Any module reset signals that are never asserted by a warm reset have reserved bit offsets and are tied to 0 (read as 0, writes are ignored).

All fields are only reset by a cold reset.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05044

Offset: 0x44

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

0	nrstpinoe	Masks hardware sequenced warm reset for nrst_pin_oe	RW	0x1

l3warmmask

The L3WARMMASK register is used by software to mask the assertion of module reset signals for hardware sequenced warm resets. There is a writeable bit for each module reset signal that is asserted by default on a hardware sequenced warm reset. If the bit is 1, the module reset signal is asserted by a hardware sequenced warm reset. If the bit is 0, the module reset signal is not changed by a hardware sequenced warm reset. The bit assignments of the *WARMMASK registers match the corresponding *MODRST registers. Any module reset signals that are never asserted by a warm reset have reserved bit offsets and are tied to 0 (read as 0, writes are ignored).

All fields are only reset by a cold reset.

Note that there is no module reset for the L3 interconnect in any *MODRST register because there would be no way for a master to remove the module reset to the L3 once asserted.

Module Instance	Base Address	Register Address
i_rst_mgr_rstmgr	0xFFD05000	0xFFD05058

FPGA Manager 4

2016.10.28

a10_5v4 Subscribe Send Feedback

The FPGA manager in the hard processor system (HPS) manages and monitors the FPGA portion of the system on a chip (SoC) device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

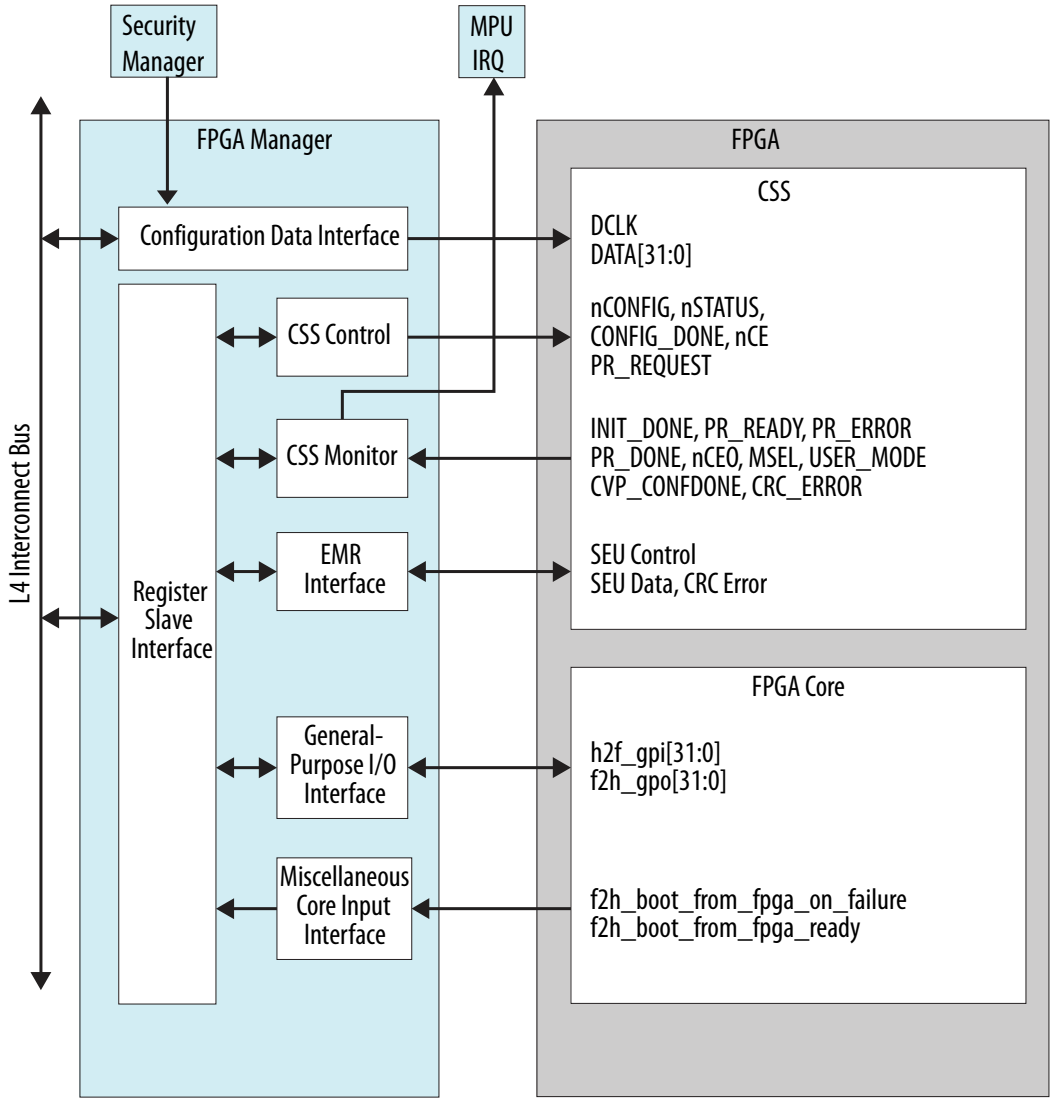
Features of the FPGA Manager

The FPGA manager provides the following functionality and features:

- Full configuration and partial reconfiguration
- CRC error message extraction
- General purpose I/O signals to the FPGA
- Boot from FPGA control
- Generation of interrupts based on FPGA status changes

FPGA Manager Block Diagram and System Integration

Figure 4-1: FPGA Manager Block Diagram



The FPGA Manager consists of the following blocks:

- Configuration Data Interface - Accepts and transfers the configuration and decryption data to the FPGA configuration sub system (CSS)
- Register Slave Interface - Accesses the control and status registers in the FPGA Manager
- CSS Control - Controls full and partial configuration of the FPGA
- CSS Monitor - Monitors the status of the FPGA during a full or partial configuration of the device

- Error Message Register (EMR) Interface - Error message extraction, in case of CRC errors in the FPGA
- General Purpose I/O Interface - Receives and drives 32 bits of general purpose I/O to and from the FPGA
- Miscellaneous Core Input Interface - Receives control input signals from the FPGA to support booting the HPS from the FPGA

Functional Description of the FPGA Manager

FPGA Configuration

You can configure the FPGA using an external device or through the HPS. This section highlights configuring the FPGA through the HPS.

The FPGA manager connects to the configuration logic in the FPGA portion of the device using a mode similar to how external logic (for example, MAX II or an intelligent host) configures the FPGA in fast passive parallel (FPP) mode. FPGA configuration through the HPS supports all the capabilities of FPP mode, including the following items:

- FPGA configuration
- Partial FPGA reconfiguration
- Decompression
- Advanced Encryption Standard (AES) encryption

Note: The FPGA manager supports a data width of 16 or 32 bits. When configuring the FPGA fabric from the HPS, Altera recommends that you always set the data width to 32 bits. For partial reconfiguration, the 16-bit and 32-bit data widths are options.

Table 4-1: MSEL Pin Settings for Each Configuration Scheme of Arria 10 Devices

Configuration Scheme	V_{CCPGM}(V)	Power-On Reset (POR) Delay	Valid MSEL[2:0]
FPP (x16 and x32)	1.8	Fast	000
		Standard	001

The FPGA Manager can be configured to accept configuration data directly from the MPU or the DMA engine. Either the processor or the DMA engine moves data from memory to the FPGA Manager data image register space `img_data_w`.

Configuration data is buffered in a 64 deep x 32 bits wide FIFO in the FPGA Manager. Status information such as FIFO empty/full and remaining depth can be accessed through a status register `imgcfg_stat`. FIFO empty/full conditions can also be enabled to generate an interrupt.

If using the DMA engine to move FPGA configuration data to the FPGA Manager, a FIFO threshold value can be set in the `dma_config` register. This value is used to control the assertion of a DMA transfer request from the FPGA Manager to the DMA engine.

Before sending FPGA configuration data to the FPGA Manager HPS, software sets the clock-to-data ratio field (`CDRATIO`) and configuration data width bit (`CFGWIDTH`) in the image control 2 register (`imgcfg_ctrl_02`).

Related Information

FPGA Status

Configuration signals from the FPGA CSS such as `INIT_DONE`, `CRC_ERROR` and `PR_DONE` are monitored by the FPGA Manager. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. Monitored signals can be read through the `imgcfg_stat` register as well as the `intr_masked_status` register. Each of the monitored signals can generate an interrupt to the MPU global interrupt controller. Each interrupt source can be enabled and the polarity of the signals generating the interrupt can also be selected through the `intr_mask` and `intr_polarity` registers in the FPGA Manager.

Error Message Extraction

Cyclic redundancy check (CRC) errors from the FPGA fabric are monitored by the FPGA Manager. Upon assertion of a CRC error signal from the FPGA, the FPGA Manager extracts information about the error including:

- Error syndrome
- Error location
- Error type

A CRC error interrupt from the FPGA manager can be enabled through software. Software can then extract the CRC error information from the error message register (EMR) data interface. The number of valid error information bits in the EMR data registers depends on the specific FPGA device.

Data AES Decryption

The configuration data interface can also be used to transmit data from the HPS to the FPGA CSS Advanced Encryption Standard (AES) decryption engine. Software should sample the status registers in FPGA manager before switching modes between FPGA configuration and AES decryption. The FPGA manager does not do anything specific to handle a situation where software starts an AES decryption while in the middle of an FPGA configuration initiated by HPS, and the end result in this case is undefined.

Boot Handshake

There are two input signals from the FPGA to control HPS boot from the FPGA. Both are synchronized within the FPGA Manager. Boot software reads these signals before accessing a boot image in the FPGA. The following table describes the functionality of these signals.

Signal	Description
f2h_boot_from_fpga_on_failure	Indicates whether a fallback second-stage boot loader image is available in the FPGA on-chip RAM at memory location 0x0. The fallback second-stage boot loader image is used only if the HPS boot ROM does not find a valid second-stage boot loader image in the selected flash memory device.
f2h_boot_from_fpga_ready	The f2h_boot_from_fpga_ready signal is used by the Boot ROM when accessing the public key stored in the FPGA. The Boot ROM will only use the signal if asserted to boot with the public key. Indicates a second-stage boot loader image is available in an FPGA on-chip RAM at memory location 0x0 and it is ready to be accessed.

General Purpose I/O

Thirty-two general purpose inputs and thirty-two general purpose outputs are provided to the FPGA and are controlled through registers in the FPGA Manager.

No interrupts are generated through the input pins. All inputs are synchronized within the FPGA Manager. Output signals should be synchronized in the FPGA.

Clock

The FPGA manager has two clock input signals which are asynchronous to each other. The clock manager generates these two clocks:

- cfg_clk—the configuration slave interface clock input and also the DCLK output reference for FPGA configuration. Enable this clock in the clock manager only when configuration is active or when the configuration slave interface needs to respond to master requests.
- l4_mp_clk—the register slave interface clock.

Related Information

Clock Manager on page 2-1

Reset

The FPGA manager has the fpga_manager_rst_n reset signal. The reset manager drives this signal to the FPGA manager on a cold or warm reset. All distributed reset signals in the FPGA manager are asserted asynchronously at the same time and deasserted synchronously to their associated clocks.

dclkcnt

Used to give software control in enabling DCLK at any time.

SW will need control of the DCLK in specific configuration and partial reconfiguration initialization steps to send spurious DCLKs required by the CB. SW takes ownership for DCLK during normal configuration, partial reconfiguration, error scenerio handshakes including SEU CRC error during partial reconfiguration, SW early abort of partial reconfiguration, and initializatin phase DCLK driving.

During initialization phase, a configuration image loaded into the FPGA can request that DCLK be used as the initialization phase clock instead of the default internal oscillator or optionally the CLKUSR pin. In the case that DCLK is requested, the DCLKCNT register is used by software to control DCLK during the initialization phase.

Software should poll the DCLKSTAT.DCNTDONE write one to clear register to be set when the correct number of DCLKs have completed. Software should clear DCLKSTAT.DCNTDONE before writing to the DCLKCNT register again.

This field only affects the FPGA if CTRL.EN is 1.

Module Instance	Base Address	Register Address

dclkcnt Fields

Bit	Name	Description	Access	Reset
31:0	cnt	Controls DCLK counter. Software writes a non-zero value into CNT and the FPGA Manager generates the specified number of DCLK pulses and decrements COUNT. This register will read back the original value written by software. Software can write CNT at any time.	RW	0x0

dclkstat

This write one to clear register indicates that the DCLKCNT has counted down to zero. The DCLKCNT is used by software to drive spurious DCLKs to the FPGA. Software will poll this bit after writing DCLKCNT to know when all of the DCLKs have been sent.

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD0300C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

jtag_config

This register is used to configure the JTAG master interface.

It is recommended that software write this register before initiating a transfer.
If the software writes to this register while an active session is in progress (as indicated by jtag_status.SessionStatus), the expected behavior is "undefined".

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD03050

Offset: 0x50

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
txSize RW 0x0

tckRatio RW 0x14								Reserved			trstEn RW 0x0	Reserved	loopBackEn RW 0x0	jtagPortEn RW 0x0	JtagHostEn RW 0x0

jtag_config Fields

Bit	Name	Description	Access	Reset
31:16	txSize	Defines the number of bits to be transmitted. Once the software kicks of the transfer via Start_ Transfer bits, the hardware will stop the transfer, when either of the below conditions are reached. a) Completed a transfer of programmed Number of TX Bits +1. b) TxFifo became empty (under-run of TxFifo). c) A Stop Transfer request received from software. So for a successful transfer of fixed number of bits, software has to make sure continuous flow of data. The exact number of bits to be transferred in the current session is 1+ the value in this register field. For example 0 -> 1 bit to be transmitted once start session is triggered. 1-> 2 bits to be transmitted.once start session is triggered.	RW	0x0
15:8	tckRatio	Ratio of TCK division. The FPGA manager clock is 100MHz. value of 4 provides a 25MHz TCK value of 20 (0x14) provides a 5MHz TCK. Maximum supported TCK frequency is 25MHz. So writing a value less than 4 to this field will cause unexpected behavior.	RW	0x14

Bit	Name	Description	Access	Reset
4	trstEn	Set this bit and then writing at least 1 data in jtag_data_w will cause a JTAG reset to happen. Please note that writing TRSTEN while a data transmission is undergoing could cause undesired effects, so it is recommended that software poll the SESSIONSTATUS bit to make sure there is no existing transfers before writing TRSTEN. Software should manually write 0 to this bit after the completion of the reset and after the SESSION-STATUS is inactive.	RW	0x0
2	loopBackEn	Enables the internal loopback mode. A typical scenario will be to set JtagHostEn=0, JtagPortEn=0, and then initiate transmits by software writes to TXFifo. All transfers should receive back on RxFifo. Also this should not affect anything external, since the Jtag ports will be gated off. **Value** **Description** 0 disable 1 enable	RW	0x0
1	jtagPortEn	This bit field gates off TDI/TMS/TCK driven to the FPGA CSS interface. This allows the software to take over JTAG but keep them tied low. If this bit is 0 the internal core logic will still be active and all the status will be updated as in regular operation. **Value** **Description** 0 disable 1 enable	RW	0x0

Bit	Name	Description	Access	Reset
0	JtagHostEn	This bit field drives the enable signal to the FPGA CSS. Please note that this enable should be driven long before you start any JTAG transactions. Value: Description 0: disable 1: enable	RW	0x0

jtag_status

status of the currently ongoing JTAG transmit or receive

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD03054

Offset: 0x54

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

jtag_kick Fields

Bit	Name	Description	Access	Reset
3	clearRxFifo	A write 1 to this bit field will empty the RxFifo. A read will always return 0.	WO	0x0
2	clearTxFifo	A write 1 to this bit field will empty the TxFifo. A read will always return 0.	WO	0x0

Bit	Name	Description	Access	Reset
1	stopSession	A write 1 to this bit field will kick off stop of an ongoing session of TX and RX. Please note that there should be alteast 1 word available in the Tx Fifo for this kick off to be successful. The status of this kick off can be read from status register SessionStatus field. stopSession has priority over startSession.	WO	0x0
0	startSession	A write 1 to this bit field will kick off a session of TX and RX. Please note that there should be alteast 1 word available in the Tx Fifo for this kick off to be successful. The status of this kick off can be read from status register SessionStatus field. stopSession has priority over startSession.	WO	0x0

jtag_data_w

A write to this field initiates a write to the TxFifo with the value provided. Please note that this is always a 32bit write, and lower 16 of these bits will be transferred over TDI and upper 16 of these bits will be transferred over TMS once the transfer is initiated. A write to this fifo when full will just be ignored. Also it is allowed to keep writing this fifo without actually intiating a transfer. A typical scenario where this is applicable is if the software want to keep a fixed number of bits ready for JTAG interface before kicking it off.

Both the fifos are 8 words deep. So you can have up to 128 bits buffered in the FIFOs. If you have more than 128 bits to be transferred, and want continuous transfer software should make sure proper data flow to avoid a Tx-Fifo under-run or Rx-Fifo over-run. A Rx-Fifo over-run will cause silent data loss, and a Tx-Fifo under-run will stop the transfer, and will stop the TCK toggles, till another transfer is initiated by software.
At 5MHz jtag clock 16x100/5 = 320 cycles of FPGA manager clock to transfer 1 word of data
At 25Mhz jtag clock 16x100/25 = 64 cycles of FPGA manager clock to transfer 1 word of data.

31:16	tmsData	Data to be transferred over TMS.	WO	0x0
15:0	tdiData		WO	0x0

jtag_data_r

A read to this field initiates a read to the RxFifo. Please note that the read always returns a 16 bit value. If the received number of bits are not aligned with 16, lower most n bits should be ignored by software. For example in the case of 6 bits received, rdata[15:10] will contain received bits and rdata[9:0] should be ignored. A read of the fifo while empty is not defined.

Both the fifos are 8 words deep. So you can have up to 128 bits buffered in the FIFOs. If you have more than 128 bits to be transferred, and want continuous transfer software should make sure proper data flow to avoid a Tx-Fifo under-run or Rx-Fifo over-run. A Rx-Fifo over-run will cause silent data loss, and a Tx-Fifo under-run will stop the transfer, and will stop the TCK toggles, till another transfer is initiated by software.
At 5MHz jtag clock 16x100/5 = 320 cycles of FPGA manager clock to transfer 1 word of data
At 25Mhz jtag clock 16x100/25 = 64 cycles of FPGA manager clock to transfer 1 word of data.

0	s2f_nenable_config	HPS override Enable for DATA, DCLK, NCE and PR_REQUEST to CSS 1: override is disabled 0: override is enabled	RW	0x1

imgcfg_ctrl_02

Allows HPS to control FPGA configuration.

The NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields drive signals to the FPGA Control Block that are logically ORed into their respective pins. These signals are always driven independent of the value of EN. The polarity of the NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields is inverted relative to their associated pins.

The MSEL (external pins), CDRATIO and CFGWDTH signals determine the mode of operation for Normal Configuration. For Partial Reconfiguration, CDRATIO is used to set the appropriate clock to data ratio, and CFGWDTH should always be set to 16-bit Passive Parallel.

AXICFGEN is used to enable transfer of configuration data by enabling or disabling DCLK during data transfers.

Bit	Name	Description	Access	Reset
24	cfgwidth	This field determines the Configuration Passive Parallel data bus width when HPS configures the FPGA. Only 32-bit Passive Parallel or 16-bit Passive Parallel are supported. When HPS does Normal Configuration, configuration should use 32-bit Passive Parallel Mode. The external pins MSEL must be set appropriately for the configuration selected. For Partial Reconfiguration, 16-bit Passive Parallel must be used. **Value** **Description** 0 PPx16 1 PPx32	RW	0x0

Bit	Name	Description	Access	Reset
17:16	cdratio	This field controls the Clock to Data Ratio (CDRATIO) for Normal Configuration and Partial Reconfiguration data transfer from the AXI Slave to the FPGA. For Normal Configuration, the value in this field must be set to be consistent to the implied CD ratio of the MSEL setting. For Partial Reconfiguration, the value in this field must be set to the same clock to data ratio in the options bits in the Normal Configuration file. **Value** — **Description** 0 — x1 1 — x2 2 — x4 3 — x8	RW	0x0
8	en_cfg_data	this is an unused software bit	RW	0x0
0	en_cfg_ctrl	If this bit is not enabled, the s2f_dclk as well as s2f_data will be always driven 0. This is to provide a mechanism by which HPS can take over the DCLK/DATA by first setting the nenable_dclk even while s2f_dclk and s2f_data from HPS is silent.	RW	0x0

imgcfg_stat

This is the unmasked status.
Value of corresponding inputs from CSS or PINs, without considering the intr_mask or intr_polarity.

Module Instance	Base Address	Register Address
i_fpga_mgr_fpgamgrregs	0xFFD03000	0xFFD03080

Offset: 0x80

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

System Manager 5

2016.10.28

a10_5v4 Subscribe Send Feedback

The system manager in the hard processor system (HPS) contains memory-mapped control and status registers (CSRs) and logic to control system level functions as well as other modules in the HPS.

The system manager connects to the following modules in the HPS:

- Direct memory access (DMA) controller
- Ethernet media access controllers (EMAC0, EMAC1, and EMAC2)
- Error Checking and Correction Controller (ECC) for RAMs
- Microprocessor unit (MPU) subsystem
- NAND flash controller
- Secure Digital/MultiMediaCard (SD/MMC) controller
- Quad serial peripheral interface (SPI) flash controller
- USB 2.0 On-The-Go (OTG) controllers (USB0 and USB1)
- Watchdog timers

Features of the System Manager

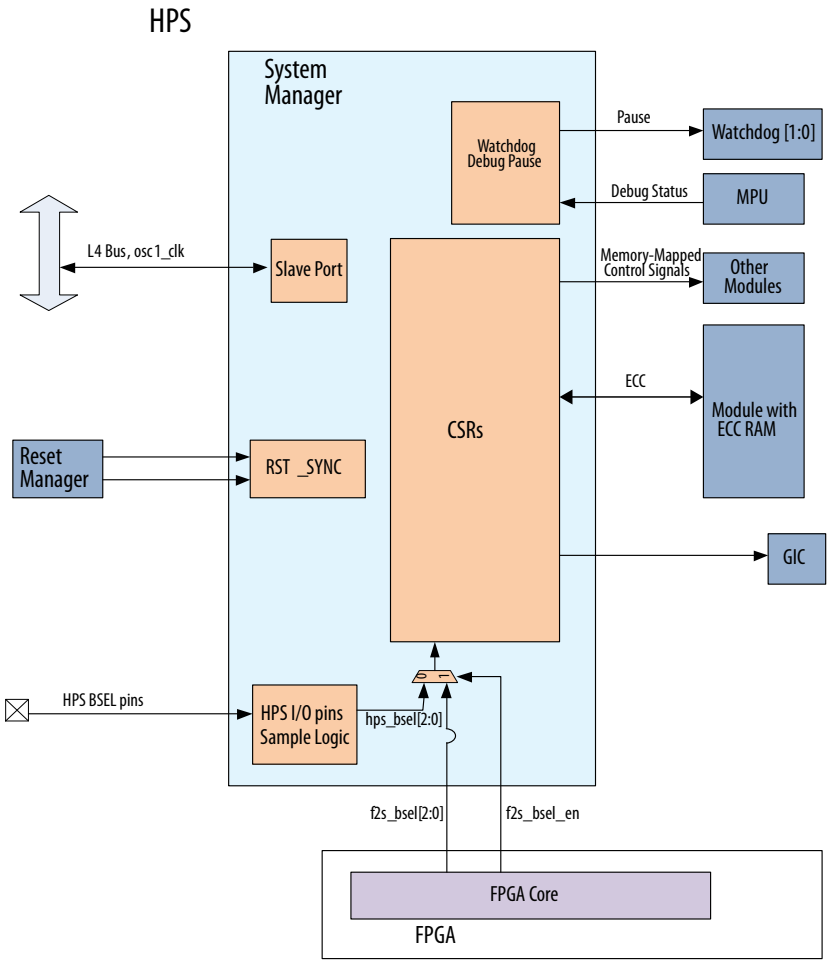
Software accesses the CSRs in the system manager to control and monitor various functions in other HPS modules that require external control signals. The system manager connects to these modules to perform the following functions:

- Sends pause signals to pause the watchdog timers when the processors in the MPU subsystem are in debug mode
- Selects the EMAC system interconnect master access options and other EMAC clock and interface options.
- Selects the SD/MMC controller clock options and system interconnect master access options.
- Selects the NAND flash controller bootstrap options and system interconnect master access option.
- Selects USB controller system interconnect master access option.
- Provides control over the DMA security settings when the HPS exits from reset.
- Provides boot source information that can be read during the boot process.
- Provides the capability to enable or disable an interface to the FPGA.
- Provides combined ECC status and interrupts from other HPS modules with ECC-protected RAM.
- Routes parity failure interrupts from the L1 caches to the Global Interrupt Controller.
- Provides the capability to inject errors during testing in the MPU L2 ECC-protected RAM.

System Manager Block Diagram and System Integration

The system manager connects to the level 4 (L4) bus through a slave interface. The CSRs connect to signals in the FPGA and other HPS modules.

Figure 5-1: System Manager Block Diagram



The system manager consists of the following:

- CSRs—Provide memory-mapped access to control signals and status for the following HPS modules:
  - EMACs
  - Debug core
  - SD/MMC controller
  - NAND controller
  - USB controllers
  - DMA controller
  - System interconnect
  - ECC memory interfaces for the following peripherals:
    - USB controllers
    - SD/MMC controller
    - Ethernet MACs
    - DMA controller
    - NAND flash controller
    - On-chip RAM
- Slave port interface—provides access to system manager CSRs for connected masters.
- Watchdog debug pause—accepts the debug mode status from the MPU subsystem and pauses the L4 watchdog timers.
- Reset Manager— system manager receives the reset signals from reset manager.

Functional Description of the System Manager

The system manager serves the following purposes:

- Provides software access to boot configuration and system information
- Provides software access to control and status signals in other HPS modules
- Provides combined ECC status and interrupt from other HPS modules with ECC-protected RAM
- Enables and disables HPS peripheral interfaces to the FPGA
- Provides eight registers that software can use to pass information between boot stages

Boot Configuration and System Information

The system manager provides boot configuration information through the `bootinfo` register. Sampled value of the HPS boot select (`BSEL`) pins are available to the Boot ROM software.

The boot source is determined by a combination of the `BSEL` pins and a fuse bit that can bypass the `BSEL` pins.

Related Information

Booting and Configuration on page 30-1

Additional Module Control

Each module in the HPS has its own CSRs, providing access to the internal state of the module. The system manager provides registers for additional module control and monitoring. To fully control each module,

you must program both the peripheral's CSR and its corresponding CSR in the System Manager. This section describes how to configure the system manager CS for each module.

DMA Controller

The security state of the DMA controller is controlled by the manager thread security (`mgr_ns`) and interrupt security (`irq_ns`) bits of the DMA register.

The `periph_ns` register bits determine if a peripheral request interface is secure or non-secure.

Note: The `periph_ns` register bits must be configured before the DMA is released from global reset.

Related Information

- **DMA Controller** on page 16-1
- **System Manager Address Map and Register Definitions** on page 5-9

NAND Flash Controller

The bootstrap control register (`nand_bootstrap`) modifies the default behavior of the NAND flash controller after reset. The NAND flash controller samples the bootstrap control register bits when it comes out of reset.

The following `nand_bootstrap` register bits control configuration of the NAND flash controller:

- Bootstrap inhibit initialization bit (`noinit`)—inhibits the NAND flash controller from initializing when coming out of reset, and allows software to program all registers pertaining to device parameters such as page size and width.
- Bootstrap 512-byte device bit (`page512`)—informs the NAND flash controller that a NAND flash device with a 512-byte page size is connected to the system.
- Bootstrap inhibit load block 0 page 0 bit (`noloadb0p0`)—inhibits the NAND flash controller from loading page 0 of block 0 of the NAND flash device during the initialization procedure.
- Bootstrap two row address cycles bit (`tworowaddr`)—informs the NAND flash controller that only two row address cycles are required instead of the default three row address cycles.

You can use the system manager's `nanad_l3master` register to control the following signals:

- ARPROT
- AWPROT
- ARDOMAIN
- AWDOMAIN
- ARCACHE
- AWCACHE

These bits define the cache attributes for the master transactions of the DMA engine in the NAND controller.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

- **NAND Flash Controller** on page 13-1
- **System Manager Address Map and Register Definitions** on page 5-9

EMAC

You can program the `emac_global` register to select either `emac_ptp_clk` from the Clock Manager or `f2s_ptp_ref_clk` from the FPGA fabric as the source of the IEEE 1588 reference clock for each EMAC.

You can use the system manager's `l3master` register to control the EMAC's `ARCACHE` and`AWCACHE` signals, by setting or clearing the (`arcache, awcache`) and (`arprot, awprot`) bits. These bits define the cache attributes for the master transactions of the DMA engine in the EMAC controllers.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

The `phy_intf_sel` bit is programmed to select between a GMII (MII), RGMII or RMII PHY interface when the peripheral is released from reset. The `ptp_ref_sel` bit selects if the timestamp reference is internally or externally generated. The `ptp_ref_sel` bit must be set to the correct value before the EMAC core is pulled out of reset.

Note: EMAC0 must be set to internal timestamp.

Related Information

- **Clock Manager** on page 2-1
- **Ethernet Media Access Controller** on page 17-1

USB 2.0 OTG Controller

The `usb*_l3master` registers in the system manager control the `HPROT` and `HAUSER` fields of the USB master port of the USB 2.0 OTG Controller.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

USB 2.0 OTG Controller on page 18-1

SD/MMC Controller

The `sdmmc_l3master` register in the system manager controls the `HPROT` and `HAUSER` fields of the SD/MMC master port.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

You can program software to select the clock's phase shift for `cclk_in_drv` and `cclk_in_sample` by setting the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smplsel`) bits of the `sdmmc` register in the system manager.

Related Information

SD/MMC Controller on page 14-1

Watchdog Timer

The system manager controls the watchdog timer behavior when the CPUs are in debug mode. The system manager sends a pause signal to the watchdog timers depending on the setting of the debug mode bits of

the L4 watchdog debug register (wddbg). Each watchdog timer built into the MPU subsystem is paused when its associated CPU enters debug mode.

Related Information

Watchdog Timer on page 24-1

Boot ROM Code

Registers in the system manager control whether the boot ROM code configures the pin multiplexing for boot pins after a warm reset. Set the warm-reset-configure-pin-multiplex for boot pins bit (warmrstcfg-pinmux) of the boot ROM code register to enable or disable this control.

Note: The boot ROM code always configures the pin multiplexing for boot pins after a cold reset.

Registers in the system manager also control whether the boot ROM code configures the I/O pins used during the boot process after a warm reset. Set the warm reset configure I/Os for boot pins bit (warmrstcfgio) of the ctrl register to enable or disable this control.

Note: By default, the boot ROM code always configures the I/O pins used by boot after a cold reset.

There can be up to four preloader images stored in flash memory. The (initswlastld) register contains the index of the preloader's last image that is loaded in the on-chip RAM.

The boot ROM software state register (bootromswstate) is a 32-bit general-purpose register reserved for the boot ROM.

The following warmram related registers are used to configure the warm reset from on-chip RAM feature and must be written by software prior to the warm reset occurring.

Table 5-1: The warmram Registers

Register	Name	Purpose
enable	Enable	Controls whether the boot ROM attempts to boot from the contents of the on-chip RAM on a warm reset.
datastart	Data start	Contains the byte offset of the warm boot CRC validation region in the on-chip RAM. The offset must be word-aligned to an integer multiple of four.
length	Length	Contains the length in bytes of the region in the on-chip RAM available for warm boot CRC validation.
execution	Execution address	Contains the global address the boot code jumps to in the on-chip RAM if the CRC validation succeeds.
crc	Expected CRC	Contains the expected CRC of the region in the on-chip RAM.

The number of wait states applied to the boot ROM's read operation is determined by the wait state bit (waitstate) of the ctrl register. After the boot process, software might require reading the code in the

boot ROM. If software has changed the clock frequency of the `l3_main_clk` after reset, an additional wait state is necessary to access the boot ROM. Set the `waitstate` bit to add an additional wait state to the read access of the boot ROM. The enable safe mode warm reset update bit controls whether the wait state bit is updated during a warm reset.

Controlling the Boot Memory Map Through the System Interconnect

The System Manager contains a register, `noc_addr_remap_value`, that controls how the system interconnect maps memory addresses starting at 0x00000000. This register remaps the bottom of the memory map to either boot ROM or on-chip RAM.

Refer to "Address Remapping" in the System Interconnect chapter for details about using the `noc_addr_remap_value` register.

Related Information

Address Remapping on page 7-19

FPGA Interface Enables

The system manager can enable or disable interfaces between the FPGA and HPS.

The global interface bit (`intf`) of the global disable register (`gbl`) disables all interfaces between the FPGA and HPS.

Note: Ensure that the FPGA in configured before enabling the interfaces and that all interfaces between the FPGA and HPS are inactive before disabling them.

You can program the individual disable register (`indiv`) to disable the following interfaces between the FPGA and HPS:

You can program the FPGA interface enable registers (`fpgaintf_en_*`) to disable the following interfaces between the FPGA and HPS:

- Reset request interface
- JTAG enable interface
- I/O configuration interface
- Boundary scan interface
- Debug interface
- Trace interface
- System Trace Macrocell (STM) interface
- Cross-trigger interface (CTI)
- NAND interface
- SD/MMC interface
- SPI Master interface
- EMAC interfaces

ECC and Parity Control

The system manager can mask the ECC interrupts from each of the following HPS modules with ECC-protected RAM:

- MPU L2 cache data RAM
- On-chip RAM
- USB 2.0 OTG controller (USB0 and USB1) RAM
- EMAC (EMAC0, EMAC1, and EMAC2) RAM
- DMA controller RAM
- NAND flash controller RAM
- Quad SPI flash controller RAM
- SD/MMC controller RAM
- DDR interfaces

The system manager can inject single-bit or double-bit errors into the MPU L2 ECC memories for testing purposes. Set the bits in the appropriate memory enable register to inject errors. For example, to inject a single bit ECC error, set the `injs` bit of the `mpu_ctrl_l2_eccregister`.

Note: The injection request is edge-sensitive, meaning that the request is latched on 0 to 1 transitions on the injection bit. The next time a write operation occurs, the data will be corrupted, containing either a single or double bit error as selected. When the data is read back, the ECC logic detects the single or double bit error appropriately. The injection request cannot be cancelled, and the number of injections is limited to once every five MPU cycles.

The system manager can also inject parity failures into the parity-protected RAM in the MPU L2 to test the parity failure interrupt handler. Set the bits of the parity fail injection register (`parityinj`) to inject parity failures.

Note: Injecting parity failures into the parity-protected RAM in the MPU L2 causes the interrupt to be raised immediately. There is no actual error injected and the data is not corrupted. Furthermore, there is no need for a memory operation to actually be performed for the interrupt to be raised.

Preloader Handoff Information

The system manager provides eight 32-bit registers to store handoff information between the preloader and the operating system. The preloader can store any information in these registers. These register contents have no impact on the state of the HPS hardware. When the operating system kernel boots, it retrieves the information by reading the preloader to OS handoff information register array. These registers are reset only by a cold reset.

Clocks

The system manager is driven by a clock generated by the clock manager.

Related Information

Clock Manager on page 2-1

Resets

The system manager receives two reset signals from the reset manager. The `sys_manager_rst_n` signal is driven on a cold or warm reset and the `sys_manager_cold_rst_n` signal is driven only on a cold reset.

This function allows the system manager to reset some CSR fields on either a cold or warm reset and others only on a cold reset.

rsv RO 0x0															

siliconid2 Fields

Bit	Name	Description	Access	Reset
31:0	rsv	Reserved for future use.	RO	0x0

wddbg

Controls the behavior of the L4 watchdogs when the CPUs are in debug mode. These control registers are used to drive the pause input signal of the L4 watchdogs. Note that the watchdogs built into the MPU automatically are paused when their associated CPU enters debug mode. Only reset by a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved												mode_1 RW 0x3		mode_0 RW 0x3	

wddbg Fields

Bit	Name	Description	Access	Reset
3:2	mode_1	Controls behavior of L4 watchdog when CPUs in debug mode. Field array index matches L4 watchdog index. Value: Description 0: Continue 1: PauseCPU0 2: PauseCPU1 3: PauseEither	RW	0x3
1:0	mode_0	Controls behavior of L4 watchdog when CPUs in debug mode. Field array index matches L4 watchdog index. Value: Description 0: Continue 1: PauseCPU0 2: PauseCPU1 3: PauseEither	RW	0x3

bootinfo

```
        Provides access to boot configuration information.
This is a read only register and a write should return error.
This register gets reset only on a cold reset.
```

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD0600C

Offset: 0xC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	bsel RO 0x0			Reserved	pin_bsel RO 0x0			Reserved	fpga_bsel RO 0x0			Reserved			fpga_bsel_en RO 0x0

bootinfo Fields

Bit	Name	Description	Access	Reset
14:12	bsel	Multiplexed Value of Boot Select from pins and fpga **Value** **Description** 0 RESERVEDx 1 FPGA 2 NAND_Flash_1_8v 3 NAND_Flash_3_0v 4 SD_MMC_EXTERNAL_TRANSCEIVER_1_8v 5 SD_MMC_INTERNAL_TRANSCEIVER_3_0v 6 QSPI_Flash_1_8v 7 QSPI_Flash_3_0v	RO	0x0

Bit	Name	Description	Access	Reset
10:8	pin_bsel	Specifies the sampled value of the HPS BSEL pins. The value of HPS BSEL pins are sampled upon deassertion of cold reset. Value — Description 0 — RESERVEDx 1 — FPGA 2 — NAND_Flash_1_8v 3 — NAND_Flash_3_0v 4 — SD_MMC_EXTERNAL_TRANSCEIVER_1_8v 5 — SD_MMC_INTERNAL_TRANSCEIVER_3_0v 6 — QSPI_Flash_1_8v 7 — QSPI_Flash_3_0v	RO	0x0

Bit	Name	Description	Access	Reset
6:4	fpga_bsel	The boot select field specifies the boot source. It is read by the Boot ROM code on a cold or warm reset to determine the boot source. The boot select value is equal to the f2s_bsel signal from the FPGA if the f2s_bsel_en signal from the FPGA is 1 or equal to the sampled value of HPS BSEL pins if the f2s_bsel_en signal from the FPGA is 0 or the FPGA is not powered on or not in User Mode (fpga_config_complete = 0). The HPS BSEL pins value are sampled upon deassertion of cold reset. **Value** **Description** 0 RESERVEDx 1 FPGA 2 NAND_Flash_1_8v 3 NAND_Flash_3_0v 4 SD_MMC_EXTERNAL_TRANSCEIVER_1_8v 5 SD_MMC_INTERNAL_TRANSCEIVER_3_0v 6 QSPI_Flash_1_8v 7 QSPI_Flash_3_0v	RO	0x0
0	fpga_bsel_en	Specifies the value of the f2s_bsel_en. f2s_bsel_en is a signal from FPGA. If 1, boot select value is equal to FPGA boot select signal (f2s_bsel). If 0, boot select value is equal to the sampled value of HPS BSEL pins. Value of f2s_bsel_en is overidden to 0x0 if FPGA is not in user mode (fpga_config_complete = 0)	RO	0x0

mpu_ctrl_l2_ecc

This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/

double bit error.
Some fileds of this register are only reset by a cold reset (ignores warm reset).
Some fields are affected by both warm and cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

mpu_ctrl_l2_ecc Fields

Bit	Name	Description	Access	Reset
16	inj_type	MPU L2 ECC error injection type. This bit will get reset on a warm reset and cold reset. Value: Description 0: single_bit 1: double_bit	RW	0x0

Bit	Name	Description	Access	Reset
8	inj_en	Error injection enable. Write 1 here to enable error injection to MPU L2. Please note that if ECC is not enabled by writing 1 to ecc_en bit there wont be any error injections. This bit will get reset on a warm reset and cold reset.	RW	0x0
0	ecc_en	Enable Single bit or Double bit error Detection and Single bit Error Correction for L2 Data RAM Only reset by a cold reset (ignores warm reset).	RW	0x0

dma

Registers used by the DMA Controller. All fields are reset by a cold or warm reset.
These register bits should be updated during system initialization prior to removing the DMA controller from reset. They may not be changed dynamically during DMA operation.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
irq_ns RW 0x0								Reserved							mgr_ns RW 0x0

7:4	awcache_0	Specifies the value of the module AWCACHE signal. Value — Description 0 — Noncache_Nonbuff 1 — Buff 2 — Cache_Nonalloc 3 — Cache_Buff_Nonalloc 4 — Reserved1 5 — Reserved2 6 — Cache_Wrthru_Rdalloc 7 — Cache_Wrback_Rdalloc 8 — Reserved3 9 — Reserved4 10 — Cache_Wrthru_Wralloc 11 — Cache_Wrback_Wralloc 12 — Reserved5 13 — Reserved6 14 — Cache_Wrthru_Alloc 15 — Cache_Wrback_Alloc	RW	0x0

Bit	Name	Description	Access	Reset
3:0	arcache_0	Specifies the value of the module ARCACHE signal. Value — Description 0 — Noncache_Nonbuff 1 — Buff 2 — Cache_Nonalloc 3 — Cache_Buff_Nonalloc 4 — Reserved1 5 — Reserved2 6 — Cache_Wrthru_Rdalloc 7 — Cache_Wrback_Rdalloc 8 — Reserved3 9 — Reserved4 10 — Cache_Wrthru_Wralloc 11 — Cache_Wrback_Wralloc 12 — Reserved5 13 — Reserved6 14 — Cache_Wrthru_Alloc 15 — Cache_Wrback_Alloc	RW	0x0

usb0_l3master

Controls the L3 master HPROT AHB-Lite signal.
These register bits should be updated only during system initialization prior to removing the peripheral from reset. They may not be changed dynamically during peripheral operation
All fields are reset by a cold or warm reset.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06038

Offset: 0x38

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1:0	phy_intf_sel	PHY Interface Select Field to select "Out of Reset", GMII (or MII), RGMII or RMII as the PHY interface. Note, the MAC speed is an output of Synopsys IP. So the System Manager PHY Select combined with MAC speed from the IP determine the clock/PHY configuration. "Out of Reset" mode implies that the MAC RX and TX internal clocks use the Clock Manager reference rather than depending on the PHY to have active clocks. **Value** — **Description** 0 — GMII_MII 1 — RGMII 2 — RMII 3 — RESET	RW	0x3

fpgaintf_en_global

Used to disable all interfaces between the FPGA and HPS. This register is reset only on a cold reset (ignores warm reset).

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06060

Offset: 0x60

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															intf RW 0x1

fpgaintf_en_global Fields

Bit	Name	Description	Access	Reset
0	intf	Used to disable all interfaces between the FPGA and HPS. Software must ensure that all interfaces between the FPGA and HPS are inactive before disabling them. Value: 0 — Disable; 1 — Enable	RW	0x1

fpgaintf_en_0

Used to disable individual interfaces between the FPGA and HPS.
This register is reset only on a cold reset (ignores warm reset).

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06064

Offset: 0x64

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															bscan RW 0x1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							cfgio RW 0x1	Reserved							rstreq RW 0x1

fpgaintf_en_0 Fields

Bit	Name	Description	Access	Reset
16	bscan	Used to disable the boundary-scan interface. This interface allows the FPGA JTAG TAP controller to execute boundary-scan instructions such as SAMPLE/PRELOAD, EXTEST, and HIGHZ. The boundary-scan interface must be enabled before attempting to send the boundary-scan instructions to the FPGA JTAG TAP controller. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x1
8	cfgio	Used to disable the CONFIG_IO interface. This interface allows the FPGA JTAG TAP controller to execute the CONFIG_IO instruction and configure all device I/Os (FPGA and HPS). This is typically done before executing boundary-scan instructions. The CONFIG_IO interface must be enabled before attempting to send the CONFIG_IO instruction to the FPGA JTAG TAP controller. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x1

Bit	Name	Description	Access	Reset
0	rstreq	Used to disable the reset request interface. This interface allows logic in the FPGA fabric to request HPS resets. This field disables the following reset request signals from the FPGA fabric to HPS:[list] [*]f2s_cold_rst_req - Triggers a cold reset of the HPS[*]f2s_warm_ rst_req - Triggers a warm reset of the HPS[*]f2s_dbg_rst_req - Triggers a debug reset of the HPS[/ list] **Value** **Description** 0 Disable 1 Enable	RW	0x1

fpgaintf_en_1

Used to disable individual interfaces between the FPGA and HPS.
This register is reset only on a cold reset (ignores warm reset).

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06068

Offset: 0x68

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved							dbgapb RW 0x1	Reserved			trace RW 0x1	Reserved			

fpgaintf_en_1 Fields

Bit	Name	Description	Access	Reset
24	ctmtrigger	Used to disable the FPGA Fabric from sending triggers to HPS debug logic. Note that this doesn't prevent the HPS debug logic from sending triggers to the FPGA Fabric. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x1
16	stmevent	Used to disable the STM event interface. This interface allows logic in the FPGA fabric to trigger events to the STM debug module in the HPS. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x1
8	dbgapb	Used to disable the debug APB interface. This interface allows the HPS debug logic to communicate with debug APB slaves in the FPGA fabric. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x1

Bit	Name	Description	Access	Reset
4	trace	Used to disable the trace interface. This interface allows the HPS debug logic to send trace data to logic in the FPGA fabric. Value: 0 — Disable; 1 — Enable	RW	0x1

fpgaintf_en_2

Used to disable individual interfaces between the FPGA and HPS.
This register is reset only on a cold reset (ignores warm reset).

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD0606C

Offset: 0x6C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

fpgaintf_en_3 Fields

Bit	Name	Description	Access	Reset
16	emac_2	Used to disable signals from the FPGA fabric to the EMAC modules that could potentially interfere with their normal operation. The array index corresponds to the EMAC module instance. Value: 0 — Disable; 1 — Enable	RW	0x0

Bit	Name	Description	Access	Reset
8	emac_1	Used to disable signals from the FPGA fabric to the EMAC modules that could potentially interfere with their normal operation. The array index corresponds to the EMAC module instance. Value: Description 0: Disable 1: Enable	RW	0x0
0	emac_0	Used to disable signals from the FPGA fabric to the EMAC modules that could potentially interfere with their normal operation. The array index corresponds to the EMAC module instance. Value: Description 0: Disable 1: Enable	RW	0x0

noc_addr_remap_value

Address remap register. This register drives the remap bits for the NOC.

This is read / write register.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														remap1 0x0	remap0 0x0

noc_addr_remap_value Fields

Bit	Name	Description	Access	Reset
1	remap1	if this bit is 0 RAM is NOT available at base address 0x0000_0000 if this bit is 1 RAM is also mapped to base address 0x0000_0000, as long as ROM is not being mapped to the same base address because of remap0 Note: ROM is always available at base address 0xFFFC_0000 RAM is always available at base address 0xFFE0_0000	RW	0x0
0	remap0	if this bit is 0 ROM is also mapped to base address 0x0000_0000 if this bit is 1 ROM is NOT available at base address 0x0000_0000 Note: ROM is always available at base address 0xFFFC_0000 RAM is always available at base address 0xFFE0_0000	RW	0x0

noc_addr_remap_set

This is a Write 1 to Set register.
Writing 0 is ignored, and writing 1 to a specific bit field sets the specific remap bit.
Reads should not return an error, but the actual read value is "Undefined" .

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD06084

mpu_status_l2_ecc

This is a read only register which reads the current mpu L2 ecc interrupt status.
A write to this register should return an error.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060A4

Offset: 0xA4

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
merr_pending 0x0	Reserved			merr_info 0x0											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
serr_pending 0x0	Reserved			serr_info 0x0											

mpu_status_l2_ecc Fields

Bit	Name	Description	Access	Reset
31	merr_pending	Unmaksed value of a pending multiple bits ECC error status.	RO	0x0
27:16	merr_info	12 bit Serr Info field. In Baum this will be the index and way information where the ECC error occured.	RO	0x0
15	serr_pending	Unmaksed value of a pending single bit ECC error status.	RO	0x0
11:0	serr_info	12 bit Serr Info field. In Baum this will be the index and way information where the ECC error occured.	RO	0x0

mpu_clear_l2_ecc

Write 1 to Clear register to clear the specific bit field of mpu l2 ecc interrupt pending status
Reads should not return an error, but the read value is undefined.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060A8

Offset: 0xA8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
merr 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
serr 0x0	Reserved														

mpu_clear_l2_ecc Fields

Bit	Name	Description	Access	Reset
31	merr	Write 1 to this field to clear the MPU L2 ECC multiple bit Error interrupt Status and the actual Interrupt.	RW	0x0
15	serr	Write 1 to this field to clear the MPU L2 ECC single bit Error interrupt Status and the actual Interrupt.	RW	0x0

mpu_status_l1_parity

```
          Parity status from L1 and scu. This is a read only register.
A write to this register should return an error.

[17] CPU1 SCU parity error
[16] CPU0 SCU parity error

[15] CPU1 BTAC parity error
[14] CPU1 GHB parity error
[13] CPU1 instruction tag RAM parity error
[12] CPU1 instruction data RAM parity error
[11] CPU1 main TLB parity error
[10] CPU1 data outer RAM parity error
```

```
[9]  CPU1 data tag RAM parity error
[8]  CPU1 data data RAM parity error.

[7]  CPU0 BTAC parity error
[6]  CPU0 GHB parity error
[5]  CPU0 instruction tag RAM parity error
[4]  CPU0 instruction data RAM parity error
[3]  CPU0 main TLB parity error
[2]  CPU0 data outer RAM parity error
[1]  CPU0 data tag RAM parity error
[0]  CPU0 data data RAM parity error.
```

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060AC

Offset: 0xAC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															en 0x0

noc_timeout Fields

Bit	Name	Description	Access	Reset
0	en	NOC Timeout Enable. You can set this bit to enable an automatic timeout that flushes all pending transactions in the HPS-to-FPGA and lightweight HPS-to-FPGA bridges when they are shutdown and reset. To use this automatic timeout, the bridges must be operating above 100 MHz. The automatic timeout duration is approximately 320 ns. If your system application handles and completes all transactions before shutting down the bridges, this bit does not need to be enabled.	RW	0x0

noc_idlereq_set

Set IDLE request to each NOC master.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060C4

4	lwsoc2fpga		not specified	0x0
0	soc2fpga		not specified	0x0

noc_idleack

Idle acknowledge value from NOC Masters. This is asserted (value 1 in the field) in response to the IDLE requests asserted by software.

Module Instance	Base Address	Register Address
i_sys_mgr_core	0xFFD06000	0xFFD060D0

Offset: 0xD0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

romhw_ctrl

Controls behavior of Boot ROM hardware.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06200 - 0xFFD0621C

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															waitstate RW 0x0

romhw_ctrl Fields

Bit	Name	Description	Access	Reset
0	waitstate	Controls the number of wait states applied to the Boot ROM's read operation. This field is cleared on a cold reset and optionally updated by hardware upon deassertion of warm reset. **Value** — **Description** 0 — Disable 1 — Enable	RW	0x0

romcode_ctrl

Contains information used to control Boot ROM code. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06204 - 0xFFD06220

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														warmrstcfgio RW 0x0	warmrstcfgpinmux RW 0x0

romcode_ctrl Fields

Bit	Name	Description	Access	Reset
1	warmrstcfgio	Specifies whether the Boot ROM code configures the IOs used by boot after a warm reset. Note that the Boot ROM code always configures the IOs used by boot after a cold reset. After the Boot ROM code configures the IOs used by boot, it always disables this field. It is up to user software to enable this field if it wants a different behavior. **Value** — **Description** 0 — disabled 1 — enabled	RW	0x0
0	warmrstcfgpinmux	Specifies whether the Boot ROM code configures the pin mux for boot pins after a warm reset. Note that the Boot ROM code always configures the pin mux for boot pins after a cold reset. After the Boot ROM code configures the pin mux for boot pins, it always disables this field. It is up to user software to enable this field if it wants a different behavior. **Value** — **Description** 0 — disabled 1 — enabled	RW	0x0

romcode_qspi_reset_command

Information used by bootrom to send specific reset command sequences to QSPI.
This register value gets reset only on a cold reset.

Below are the definisions used by bootrom
0xXXXXXX00: Don't software reset.
0xXXXXXX01: Send 0x66, 0x99 as reset command.
0xXXXXXX02: Send 0xFF as reset command.
0xXXXXXX03: Send TBA as reset command.

There is also a custom command for devices we don't know about yet.

```
0xXXXXZZ81: Send byte 0xZZ as reset command.
0xXXWWZZ82: Send byte 0xZZ, 0xWW as reset command.
0xYYWWZZ83: Send byte 0xZZ, 0xWW, 0xYY as reset command.
```

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06208 - 0xFFD06224

Offset: 0x8

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
value RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

romcode_qspi_reset_command Fields

Bit	Name	Description	Access	Reset
31:0	value	Address for CPU1 to start executing at after coming out of reset.	RW	0x0

romcode_initswstate

```
        Initial Software loaded by the Boot ROM writes the magic
value 0x49535756 (ISWV in ASCII) to this register when it has reached
a valid state.
Reset only on a cold reset.
```

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD0620C - 0xFFD06228

Offset: 0xC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
value RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

romcode_initswstate Fields

Bit	Name	Description	Access	Reset
31:0	value	Written with magic value. Value: Description 0: Invalid 1230198614: Valid	RW	0x0

romcode_initswlastld

Contains the index of the last Initial Software image loaded by the Boot ROM from the boot device.
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06210 - 0xFFD0622C

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														index RW 0x0	

romcode_initswlastld Fields

Bit	Name	Description	Access	Reset
1:0	index	Index of last image loaded.	RW	0x0

warmram_enable

Enables or disables the warm reset from On-chip RAM feature. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06218 - 0xFFD06234

Offset: 0x18

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
magic RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
magic RW 0x0															

warmram_enable Fields

Bit	Name	Description	Access	Reset
31:0	magic	Controls whether Boot ROM will attempt to boot from the contents of the On-chip RAM on a warm reset. When this feature is enabled, the Boot ROM code will not configure boot IOs, the pin mux, or clocks. Note that the enable value is a 32-bit magic value (provided by the enum). **Value** — **Description** 0x0 — Boot ROM code will not attempt to boot from On-chip RAM on a warm reset 0xae9efebc — Boot ROM code will attempt to boot from On-chip RAM on a warm reset	RW	0x0

warmram_datastart

Offset into On-chip RAM of the start of the region for CRC validation
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD0621C - 0xFFD06238

Offset: 0x1C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
offset RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

warmram_datastart Fields

Bit	Name	Description	Access	Reset
31:0	offset	Contains the byte offset into the On-chip RAM of the start of the On-chip RAM region for the warm boot CRC validation. The offset must be an integer multiple of 4 (i.e. aligned to a word). The Boot ROM code will set the top 16 bits to 0xFFFF and clear the bottom 2 bits.	RW	0x0

warmram_length

Length of region in On-chip RAM for CRC validation. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06220 - 0xFFD0623C

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
size RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
size RW 0x0															

warmram_length Fields

Bit	Name	Description	Access	Reset
31:0	size	Contains the length (in bytes) of the region in the On-chip RAM for the warm boot CRC validation. If the length is 0, the Boot ROM won't perform CRC calculation and CRC check to avoid overhead caused by CRC validation. If the START + LENGTH exceeds the maximum offset into the On-chip RAM, the Boot ROM won't boot from the On-chip RAM. The length must be an integer multiple of 4. The Boot ROM code will clear the top 16 bits and the bottom 2 bits.	RW	0x0

warmram_execution

Offset into On-chip RAM to enter to on a warm boot. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06224 - 0xFFD06240

Offset: 0x24

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
offset RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

warmram_execution Fields

Bit	Name	Description	Access	Reset
31:0	offset	Contains the global address into the On-chip RAM that the Boot ROM jumps to if the CRC validation succeeds. This value is a logical address, not an offset from a base address.	RW	0x0

warmram_crc

Length of region in On-chip RAM for CRC validation. Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06228 - 0xFFD06244

Offset: 0x28

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
expected RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
expected RW 0x0															

warmram_crc Fields

Bit	Name	Description	Access	Reset
31:0	expected	Contains the expected CRC of the region in the On-chip RAM.The Boot ROM code calculates the actual CRC for all bytes in the region specified by the DATA START an LENGTH registers. The contents of the EXECUTION register (after it has been read and modified by the Boot ROM code) is also included in the CRC calculation. The contents of the EXECUTION register is added to the CRC accumulator a byte at a time starting with the least significant byte. If the actual CRC doesn't match the expected CRC value in this register, the Boot ROM won't boot from the On-chip RAM. The CRC is a standard CRC32 with the polynomial: x^32 + x^26 + x^23 + x^22 + x^16 + x^12 + x^11 + x^10 + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 There is no reflection of the bits and the initial value of the remainder is 0xFFFFFFFF and the final value is exclusive ORed with 0xFFFFFFFF.	RW	0x0

isw_handoff

These registers are used to store handoff infomation between the preloader and the OS. These 8 registers can be used to store any information. The contents of these registers have no impact on the state of the HPS hardware.
A total of 8 x 32 bit registers for Second State Boot Loader handoff
Reset only on a cold reset.

Module Instance	Base Address	Register Address
i_sys_mgr_rom	0xFFD06200	0xFFD06230 - 0xFFD0624C

Offset: 0x30 - 0x4C

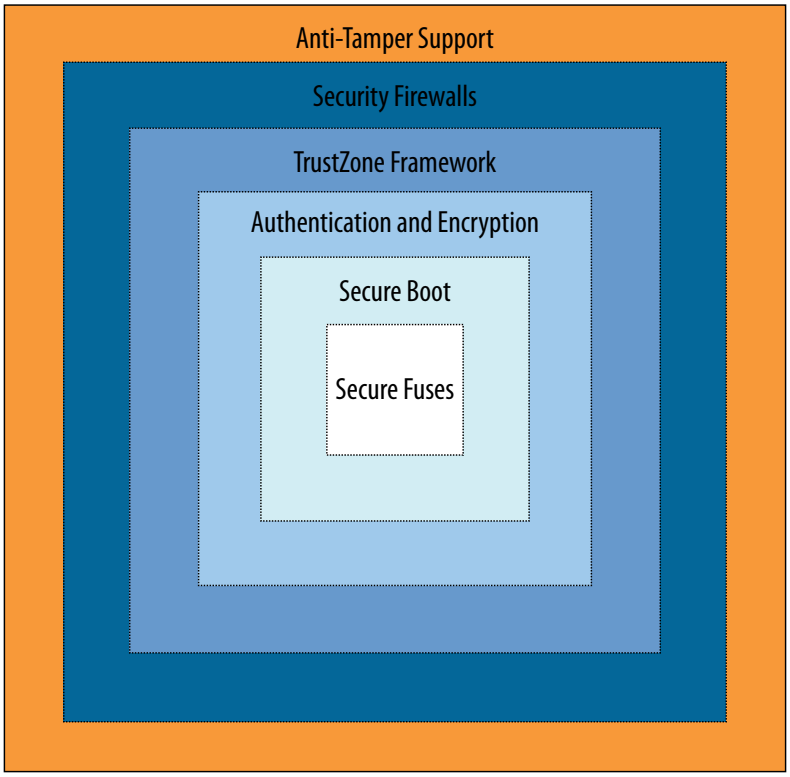
Note: For a complete NDA version of the entire Security SoC chapter, address map and register definitions, contact your local field sales office.

The Arria 10 SoC provides the framework for implementing secure systems by offering a layered hardware and software solution. A dedicated Security Manager module in the Hard Processor System (HPS) supervises secure initialization of the SoC and manages system response during tamper events. User fuses offer secure boot options and registers within the Security Manager provide further enhancement of secure states. Using Elliptical Curve Digital Signal Algorithm (ECDSA256) with Secure Hash Algorithm (SHA256) and Advanced Encryption Standard (AES) algorithms in the FPGA's Configuration Subsystem (CSS), boot images can be authenticated and decrypted. The integration of the ARM TrustZone® technology and security firewalls within the Arria 10 system interconnect provides defined partitioning in the device for secure and non-secure accesses. Protection mechanisms are integrated into debug components of the SoC to allow varying levels of visibility for debug.

Figure 6-1: Arria 10 Layered Security Solution



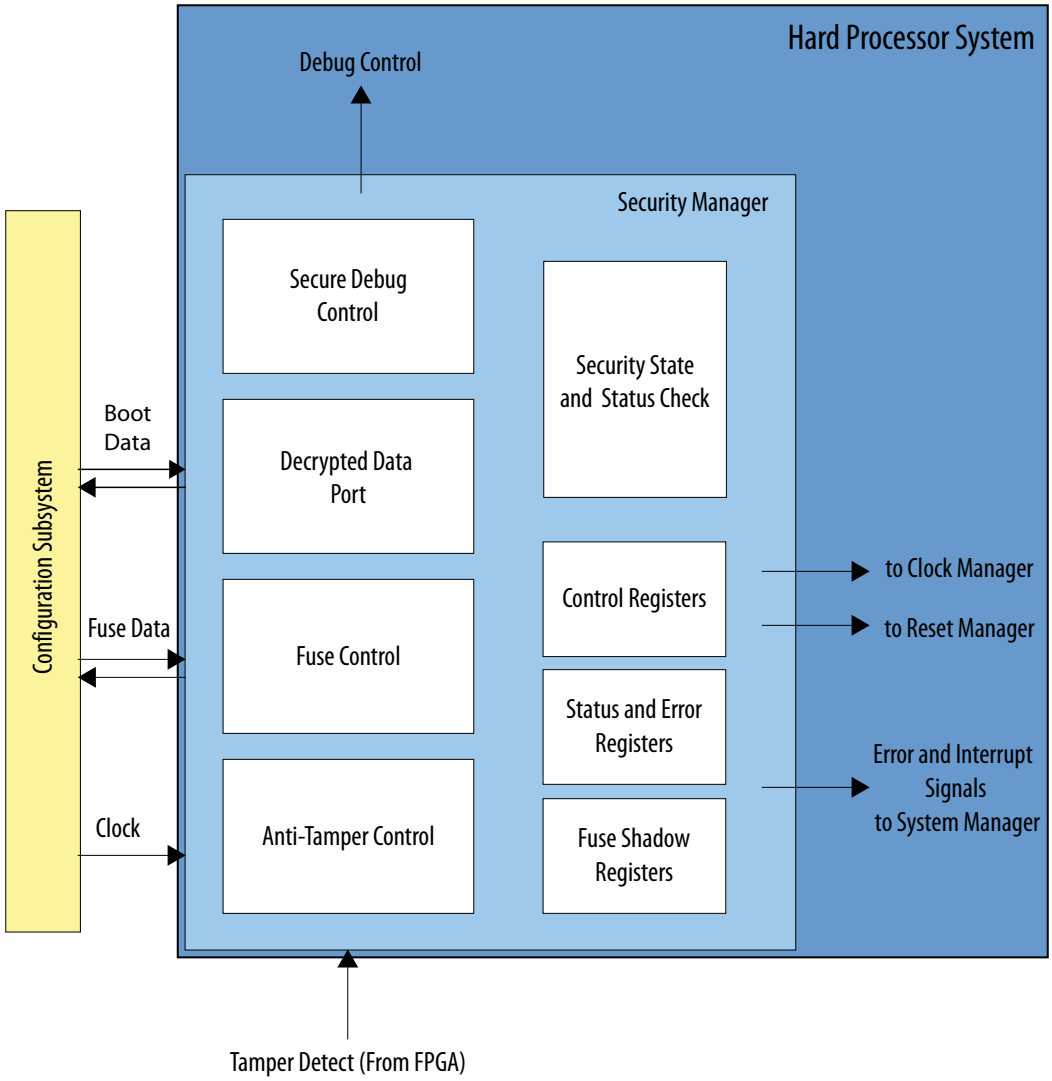
Security Manager

The Security Manager module is integrated in the Hard Processor System (HPS) and provides the overall management of security within the SoC, including:

- Recognition of secure fuse configuration
- Secure state control and status check of security features
- Secure boot options
- Varying levels of debug visibility
- Anti-Tamper support

Security Manager Block Diagram

Figure 6-2: Security Manager Block Diagram



Functional Overview

The Security Manager integrates several functions that support the TrustZone technology, manage security states in the device, and hold secure fuse information.

The main components of the Security Manager architecture include:

- Fuse Control:

  When the HPS is powered, the Security Manager ensures reliable and verified receipt of the fuse information from the Configuration Subsystem (CSS) in the FPGA, stores it in fuse shadow registers and can request further fuse information.
- Security State and Status Check:

  This sub-module holds the security state of the system, which is controlled by the fuse bits, hardware and software programming. This sub-module also has the ability to check and raise the level of security.
- Encryption Data Port:

  This interface receives authenticated and decrypted boot images from the CSS.

  - Support for ECDSA256 (SHA256) authenticated boot.
  - Support for AES-based encrypted boot.
- Registers:

  - Control Registers configure security state and debug options for the device.
  - Status and Error Registers flag transmission errors and interrupts.
  - Fuse Shadow Registers hold a copy of the user fuse information.
- Anti-Tamper Control:

  On a tamper event, this module sends a signal to the Reset Manager to initiate the scrambling and clearing of all memories, including on-chip RAM, peripheral memories, L1 cache and L2 cache. Upon completion, the Security Manager sends a signal to the FPGA to indicate that the anti-tamper event has been handled.

Functional Description

Secure Initialization Overview

Secure initialization allows the device to boot and configure in a secured state.

Secure initialization begins with the CSS module. On FPGA power-up, the Configuration Subsystem (CSS) powers, initializes and loads the fuse bits. The CSS sends the FPGA its fuse configuration information. If the HPS is powered, the CSS sends the HPS fuse information to the Security Manager. This information is held in the `HPS_fusesec` shadow register in the Security Manager.

When the Security Manager is released from reset, it requests configuration information from the CSS and performs security checks. At this point, the rest of the HPS is still in reset. The security checks validate whether the state of each security option is valid. The Security Manager decodes the fuse bits and brings the rest of the HPS out of reset.

If there are errors in the initial transmission of the secure fuse information, the HPS stays in reset and no automatic retry occurs. Only an FPGA re-configuration causes a retry.

When the HPS is released from reset, the Security Manager sends signals to initialize the system blocks, such as the Clock Manager, FPGA Manager, System Manager. The clock control fuse information is

automatically sent to the Clock Manager, the memory control fuse information is automatically sent to the Reset Manager and all other fuse functions (authentication, encryption, and public key source and length) are stored in a memory-mapped location for the boot ROM code to read. After these tasks are successfully completed, CPU0 comes out of reset in a secure state.

After CPU0 is released from reset, the boot ROM begins executing. At this time, the HPS is in a trusted state and the boot ROM code is guaranteed to execute as expected. For both secure and non-secure boot, all slave peripherals are brought out of reset in a secure state.

After initial security controls have been set, the boot ROM determines the second-stage boot loader source from the `bootinfo` register in the System Manager. The boot source can be from external memory through the HPS or through the FPGA. If the second-stage boot loader code comes from HPS external memory, then the boot ROM configures the clock and the interface to external memory.

When the boot ROM attempts to read from the flash, it looks for one of four images in external memory. Initially, it looks for image 0. If it is found, the image is authenticated, decrypted, or both depending on the requirements of the current security state. If these steps are successful, then the image is executed. However, if any of these steps fail, then the boot ROM moves onto the next image until it runs out of images.

For example, during a secure boot, the second-stage boot loader header includes an authentication key and the incoming image is authenticated. If indicated from the current security state, the image may be decrypted as well. The boot ROM contains functions to establish transitive trust to the second-stage boot code loaded from external flash or from the FPGA into on-chip RAM. If trust cannot be established in a secure boot, the HPS does not come out of reset and can attempt to load a different second-stage boot image.

For comprehensive information on the booting and boot image partitioning refer to the *Booting and Configuration* appendix of the *Arria 10 Hard Processor Technical Reference Manual*.

If all the images fail, it attempts to locate an image from the FPGA fabric and boot from there. If the FPGA boot fails, then it halts.

If the HPS receives its second-stage boot loader code from the FPGA, it waits for the FPGA to finish configuration before it obtains the image from FPGA RAM.

If required, a portion of the second-stage boot loader header can be used to raise security states of security features in the device that are currently in non-secure mode.

Related Information

  For more information about the boot process refer to the *Booting and Configuration* appendix.

Secure Fuses

During initialization of the device, the Configuration Subsystem (CSS) sends the value of the HPS secure fuses to the HPS and holds a copy of the FPGA secure fuses. The HPS and FPGA each hold their own fuse values. However, a copy of these fuse values is held in the `HPS_fusesec` and `fpga_fusesec` registers within the Security Manager.

The following table details the HPS security fuse bits sent by the CSS to the Security Manager and contained within the HPS_fusesec register. A "blown" fuse state is represented by a 1 in the HPS_fusesec register and a "not blown" fuse state is represented by a 0.

Table 6-1: HPS_fusesec Register Description

Bits	Name	Description
31:27	Reserved	Bit values in this field are undefined.
26:23	csel_f	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the *Clock Configuration* section for more information on CSEL encodings.
22	dbg_access_f	This fuse determines the initial state of the debug access domains.
21	dbg_lock_JTAG	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. • 0x0= HPS JTAG access level can be changed through the sec_jtagdbg register. • 0x1= HPS JTAG access level cannot be changed (locked).
20	dbg_lock_DAP	This field indicates if the DAP access level can be changed through software when the HPS is released from reset. • 0x0= The DAP access level can be changed through the sec_dapdbg register. • 0x1= The DAP access level cannot be changed (locked).
19	dbg_lock_CPU0	This field indicates if the CPU0 debug access level can be changed through software when the HPS is released from reset. • 0x0= CPU0 debug access level can be changed through the sec_cpu0dbg register. • 0x1= CPU0 debug access level cannot be changed (locked).
18	dbg_lock_CPU1	This field indicates if the CPU1 debug access level can be changed through software when the HPS is released from reset. • 0x0= The CPU1 debug access level can be changed through the sec_cpu1dbg register. • 0x1= The CPU1 debug access level cannot be changed (locked).

Bits	Name	Description
17	dbg_lock_CS	This field indicates if the CoreSight debug access level can be changed through software when the HPS is released from reset. • 0x0= The CoreSight debug access level can be changed through the sec_csdbg register. • 0x1= The CoreSight debug access level cannot be changed (locked).
16	dbg_lock_FPGA	This field indicates if the FPGA debug access level can be changed through software when the HPS is released from reset. • 0x0= The FPGA debug access level can be changed through the sec_fpgadbg register. • 0x1= The FPGA debug access level cannot be changed (locked).
15:12	Reserved	Bit values in this field are undefined.
11	clr_ram_order_f	This fuse value determines how RAMs are cleared during a tamper event. • 0x0= All RAMs are cleared in parallel. • 0x1= All RAMs are cleared in series.
10	clr_ram_cold_f	This fuse value indicates what happens to the RAM on a cold reset. • 0x0= All RAMs are not cleared on a cold reset. • 0x1= All RAMs are cleared on a cold reset.
9	clr_ram_warm_f	This fuse value indicates what happens to the RAMs on a warm reset. • 0x0= All RAMs are not cleared on a warm reset. • 0x1= All RAMs are cleared on a warm reset.
8	oc_boot_f	This fuse value determines if the second-stage boot code is allowed to boot from on-chip RAM. • 0x0= Second-stage boot can be from on-chip RAM if enabled by the System Manager. • 0x1= Second-stage boot is not from on-chip RAM.

Bits	Name	Description
7	hps_clk_f	This fuse value selects the clock used for the boot process and in the case of a tamper event, memory scrambling. • 0x0= The external oscillator, EOSC1, is used for boot. • 0x1= The internal oscillator, cb_intosc_ls_clk, is used for boot.
6	fpga_boot_f	If blown, this fuse value allows the FPGA to configure independently and allows the HPS to boot from an encrypted next-stage boot source that was decrypted into the FPGA. • 0x0= Booting is dependent on the BSEL pins. • 0x1= HPS only boots from the FPGA; BSEL options are ignored and CSEL fuse options are ignored.
5	aes_en_f	This fuse value indicates if a decryption of the flash image is always performed. • 0x0= An AES decryption of the flash image is determined from the second stage boot loader header. • 0x1= An AES decryption of the flash image is always performed.
4:2	kak_src_f	This bit field indicates the source of the Key Authorization Key (KAK) which can be in: • Proprietary ROM • FPGA logic elements • User fuses
1	kak_len_f	This fuse value indicates the Key Authorization Key (KAK) length: • 0x0= 256 bits • 0x1= 384 bits
0	authen_en_f	This fuse value determines whether authentication of flash images is required prior to execution. • 0x0= No authentication of the flash image is required prior to execution. • 0x1= HPS authentication of all flash images is required prior to execution.

At initialization, the FPGA also receives fuse information that is pertinent to its configuration. The HPS can read this information through a secure serial interface, which shifts the FPGA fuse values into the

fpga_fusesec register in the Security Manager. The CSS shifts in a 32-bit value although some of the bits are considered reserved.

Security State

The security state of the entire device is defined by the combination of the security state of the HPS and the FPGA.The initial security state of the device is determined by the fuse settings in the SoC. The values of these fuses are written to two shadow registers within the Security Manager: the hps_fusesec and the fpga_fusesec registers.

Each feature's security level can be increased from its initial fuse level through software, and for debug, through hardware as well. Changes to security level can only increase security and can never lower security. Both the HPS and FPGA have a mechanism to load security option bits as part of the second-stage boot loader and POF file, respectively, which can perform a check of the current security state and raise the security level.

Security Check

The Security Manager has the capability to perform security checks to identify discrepancies between the actual and expected security level so that measured actions can be taken through software and hardware if required.

There are three types of security checks that can be performed by the Security Manager:

- A fuse security level check
- A hardware access security level check
- A software access security level check

Secure Serial Interface

The HPS and FPGA communicate through a secure serial interface. The interface allows security of the HPS to be separate from the security of the FPGA. Software can initiate a request of the serial fuse interface via the Security Manager register.

Secure Debug

Debug logic in the Security Manager controls whether to enable or disable the JTAG, CPUs, Debug Access Port (DAP) and CoreSight™ domains. Debug access is determined by a combination of debug fuses, option bits, and registers that change the default state and set the functional state of debug peripherals.

During a power-on reset, access to all debug domains are prevented. During a warm reset, access to all debug domains except JTAG are prevented. Once a cold or warm reset is exited, the default debug access is defined by the value of the dbg_disable_access fuse and the dbg_lock* fuses. When the dbg_disable_access fuse is blown, HPS debug accesses to all domains are disabled by default out of reset. If the fuse is not blown, then the initial HPS debug state out of reset is enabled. To ensure that the device is brought up in a secure state, the dbg_disable_access fuse must be blown.

Related Information

- **ARM Debug Permissions**
  Refer to this location for information on debug signals and permissions.
- **ARM Infocenter**
  For more information about debug, refer to the ARM Cortex-A9 Technical Reference Manual.

MPU

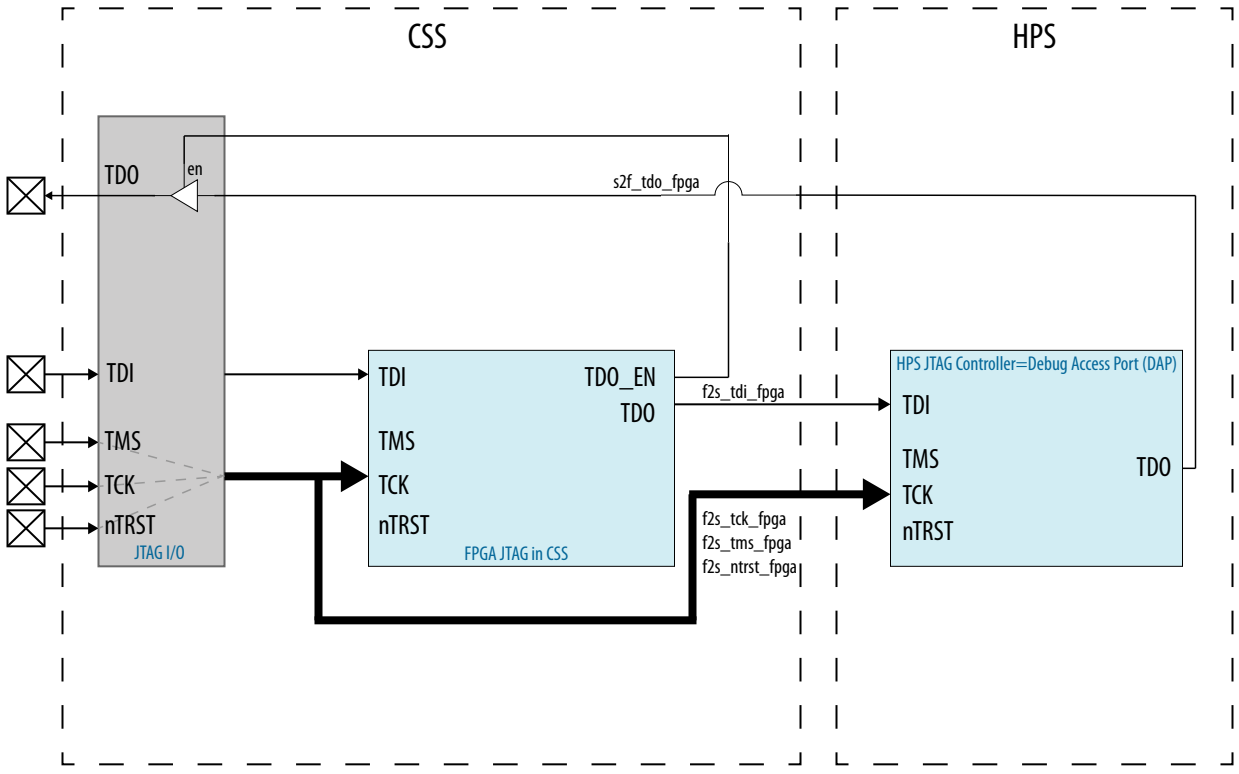
The MPU supports invasive and non-invasive debug. Invasive debug allows the user to control and observe the processor. Non-invasive debug allows you to observe the processor but not control it and is always available as part of invasive debug. The `NIDEN` and `SPNIDEN` signals are used for non-invasive debug in the MPU.

JTAG

The HPS and FPGA share a common set of JTAG pins and each have their own TAP controller which are chained together inside the device.

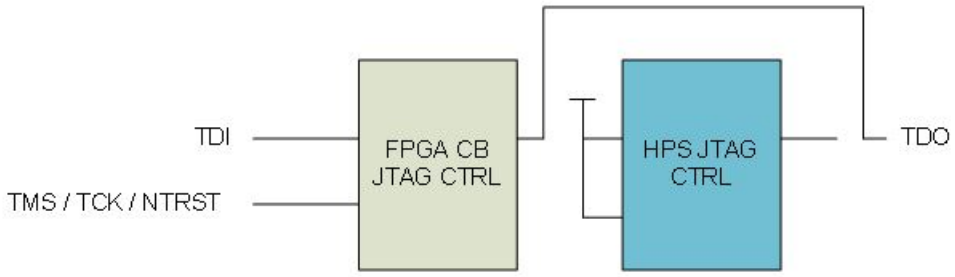
In the default JTAG configuration, the FPGA and HPS JTAG controllers are daisy-chained and controlled by an external JTAG port. The HPS JTAG controller is also referred to as the Debug Access Port.

Figure 6-3: JTAG Chaining



During power-on-reset, the JTAG and all debug domains are disabled. After the device is released from reset, the debug fuses are read by the Configuration Subsystem to determine if the external JTAG port or the JTAG controller to the FPGA or HPS is bypassed. Bypass can additionally be enabled through option bits in the Security Option registers discussed in the *Security State* section.

Figure 6-4: HPS JTAG Bypass



Reset Manager

To avoid unsecure snooping of RAM contents, the Security Manager can send signals to the Reset Manager to clear all RAM on a cold or warm reset.

These signals are the result of fuse programming combined with the configuration bits found in the `HPS_Swoptset` and `HPS_secopt1` register in the Security Manager.

In addition, the fuse information that determines whether the RAMs are cleared in series or parallel is also sent to the Reset Manager. Clearing the memory in series prevents a power spike that could occur with parallel clearing of RAM. The policies for how or when security states take affect can be programmed in the `HPS_secopt1` register. Refer to the "Security State" section for more information.

The RAM instances that are cleared during a warm or cold reset are:

- On-chip RAM
- USB0
- USB1
- SD/MMC
- EMAC0 RX and TX buffer
- EMAC1 RX and TX buffer
- EMAC2 RX and TX buffer
- DMA
- NAND read data, write data, and ECC RAMs
- QSPI
- MPU RAM

If a tamper event occurs, the Security Manager notifies the Reset Manager and the following sequence occurs:

1. All domain resets are asserted.
2. All RAMs are cleared.
3. The Reset Manager enters a dead state waiting for a POR release from Security Manager. All cold reset sources except Security Manager are ignored.

When FPGA POR and HPS POR are asserted, the Security Manager goes into reset.

Related Information

  For more information regarding Security States, refer to the "Security State" section.
- **Reset Manager** on page 3-1
  For more information about reset, refer to the *Reset Manager* chapter.

Clock Configuration

Security Manager is driven by an internal oscillator, `cb_intosc_hs_clk`, in the Configuration Subsystem. This clock has wide variation across process and temperature. Once the Security Manager reads the fuse information, it drives the boot clock configuration to the Clock Manager. The Clock Manager samples the clock configuration on a cold and warm reset. If the `hps_clk_f` fuse is blown, the internal oscillator divided by 2, `cb_intosc_hs_div2_clk`, is used as the boot clock. If the fuse is not blown, an external oscillator is used. During boot ROM execution, the boot code configures the device clock based on the CSEL fuse settings or software code. The `cb_intosc_hs_div2_clk` can be considered the secure reference clock option.

The CSEL fuse settings have different meanings depending on how the hps_clk_f fuse is configured. When the hps_clk_f fuse is not blown, the external oscillator is the boot clock input.

Table 6-2: CSEL Encodings for hps_clk_f = 0

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	When no fuses are blown, the boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (`EOSC1`), which must be in the range of 10 to 50 MHz. No PLL is enabled.	External Oscillator, `EOSC1` (10 to 50 MHz)
0x1	This encoding is typically used during a warm reset if you have already configured your clocks or PLL in the clock manager and would like to continue to use this configuration. If this is encoding is selected, no changes are made to these settings and the clock configuration is essentially user selected. If this is encoding is used during a power-on reset, then whatever the default reset values of the clocks are used.	User-selected clock source. Refer to the *Clock Manager* chapter for clock register settings.

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x2	Reserved	External Oscillator, EOSC1 (10 to 50 MHz)
0x3	Reserved	External Oscillator, EOSC1 (10 to 50 MHz)
0x4	Reserved	External Oscillator, EOSC1 (10 to 50 MHz)
0x5	Reserved	External Oscillator, EOSC1 (10 to 50 MHz)
0x6	Reserved	External Oscillator, EOSC1 (10 to 50 MHz)
0x7	External oscillator input clock, EOSC1, is in the range of 10 to 15 MHz	533 to 800Mhz
0x8	External oscillator input clock, EOSC1, is in the range 15 to 20 MHz.	600 to 800Mhz
0x9	External oscillator input clock, EOSC1, is in the range 20 to 25 MHz.	640 to 800Mhz
0xA	External oscillator input clock, EOSC1, is in the range 25 to 30 MHz.	666 to 800Mhz
0xB	External oscillator input clock, EOSC1, is in the range 30 to 35 MHz.	685 to 800Mhz
0xC	External oscillator input clock, EOSC1, is in the range 35 to 40 MHz.	700 to 800Mhz
0xD	External oscillator input clock, EOSC1, is in the range 40 to 45 MHz.	711 to 800Mhz
0xE	External oscillator input clock, EOSC1, is in the range 45 to 50 MHz.	720 to 800Mhz
0xF	The boot ROM returns clocks back to their default (bypass) boot mode and the CPU is driven by the external oscillator (OSC1). No PLL is enabled.	External Oscillator (10 to 50 MHz)

Table 6-3: CSEL Encodings for hps_clk_f = 1

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0x0	Bypass mode; in this mode all clocks are reset and boot mode is ensured active; `cb_intosc_hs_div2_clk` (`cb_intosc_hs` clock divided by 2) is used.	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x1	This encoding is typically used during a warm reset if you have already configured your clocks or PLL in the Clock Manager and would like to continue to use this configuration. If this is encoding is selected, no changes are made to these settings and the clock configuration is essentially user selected. If this is encoding is used during a power-on reset, then whatever the default reset values of the clocks are used.	User-selected clock source. Refer to the *Clock Manager* chapter for clock register settings.
0x2	PLL is used with the internal oscillator (30 to 100 MHz)	120 to 800 MHz
0x3	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x4	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x5	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x6	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x7	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x8	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0x9	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0xA	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0xB	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0xC	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0xD	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)
0xE	Reserved	`cb_intosc_hs_div2_clk` (60 to 200 MHz)

CSEL[3:0] Fuse Value	Description	MPU Clock Value
0xF	Bypass mode; reset all clocks and ensure boot mode is active; `cb_intosc_hs_div2_clk` is used.	`cb_intosc_hs_div2_clk` (60 to 200 MHz)

FPGA Security Features

The FPGA has several security fuses which can control the following functions:

- Limiting acceptance of only encrypted and authenticated POFs
- Disabling partial reconfiguration and scrubbing
- Disabling test access
- Disabling external configuration
- Limiting JTAG access
- Bypassing HPS or FPGA JTAG
- Locking or disabling the battery-backed volatile key
- Disabling the OTP key

Note that there is a fuse sent to the FPGA CSS, called hps_jtag_bypass, which performs the same function of removing the HPS from the JTAG chain. However, this fuse is a permanent disable, whereas using software to program the sec_jtagdbg register has the same affect, but may be changed later by software.

Secure Boot

No ordering of boot or FPGA configuration is required because the FPGA and HPS may be brought up in any order, and they can both raise the security level of the entire device at any time before user code is loaded to execute.

The SoC may securely boot in one of three ways:

1. The HPS boot and FPGA configuration occur separately.
2. The HPS boots from the FPGA after the FPGA is configured
3. The HPS boots first and configures the FPGA.

Note: The device has the capability to execute standard non-secure boot in any of these three ways, as well. In this section, only secure booting mechanisms are reviewed.

Note: The FPGA must be powered on for the HPS to come out of reset properly.

Related Information

Booting and Configuration on page 30-1
For more information about the boot process refer to the *Booting and Configuration* appendix.

Boot Configuration

Booting configuration is provided from a combination of the `BSEL` pins and the boot mode fuses. The `BSEL` pins indicate if the boot source is the FPGA or one of the HPS flash interfaces. If the `fpga_boot_f` fuse is blown, it overrides these pin values. The `fpga_boot_f` fuse value can be read from the `hps_fusesec` register.

Table 6-4: BOOTSEL Field Values and Flash Device Selection

BOOTSEL Field Value	Flash Device
0x0	Reserved
0x1	FPGA (HPS-to-FPGA bridge)
0x2	1.8 V NAND flash memory
0x3	3.0 V NAND flash memory
0x4	1.8 V SD/MMC flash memory with external transceiver
0x5	3.0 V SD/MMC flash memory with internal transceiver
0x6	1.8 V quad SPI flash memory
0x7	3.0 V quad SPI flash memory

Within the device, there are fuses that provide some of the boot mode configuration information. The fuse values can be read through the `HPS_fusesec` register:

Table 6-5: `HPS_fusesec` Register Description

Bits	Name	Description
31:27	`Reserved`	Bit values in this field are undefined.
26:23	`csel_f`	This field indicates the value of the clock select fuses that are available for configuring the clock for the boot interface and for the PLLs. Refer to the *Clock Configuration* section for more information on CSEL encodings.
22	`dbg_access_f`	This fuse determines the initial state of the debug access domains.

Bits	Name	Description
21	dbg_lock_JTAG	This field indicates if the HPS JTAG access level can be changed through software when the HPS is released from reset. • 0x0= HPS JTAG access level can be changed through the sec_jtagdbg register. • 0x1= HPS JTAG access level cannot be changed (locked).
20	dbg_lock_DAP	This field indicates if the DAP access level can be changed through software when the HPS is released from reset. • 0x0= The DAP access level can be changed through the sec_dapdbg register. • 0x1= The DAP access level cannot be changed (locked).
19	dbg_lock_CPU0	This field indicates if the CPU0 debug access level can be changed through software when the HPS is released from reset. • 0x0= CPU0 debug access level can be changed through the sec_cpu0dbg register. • 0x1= CPU0 debug access level cannot be changed (locked).
18	dbg_lock_CPU1	This field indicates if the CPU1 debug access level can be changed through software when the HPS is released from reset. • 0x0= The CPU1 debug access level can be changed through the sec_cpu1dbg register. • 0x1= The CPU1 debug access level cannot be changed (locked).
17	dbg_lock_CS	This field indicates if the CoreSight debug access level can be changed through software when the HPS is released from reset. • 0x0= The CoreSight debug access level can be changed through the sec_csdbg register. • 0x1= The CoreSight debug access level cannot be changed (locked).

Bits	Name	Description
16	dbg_lock_FPGA	This field indicates if the FPGA debug access level can be changed through software when the HPS is released from reset. • 0x0= The FPGA debug access level can be changed through the sec_fpgadbg register. • 0x1= The FPGA debug access level cannot be changed (locked).
15:12	Reserved	Bit values in this field are undefined.
11	clr_ram_order_f	This fuse value determines how RAMs are cleared during a tamper event. • 0x0= All RAMs are cleared in parallel. • 0x1= All RAMs are cleared in series.
10	clr_ram_cold_f	This fuse value indicates what happens to the RAM on a cold reset. • 0x0= All RAMs are not cleared on a cold reset. • 0x1= All RAMs are cleared on a cold reset.
9	clr_ram_warm_f	This fuse value indicates what happens to the RAMs on a warm reset. • 0x0= All RAMs are not cleared on a warm reset. • 0x1= All RAMs are cleared on a warm reset.
8	oc_boot_f	This fuse value determines if the second-stage boot code is allowed to boot from on-chip RAM. • 0x0= Second-stage boot can be from on-chip RAM if enabled by the System Manager. • 0x1= Second-stage boot is not from on-chip RAM.
7	hps_clk_f	This fuse value selects the clock used for the boot process and in the case of a tamper event, memory scrambling. • 0x0= The external oscillator, EOSC1, is used for boot. • 0x1= The internal oscillator, cb_intosc_ls_clk, is used for boot.

Bits	Name	Description
6	fpga_boot_f	If blown, this fuse value allows the FPGA to configure independently and allows the HPS to boot from an encrypted next-stage boot source that was decrypted into the FPGA. • 0x0= Booting is dependent on the BSEL pins. • 0x1= HPS only boots from the FPGA; BSEL options are ignored and CSEL fuse options are ignored.
5	aes_en_f	This fuse value indicates if a decryption of the flash image is always performed. • 0x0= An AES decryption of the flash image is determined from the second stage boot loader header. • 0x1= An AES decryption of the flash image is always performed.
4:2	kak_src_f	This bit field indicates the source of the Key Authorization Key (KAK) which can be in: • Proprietary ROM • FPGA logic elements • User fuses
1	kak_len_f	This fuse value indicates the Key Authorization Key (KAK) length: • 0x0= 256 bits • 0x1= 384 bits
0	authen_en_f	This fuse value determines whether authentication of flash images is required prior to execution. • 0x0= No authentication of the flash image is required prior to execution. • 0x1= HPS authentication of all flash images is required prior to execution.

Secure Boot Process

Secure boot allows the HPS to release from reset into a known state and then validate the authenticity and integrity of the second-stage boot loader code prior to executing it. Secure boot ensures that only authorized code is executed on the system. In addition, the system has the option to configure the FPGA from the HPS, which provides a secure boot mechanism for the FPGA portion of the SoC. In this mode, the HPS boot code can authenticate the FPGA POF prior to loading it.

The HPS and FPGA can also be booted securely but independently, with the HPS executing authenticated and decrypted user code out of external RAM and the FPGA receiving an encrypted FOP configuration file by enabling an FPGA configuration source through the MSEL pins.

Boot ROM code runs on CPU0 and CPU1 is held in reset. Once control passes to the second-stage boot loader, CPU1 can be released from reset.

Authentication and Decryption

Authentication is provided for the second-stage boot loader code and both the HPS and FPGA can utilize the AES algorithms in the Configuration Subsystem (CSS) to decrypt boot images and POF files, respectively.

Three levels of boot are available to the device:

- Authentication only: The second-stage boot loader code is not encrypted, but there are public key signatures attached to the image and the code only executes if all of the signatures pass. ECDSA256 (SHA 256) is used for authenticated boot.
- Decryption only: The user boot code is encrypted and must be decrypted before execution. AES-based algorithms in the FPGA are used for decryption.
- Authentication and Decryption: The user boot code is encrypted and signed.

If authentication and decryption are enabled, the data is first authenticated and then decrypted using the AES algorithms. Authentication is performed using the public key authorization key (KAK) held in the user fuses. The KAK can be 256 bits. The KAK public key authentication fuses are lockable by the user in groups of 64 bits or less.

The Security Manager's hps_fusesec register can be read to identify the source of the public (root) key used for authentication of the second-stage boot loader. The source of the public (root) key can be one of the following:

- External software
- Altera ROM
- FPGA logic elements
- User Access Fuses (UAF)

AES decryption algorithms are available through the FPGA CSS and are enabled prior to decryption through a combination of user fuses and software programming. Elliptic curve cryptographic algorithms are used in an authenticated boot. Decrypted data is sent to the Security Manager to be read by the CPU or DMA.

The FPGA has higher priority in the CSS, and the FPGA AES algorithms abort decryption and authentication of data if the FPGA starts configuration or reconfiguration.

Anti-Tamper

The Security Manager receives a tamper detection signal when a tamper event is detected in the device.

Anti-tamper logic can be implemented in the FPGA soft logic to detect a tamper event. No tamper detection is available until the FPGA is configured. The user must define the anti-tamper design. Some examples of tamper detection that could be implemented are:

- Using the FPGA voltage sensor to detect any IR drops across the device.
- Using an A/D controller to detect temperature changes in the device due to tamper.
- Assigning loaner I/O as dedicated tamper pins to detect package break-away.

The tamper detection signal sent to the Security Manager, `anti_tamper_in`, is an active low signal. When there is no tamper event, it is driven to 1. The Security Manager also provides a tamper acknowledge signal to the FPGA interface. The tamper event input to the HPS is gated with a signal indicating the completion of FPGA configuration. This prevents an inadvertent tamper event assertion or tamper response from the HPS to the rest of the system.

When the Security Manager receives a tamper detection assertion, it prepares the system to go into reset and notifies the Reset Manager of the event. When the Reset Manager receives the tamper event assertion from the Security Manager, it drives all the peripherals and MPU into reset. It asserts a request and enables all peripherals memories to initiate a memory scramble and a memory clear, either in series or parallel, depending on the information sent from the Security Manager. The memory clearing includes the on-chip RAM, peripheral memories, L1 caches, and L2 cache. Once the memory scramble and clear completes, each module sends an acknowledgment back to the Reset Manager.

Upon completion of memory scrambling of all IPs, the Security Manager sends a response to the FPGA indicating that a tamper event has been handled in the HPS. This response is followed by HPS entering into a cold reset without exiting until another power cycle occurs. Both Security Manager and Reset Manager enter reset. Other resets, such as warm reset or cold reset, do not affect the state of the Security Manager or the Reset Manager.

If the FPGA POR is de-asserted while the HPS is in a tamper event reset, then the Security Manager goes back to the reset state.

Security System Extensions

Beyond the Security Manager module, other secure features can be implemented at a system level within the SoC.

TrustZone

The Cortex-A9 MPU subsystem has integrated TrustZone technology, which provides a system solution to protect application platforms from malicious attack. The TrustZone hardware and supporting software are designed to provide a strong security solution regardless of the operating environment. TrustZone creates a separation between the secure and non-secure areas of the SoC and allows the designer to choose which assets in a design are designated as secure and non-secure.

TrustZone security is implemented in the Cortex-A9 MPU subsystem in three ways:

- Hardware partitioning through the implementation of firewalls: Resources can be assigned and identified as secure or non-secure.
- Virtual processor execution: Each core can context switch between secure and non-secure operation.
- Secure debug control: Both secure and non-secure hardware debug exist and the type of debug allowed can be configured by the user.

Secure Partitioning

System interconnect and cache accesses as well as processor execution can be securely partitioned using the TrustZone infrastructure.

Secure Bus Accesses

The Cortex-A9 MPCore and other masters that utilize the system interconnect can be configured for secure or non-secure accesses.

Master accesses drive a protection signal, `AxPROT[1]`, to communicate the security level of the attempted transaction. The Cortex-A9 drives this signal low for secure accesses and high for non-secure accesses. The secure firewalls determine whether the access is allowed or not. A slave access type defaults to secure if no other configuration is programmed. Users can define whether a bus error is generated or if a bus failure occurs when a secure access is violated.

Note: Secure processor configuration is programmed through the `CP15` register.

Related Information

- **Arria 10 HPS Secure Firewalls** on page 6-24
  For more detailed information about secure bus accesses, refer to the "Secure Firewall" section.
- **SoC Security** on page 6-1
  For more information about SoC Security, refer to the *SoC Security* Chapter.

Secure Cache Accesses

Secure and non-secure partitioning also extends to the L1 and L2 caches.

There is a 32-bit physical address space for secure and non-secure transactions and a 33rd bit is provided to indicate security. The cache is able to store both secure and non-secure lines.

The Accelerator Coherency Port (ACP) in the ARM Cortex-A9 MPCore can be used with TrustZone technology. The security state of the masters using the ACP must be the same as the Cortex-A9 processor.

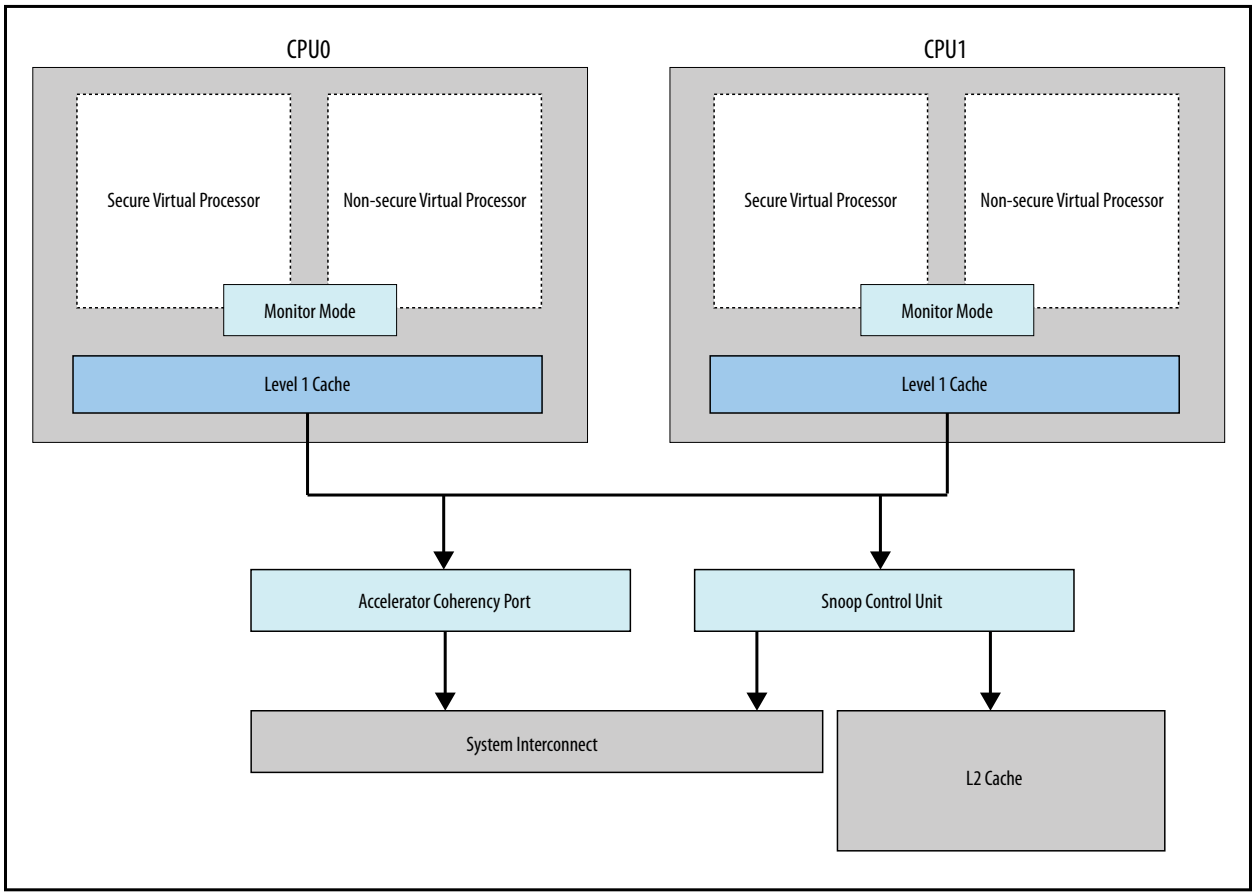
Related Information

- **ARM TrustZone**
  Refer to this location for information about virtual core operation.
- **SoC Security** on page 6-1
  For more information about SoC Security, refer to the *SoC Security* Chapter.

Virtual Processor Operation

Two virtual processors (secure and non-secure) with context switch capability (monitor mode) exist for each Cortex-A9 processor core. The secure virtual processor only accesses secure resources and the non-secure virtual processor only accesses non-secure resources.

Figure 6-5: Virtual Processor Environment with Monitor Mode



A context switch to secure operation is achieved through a secure monitor call (SMC) instruction or the following hardware exceptions (if configured to do so):

- IRQ interrupt
- Faster Interrupt Request (FIQ) interrupt
- External data abort
- External prefetch abort

When a context switch occurs, the state of the current mode is saved and restored on the next context switch or on a return from exception.

Exception Vector Tables

Three exception vector tables are provided for the MPU with TrustZone:

1. Non-secure
2. Secure
3. Monitor mode

Typically IRQs are used for non-secure interrupts and FIQs are used for secure interrupts. The location of each of the three vector tables can be moved at runtime.

The Generic Interrupt Controller (GIC) can handle secure and non-secure interrupts and prevent non-secure accesses from reading or modifying the configuration of a secure interrupt. An interrupt can be made secure by programming the appropriate bits in the Interrupt Security Register. Secure interrupts are always given a higher priority than non-secure interrupts.

Arria 10 HPS Secure Firewalls

You can use the system interconnect firewalls to enforce security policies for slave and memory regions in the system interconnect.

The firewalls support the following features:

- Secure or non-secure access configurable per peripheral
- Privileged or user access configurable for some peripherals
- Per-transaction security

Each firewall contains the security configuration registers (SCRs) that set security policies and define which transactions are allowed to go through the firewall. If you want to generate an error any time a transaction is blocked in the firewall, then you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address 0xFFD13400. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Altera recommends you to set the `error_response` bit in the `global` register.

There are five main firewalls in the HPS:

- Peripheral
- System
- HPS-to-FPGA
- On-Chip RAM
- SDRAM (which includes DDR and DDR L3 firewalls)

Figure 6-9: On-Chip RAM Firewall

Up to six regions of the on-chip RAM can be partitioned for non-secure accesses.

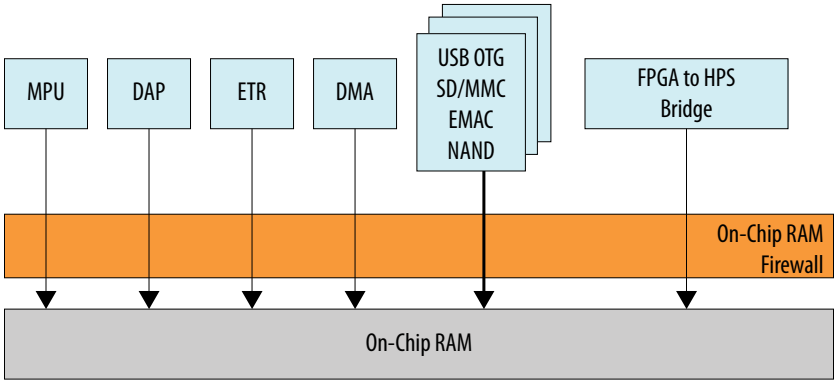

Figure 6-10: SDRAM firewall

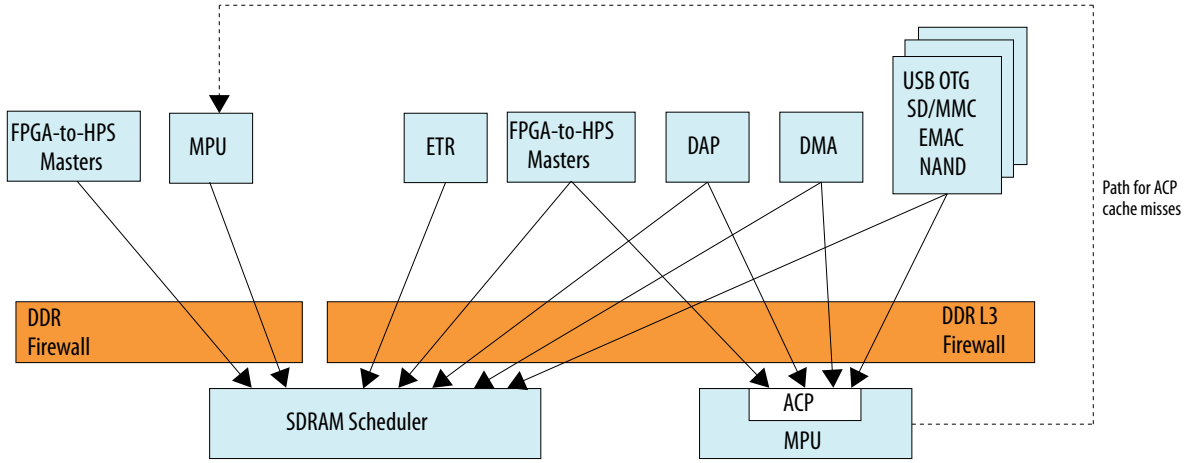
Transactions from the DMA, ETR, DAP, FPGA-to-HPS masters or HPS masters (USB, SD/MMC, EMAC, NAND) are routed to either the ACP or the SDRAM scheduler depending on the cacheable bit. Only cacheable transactions are routed to the ACP, with non-cacheable transactions being routed directly to the SDRAM scheduler. If an access to the ACP results in a cache miss in the L1 and L2 cache systems, then the MPU master M1 issues a transaction to the SDRAM scheduler. Only cacheable transactions go through to the ACP. If a cache miss occurs on the ACP cycle, then the MPU masters a new transaction to the SDRAM scheduler. Accesses from the MPU or FPGA-to-SOC masters that are tightly coupled to the MPU go through the DDR firewall only.

Note: The dotted line in the diagram represents the path taken when an ACP access occurs and misses in the L1 and L2 cache.



Secure Transaction Protection

The interconnect provides two levels of transaction protection.

The two levels of transaction protection are:

- Security Firewalls:

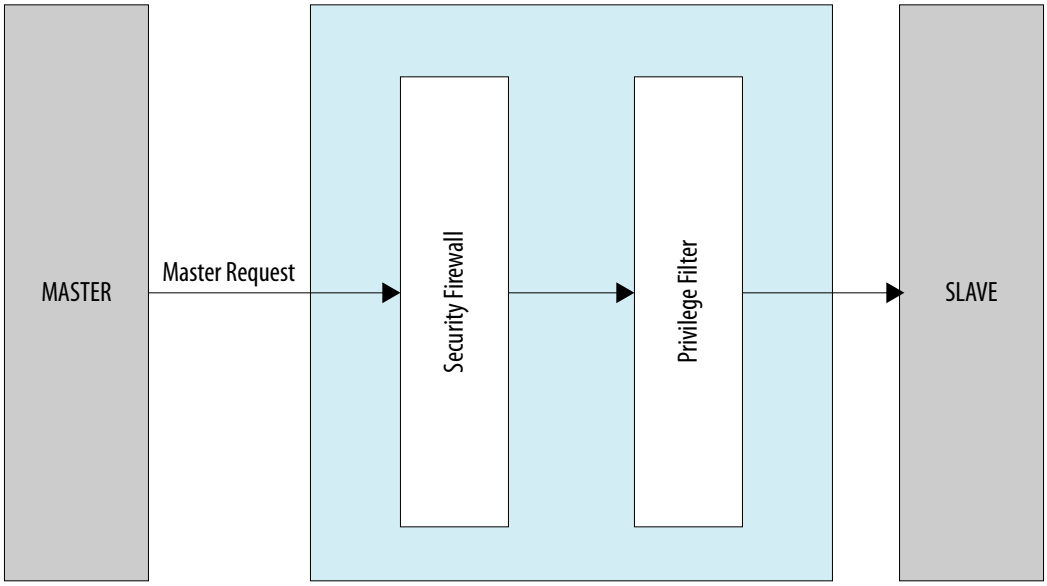
  Security firewalls enforce the Secure World read and write transactions. The term "security firewall" and "firewall" may be used interchangeably within the context of this section.
- Privilege filter

  The privilege filter leverages the firewall mechanism and provides additional filtering by allowing control of the privilege level of L4 slave transactions. The privilege filter applies to writes only.

All slaves on the SoC are placed behind a security firewall. A subset of slaves are also placed behind a privilege filter. Transactions to these slaves pass through two firewall structures as shown in the figure below. The transaction packet must pass both a security firewall and the privilege filter to reach the slave. A transaction error causes random data or a slave error depending on where the transaction failed and how the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module is programmed.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Altera recommends you to set the `error_response` bit in the `global` register.

Figure 6-11: Successful Secure Transaction Path



Each firewall has an associated firewall register which can be programmed by the DAP, FPGA fabric or MPU in secure mode only. A subset of the L4 slaves can additionally be programmed to configure their privilege filter policy.

Peripheral and System Firewalls

The peripheral and system firewalls each have a group of Security Configuration Registers (SCRs) that can be programmed by the DAP, FPGA fabric or MPU only in secure mode.

The peripheral and system firewalls can be configured by programming the security bits in the SCR blocks. Each slave has an SCR containing a security bit for each available master, which enables a different security access level to be programmed for each master-slave pair. At reset, all accesses are configured to be secure. When a master-slave security bit is 0, only secure packets are allowed to pass the firewall and reach the intended target. When the master-slave security bit is 1, the firewall passes the transaction.

Table 6-10: Security Bit Value

Secure Flag Value	Access
0	Only secure packets are allowed to pass the firewall.
1	Transaction packets are allowed to pass the firewall.

When a transaction packet is sent from a master, the master also drives a secure flag signal on the bus. This flag indicates whether the attempted transaction from the master is secure or non-secure. For AXI master accesses, this flag is the `~AxPROT[1]` signal.

For L4 ECC, L4 system or L4 DDR master accesses, this flag is the `MSecure[0]` signal.

When the flag signal is driven high, it indicates a secure access. When the flag signal is low, it indicates a non-secure access.

Secure Transaction Example

A successful secure access attempt by a master, depends on the security bit configuration in the Security Control Register and the value of the master secure flag sent by the master.

All SoC transactions are set to secure out of reset with a return of random data when transactions are blocked. If you want an error response returned for blocked transactions, you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address 0xFFD13400. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Altera recommends you to set the `error_response` bit in the `global` register.

To initiate a secure transaction:

1. The master drives the address of the slave as well as the master secure flag signal, indicating that the access is intended to be secure.
2. The firewall compares the programmed security bit of the master-slave peripheral pair to the master secure flag signal to determine if the access is valid.
3. If the access is valid, the transaction passes to the next level. If the access is not valid, random data is fed back to the master.

Table 6-11: Peripheral and System Transaction Results

Security Bit in Firewall Register	Master Secure Flag	Transaction Pass/Fail	Transaction Type
0	0	No	None (Blocked transaction)
0	1	Yes	Secure
1	0	Yes	Non-secure
1	1	Yes	Secure

Non-secure Transaction Configuration

When the SoC is released from reset, only secure transactions are allowed through the firewalls. The user must configure any master-slave pairs that are required to be non-secure.

The SCR registers must be accessed in secure mode to configure the firewall access to non-secure.

1. After the SoC is released from reset, the MPU, FPGA2SOC masters or the DAP accesses the required Security Configuration Register (SCR) by executing a secure write. The peripheral firewall SCR registers are within the `soc_noc_fw_l4_per` register group and the system firewall SCR registers are found within the `soc_noc_fw_l4_sys` register group.
2. To configure the slave to allow a non-secure access by a master, set the corresponding security bit to 1.

The configured master is able to successfully execute a non-secure read or write to the configured slave.

HPS-to-FPGA Firewall

The HPS-to-FPGA firewall is used to filter access to all the FPGA, including the HPS-to-FPGA bridge and the lightweight HPS-to-FPGA bridge.

The secure firewall for the HPS-to-FPGA can be disabled by programming the `lwsoc2fpga` register and `soc2fpga` register within the `noc_fw_soc2fpga` group.

On-Chip RAM Firewall

At reset all memories are secure. Out of reset, regions of memories can be configured for non-secure accesses.

The on-chip RAM is divided into six regions, where the granularity of the address boundary is 4 KB. Within each region, a non-secure or shared memory region can be assigned by programming a `base` and `limit` value in the corresponding `regionNaddr` register, with `N` denoting the region number. Each of these regions can be enabled by writing to the `enable` register or setting the corresponding bit in the `enable_set` register.

When an incoming transaction falls within any enabled non-secure regions, the firewall allows both secure and non-secure packets. When the transaction is outside of any enabled regions, the firewall only allows secure packets.

When a transaction packet is sent from a master, the master also drives a secure master flag signal on the bus. This flag indicates whether the attempted transaction from the master is for a secure or non-secure memory region. When the flag signal is driven high, it indicates a secure access. When the flag signal is low it indicates a non-secure access.

On-Chip RAM Transaction Configuration

Because all memories are secure when they exit reset, the on-chip RAM Security Control Register block must be configured by a secure master before non-secure or shared memory accesses are allowed.

1. Configure the `base` and `limit` fields of the `regionNaddr` register, where `N` denotes the region number.
2. Enable the non-secure memory region by setting the corresponding `regionNenable` bit in the `enable_set` register, where `N` denotes the region number.

SDRAM Firewall

Two SDRAM firewalls are implemented to allow a different security policy depending on the master.

One firewall filters accesses from the MPU and the FPGA-to-SDRAM interface. The other firewall filters accesses from all other masters on the HPS and applies the same security policy to both coherent and non-coherent accesses. Both firewalls are logically and physically split within the interconnect.

The SDRAM Firewall supports a minimum region size of 64 KB. Each master is allowed a different number of firewall regions:

- The MPU can have up to four firewall regions.
- The FPGA-to-SDRAM interface can have up to twelve firewall regions.
- Any HPS bus master can have up to eight firewall regions.

Privilege Filter

If a transaction packet has passed the security firewall, it may pass through a privilege filter. The privilege filter only applies to writes. All reads are passed without exception.

The privilege filter decodes the incoming user or privilege accesses and determines whether to pass or fail the transaction. It is separate from the security firewall and transactions generally carry both privilege and secure bits. The privilege filters are configured in the interconnect by executing a read-modify-write to the

l4_priv register or setting individual bits in the l4_set register. If a privilege bit is set, both privilege and user mode transactions are allowed to the slave. If a privilege bit is cleared using the l4_clear register, then only privileged transactions are allowed to the slave.

The following slaves can be programmed using the privilege registers in the interconnect module:

- HPS-to-FPGA bridge
- Lightweight HPS-to-FPGA bridge
- UARTs
- SP Timers
- I2C Modules
- GPIO
- SD/MMC
- QSPI
- EMAC Modules
- SPI
- Secure and non-secure DMA
- USB
- NAND Controller

The following table shows the result of privileged and user master accesses based on the value of the programmed privilege bit for a particular slave.

Note: All read accesses pass regardless of the privilege bit value.

Table 6-12: Privilege Filter Transaction

Read/Write	Privilege Signal	Privilege bit	Transaction Pass/Fail
Read	0	0	Pass
	0	1	Pass
	1	0	Pass
	1	1	Pass
Write	0	0	Fail
	0	1	Pass
	1	0	Pass
	1	1	Pass

Master Security Policy

Each master has an inherent security transaction capability.

Masters accessing slaves can be configured to one of three different security policies:

- Per transaction: The master is capable of generating secure and non-secure transactions.
- Secure: The master only supplies secure transactions.
- Non-secure: The master only generates non-secure transactions.

At reset, all accesses default to secure transactions. The table below details the transaction capability of each master within the SoC. Some masters are only capable of non-secure transactions.

Table 6-13: Master Transaction Capability

Master	Transaction Capability
DMA	Secure/Non-secure
DAP	Secure/Non-secure
USB OTG 0/1	Non-secure
SD/MMC	Non-secure
EMAC0/1/2	Secure/Non-secure
NAND	Non-secure
FPGA-to HPS Bridge	Secure/Non-secure
ETR	Secure/Non-secure
MPU	Secure/Non-secure
FPGA-to-SDRAM	Secure/Non-secure

Security policies are based on secure and privilege attributes. For instance, if CPU0 is configured to access NAND registers in both secure and non-secure mode and CPU0 attempts an access when the core is in secure or non-secure mode, no error occurs. However, if CPU0 is allowed to access NAND registers only in secure mode and CPU0 is operating in non-secure mode, then CPU0 receives an error response when accessing the NAND registers. If both the security firewall and privilege firewall are implemented, security firewall filters all of the accesses. If an access fails, random data or an error response is sent to the master, depending on how the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module is programmed. If access is granted by the security firewall, then the transaction enters the privilege firewall. If access is granted, the request enters the peripheral IP.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Altera recommends you to set the `error_response` bit in the `global` register.

Secure Interconnect Reset

When the SoC is released from reset, every slave on the interconnect is in the secure state (boot secure).

The only masters capable of secure accesses out of reset are:

- MPU
- DAP
- HPS-to-FPGA fabric

Revision History

The table below holds the document revision history for *SoC Security* Chapter.

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
May 2016	2016.05.27	Maintenance release
May 2016	2016.05.03	• Added note regarding blocked firewall transaction responses in the "Secure Firewall" section • Updated content and added figures to "JTAG" section
November 2015	2015.11.02	Clarified initialization steps in "Secure Initialization Overview" section
May 2015	2015.05.04	Added Address Map and Register information.
December 2014	2014.12.15	• Added "Secure Fuses" section under "Secure Initialization" section. • Added summary of "Security State" and "Security Check" and "Secure Serial Interface" features. • Added "MPU" and "JTAG" sub-sections to the "Secure Debug" section. • Added information regarding CSEL programming in the "Clock Configuration" section. • Added "FPGA Security Features" section
August 2014	2014.08.18	Initial Release

System Interconnect 7

2016.10.28

a10_5v4 Subscribe Send Feedback

The components of the hard processor system (HPS) communicate with one another, and with other portions of the SoC device, through the system interconnect. The system interconnect consists of the following blocks:

- The main level 3 (L3) interconnect
- The SDRAM L3 interconnect
- The level 4 (L4) buses

The system interconnect is the main communication bus for the MPU and all IPs in the SoC device.

The system interconnect is implemented by the Arteris FlexNoC network-on-chip (NoC) interconnect module.

The system interconnect supports the following features:

- An L3 interconnect that provides high-bandwidth routing between masters and slaves in the HPS
- SDRAM L3 interconnect, providing access to a hard memory controller in the FPGA fabric through a multiport front end (MPFE) scheduler for sharing the external SDRAM between multiple masters in the SoC device
- Independent L4 buses running in several clock domains. These buses handle data traffic for low- to mid-level bandwidth slave peripherals and accesses to peripheral control and status registers throughout the address map.
- On-chip debugging and tracing capabilities
- Security firewalls with the following capabilities:
  - Secure or nonsecure access configured per peripheral
  - Privileged or user access configured per peripheral (for some peripherals)
  - Security optionally configured per transaction at the master
- Quality of service (QoS) with three programmable levels of service on a per-master basis

For information about the FlexNoC Network-on-Chip Interconnect, refer to the Arteris website.

About the System Interconnect

Features of the System Interconnect

The system interconnect supports high-throughput peripheral devices. The system interconnect has the following characteristics:

- Byte oriented address handling
- Data bus width up to 128 bits
- ARM TrustZone-compliant firewall and security support, with additional security features configurable per master
- Programmable quality-of-service (QoS) optimization
- Dedicated SDRAM L3 interconnect, providing access and scheduling for the hard memory controller in the FPGA portion of the SoC device
- On-chip debug and tracing capabilities
- Multiple independent L4 buses with independent clock domains and protocols

  The L4 buses are each connected to a master in the main L3 interconnect for control and status register access. Each L4 bus is 32 bits wide and is connected to multiple slaves. The L4 buses also provide a low- to mid-level tier of the system interconnect for lower-bandwidth slave peripherals. Each L4 bus is 32 bits wide and operates in a separate clock domain.

System Interconnect Block Diagram and System Integration

System Interconnect Block Diagram

The following figures show the system interconnect, including the main L3 interconnect, SDRAM L3 interconnect, and L4 buses.

Figure 7-1: High-Level System Interconnect Block Diagram

The following figure shows the relationships among the system interconnect and other major SoC components.

More detailed information about the SDRAM L3 interconnect

System Interconnect Architecture

The system interconnect has a transaction-based architecture that functions as a partially-connected fabric. Not all masters can access all slaves.

The system interconnect is a network on chip (NoC) providing interface widths up to 128 bits, connecting to the L4 slave buses and to HPS and FPGA masters and slaves.

The system interconnect provides low-latency connectivity to the following bridges:

- HPS-to-FPGA bridge
- Lightweight HPS-to-FPGA bridge
- FPGA-to-HPS bridge
- Three FPGA-to-SDRAM ports

SDRAM L3 Interconnect Architecture

The SDRAM L3 interconnect provides access to the hard memory controller in the FPGA portion of the SoC device.

The SDRAM L3 interconnect is part of the system interconnect, and includes these components:

- SDRAM scheduler
- SDRAM adapter

The SDRAM L3 interconnect operates in a clock domain that is 1/2 the speed of the hard memory controller clock.

Arria 10 HPS Secure Firewalls

You can use the system interconnect firewalls to enforce security policies for slave and memory regions in the system interconnect.

The firewalls support the following features:

- Secure or non-secure access configurable per peripheral
- Privileged or user access configurable for some peripherals
- Per-transaction security

Each firewall contains the security configuration registers (SCRs) that set security policies and define which transactions are allowed to go through the firewall. If you want to generate an error any time a transaction is blocked in the firewall, then you must set the `error_response` bit in the `global` register of the `noc_fw_ddr_l3_ddr_scr` module at base address 0xFFD13400. If this bit is clear, transactions blocked by the firewall return random data.

Note: Future devices may not support the return of random data and may only support an error response for blocked firewall transactions. For designs that may be ported to future devices, Altera recommends you to set the `error_response` bit in the `global` register.

There are five main firewalls in the HPS:

- Peripheral
- System
- HPS-to-FPGA
- On-Chip RAM
- SDRAM (which includes DDR and DDR L3 firewalls)

About the Rate Adapters

The L3 interconnect contains a rate adapter wherever a low-bandwidth channel transfers data to a high-bandwidth channel.

Related Information

Functional Description of the Rate Adapters on page 7-26

About the SDRAM L3 Interconnect

The hard processor system (HPS) provides a specialized SDRAM L3 Interconnect dedicated to SDRAM accesses.

The SDRAM L3 Interconnect contains an SDRAM scheduler and an SDRAM adapter. The SDRAM scheduler functions as a multi-port front end (MPFE) for multiple HPS masters. The SDRAM adapter is responsible for connecting the HPS to the SDRAM hard memory controller in the FPGA portion of the device. The SDRAM L3 interconnect is part of the system interconnect.

Features of the SDRAM L3 Interconnect

The SDRAM L3 interconnect supports the following features:

- Connectivity to the SDRAM hard memory controller supporting:
  - DDR4-SDRAM
  - DDR3-SDRAM
- Integrated SDRAM scheduler, functioning as a multi-port front end (MPFE)
- Configurable SDRAM device data widths
  - 16-bit, with or without 8-bit error-correcting code (ECC)
  - 32-bit, with or without 8-bit ECC
  - 64-bit, with or without 8-bit ECC
- High-performance ports
  - MPU subsystem port
  - Main L3 interconnect port
  - Three FPGA ports
    - Two 32-, 64-, or 128-bit ports
    - One 32- or 64-bit port
  - Firewall and security support port

Note: At system startup, the SDRAM I/O pins can be configured separately from the FPGA fabric, allowing the SoC HPS to boot before any soft logic is configured in the FPGA.

SDRAM L3 Interconnect Block Diagram and System Integration

The SDRAM L3 interconnect is composed of two main blocks: SDRAM adapter and SDRAM scheduler.

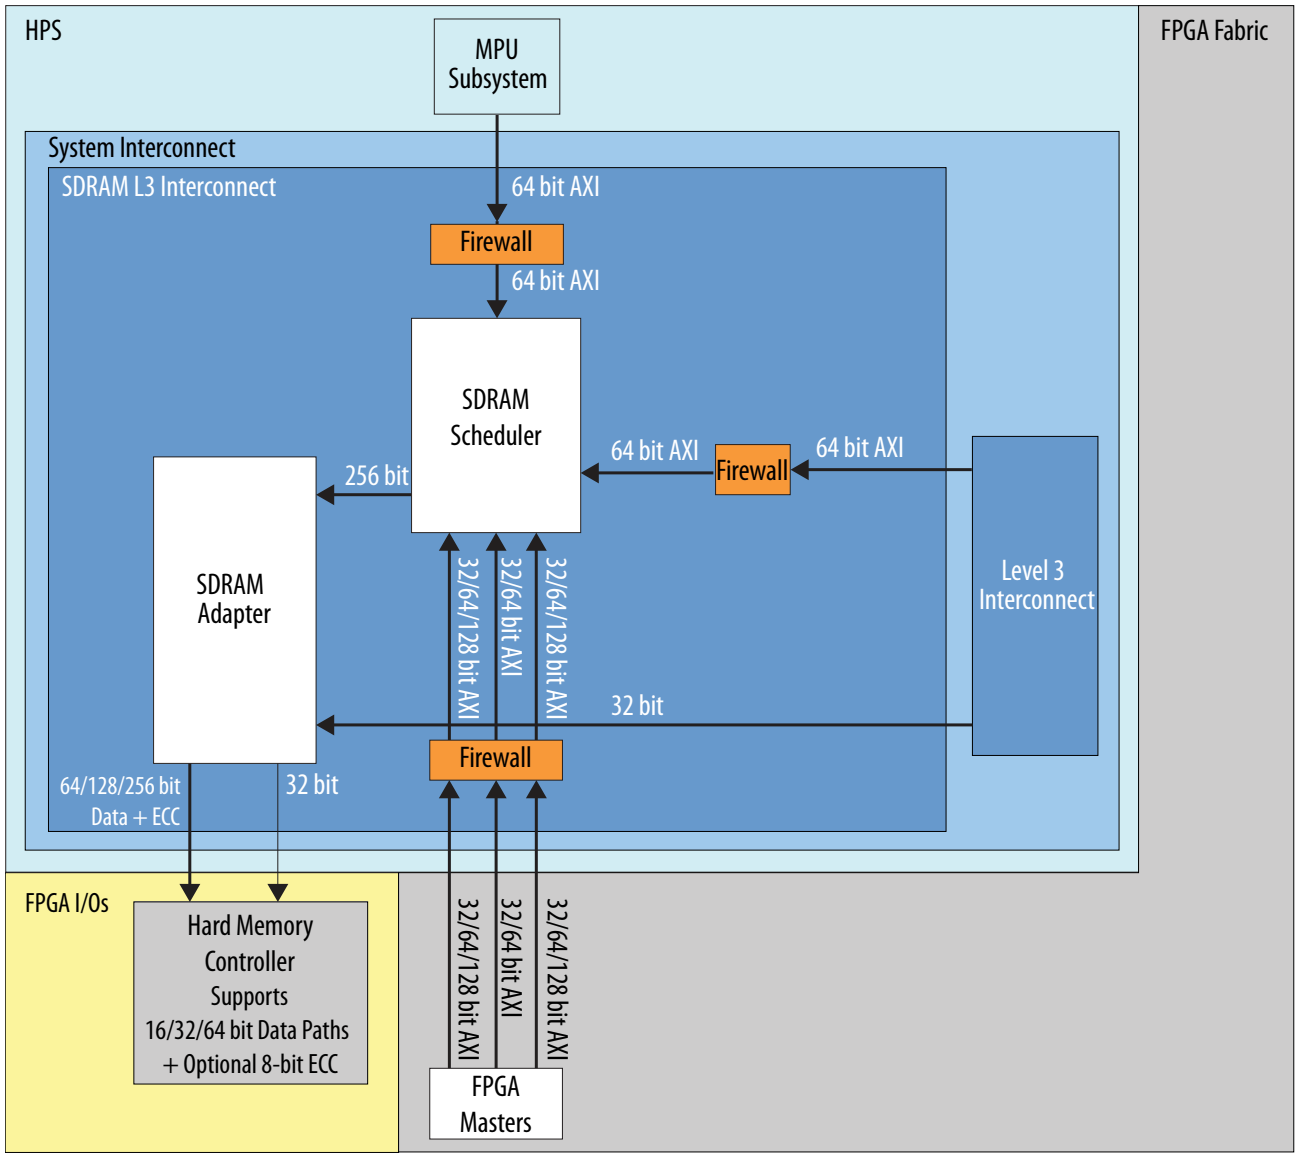
The SDRAM adapter is responsible for bridging the hard memory controller in the FPGA fabric to the SDRAM scheduler. The adapter is also responsible for ECC generation and checking.

The ECC register interface provides control to perform memory and ECC logic diagnostics.

The SDRAM scheduler is an MPFE, responsible for arbitrating collisions and optimizing performance in traffic to the SDRAM controller in the FPGA portion of the device.

Three ARM Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) ports are exposed to the FPGA fabric, allowing soft logic masters to access the SDRAM controller through the same scheduler unit as the MPU subsystem and other masters within the HPS. The MPU has access to the SDRAM adapter's control interface to the hard memory controller.

Figure 7-8: SDRAM L3 Interconnect Block Diagram



The hard memory controller in the FPGA portion of the device has a dedicated connection to the SDRAM L3 interconnecct. This connection allows the hard memory controller to become operational before the rest of the FPGA has been configured.

About the SDRAM Scheduler

The SDRAM scheduler functions as a multi-port front end (MPFE), scheduling transactions from multiple masters to the SDRAM.

The SDRAM scheduler supports the following masters:

- The MPU
- The L3 system interconnect
- The FPGA-to-SDRAM bridges

The SDRAM scheduler arbitrates among transactions initiated by the masters, and determines the order of operations. The scheduler arbitrates among the masters, ensuring optimal interconnect performance based on configurable quality-of-service settings.

The SDRAM scheduler can be configured through the registers.

Related Information

- **Functional Description of the QoS Generators** on page 7-34
  Detailed description of the system interconnect's quality-of-service features
- **Quality of Service in the SDRAM Scheduler** on page 7-30

About Quality of Service and Arbitration

The system interconnect supports quality-of-service (QoS) optimization through programmable QoS generators. The QoS generators are located on interconnect initiators, which correspond to master interfaces. Each QoS generator creates control signals that prioritize the handling of individual transactions to meet performance requirements.

The purpose of controlling QoS is to prevent one initiator from using up the interconnect's bandwidth at the expense of other initiators.

Proper QoS settings depend on your performance requirements for each component and peripheral, and for system performance as a whole. Altera recommends that you become familiar with QoS optimization techniques before you try to change the QoS settings in the HPS system interconnect.

Related Information

- **Functional Description of the QoS Generators** on page 7-34

About the Service Network

The service network is physically separate from the NoC datapath.

Through the service network, you can perform these tasks:

- Access internal interconnect registers
- Update master and slave peripheral security features

About the Observation Network

The observation network connects probes to the CoreSight trace funnel through the debug channel. It is physically separate from the NoC datapath.

The observation network connects probes to the observer, which is a port in the CoreSight trace funnel. Through the observation network, you can perform these tasks:

- Enable error logging
- Selectively trace transactions in the system interconnect
- Collect HPS transaction statistics and profiling data

The observation network consists of probes in key locations in the interconnect, plus connections to observers. The observation network works across multiple clock domains, and implements its own clock crossing and pipelining where needed.

The observation network sends probe data to the CoreSight subsystem through the ATB interface. Software can enable probes and retrieve probe data through the interconnect observation registers.

Related Information

Functional Description of the Observation Network on page 7-40

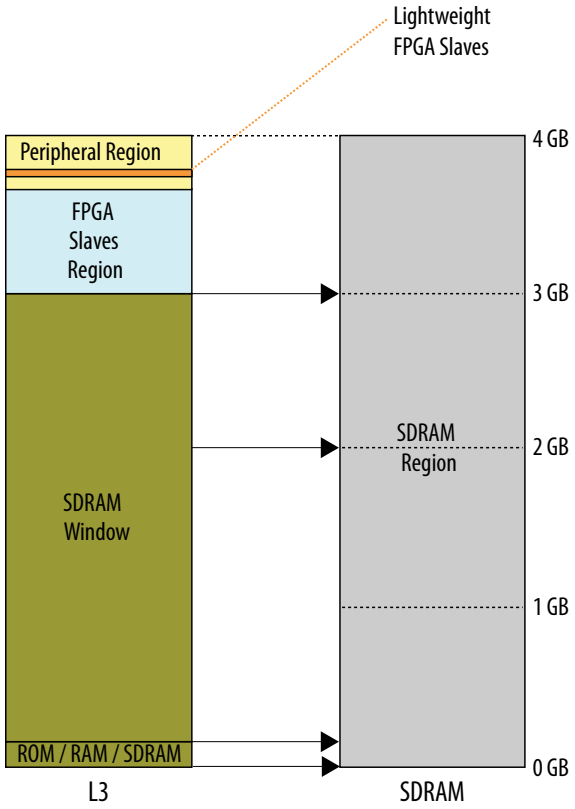
Functional Description of the System Interconnect

The system interconnect provides access to a 4 GB address space.

Address spaces are divided into one or more nonoverlapping contiguous regions.

Figure 7-9: HPS Address Space Relationships

Positions of HPS address spaces. For readability, some memory regions are shown out-of-scale to their addresses.



The window regions provide access to other address spaces. The thin black arrows indicate which address space is accessed by a window region (arrows point to accessed address space).

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

Table 7-1: Common Address Space Regions

Region Name	Description	Base Address	Size
FPGASLAVES	FPGA slaves	0xC0000000	960 MB
PERIPH	Peripheral	0xFC000000	64 MB
LWFPGASLAVES [8]	Lightweight FPGA slaves	0xFF200000	2 MB

Related Information

Arria 10 HPS Available Address Maps on page 7-13
Details of the L3 and MPU address maps

System Interconnect Address Spaces

The system interconnect supports multiple address spaces.

Each address space uses some or all of the 4 GB address range. The address spaces overlap. Depending on the configuration, different address spaces are visible in different regions for each master.

The following address spaces are available:

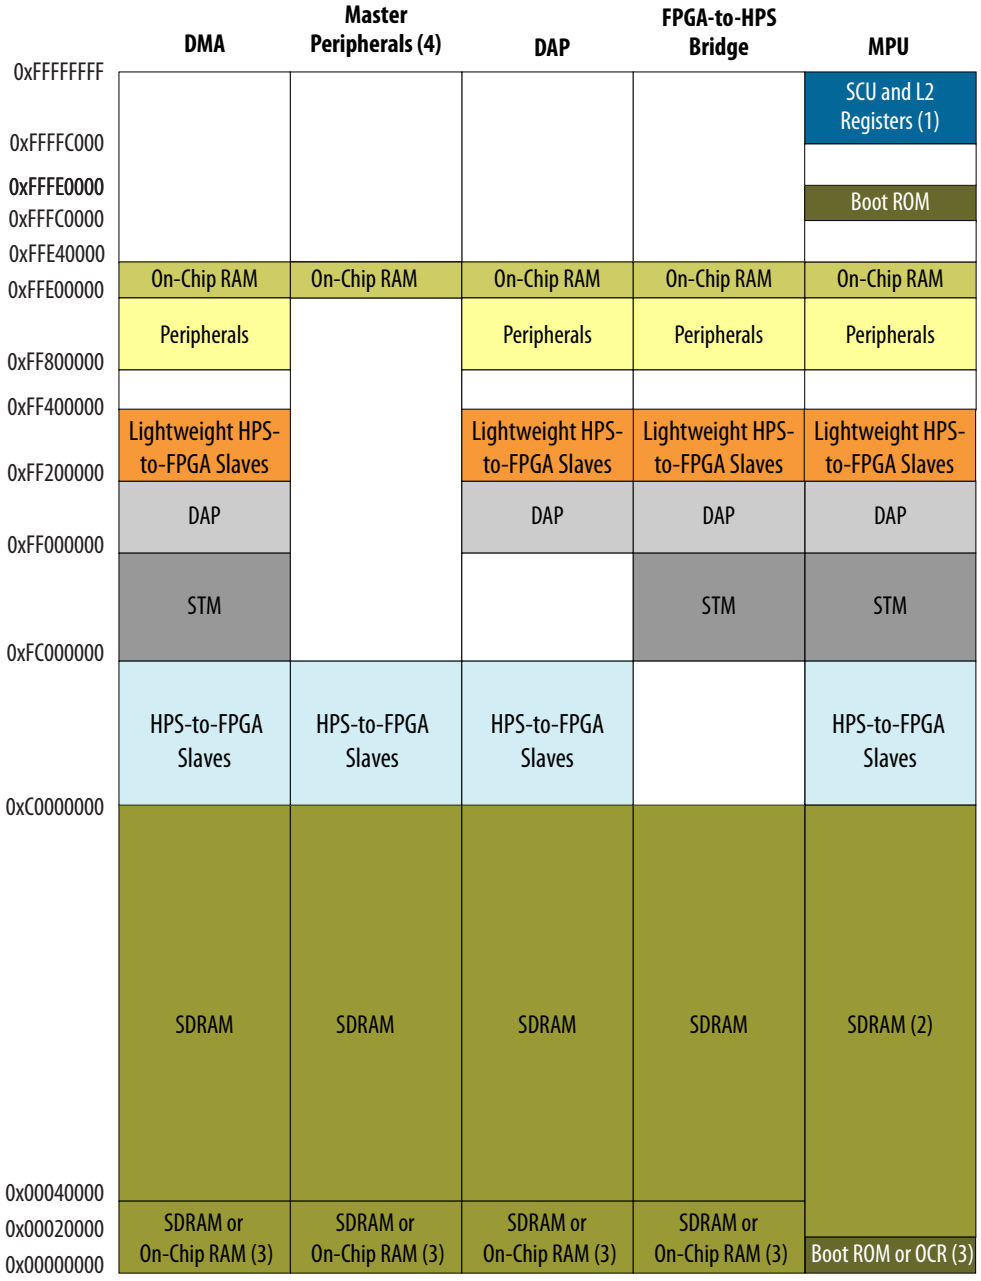
- The L3 address space
- The MPU address space
- The SDRAM address space

Arria 10 HPS Available Address Maps

The following figure shows the default system interconnect address maps for all masters. The figure is not to scale.

[8] The LWFPGASLAVES region is part of the "PERIPH" region.

Figure 7-10: Address Maps for System Interconnect Masters



Notes on Address Maps

(1) Transactions on these addresses are directly decoded by the SCU and L2 cache.

(2) The MPU accesses SDRAM through a dedicated port to the SDRAM scheduler. The SDRAM window size also depends on L2 cache filtering.

(3) This region can be configured to access on-chip RAM, by using the `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the system manager.

(4) The following peripherals can master the interconnect:

- Ethernet MACs
- USB-2.0 OTG controllers
- NAND controller
- ETR
- SD/MMC controller

For the MPU L3 master, either the boot ROM or on-chip RAM can map to address 0x0 and obscure the lowest 128 KB or 256 KB of SDRAM.

At boot time, the MPU does not have access to the SDRAM address space from the top of ROM or on-chip RAM to 0x00100000. This is because the MPU's SDRAM access is controlled by the MPU L2 filter registers, which only have a granularity of 1 MB. After booting completes, the MPU can change address filtering to use the lowest 1 MB of SDRAM.

For non-MPU masters, either the on-chip RAM or the SDRAM maps to address 0x0. When mapped to address 0x0, the on-chip RAM obscures the lowest 256 KB of SDRAM for non-MPU masters.

Arria 10 HPS L3 Address Space

The Arria 10 HPS L3 address space is 4 GB and applies to all L3 masters except the MPU subsystem.

The system interconnect `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the System Manager, determine if the address space starting at address 0x0 is mapped to the on-chip RAM (256 KB) or the SDRAM. SDRAM is mapped to address 0x0 on reset.

The L3 address space configurations contain the regions shown in the following table:

Table 7-2: L3 Address Space Regions

Description	Condition	Base Address	End Address	Size
SDRAM window (without on-chip RAM)	`remap0` set, `remap1` clear (9)	0x00000000	0xBFFFFFFF	3 GB

(9) For details about the `noc_addr_remap_value` register, refer to "Memory Map Remap Bits"

Description	Condition	Base Address	End Address	Size
On-chip RAM (low mapping)	`remap0` set, `remap1` set (9)	0x00000000	0x0003FFFF	256 KB
SDRAM window (with on-chip RAM)	`remap0` set, `remap1` set (9)	0x00040000	0xBFFFFFFF	3145471 KB = 3 GB - 256 KB
HPS-to-FPGA	Not visible to FPGA-to-HPS bridge.	0xC0000000	0xFBFFFFFF	960 MB
System trace macrocell	Always visible to DMA and FPGA-to-HPS	0xFC000000	0xFEFFFFFF	48 KB
Debug access port	Not visible to master peripherals. Always visible to other masters.	0xFF000000	0xFF1FFFFF	2 MB
Lightweight HPS-to-FPGA	Not visible to master peripherals. Always visible to other masters.	0xFF200000	0xFF3FFFFF	2 MB
Peripherals	Not visible to master peripherals. Always visible to other masters.	0xFF800000	0xFFFDFFFF	8064 KB
On-chip RAM (high mapping)	Always visible	0xFFE00000	0xFFFE3FFF	256 KB

The boot ROM and internal MPU registers (SCU and L2) are not accessible to L3 masters.

Cache coherent memory accesses have the same view of memory as the MPU.

SDRAM Window Region

The SDRAM window region is 3 GB and provides access to the bottom 3 GB of the SDRAM address space.

On-Chip RAM Region, Low Mapping

The system interconnect `noc_addr_remap_value` register determines if the 256 KB starting at address 0x0 is mapped to the on-chip RAM or the SDRAM. The SDRAM is mapped to address 0x0 on reset.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to 960 MB of slaves in the FPGA fabric through the HPS-to-FPGA bridge.

Lightweight HPS-to-FPGA Slaves Region

The lightweight HPS-to-FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region includes slaves connected to the L3 interconnect and L4 buses.

On-Chip RAM Region, High Mapping

The on-chip RAM is always mapped (independent of the boot region contents).

  More information about L3 address space mapping is in the *Introduction to the Hard Processor System* chapter.
- **Cortex-A9 Microprocessor Unit Subsystem** on page 9-1
  For general information about the MPU subsystem, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter.

MPU Address Space

The MPU address space is 4 GB and applies to MPU masters.

Addresses generated by the MPU are decoded in three ways:

- By default, MPU accesses to locations between 0x100000 (1 MB) to 0xC0000000 (3 GB) are made to the SDRAM controller.
- Addresses in the SCU and L2 register region (0xFFFFC000 to 0xFFFFFFFF) are the SCU and L2 bus.
- Accesses to all other locations are made to the L3 interconnect.

The MPU L2 cache controller contains a master connected to the main L3 interconnect and a master connected to the SDRAM L3 interconnect.

The system interconnect `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers, in the System Manager, determine if the address space starting at address 0x0 is mapped to the on-chip RAM (256 KB) or the ROM (128 KB). The ROM is mapped to address 0x0 on reset.

The MPU address space contains the following regions:

Table 7-3: MPU Default Address Space Regions

Description	Condition	Base Address	End Address	Size
Boot ROM	`remap0` clear, `remap1` clear (10)	0x00000000	0x0001FFFF	128 KB
SDRAM window	Always visible	0x00100000	0xBFFFFFFF	3071 MB (3 GB – 1 MB)
HPS-to-FPGA	Always visible	0xC0000000	0xFBFFFFFF	960 MB (1 GB – 64 MB)

(10) For details about the `noc_addr_remap_value` register, refer to "Memory Map Remap Bits".

Description	Condition	Base Address	End Address	Size
System trace macrocell	Always visible	0xFC000000	0xFFEFFFFF	48 KB
Debug access port	Always visible	0xFF000000	0xFF1FFFFF	2 MB
Lightweight HPS-to-FPGA	Always visible	0xFF200000	0xFF3FFFFF	2 MB
Peripherals	Always visible	0xFF800000	0xFFDFFFFF	6 MB
On-chip RAM	Always visible	0xFFE00000	0xFFFE3FFF	256 KB
Boot ROM	Always visible	0xFFFC0000	0xFFFDFFFF	128 KB
SCU and L2 registers	Always visible	0xFFFFC000	0xFFFFFFFF	16 KB

Boot Region

The boot region is 1 MB, based at address 0x0. The boot region is visible to the MPU only when the L2 address filter start register is set to 0x100000. The L3 `noc_addr_remap_value` control register determines if the boot region is mapped to the on-chip RAM or the boot ROM.

The boot region is mapped to the boot ROM on reset. Only the lowest 128 KB of the boot region are legal addresses because the boot ROM is only 128 KB.

When the L2 address filter start register is set to 0, SDRAM obscures access to the boot region. This technique can be used to gain access to the lowest SDRAM addresses after booting completes.

SDRAM Window Region

The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space. The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries.

The boundaries are megabyte-aligned. Addresses within the boundaries route to the SDRAM master, while addresses outside the boundaries route to the system interconnect master.

Addresses in the SDRAM window match addresses in the SDRAM address space. Thus, the lowest 1 MB of the SDRAM is not visible to the MPU unless the L2 address filter start register is set to 0.

HPS-to-FPGA Slaves Region

The HPS-to-FPGA slaves region provides access to slaves in the FPGA fabric through the HPS-to-FPGA bridge. Software can move the top of the SDRAM window by writing to the L2 address filter end register. If higher addresses are made available in the SDRAM window, part of the FPGA slaves region might be inaccessible to the MPU.

Lightweight HPS-to-FPGA Slaves Region

The lightweight FPGA slaves provide access to slaves in the FPGA fabric through the lightweight HPS-to-FPGA bridge.

Peripherals Region

The peripherals region is near the top of the address space. The peripherals region includes slaves connected to the L3 interconnect and L4 buses.

On-Chip RAM Region

The on-chip RAM is always mapped near the top of the address space, independent of the boot region contents.

Boot ROM Region

The boot ROM is always mapped near the top of the address space, independent of the boot region contents.

SCU and L2 Registers Region

The SCU and L2 registers region provides access to internally-decoded MPU registers (SCU and L2).

SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces varies.

There are cacheable and non-cacheable views into the SDRAM space. When a master of the system interconnect performs a cacheable access to the SDRAM, the transaction is performed through the ACP port of the MPU subsystem. When a master of the system interconnect performs a non-cacheable access to the SDRAM, the transaction is performed through the 32-bit main L3 interconnect master of the SDRAM L3 interconnect.

Address Remapping

The system interconnect supports address remapping through the `noc_addr_remap_value`, `noc_addr_remap_set`, and `noc_addr_remap_clear` registers in the system manager. Remapping allows software to control which memory device (on-chip RAM or boot ROM) is accessible at address 0x0. The remap registers can be modified by the MPU and the FPGA-to-HPS bridge.

The following master interfaces are affected by the remap bits:

- MPU master interface
  - L2 cache master 0 interface
- Non-MPU master interfaces
  - DMA master interface
  - Master peripheral interfaces
  - Debug Access Port (DAP) master interface
  - FPGA-to-HPS bridge master interface

Related Information

  For more information about setting registers in the system manager, refer to the *System Manager* chapter.

Memory Map Remap Bits

Table 7-4: Remap Bit Usage

remap0	remap1	0x00000000 (MPU Master Interface)	0x00000000 (Non-MPU Master Interfaces)	0xFFE00000 (All Maps)	0xFFFC0000 (MPU & DAP)
0	0	Boot ROM	SDRAM	On-Chip RAM	Boot ROM
0	1	Invalid setting			
1	0	SDRAM	SDRAM	On-Chip RAM	Boot ROM
1	1	On-Chip RAM	On-Chip RAM	On-Chip RAM	Boot ROM

L2 filter registers in the MPU subsystem, not the interconnect, allow the SDRAM to be remapped to address `0x0` for the MPU.

Secure Transaction Protection

The system interconnect provides two levels of secure transaction protection:

- Security firewalls—Enforce secure read and write transactions.
- Privilege filter—Leverages the firewall mechanism and provides additional security by filtering the privilege level of L4 slave transactions. The privilege filter applies to writes only.

All slaves on the SoC are placed behind a security firewall. A subset of slaves are also placed behind a privilege filter. Transactions to these slaves must pass both a security firewall and the privilege filter to reach the slave.

Related Information

Functional Description of the Firewalls on page 7-27

System Interconnect Master Properties

The system interconnect connects to slave interfaces through the main L3 interconnect and SDRAM L3 interconnect.

Table 7-5: System Interconnect Master Interfaces

Master	Interface Width	Clock	Security	SCR(11) Access	Privilege	Issuance (Read/ Write/ Total)	Type
MPU Subsystem L2 cache M0/1	64	mpu_l2ram_ clk	Per Transaction	Yes	Transaction based	7/12/23	AXI

Related Information

SoC Security on page 6-1
For more information about master/slave security, refer to the *SoC Security* chapter.

Master Caching and Buffering Overrides

Some of the peripheral masters connected to the system interconnect do not have the ability to drive the caching and buffering signals of their interfaces. The system manager provides registers so that you can enable cacheable and bufferable transactions for these masters. The system manager drives the caching and buffering signals of the following masters:

Master Peripheral	System Manager Registers
EMAC0, EMAC1, and EMAC2	`emac0`, `emac1`, and `emac2`
USB OTG 0 and USB OTG 1	`usb0_l3master` and `usb1_l3master`
NAND flash	`nand_l3master`
SD/MMC	`sdmmc_l3master`

[11] Security control register (SCR)
[12] Ensure that Avalon-MM burst transactions into the HPS do not cross the 4 KB address boundary restriction specified by the AXI protocol.

At reset time, the system manager drives the cache and buffering signals for these masters low. In other words, the masters listed do not support cacheable or bufferable accesses until you enable them after reset. There is no synchronization between the system manager and the system interconnect, so avoid changing these settings when any of the masters are active.

Related Information

System Manager on page 5-1
For more information about enabling or disabling this feature, refer to the *System Manager* chapter.

System Interconnect Slave Properties

The system interconnect connects to various slave interfaces through the main L3 interconnect, the SDRAM L3 interconnect, and the L4 peripheral buses. After reset, all slave interfaces are set to the secure state.

Table 7-6: System Interconnect Slave Interfaces

Slave	Interface Width	Clock	Acceptance (Read/ Write/Total) (13)	Security	Privilege	Interface Type
SP Timer 0/1/2/3	32	l4_sp_clk	1/1/1	Boot Secure (14)	User Mode	APB(15)
I2C 0/1/2/3/4	32	l4_sp_clk	1/1/1	Boot Secure	User Mode	APB (15)
UART 0/1	32	l4_sp_clk	1/1/1	Boot Secure	User Mode	APB (15)
GPIO 0/1/2	32	l4_sp_clk	1/1/1	Boot Secure	User Mode	APB(15)
SD/MMC CSR	32	l4_mp_clk	1/1/1	Boot Secure	User Mode	APB(15)
EMAC 0/1/2	32	l4_mp_clk	1/1/1	Boot Secure	User Mode	APB(15)
OSC Timer 0/1/2/3	32	l4_sys_free_clk	1/1/1	Secure (16)	Privileged	OCP
Watchdog 0/1/2/3	32	l4_sys_free_clk	1/1/1	Secure	Privileged	APB(15)
Clock Manager	32	l4_sys_free_clk	1/1/1	Secure	Privileged	OCP
Reset Manager	32	l4_sys_free_clk	1/1/1	Secure	Privileged	OCP

(13) Acceptance is the maximum number of transactions accepted.
(14) "Boot Secure" means the slave is in the secure state after reset.
(15) The Advanced Peripheral Bus (APB™) slave does not support byte enables. All writes must be 32 bits wide.
(16) "Secure" means that the slave is permanently in the secure state.

Slave	Interface Width	Clock	Acceptance (Read/ Write/Total) (13)	Security	Privilege	Interface Type

List of SDRAM L3 Interconnect Clocks

Table 7-8: SDRAM L3 Interconnect Clocks

Clock Name	Description	Synchronous to l3_main_free_clk
hmc_free_clk	Clock from the hard memory controller. Clocks the SDRAM L3 interconnect. The hmc_free_clk frequency is ½ the interface clock frequency.	N
f2s_sdram_clk [2:0]	Clocks the FPGA-to-SDRAM interfaces.	N

System Interconnect Resets

The system interconnect has one reset signal, l3_rst_n. The reset manager drives this signal to the system interconnect on a cold or warm reset.

Related Information

Reset Manager on page 3-1

Functional Description of the Rate Adapters

Rate adapters are used at points in the system interconnect where there are bandwidth discontinuities, to ensure efficient use of interconnect data pathways. They are placed where a low-bandwidth source feeds a high-bandwidth destination. For this reason, they are sometimes positioned at the response side (where the Master is faster) and sometimes at the request side (where the Slave is faster).

The following table shows the rate adapters.

Table 7-9: Rate Adapter Modules

Rate Adapter Module Name	Data Path
noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter	Data packets from the SDRAM L3 interconnect in response to the MPU
noc_mpu_m0_MPU_M0_rate_adResp_main_RateAdapter	Data packets from the L3 interconnect in response to the MPU
noc_mpu_m0_L4_MP_rate_ad_main_RateAdapter	Data packets carrying requests from L4 master peripherals to the L3 interconnect
noc_mpu_m0_fpga2soc_rate_ad_main_RateAdapter	Data packets carrying requests from the FPGA-to-HPS bridge master to the L3 interconnect
noc_mpu_m0_L3Tosoc2fpgaResp_main_RateAdapter	Data packets from the HPS-to-FPGA and lightweight HPS-to-FPGA bridges in response to the L3 interconnect
noc_mpu_m0_acp_rate_ad_main_RateAdapter	Data packets carrying requests from the L3 interconnect to the ACP

Functional Description of the Firewalls

Security

Slave Security

The system interconnect enforces security through the slave settings. The slave settings are controlled by the NoC Security Control Register (SCR) in the service network. Each L3 and L4 slave has its own security check and programmable security settings. After reset, every slave of the system interconnect is set to a secure state (referred to as boot secure). Only secure masters are allowed to access secure slaves.

The NoC implements five firewalls to check the security state of each slave, as listed in the following table. At reset time, all firewalls default to the secure state.

Table 7-10: NoC Firewalls

Name	Function
On-Chip RAM Firewall	Filter access to on-chip RAM
Peripherals Firewall	Filter access to slave peripherals (SPs) in the following buses: • L4 main bus • L4 master peripherals bus • L4 AHB bus • L4 slave peripherals bus
System Firewall	Filter access to system peripherals in the following components: • L4 system bus • L4 ECC bus • DAP
HPS-to-FPGA Firewall	Filter access to FPGA through the following bridges: • HPS-to-FPGA bridge • Lightweight HPS-to-FPGA bridge
DDR and DDR L3 Firewalls	Filter access to DDR SDRAM

At reset, the privilege filters are configured to allow certain L4 slaves to receive only secure transactions. Software must either configure bridges secure at startup, or reconfigure the privilege filters to accept nonsecure transactions. You can reconfigure the privilege filters through the `l4_priv` register in the `noc_l4_priv_l4_priv_filter` module.

To change the security state, you must perform a secure write to the appropriate SCR register of a secure slave. A nonsecure access to the SCR register of a secure slave triggers a response with random data. A nonsecure access does not trigger a bus error.

Related Information

l4_priv on page 7-191
Privilege bits, used to enable or disable nonsecure access to individual L4 slaves

Master Security

Masters of the system interconnect are either secure, nonsecure, or the security is set on a per transaction basis. L2 cache masters 0 and 1, the FPGA-to-HPS bridge, DMA, the Ethernet MACs, and the DAP perform secure and nonsecure accesses on a per-transaction basis. All other system interconnect masters perform nonsecure accesses.

Accesses to secure slaves by unsecure masters result in a response with random data.

Related Information

System Interconnect Master Properties on page 7-20

Functional Description of the SDRAM L3 Interconnect

The SDRAM L3 interconnect consists of two main blocks, serving the following two main functions:

- The SDRAM scheduler provides multi-port scheduling between the SDRAM L3 interconnect masters and the hard memory controller in the FPGA portion of the SoC. The SDRAM L3 interconnect is mastered by the MPU, the main L3 interconnect, and FPGA-to-SDRAM ports.
- The SDRAM adapter provides connectivity between the SDRAM L3 interconnect masters and the hard memory controller.

The SDRAM L3 interconnect also includes firewalls that can protect regions of SDRAM from unauthorized access.

The hard memory controller is physically located in the FPGA portion of the device, and therefore it is in a separate power domain from the HPS. The HPS cannot use the SDRAM L3 interconnect until the FPGA portion is powered up.

Functional Description of the SDRAM Scheduler

The SDRAM scheduler functions as a multi-port front end (MPFE), scheduling transactions from multiple masters to the SDRAM.

The SDRAM scheduler manages transactions to the memory access regions in the SDRAM. These memory regions are defined by the SDRAM L3 firewalls. The second-stage bootloader is expected to program the scheduler with the correct timings to implement optimal access patterns to the hard memory controller.

The SDRAM scheduler has the following features:

- Five input connections
  - One 64-bit connection from the MPU
  - One 64-bit connection from the main L3 interconnect
  - Two 128/64/32-bit connections from the FPGA
  - One 64/32-bit connection from the FPGA
- Single 256-bit connection to the SDRAM L3 adapter
  - Capable of issuing transactions at the memory device line rate
  - Traffic is comprised of aggregate inputs

Related Information

SDRAM L3 Firewalls on page 7-32

Monitors for Mutual Exclusion

The SDRAM scheduler implements support for mutually-exclusive (mutex) accesses on all ports to the SDRAM L3 interconnect.

The process for a mutually-exclusive access is as follows:

1. A master attempts to lock a memory location by performing an exclusive read from that address.
2. The master attempts to complete the exclusive operation by performing an exclusive write to the same address location.
3. The exclusive write access is signaled as:
   - Failed if another master has written to that location between the read and write accesses. In this case the address location is not updated.
   - Successful otherwise.

To support mutually-exclusive accesses from the MPU, the memory must be configured in the MMU page tables as normal memory, shareable, or non-cacheable.

Related Information

- **On-Chip Memory** on page 12-1
- **Embedded Peripheral IP User Guide**
  Contains detailed information about the Altera mutex core

Exclusive Access Support

To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM scheduler. The AXI buses that interface to the scheduler provide `ARLOCK[0]` and `AWLOCK[0]`, signals which are used by the scheduler to arbitrate for exclusive access to a memory location. The SDRAM scheduler contains six monitors. Each monitor can be used by any of the following exclusive-capable masters:

- CPU 0
- CPU 1
- FPGA-to-HPS bridge
- FPGA-to-SDRAM0 port
- FPGA-to-SDRAM1 port
- FPGA-to-SDRAM2 port

Each master can lock only one memory location at a time.

Quality of Service in the SDRAM Scheduler

You can apply QoS settings to each port of the SDRAM scheduler to control the bandwidth available to each master.

The SDRAM scheduler controls arbitration priorities internally for optimal end-to-end quality of service. Each master on the SDRAM scheduler has software-programmable QoS signals. These signals are propagated to the scheduler and used as arbitration criteria for access to SDRAM.

For information about programming quality of service for the FPGA-to-SDRAM masters, refer to "Functional Description of the QoS Generators".

Related Information

Functional Description of the QoS Generators on page 7-34

Functional Description of the SDRAM Adapter

The SDRAM adapter connects the SDRAM scheduler with the Hard Memory Controller.

The SDRAM adapter provides the following functionality:

- Connects the OCP master to the hard memory controller
- ECC generation, detection, and correction
- Operates at memory half rate
  - Matches interface frequency of the single port memory controller in the FPGA
  - Connectivity to the MPU, main L3 interconnect, and FPGA undergo clock crossing

ECC

The SDRAM Adapter ECC can detect and correct single-bit errors and detect double-bit errors.

The addresses are merged with data and are used for checking. This configuration detects if correct write data is written to an incorrect location in memory; and if correct data is read from an incorrect location in memory.

Note: Data and address errors are detected independently.

ECC Write Behavior

When data is written to SDRAM, the SDRAM controller generates an ECC based on the write data and the write address.

If the write transaction is a partial write (less than 64 bits wide), the SDRAM adapter implements it as a read-modify-write (RMW) sequence, as follows:

- Reads existing data from the specified address
- Combine the write data with the existing data
- Generates the ECC based on the combined data and the write address
- Writes the combined data back to the write address

ECC Read Behavior

When data is read from SDRAM, the SDRAM controller checks the ECC to determine if the data or address is incorrect. It handles the following cases:

- If the SDRAM controller finds a single-bit data error, it corrects in the data returned to the master. You can also enable the SDRAM adapter to write the corrected data back to memory.
- If the SDRAM controller finds a double-bit data error, the SDRAM L3 interconnect issues an interrupt. Double-bit errors cannot be corrected.
- If the SDRAM controller finds an error in the address, indicating an address bit upset between the adapter and the HMC, the SDRAM L3 interconnect hardware issues a bus error.

SDRAM Adapter Interrupt Support

The SDRAM adapter supports the following three interrupts:

- The status interrupt occurs when:
  - Calibration is complete.
  - The ECC is unable to schedule an auto-correction write-back to memory. This occurs only when the auto-write-back FIFO is full.
- The ECC read-back interrupt occurs when an ECC single-bit error is detected in the read data. When this happens, the return data is corrected and returned to the NoC.
- The double-bit or fatal error interrupt occurs when any of the following three errors happens:
  - A double-bit error in the read data has been detected, which cannot be corrected.
  - A single-bit error has been detected in the address field. This means that the data that the adapter is returning has no bit errors, but is not the requested data. When this happens, the adapter returns a data error along with the data.
  - Any of the DDR4 devices have triggered their ALERT pins.
    - Address or command parity check has failed
    - Write data CRC check has failed
    - Cannot gracefully recover because SDRAMs are not providing feedback on failure case

SDRAM Adapter Clocks

All the logic in the SDRAM adapter is synchronous and effectively running off a single clock, `hmc_free_clk`, which is provided by the hard memory controller.

SDRAM L3 Firewalls

All data that is routed to the SDRAM scheduler must pass through the firewalls.

The SDRAM L3 firewalls define memory access regions in the SDRAM. Each SDRAM L3 interconnect master has its own memory access regions, independent of the other masters. The firewalls define whether each memory access region is protected or unprotected relative to its master. The number of available memory access regions for each master is shown in the following table.

Table 7-11: Memory Access Regions for SDRAM Masters

SDRAM L3 Interconnect Master	Number of Memory Access Regions
MPU	4
Main L3 interconnect (including the FPGA-to-HPS bridge)	8
FPGA-to-SDRAM port 0	4
FPGA-to-SDRAM port 1	4
FPGA-to-SDRAM port 2	4

The SDRAM L3 interconnect regulates access to the hard memory controller with the firewalls, which support secure regions in the SDRAM address space. Accesses to the SDRAM pass through the firewalls and then through the scheduler.

Related Information

SoC Security on page 6-1

SDRAM L3 Interconnect Resets

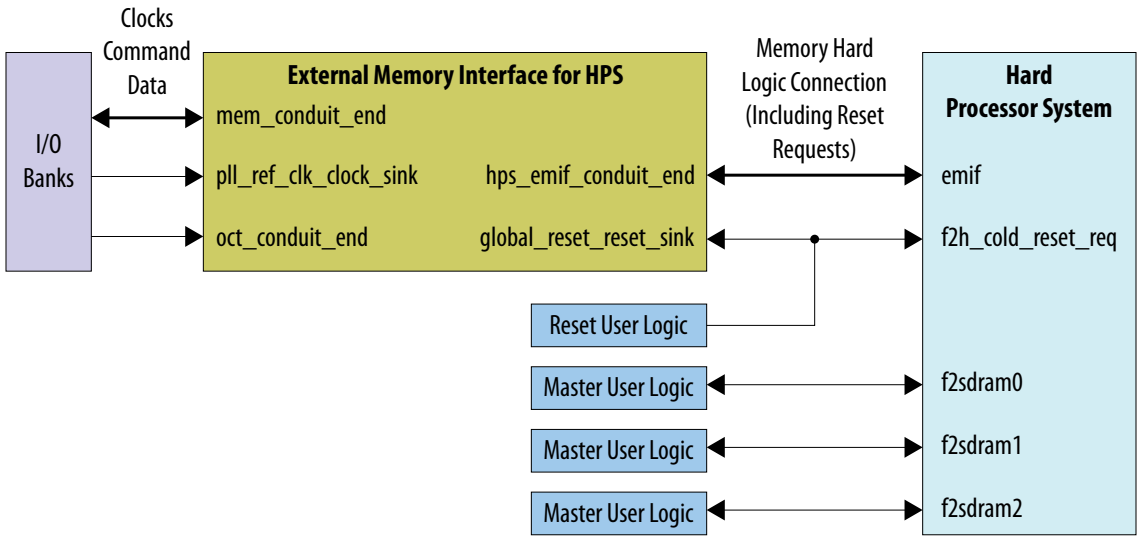
The reset signal `l3_rst_n` resets the system interconnect and the SDRAM L3 interconnect, but not the hard memory controller.

The reset signal in the hard memory controller is automatically connected to the SDRAM L3 interconnect when you instantiate the HPS component. For information about resetting the hard memory controller, refer to the *External Memory Interfaces in Arria 10 Devices* chapter of the *Arria 10 Core Fabric and General Purpose I/O Handbook*.

Soft logic in the FPGA must support the `global_reset_n` signal correctly. Refer to the *Instantiating the HPS Component* chapter for information about `global_reset_n`.

To optionally preserve the contents of the SDRAM on reset, refer to "Reset Handshaking" in the *Reset Manager* chapter.

Figure 7-11: Recommended SDRAM Reset Connections



Note: It is important to connect the reset user logic directly to both the HPS and the hard memory controller. If the hard memory controller is reset while the HPS is still running, the HPS is unable to access any external SDRAM memory.

  Refer to the *External Memory Interfaces in Arria 10 Devices* chapter for information about resetting the hard memory controller.

Functional Description of the QoS Generators

Quality of service is managed by information generated at each initiator interface by a QoS generator.

At the entry points to the system interconnect, the QoS generators create signals and other information that control how much interconnect bandwidth is allocated to transactions. The QoS information is used at each interconnect arbitration node to assign a packet priority.

Related Information

- **About Quality of Service and Arbitration** on page 7-11
- **Quality of Service in the SDRAM Scheduler** on page 7-30

QoS Generators in the Interconnect Architecture

The principal masters into the system interconnect are equipped with QoS generators.

The following table shows the network initiators (masters) that support QoS generation.

Table 7-12: QoS Generators on Initiators

Master Name(s)	Default QoS Generator Mode	Clock
MPU Subsystem L2 cache M0/1	Limiter	`mpu_l2ram_clk`
FPGA-to-HPS Bridge	Limiter	`fpga2hps_clk`
FPGA-to-SDRAM Ports	Regulator	`f2h_sdram_clk`
DMA	Limiter	`l4_main_clk`
EMAC 0/1/2	Regulator	`l4_mp_clk`
USB OTG 0/1	Regulator	`l4_mp_clk`
NAND	Regulator	`l4_mp_clk`
SD/MMC	Regulator	`l4_mp_clk`

Related Information

QoS Generator Modes on page 7-35

QoS Mechanisms

The QoS generators influence arbitration priorities by manipulating urgency, pressure, and hurry.

When two or more packets compete for an interconnect resource at an arbitration node, the arbitration logic selects the packet with the highest priority. QoS generators can control the behavior of the arbitration logic by modifying the priority of packets through urgency, pressure, and hurry.

The QoS controls for each initiator are separated into read and write QoS controls.

Related Information

Functional Description of the Arbitration Logic on page 7-39

Packet Urgency

A QoS generator assigns an urgency level to each packet when the packet data arrives at an interconnect master port.

The urgency level is attached to the packet as long as it is moving through the interconnect. Urgency is the primary QoS mechanism.

Pressure Propagation

Each active channel in the interconnect has a pressure level, which can change depending on the traffic through the channel.

The pressure is based on the urgency of packets waiting for that channel. If a higher-priority packet requests a channel that is already active, the channel's urgency increases.

When a packet arrives at an arbitration node, its priority is either its urgency or its pressure, whichever is greater. If the pressure is greater than the urgency, the arbitration logic moves the packet through more quickly to free up the channel for the higher-urgency packet that created the pressure.

Hurry

Each initiator has a hurry level, which can change depending on the bandwidth usage and the QoS generator mode.

When the hurry level is increased at an initiator, it has the effect of setting the urgency of that initiator's transactions to at least the same level as the hurry. As a result, the targets respond to the transactions more quickly.

QoS Generator Modes

Each QoS generator can operate in any of the following modes:

- Limiter
- Regulator
- Fixed

For the default QoS generator mode for each initiator, refer to "QoS Generators in the Interconnect Architecture".

QoS generators can also be set to bypass mode. In this case, QoS signals are provided by the component connected to the master interface.

Related Information

QoS Generators in the Interconnect Architecture on page 7-34
Default QoS modes for each initiator

Limiter Mode

In limiter mode, the QoS generator controls the initiator's access to the interconnect, by monitoring the amount of data transmitted and received in a sliding time window.

The purpose of limiter mode is to place a hard bound on the initiator's throughput. This avoids flooding the interconnect with transactions from that initiator. When a programmable bandwidth threshold is exceeded, the initiator stops accepting new requests. As the time window moves forward, the total bandwidth usage in the window falls, and the initiator resumes accepting requests.

In limiter mode, the QoS generator combines read and write requests to determine the bandwidth usage.

Related Information

Programming QoS Limiter Mode on page 7-36

Regulator Mode

In regulator mode, the QoS generator maintains bandwidth usage to transaction targets at a programmed level, by adjusting urgency, pressure, and hurry.

Regulator mode controls bandwidth usage more smoothly than limiter mode. This mode is useful in achieving real-time performance.

When the initiator's bandwidth usage exceeds the specified threshold, the QoS decreases the urgency, pressure, and hurry levels. When bandwidth usage is too low, the QoS increases urgency, pressure and hurry. Software can program the desired bandwidth threshold, the saturation, and maximum and minimum levels for urgency, pressure, and hurry.

Related Information

Programming QoS Regulator Mode on page 7-37

Fixed Mode

In fixed mode, the QoS generator assigns a fixed urgency to each packet. Software can configure separate urgencies for read and write transactions.

Related Information

Programming QoS Fixed Mode on page 7-38

Controlling Quality of Service from Software

You can programmatically configure the QoS generator for each initiator through the QoS registers.

Note: Before accessing the registers for any QoS generator, you must ensure that the corresponding peripheral is not in reset. Otherwise, the register access results in a bus error, causing a CPU fault.

Programming QoS Limiter Mode

To put the QoS generator in limiter mode, set the registers as shown in the following table.

Table 7-13: QoS Generator Register Values for Limiter Mode

Register	Field	Value
`I_main_QosGenerator_Mode`	`MODE`	1
`I_main_QosGenerator_Priority`	`P0`	Urgency for write transations
`I_main_QosGenerator_Priority`	`P1`	Urgency for read transations
`I_main_QosGenerator_Bandwidth`	`BANDWIDTH`	Maximum bandwidth, in units of (bytes/cycle)/256

Register	Field	Value
I_main_QosGenerator_Saturation	SATURATION	Measurement window for bandwidth, in units of bytes/16. This register specifies the maximum number of bytes that the initiator can transmit or receive at full speed before the limiter triggers.

When you switch QoS modes, the bandwidth counter is reset.

Related Information

Programming QoS Regulator Mode

To put the QoS generator in regulator mode, set the registers as shown in the following table.

Table 7-14: QoS Generator Register Values for Regulator Mode

Register	Field	Value
I_main_QosGenerator_Mode	MODE	3
I_main_QosGenerator_Priority	P0	Packet urgency when the actual throughput exceeds the threshold set in I_main_QosGenerator_Bandwidth.
I_main_QosGenerator_Priority	P1	Packet urgency when the actual throughput is less than the threshold set in I_main_QosGenerator_Bandwidth. P0 must be less than or equal to P1.
I_main_QosGenerator_Bandwidth	BANDWIDTH	Desired throughput, in units of (bytes/cycle)/256
I_main_QosGenerator_Saturation	SATURATION	Measurement window for bandwidth, in units of bytes/16.

When you switch QoS modes, the bandwidth counter is reset.

Related Information

  List of QoS registers

Programming QoS Fixed Mode

To put the QoS generator in fixed mode, set the registers as shown in the following table.

Table 7-15: QoS Generator Register Values for Fixed Mode

Register	Field	Value
I_main_QosGenerator_Mode	MODE	0
I_main_QosGenerator_Priority	P0	Urgency for write transations
I_main_QosGenerator_Priority	P1	Urgency for read transations

Related Information

QoS Generator Registers on page 7-38
List of QoS registers

QoS Generator Registers

There is a register set for each QoS generator.

Each QoS generator's register set includes the register types shown in the following table.

Table 7-16: QoS Generator Register Types

Name	Purpose
I_main_QosGenerator_Priority	Specifies packet urgencies. Register usage depends on the QoS generator mode.
I_main_QosGenerator_Mode	Specifies the QoS generator mode (limiter, regulator, fixed, or bypass).
I_main_QosGenerator_Bandwidth	Specifies the bandwidth threshold for limiter and regulator modes.
I_main_QosGenerator_Saturation	Specifies the bandwidth measurement time window for limiter and regulator modes.

The actual register names consist of the register type plus a prefix specific to the QoS generator. For example, the registers for MPU subsystem L2 cache master 0 are:

- mpu_m0_I_main_QosGenerator_Priority
- mpu_m0_I_main_QosGenerator_Mode
- mpu_m0_I_main_QosGenerator_Bandwidth
- mpu_m0_I_main_QosGenerator_Saturation
- mpu_m0_I_main_QosGenerator_ExtControl

The following table lists the prefixes for all QoS generators.

Table 7-17: QoS Register Name Prefixes

Initiator	Register Name Prefix
MPU Subsystem L2 Cache Master 0	`mpu_m0_`
MPU Subsystem L2 Cache Master 1	`mpu_m1_`
FPGA-to-HPS Bridge	`fpga2soc_axi32_`
FPGA-to-HPS Bridge	`fpga2soc_axi64_`
FPGA-to-HPS Bridge	`fpga2soc_axi128_`
DMA Controller	`dma_m0_`
Ethernet MAC 0	`emac0_m_`
Ethernet MAC 1	`emac1_m_`
Ethernet MAC 2	`emac2_m_`
USB-2 OTG 0	`usb0_m_`
USB-2 OTG 1	`usb1_m_`
NAND Flash Controller	`nand_m_`
SD/MMC Controller	`sdmmc_m_`
FPGA-to-SDRAM Port 0	`fpga2sdram0_axi32_`
FPGA-to-SDRAM Port 0	`fpga2sdram0_axi64_`
FPGA-to-SDRAM Port 0	`fpga2sdram0_axi128_`
FPGA-to-SDRAM Port 1	`fpga2sdram1_axi32_`
FPGA-to-SDRAM Port 1	`fpga2sdram1_axi64_`
FPGA-to-SDRAM Port 2	`fpga2sdram2_axi32_`
FPGA-to-SDRAM Port 2	`fpga2sdram2_axi64_`
FPGA-to-SDRAM Port 2	`fpga2sdram2_axi128_`

QoS Address Map and Register Descriptions

Functional Description of the Arbitration Logic

The interconnect arbitration logic handles situations in which multiple simultaneous packets need the same interconnect resource.

The system interconnect contains arbitration nodes at each point where multiple packets might demand the same resource. Each arriving packet has a priority. When multiple packets of different priorities arrive simultaneously at a node, the arbitration logic grants the resource to the highest-priority packet.

If there are simultaneous packets with the same priority, the system interconnect uses a simple round-robin (least recently used) algorithm to select the packet.

Each packet's priority is determined by urgency, pressure, and hurry, as described in "QoS Mechanisms".

QoS Mechanisms on page 7-34

Functional Description of the Observation Network

Probes

The system interconnect includes the probes shown in the following table.

Table 7-18: Observation Probes

Probe Name	Probe ID	Probe Type	Probe Target(s)	Packet Tracing and Statistics	Transaction Profiling	Error Logging
MPU	6	Packet	MPU master 0	•		
SOC2FPGA	5	Packet	• HPS-to-FPGA bridge • Lightweight HPS-to-FPGA bridge	•		
DDR	10	Packet	SDRAM adapter	•		
EMAC	4	Packet	EMAC0		•	
EMAC	4	Packet	• EMAC1 • EMAC2	•		
ERROR	n/a	Error	• HPS-to-FPGA bridge • Lightweight HPS-to-FPGA bridge`			•

The probe ID is available on the ATB trace bus.

Packet Tracing, Profiling, and Statistics

Packet probes perform packet tracing, profiling and statistics. The following table shows how each packet probe is configured. All statistics counters are 16 bits wide, and all probes can generate level alarms from the statistics counter. All probes use the CoreSight cross-trigger protocol.

Table 7-19: Packet Probe Characteristics

Probe Name	Purpose	Number of Filters	Statistics Counters Can Count Enabled Bytes	Packet Payloads Included in Trace Data	Number of Statistics Counters
MPU	MPU	1	No	No	4
SOC2FPGA	HPS-to-FPGA bridge	2	No	No	4

Probe Name	Purpose	Number of Filters	Statistics Counters Can Count Enabled Bytes	Packet Payloads Included in Trace Data	Number of Statistics Counters
EMAC	Ethernet MAC	2	No	No	4
DDR	SDRAM	4	Yes	Yes	2

Packet Filtering

You can set up filters to control how the observation network handles traced packets.

Filters can perform the following tasks:

- Select which packets the observation network routes to CoreSight
- Trigger a trace alarm when a packet meets specified criteria

Statistics Collection

To collect packet statistics, you specify packet criteria and set up counters for packets that meet those criteria. You can set up the observation network to trigger an alarm when a counter reaches a specified level.

Transaction Profiling

A transaction probe is available on Ethernet MAC 0. You can use the transaction probe to measure either the transaction latency or the number of pending packets on EMAC0. Data are collected as a histogram.

The EMAC0 transaction probe is configured as shown in the following table.

Table 7-20: EMAC0 Transaction Probe Configuration

Number of simultaneously tracked transactions	4
Width of counters	10 bits
Available delay threshholds	64, 128, 256, 512
Available pending transaction count thresholds	2, 4, 8
Number of comparators	3
Number of histogram bins	4

Profiling Transaction Latency

In latency mode (also called delay mode), one of the four delay threshold values can be chosen for each comparator. The threshold values represent the number of clock cycles that a transaction takes from the time the request is issued to the time the response is returned.

Profiling Pending Transactions

In pending transaction mode, one of the three available transaction count threshold values can be chosen for each comparator. The threshold values represent the number of requests pending on EMAC0.

Packet Alarms

Packet alarms can be used to trigger software interrupts.

The following types of alarms are available:

- Trace alarms—You can examine trace alarms through the system interconnect registers.
- Statistics alarms

Error Logging

The error probe logs errors on initiators, targets, and firewalls.

Configuring the Rate Adapters

The default settings for the rate adapters are as shown in the following table.

Table 7-21: Rate Register Default Settings

Rate Register Name	Default
MPU_M1toDDRResp_main_RateAdapter_Rate	0x0
MPU_M0_rate_adResp_main_RateAdapter_Rate	0x0
L4_MP_rate_ad_main_RateAdapter_Rate	0x100
fpga2soc_rate_ad_main_RateAdapter_Rate	0x0
L3Tosoc2fpgaResp_main_RateAdapter_Rate	0x0
acp_rate_ad_main_RateAdapter_Rate	0x0

Configuring the SDRAM Scheduler

FPGA Port Configuration

The FPGA has three outputs that pass through the firewall before connecting to the SDRAM scheduler.

You can configure the FPGA-to-SDRAM (F2SDRAM) ports to data widths of 32, 64, or 128 bits:

- F2SDRAM 0 - 32-, 64-, or 128-bit data widths
- F2SDRAM 1 - 32- or 64-bit data widths
- F2SDRAM 2 - 32-, 64-, or 128-bit data widths

There are four port configurations that are a combination of the SDRAM ports 0 - 2 that you are able to select. Once a port configuration is selected, you can choose to disable ports that you do not need.

Note: The total data width of all interfaces is limited to a maximum of 256 bits in the read direction and 256 bits in the write direction.

Port Configuration	F2SDRAM 0	F2SDRAM 1	F2SDRAM 2
1	32-bit	32-bit	32-bit
2	64-bit	64-bit	64-bit
3	128-bit	unused	128-bit
4	128-bit	32-bit	64-bit

Memory Timing Configuration

The SDRAM L3 interconnect provides fully-programmable timing parameter support for all JEDEC-specified timing parameters.

The following lists the handoff information used to control the SDRAM scheduler:

- The scheduler is aware of the SDRAM timing so that it can guide traffic into the hard memory controller.
- This information is not used to control the subsystem that sets up memory timings in the hard memory controller hardware.

Configuring SDRAM Burst Sizes

You can optimize memory throughput by adjusting the SDRAM burst lengths for read and write transactions. The best burst length values are application-dependent. Altera recommends that you follow guidelines in *Arria 10 SoC Device Design Guidelines* to determine the optimal burst lengths.

Related Information

  Download **Arria 10 FPGA-to-HPS Bridges design example (.zip file)** for use with the *Arria 10 SoC Device Design Guidelines*.

Configuring the Hard Memory Controller

SDRAM Adapter Memory Mapped Registers

The SDRAM adapter memory mapped registers (MMRs) are used for configuring and reading ECC status; and configuring data width adaptation for 16-, 32-, and 64-bit data widths.

Hard Memory Controller Memory Mapped Registers

The FPGA hard memory controller MMRs are used for determining the state of the hard memory controller interface, and for triggering the hard memory controller into a reset state along with the I/O. The FPGA hard memory controller MMRs can be programmed as secure or non-secure.

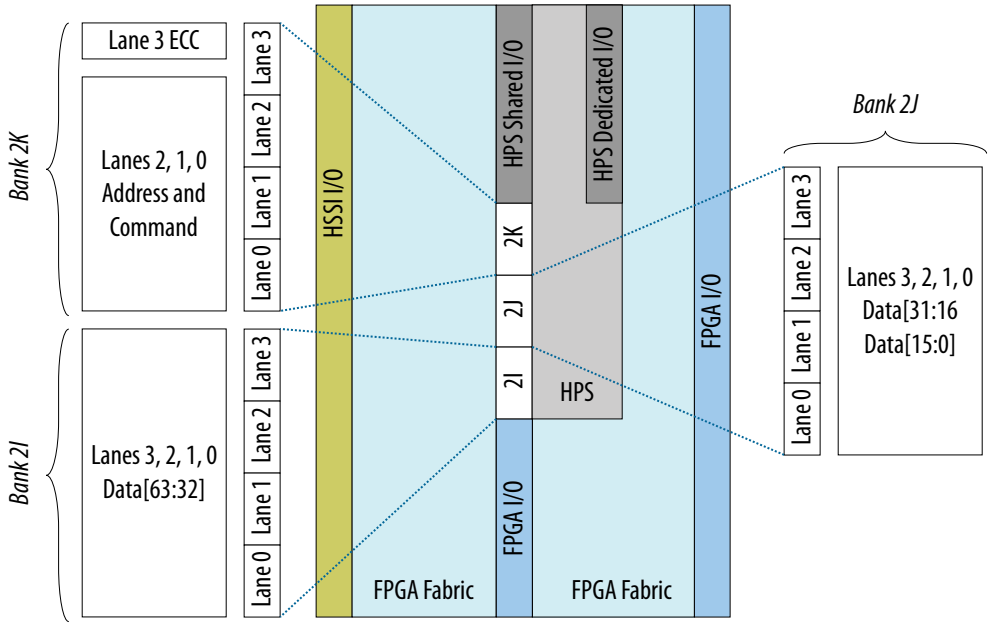
Sharing I/Os between the EMIF and the FPGA

Arria 10 SoC devices have three modular I/O banks to connect the HPS to an SDRAM (2K, 2J, and 2I) through a dedicated HPS EMIF.

Each bank has four I/O lanes that correspond to:

- Lane 3: IO[47:36]
- Lane 2: IO[35:24]
- Lane 1: IO[23:12]
- Lane 0: IO[11:0]

Figure 7-12: HPS Hard Memory Controller



To use SDRAM, you instantiate the HPS EMIF in Qsys, by selecting the **Arria 10 External Memory Interfaces for HPS** component. Quartus Prime software assigns the correct banks and lanes for the SDRAM I/O.

I/Os in these three banks can be shared between the HPS EMIF and FPGA. Quartus Prime software enforces the following guidelines on shared I/Os:

- Modular I/O banks 2K, 2J and 2I can be used entirely as FPGA GPIO when there is no HPS EMIF in the system.
- Bank 2K:
  - If there is an HPS EMIF in the system, lane 3 is used for ECC for the SDRAM. Unused pins in lane 3 may be used as FPGA inputs only.
  - Lanes 2, 1, and 0 are used for address and command for the SDRAM. Unused pins in these lanes may be used as FPGA inputs or outputs.
- Bank 2J:
  - If there is an HPS EMIF in the system, bank 2J is used for data bits [31:0].
    - With 16-bit data widths, unused pins in the two lanes of bank 2J used for data can be used as inputs only. The pins in the remaining two lanes can be used as FPGA inputs or outputs.
    - With 32-bit data widths, unused pins bank 2J can be used as FPGA inputs only.
- Bank 2I:
  - If there is an HPS EMIF in the system, bank 2I is used for data bits [63:32]
    - With 64-bit data widths, unused pins in bank 2I can be used as FPGA inputs only.
    - With 32- or 16-bit data widths, bank 2I can be used as FPGA inputs or outputs.

System Interconnect Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions** .

io48_hmc_mmr Address Map

Module Instance	Base Address	End Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFAFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

counter0mask Fields

Bit	Name	Description	Access	Reset
31:0	counter_zero_mask	Performance monitoring register. This register is used to mask off the internal signals selected by the debug select byte to either examine a bit (and expect it to be a one or a zero) or to ignore the bit.	RW	0x0

counter1mask

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA104

Offset: 0x104

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
counter_one_mask 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
counter_one_mask 0x0															

counter1mask Fields

Bit	Name	Description	Access	Reset
31:0	counter_one_mask	Performance monitoring register. This register is used to mask off the internal signals selected by the debug select byte to either examine a bit (and expect it to be a one or a zero) or to ignore the bit.	RW	0x0

counter0match

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA108

Offset: 0x108

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
counter_zero_match 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
counter_zero_match 0x0															

counter0match Fields

Bit	Name	Description	Access	Reset
31:0	counter_zero_match	Counts events which happens during the sample window which counter_zero_mask was satisfied.	RW	0x0

counter1match

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA10C

Offset: 0x10C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
counter_one_match 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
counter_one_match 0x0															

counter1match Fields

Bit	Name	Description	Access	Reset
31:0	counter_one_match	Counts events which happens during the sample window which counter_one_mask was satisfied.	RW	0x0

niosreserve0

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA110

Offset: 0x110

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
nios_reserve0 0x0															

niosreserve0 Fields

Bit	Name	Description	Access	Reset
15:0	nios_reserve0	Reserved register0 for Nios	RW	0x0

niosreserve1

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA114

Offset: 0x114

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
nios_reserve1 0x0															

niosreserve1 Fields

Bit	Name	Description	Access	Reset
15:0	nios_reserve1	Reserved register1 for Nios	RW	0x0

niosreserve2

Module Instance	Base Address	Register Address
i_io48_hmc_mmr_io48_mmr	0xFFCFA000	0xFFCFA118

Offset: 0x118

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
nios_reserve2 0x0															

niosreserve2 Fields

Bit	Name	Description	Access	Reset
15:0	nios_reserve2	Reserved register2 for Nios	RW	0x0

ecc_hmc_ocp_slv_block Address Map

Module Instance	Base Address	End Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFDFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

IP_REV_ID

IDO Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB000

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev #These bits indicate the silicon revision number	RO	0x0

DDRIOCTRL

DDR IO Control Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														IO_SIZE 0x0	

DDRIOCTRL Fields

Bit	Name	Description	Access	Reset
1:0	IO_SIZE	External Configuration of DDR IO size. This field indicates the width of the external DDR to which the hard memory cotnroller is interfacing. These bits are configured at the start to indicate the external DDRIO size. 0x0 = DDR IO x16. default value after reset 0x1 = DDR IO x32 0x2 = DDR IO x64	RW	0x0

DDRCALSTAT

DDR Calibration Register

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB00C

Offset: 0xC

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CAL 0x0

DDRCALSTAT Fields

Bit	Name	Description	Access	Reset
0	CAL	DDR calibration status. This field indicates the calibration status of the hard memory controller's I/O column. During this time the DDR memory is not available. 0x0: When clear, calibration is either on going, hasn't started or failed. 0x1: When set to 1, calibration has succeeded.	RO	0x0

MPR_0BEAT1

Multipurpose register [31:0] for first beat

Module Instance	Base Address	Register Address

Reserved							CNT_RST 0x0	Reserved							ECC_EN 0x0

ECCCTRL1 Fields

Bit	Name	Description	Access	Reset
16	AUTOWB_CNT_RST	Reset the auto-write back internal counter to zero. The auto-write back counter is reset to zero when the INTONCMP bit in the INTMODE register is set. 1'b0 : No effect on auto-write back internal counter. Default value after reset 1'b1 : Reset the auto-write back internal counter to zero	RW	0x0
8	CNT_RST	Reset of internal counter. The internal counter is reset to zero when the INTONCMP bit in the INTMODE register is set. 1'b0: No effect on internal counter. Dafault value after reset 1'b1: Reset the internal counter to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic. This bit is used to detect and correct any errors within RAM during memory access. 1'b0:ECC block is disabled. Default value after reset. 1'b1: ECC block is enabled. Every RAM access will verify the data and generate any necessary error requests.	RW	0x0

ECCCTRL2

ECC control 2.

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB104

Offset: 0x104

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															OVRW_RB_ECC_EN 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RMW_EN 0x0	Reserved							AUTOWB_EN 0x0

ECCCTRL2 Fields

Bit	Name	Description	Access	Reset
16	OVRW_RB_ECC_EN	Overwrite the read-back ecc code during RMW process if a double byte error is detected. 1'b0: write the read-back ECC from RMW process if derr is detected. Default value after reset. 1'b1: write of 1 will overwrite the ECC overwrite feature.	RW	0x0
8	RMW_EN	Enable read modify write logic. When ECC is enabled and sub word accesses require correct ECC to be calculated, this bit should be enabled. RMW_EN bit should be disabled when ECC_EN is disabled. 1'b0: disable RMW logic. Default value after reset. 1'b1: enable RMW logic.	RW	0x0

Bit	Name	Description	Access	Reset
0	AUTOWB_EN	Enable auto write back correction feature. When a single-bit error is detected on outgoing reads, the hard memory controller adaptor schedules the corrected data and ECC to the written to the DDR memory. This bit enables auto correction of DDR memory. 1'b0: disable auto WB drop correction. Default value after reset. 1'b1: enable auto WB drop correction.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB110

Offset: 0x110

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													HMI_INTREN 0x0	DERRINTEN 0x0	SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
2	HMI_INTREN	Enables GP HMI interrupt. This bit is used to enable the general purpose HMI interrupt error interrupt to system manager. When this bit is enabled along with autoWB_drop_en, it compares the internal counter with autoWB_drop_cntreg value. If the value is greater than or equal to, then the interrupt will be asserted.. 1'b0: hmi interrupt generation logic is disabled. 1'b1: hmi interrupt generation logic is enabled.	RW	0x0
1	DERRINTEN	This bit is used to enable the double bit error interrupt to system manager.When dbe error occurs, bus error is always generated with the transaction.DERR interrupt (derr_req)will be generated when this bit is enabled. 1'b0: DBE interrupt generation logic is disabled. 1'b1: DBE interrupt generation logic is enabled,	RW	0x0
0	SERRINTEN	This bit is used to enable the single bit error to system manager. It enables the interrupt modes (sbe request,compare match) 1'b0: SBE interrupt generation logic is disabled. 1'b1: SBE interrupt generation logic is enabled,	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB114

Offset: 0x114

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved													HMI_INTRR 0x0	DERRINTR 0x0	SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
2	HMI_INTRR	This bit is used to reset the general purpose HMI interrupt error interrupt to system manager 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset HMI_INTREN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0
1	DERRINTR	This bit is used to reset the double-bit error interrupt bit. Reads reflect DERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset DERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Interrupt mode

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB11C

Offset: 0x11C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							AFICAL_EN 0x0	Reserved							INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							EXT_ADDRPARITY_EN 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
24	AFICAL_EN	Enable interrupt of memory interface calibration success. This bit is used to enable interrupt of memory interrupt calibration success. The hmi_intr signal will be asserted on a match. 1'b0: HMI interrupts on compare match is disabled. 1'b1: HMI interrupts on compare matched is enabled.	RW	0x0

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare match. This bit is used to enable interrupt when the internal counter and SERRCNTA value matches. serr_req signal will be asserted on a match. 1'b0: SERR interrupt on compare match is disabled 1'b1: SERR interrupt on compare match is enabled	RW	0x0
8	EXT_ADDRPARITY_EN	Enable address parity for DDR4 memories. This bit is used to enable the interrupt that generate externally when address parity is detected. when enabled, this will be generating derr_req signal 1'b0: disable address parity on DERR interrupt 1'b1: enable address parity on DERR interrupt	RW	0x0
0	INTMODE	Interrupt mode for single-bit error.This is disabled when SERRINTEN is disabled in the ERRINTEN register. 1'b0: interrupt disbaled 1'b1: generate interrupt on every SERR	RW	0x0

INTSTAT

Interrupt status

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB120

Offset: 0x120

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved													DERRBUSFLG 0x0	ADDRPARFLG 0x0	ADDRMTCFLG 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													HMI_PENA 0x0	DERRPENA 0x0	SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
18	DERRBUSFLG	This bit is used to indicate that the last transaction was flagged with double-bit error. 1'b0: no effect. 1'b1: indicates double-bit error has occured. This will drive the bus to respond the read with bus error. Write of one will clear this register double-but bus error. Bus error occurs as part of the transaction but this indicates the SW the cause of the error. This should only occur once per transaction	RW	0x0
17	ADDRPARFLG	External address parity flag for DDR4 memory. This bit is used to flag external address parity flag which is driven with derr_req port. 1'b0: No Effect. 1'b1: Read of one indicates double-bit interrupt has occurred. Write of one will clear this register last address parity flag.	RW	0x0

Bit	Name	Description	Access	Reset
16	ADDRMTCFLG	Address mismatch error flag. This bit is used to indicate the last transaction was flagged with address mismatch error. 1'b0: No effect. 1'b1: indicates address mismatch error has occured. This will drive the bus to respond the read with bus error. Write of one will clears this register address mismatch error. Bus error occurs as part of the transaction but this indicates the SW the cause of the error. This should occur once per transaction.	RW	0x0
2	HMI_PENA	HMI interrupt pending This bit is used to clear the pending hmi interrupt bit. 1'b0: No effect 1'b1: indicates hmi interrupt is pending. Write of one will clear the pending interrupt. This will de-assert the hmi_intr signal.	RW	0x0
1	DERRPENA	Double bit error pending This bit is used to clear the pending double-bit error. 1'b0: No effect. 1'b1: indicates DBE is pending. Write of one will clear the pending DBE. This will de-assert the derr_req signal.	RW	0x0
0	SERRPENA	Single-bit error pending This bit is used to clear the pending single-bit error. 1'b0: No effect. 1'b1: indicates SBE is pending. Write of one will clear the pending. This will de-assert the serr_req signal.	RW	0x0

DIAGINTTEST

Enable diagnostic errors

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB124

Offset: 0x124

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							TADDRPAR 0x0	Reserved							TADDRMTC 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

DIAGINTTEST Fields

Bit	Name	Description	Access	Reset
24	TADDRPAR	Diagnostic of address parity of DDR4. This bit is used to test the address parity error path. 1'b0: Disables generating address match bus error as part of the transaction. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager. By writing to this bit, ADDRPARFLG bit in the INTSTAT register will be pending. Write of one to ADDRPARFLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.	RW	0x0

Bit	Name	Description	Access	Reset
16	TADDRMTC	Diagnostic enable of Address mismatch error. This bit is used to flag that the last transaction was flagged with address mismatch error. 1'b0: Disables generating address match bus error as part of the transaction. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager without going through the ECC decoder address mismatch logic. By writing to this bit, ADDRMTCFLG bit in the INTSTAT register will be pending. Write of one to ADDRMTCFLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.	RW	0x0
8	TDERRA	Diagnostic enable of Double-bit error. This bit is used to test double-bit error. 1'b0: Write of zero has no effect. 1'b1: When this bit is set to 1, derr_req signal is generated to the system manager without going through the ECC decoder logic. By writing to this bit, DERRBUSFLG bit in the INTSTAT register will be pending. Write of one to DERRBUSFLG will clear this bit. SW needs to explicitly write to DERRPENA to clear it.	RW	0x0
0	TSERRA	This bit is used to test a single-bit error. 1'b0: Write of zero has no effect. 1'b1: When this bit is set to 1, serr_req signal is generated to the system manager without going through the ECC decoder logic. By writing to this bit, SERRPENA bit in the INTSTAT register will be pending. Write of one to SERRPENA will clear this bit.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB128

Offset: 0x128

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							AUTOWB_DROP_FLG 0x0	Reserved							CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
8	AUTOWB_DROP_FLG	Auto writeback counter match flag. This bit indicates that the internal autoWB counter and autoWB_drop_cnt value matched. 1'b0: read indicates match check of hmi_intr interrupt on compare match is disabled. 1'b1: read indicates compare has matched. Write of one will clear the pending compare match. This will not de-assert the hmi_intr signal - software needs to write to hmi_intrpen bit to clear the interrupt. When the match occurs, additional errors will not increment count until the compare status flag is cleared. If the software does not change the autoWB_drop_cnt register prior to clearing this flag or reset the autoWB counter, next increment of internal autoWB counter could set this flag in the next cycle.	RW	0x0
0	CMPFLGA	Counter Match occurred flag. This bit indicates that the internal counter and SERRCNT value matched. 1'b0: read indicates match check of SERR interrupt on compare match is disabled. 1'b1: read indicates compare has matched. Write of one will clear the pending compare match. This will not de-assert the serr_req signal - software needs to write to serrpen bit to clear the interrupt. When the match occurs, additional errors will not increment count until the compare status flag is cleared. If the software does not change the SERRCNT register prior to clearing this flag or reset the internal counter, next increment of internal counter could set this flag again in the next cycle.	RW	0x0

DERRADDRA

Double-bit error address

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB12C

Offset: 0x12C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DADDRESS 0x0															

DERRADDRA Fields

Bit	Name	Description	Access	Reset
31:0	DADDRESS	Last double-bit error address at 256-bit boundary. This register shows the address of the current double-bit error. RAM size will determine the maximum number of address bits. This address is logged when a new derr_req or bus error is generated to the system. This is gated by the ecc_en enable bit and derrinten bit.	RO	0x0

SERRADDRA

Single-bit error address

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB130

Offset: 0x130

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SADDRESS 0x0															

SERRADDRA Fields

Bit	Name	Description	Access	Reset
31:0	SADDRESS	Last single-bit error address at 256-bit boundary. This register shows the address of the current single-bit error. This address is logged when a new serr_req is generated to the system. This is gated by the single-bit error interrupt enable and ecc_en.	RO	0x0

AUTOWB_CORRADDR

This register shows the address of the current autoWB correction SBE.

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB138

Offset: 0x138

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SWBADDRESS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWBADDRESS 0x0															

AUTOWB_CORRADDR Fields

Bit	Name	Description	Access	Reset
31:0	SWBADDRESS	recent autoWB correction address. This register shows the address of the current autoWB correction single-bit error. This address is logged when a new serr_req is generated to the system. This is gated by the single-bit error interrupt enable and ecc_en. Note that when a single-bit error occurs, an address is logged regardless of whether auto-correction is enabled or not. If you have not enabled auto-correction, this register can be ignored.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB13C

Offset: 0x13C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Compare value for the internal single-bit errors. This register sets the value to compare with the internal counter. Software should write to this register before enabling the interrupt on compare. 0x0: If the serrcnt bits are not modified before enabling the intoncmp, internal counter=0 and serrcnt=0, serr compare interrupt will not occur. Default after reset. Nonzero: if internal counter == serrcnt == nonzero will create a serr compare interrupt. When the compare matches, autoWB_drop_cmpflga will be set.	RW	0x0

AUTOWB_DROP_CNTREG

Maximum counter value for AUTOWB correction interrupt

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB140

Offset: 0x140

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CNT 0x1															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT 0x1															

AUTOWB_DROP_CNTREG Fields

Bit	Name	Description	Access	Reset
31:0	CNT	Compare value for the internal autoWB correction count. This register sets the value to compare with the autoWB internal counter. Software should write to this register before enabling the interrupt on compare. 0x1: If the autoWB_drop_cntreg bits are not modified before enabling the hmi_intr, autoWB internal counter=0 and autoWB_dop_cnt =1, serr compare interrupt will not occur. Default after reset. Nonzero: if autoWB internal counter == autoWB_drop_cnt == nonzero will create a serr compare interrupt. When the compare matches, autoWB_ drop_flg will be set.	RW	0x1

ECC_REG2WRECCDATABUS

ECC from register associated to data which will be written to the RAM

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB144

Offset: 0x144

Access: RW

Bit Fields

ECC1BUS 0x0								ECC0BUS 0x0							

ECC_REG2RDECCDATABUS Fields

Bit	Name	Description	Access	Reset
31:24	ECC3BUS	ECC from register associated to RD data [255:192] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
23:16	ECC2BUS	ECC from register associated to RD data [191:128] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
15:8	ECC1BUS	ECC from register associated to RD data [127:64] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0
7:0	ECC0BUS	ECC from register associated to RD data [63:0] which will be written to hmc ecc. Based on the DDR IO width, unimplemented bytes of this register will read as zero.	RW	0x0

ECC_DIAGON

Enable diagnostics access

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB150

Offset: 0x150

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ECCDIAGON 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														RDDIAGON 0x0	WRDIAGON 0x0

ECC_DIAGON Fields

Bit	Name	Description	Access	Reset
16	ECCDIAGON	ECC diagnostics mode. 1'b0: ECC diagnostics logic is disabled. ECC encoder bypass is disabled. 1'b1: ECC diagnostics logic is enabled. Direction of ECC data from the register to data bus or data bus to ecc register is determined by ECC_rddiagon or ECC_wrdiagon.	RW	0x0
1	RDDIAGON	Read diagnostics mux enabled. This overrides the data entering the ECC decoder. 1'b0: Read diagnostics path via the ecc_rdata2regbus or ecc_reg2rdatabus is disabled. 1'b1: Read diagnostics path via the ecc_rdata2regbus or ecc_reg2rdatabus is enabled. Both Rddiagon and Wrdiagon bits can be enabled.	RW	0x0

Bit	Name	Description	Access	Reset
0	WRDIAGON	Write diagnostics mux enabled. This overrides the encoder output with the register data ecc. 1'b0: Write diagnostics path via the ecc_reg2wdatabus is disabled. 1'b1: Write diagnostics path via the ecc_reg2wdatabus is enabled. Both Rddiagon and Wrdiagon bits can be enabled.	RW	0x0

ECC_DECSTAT

Diagnostic decoder status

Module Instance	Base Address	Register Address
ecc_hmc_ocp_slv_block	0xFFCFB000	0xFFCFB154

Offset: 0x154

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						RATE RW 0x0									

MPU_M1toDDRResp_main_RateAdapter_Rate Fields

Bit	Name	Description	Access	Reset
9:0	RATE	The ratio of outgoing to incoming throughput. This value determines what portion of a received packet will be stored before its head is transmitted. An optimal setting avoids transmitting bubbles, while adding no delay to packets. The ratio is expressed as 256 / (ratio - 1). The value for rate must be rounded up except when ratio is greater than 4, in which case it must be rounded down. For example, a 4:1 ratio of outgoing to incoming throughput would be indicated by value 0x055. Note that throughput is the product of clock frequency x data bus width. A value of 0x000 causes the rate adapter to store a packet until either the entire packet is received or the buffer becomes full.	RW	0x0

MPU_M1toDDRResp_main_RateAdapter_Bypass

Module Instance	Base Address	Register Address
i_noc_mpu_m0_MPU_M1toDDRResp_main_RateAdapter	0xFFD11100	0xFFD1110C

Reserved															BYPASS RW 0x0

MPU_M1toDDRResp_main_RateAdapter_Bypass Fields

Bit	Name	Description	Access	Reset
0	BYPASS	Disable the rate adaptation capability. This causes the rate adapter to act as a FIFO by transmitting received words, without delay, as soon as they can be transmitted. This setting is useful when the incoming throughput is equal to or greater than the downstream throughput.	RW	0x0

noc_mpu_m0_MPU_M0_rate_adResp_main_RateAdapter Address Map

Reserved						RATE RW 0x0									

MPU_M0_rate_adResp_main_RateAdapter_Rate Fields

Bit	Name	Description	Access	Reset
9:0	RATE	The ratio of outgoing to incoming throughput. This value determines what portion of a received packet will be stored before its head is transmitted. An optimal setting avoids transmitting bubbles, while adding no delay to packets. The ratio is expressed as 256 / (ratio - 1). The value for rate must be rounded up except when ratio is greater than 4, in which case it must be rounded down. For example, a 4:1 ratio of outgoing to incoming throughput would be indicated by value 0x055. Note that throughput is the product of clock frequency x data bus width. A value of 0x000 causes the rate adapter to store a packet until either the entire packet is received or the buffer becomes full.	RW	0x0

Reserved						RATE RW 0x0									

acp_rate_ad_main_RateAdapter_Rate Fields

Bit	Name	Description	Access	Reset
9:0	RATE	The ratio of outgoing to incoming throughput. This value determines what portion of a received packet will be stored before its head is transmitted. An optimal setting avoids transmitting bubbles, while adding no delay to packets. The ratio is expressed as 256 / (ratio - 1). The value for rate must be rounded up except when ratio is greater than 4, in which case it must be rounded down. For example, a 4:1 ratio of outgoing to incoming throughput would be indicated by value 0x055. Note that throughput is the product of clock frequency x data bus width. A value of 0x000 causes the rate adapter to store a packet until either the entire packet is received or the buffer becomes full.	RW	0x0

7:0	USERID	Field containing a user defined value, not used anywhere inside the IP itself.	RO	0x0

ddr_T_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD12008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTBYTEALWAYSCHAINABLEEN RW 0x0	INTRUSIVEMODE RW 0x0	STATCONDDUMP RW 0x0	ALARMEN RW 0x0	STATEN RW 0x0	PAYLOADEN RW 0x0	TRACEEN RW 0x0	ERREN RW 0x0

ddr_T_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters.When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RW	0x0
5	STATCONDDUMP	When set, register field StatCond-Dump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inopera-tive. When parameter statisticsCoun-terAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0

Bit	Name	Description	Access	Reset
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sendS statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set ot 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

ddr_T_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Probe	0xFFD12000	0xFFD1200C

ddr_T_main_Probe_TraceAlarmEn Fields

Bit	Name	Description	Access	Reset
4:0	TRACEALARMEN	Register TraceAlarmEn controls which lookup table or filter can set the TraceAlarm signal output once the trace alarm status is set. The number of bits in register TraceAlarmEn is determined by the value set for parameter nFilter + 1.Bit nFilter controls the lookup table output, and bits nFilter:0 control the corresponding filter output. When parameter nFilter is set to None, TraceAlarmEn is reserved.	RW	0x0

ddr_T_main_Scheduler_DdrTiming Fields

Bit	Name	Description	Access	Reset
31	BWRATIO	When set to zero, one DRAM clock cycle (two DDR transfers) is used to transfer each word of data. When set to one, two DRAM clock cycles (four DDR transfers) are used to transfer each word of data. This is applicable when half of a DRAM data bus width is used.	RW	0x1
30:26	WRTORD	The minimum number of scheduler clock cycles between the last DRAM Write command and a Read command (WL x tCkD + tWTR). tCkD is the DRAM clock period.	RW	0xB
25:21	RDTOWR	The minimum number of scheduler clock cycles between the last DRAM Read command and a Write command (DDR3: (RL – WL + 2) x tCkD). tCkD is the DRAM clock period.	RW	0x1
20:18	BURSTLEN	The DRAM burst duration on the DRAM data bus in scheduler clock cycles. Also equal to scheduler clock cycles between two DRAM commands (BL / 2 x tCkD). tCkD is the DRAM clock period.	RW	0x2

Bit	Name	Description	Access	Reset
17:12	WRTOMISS	The minimum number of scheduler clock cycles between the last DRAM Write command and a new Read or Write command in another page of the same bank (WL x tCkD + tWR + tRP + tRCD). tCkD is the DRAM clock period.	RW	0x21
11:6	RDTOMISS	The minimum number of scheduler clock cycles between the last DRAM Read command and a new Read or Write command in another page of the same bank (tRTP + tRP + tRCD – BL x tCkD / 2). tCkD is the DRAM clock period.	RW	0x13
5:0	ACTTOACT	The minimum number of scheduler clock cycles between two consecutive DRAM Activate commands on the same bank (tRC/ tCkG). tCkG is the clock period of the SoC DRAM scheduler.	RW	0x1C

ddr_T_main_Scheduler_DdrMode

ddr mode definition.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_ddr_T_main_Scheduler	0xFFD12400	0xFFD12410

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

nand_register

Per-Master Security bit for nand register

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

nand_register Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to nand_ register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to nand_ register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to nand_ register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to nand_ register. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

nand_data

Per-Master Security bit for nand_data

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

nand_data Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

Bit	Name	Description	Access	Reset
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to nand_data. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

qspi_data

Per-Master Security bit for qspi_data

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0

Bit	Name	Description	Access	Reset
16	fpga2soc	Security bit configuration for transactions from fpga2soc to i2c4. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to i2c4. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to i2c4. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

sp_timer0

Per-Master Security bit for sp_timer0

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13064

Offset: 0x64

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

sp_timer0 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to sp_timer0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to sp_timer0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to sp_timer0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to sp_timer0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

sp_timer1

Per-Master Security bit for sp_timer1

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13068

Offset: 0x68

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

sp_timer1 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to sp_timer1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to sp_timer1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to sp_timer1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

Bit	Name	Description	Access	Reset
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to sp_timer1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

uart0

Per-Master Security bit for uart0

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD1306C

Offset: 0x6C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

uart0 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

Bit	Name	Description	Access	Reset
16	fpga2soc	Security bit configuration for transactions from fpga2soc to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to uart0. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

uart1

Per-Master Security bit for uart1

Module Instance	Base Address	Register Address
noc_fw_l4_per_l4_per_scr	0xFFD13000	0xFFD13070

Offset: 0x70

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							dma RW 0x0	Reserved							mpu_m0 RW 0x0

uart1 Fields

Bit	Name	Description	Access	Reset
24	ahb_ap	Security bit configuration for transactions from ahb_ap to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
16	fpga2soc	Security bit configuration for transactions from fpga2soc to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
8	dma	Security bit configuration for transactions from dma to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0
0	mpu_m0	Security bit configuration for transactions from mpu_m0 to uart1. When cleared (0), only Secure transactions are allowed. When set (1), both Secure and Non-Secure transactions are allowed.	RW	0x0

noc_fw_l4_sys_l4_sys_scr Address Map

Module Instance	Base Address	End Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD131FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_ecc

Per-Master Security bit for dma_ecc

Module Instance	Base Address	Register Address
noc_fw_l4_sys_l4_sys_scr	0xFFD13100	0xFFD13108

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							ahb_ap RW 0x0	Reserved							fpga2soc RW 0x0

hpsregion0addr

Base and Limit definition for HPS Region 0

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD1340C

Offset: 0xC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion0addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion1addr

Base and Limit definition for HPS Region 1

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13410

Offset: 0x10

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion1addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion2addr

Base and Limit definition for HPS Region 2

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13414

Offset: 0x14

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion2addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0

Bit	Name	Description	Access	Reset
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion3addr

Base and Limit definition for HPS Region 3

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13418

Offset: 0x18

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion3addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion4addr

Base and Limit definition for HPS Region 4

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD1341C

Offset: 0x1C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion4addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion5addr

Base and Limit definition for HPS Region 5

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13420

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion5addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion6addr

Base and Limit definition for HPS Region 6

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13424

Offset: 0x24

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
base RW 0x0															

hpsregion6addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

hpsregion7addr

Base and Limit definition for HPS Region 7

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD13428

Offset: 0x28

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
limit RW 0x0

base RW 0x0															

hpsregion7addr Fields

Bit	Name	Description	Access	Reset
31:16	limit	Limit defines the 16 bit MSB of the address field. Remaining LSB field is all ones. Region end address is {limit, 16'hFFF}	RW	0x0

Bit	Name	Description	Access	Reset
15:0	base	Base defines the 16 bit MSB of the address field. Remaining LSB field is all zeros. Region start address is {base, 16'h000}	RW	0x0

global

Global Firewall Control Register. This register will store various overrides that change default firewall behavior on the entire interconnect.

Module Instance	Base Address	Register Address
noc_fw_ddr_l3_ddr_scr	0xFFD13400	0xFFD1342C

Offset: 0x2C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															error_response RW 0x0

global Fields

Bit	Name	Description	Access	Reset
0	error_response	When 0, transactions blocked by the firewall will silently fail (i.e successful completion with random data). When 1, transactions blocked by the firewall will return error	RW	0x0

noc_fw_soc2fpga_soc2fpga_scr Address Map

Module Instance	Base Address	End Address
noc_fw_soc2fpga_soc2fpga_scr	0xFFD13500	0xFFD13FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

31:8	FLEXNOCID	Field containing the build revision of the software used to generate the IP HDL code.	RO	0x129FF
7:0	USERID	Field containing a user defined value, not used anywhere inside the IP itself.	RO	0x0

Probe_SoC2FPGA_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_SoC2FPGA_main_Probe	0xFFD14000	0xFFD14008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTBYTEALWAYSCHAINABLEEN RW 0x0	INTRUSIVEMODE RO 0x0	STATCONDDUMP RW 0x0	ALARMEN RW 0x0	STATEN RW 0x0	PAYLOADEN RW 0x0	TRACEEN RW 0x0	ERREN RW 0x0

Probe_SoC2FPGA_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters.When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RO	0x0
5	STATCONDDUMP	When set, register field StatCond-Dump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inopera-tive. When parameter statisticsCoun-terAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sendS statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0

Bit	Name	Description	Access	Reset
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set ot 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

Probe_SoC2FPGA_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_SoC2FPGA_main_Probe	0xFFD14000	0xFFD1400C

Offset: 0xC

Probe_SoC2FPGA_main_Probe_Counters_3_PortSel Fields

Bit	Name	Description	Access	Reset
0	COUNTERS_3_PORTSEL	Register PortSel indicates which NTTP link is associated with the counter. The register can be changed at any time, with the change effective immediately. The LUT and FILTx sources do not depend on this NTTP port selection.	RW	0x0

Probe_SoC2FPGA_main_Probe_Counters_3_Src

Register CntSrc indicates the event source used to increment the counter. Unassigned values (non-existing Press level or ExtEvent index, or unimplemented Filter) are equivalent to OFF.

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_SoC2FPGA_main_Probe	0xFFD14000	0xFFD14174

Offset: 0x174

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Probe_emacs_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD14408

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTBYTEALWAYSCHAINABLEEN RW 0x0	INTRUSIVEMODE RO 0x0	STATCONDDUMP RW 0x0	ALARMEN RW 0x0	STATEN RW 0x0	PAYLOADEN RW 0x0	TRACEEN RW 0x0	ERREN RW 0x0

Probe_emacs_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters.When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RO	0x0
5	STATCONDDUMP	When set, register field StatCond-Dump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inopera-tive. When parameter statisticsCoun-terAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sendS statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0

Bit	Name	Description	Access	Reset
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set ot 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

Probe_emacs_main_Probe_CfgCtl

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_Probe	0xFFD14400	0xFFD1440C

Probe_emacs_main_TransactionStatProfiler_Thresholds_0_2 Fields

Bit	Name	Description	Access	Reset
1:0	THRESHOLDS_0_2	Register Thresholds_i_j contains the threshold index "2" that allows computation of threshold values.	RW	0x0

Probe_emacs_main_TransactionStatProfiler_OverflowStatus

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD1486C

Offset: 0x6C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															OVERFLOW STATUS RO 0x0

Probe_emacs_main_TransactionStatProfiler_OverflowStatus Fields

Bit	Name	Description	Access	Reset
0	OVERFLOWSTATUS	Bit n of register OverflowStatus is set to 1 if a start event occurs on observed port n and eitherof the following conditions occurs: All tenure counters allocated to the port are already in use. No tenure lines have been allocated to the port. The number of bits in this register is equal to the value set for parameter nObservable.	RO	0x0

Probe_emacs_main_TransactionStatProfiler_OverflowReset

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14870

Offset: 0x70

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															OVERFLOW RESET RW 0x0

Probe_emacs_main_TransactionStatProfiler_OverflowReset Fields

Bit	Name	Description	Access	Reset
0	OVERFLOWRESET	Register OverflowReset is a pulse register that clears overflow status bits per observed port on each write access. OverflowReset = nObservable. Writing 0x2 clears the overflow status of observed port 1.	RW	0x0

Probe_emacs_main_TransactionStatProfiler_PendingEventMode

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14874

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															PENDINGEVENTMODE RW 0x0

Probe_emacs_main_TransactionStatProfiler_PendingEventMode Fields

Bit	Name	Description	Access	Reset
0	PENDINGEVENTMODE	Register pendingEventMode is a 1-bit register that configures the pending event mode. When set to 0 (CYCLE), and when register mode is set to PENDING, the pending event is generated on each cycle when the counter is greater than zero.When set to 1 (STOP) the pending event is generated on each stop event.	RW	0x0

Probe_emacs_main_TransactionStatProfiler_PreScaler

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_emacs_main_TransactionStatProfiler	0xFFD14800	0xFFD14878

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								PRESCALER RW 0x0							

Probe_emacs_main_TransactionStatProfiler_PreScaler Fields

Bit	Name	Description	Access	Reset
7:0	PRESCALER	8Register Prescaler is an-bit pre-scaling register that accepts any pre-scaling value between 1 (default) and 256. If set to 0, pre-scaling is disabled. If set to any other supported value "n", the threshold counter value is divided by (n + 1).	RW	0x0

noc_mpu_m0_cs_obs_at_main_AtbEndPoint Address Map

Module Instance	Base Address	End Address
i_noc_mpu_m0_cs_obs_at_main_AtbEndPoint	0xFFD14900	0xFFD1497F

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

cs_obs_at_main_ErrorLogger_0_ErrClr Fields

Bit	Name	Description	Access	Reset
0	ERRCLR	Set to 1 to clear ErrVld. NOTE The written value is not stored in ErrVld. A read always returns 0.	RW	0x0

cs_obs_at_main_ErrorLogger_0_ErrLog0

Stores NTTP packet header fields Lock, Opc, ErrCode, Len1 and indicates version of NTTP transport protocol

Module Instance	Base Address	Register Address
i_noc_mpu_m0_cs_obs_at_main_ErrorLogger_0	0xFFD14980	0xFFD14994

Offset: 0x14

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FORMAT RO 0x1	Reserved							LEN1 RO 0x0

Probe_MPU_main_Probe_MainCtl

Register MainCtl contains probe global control bits. The register has seven bit fields:

Module Instance	Base Address	Register Address
i_noc_mpu_m0_Probe_MPU_main_Probe	0xFFD15000	0xFFD15008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								FILTBYTEALWAYSCHAINABLEEN RW 0x0	INTRUSIVEMODE RO 0x0	STATCONDDUMP RW 0x0	ALARMEN RW 0x0	STATEN RW 0x0	PAYLOADEN RW 0x0	TRACEEN RW 0x0	ERREN RW 0x0

Probe_MPU_main_Probe_MainCtl Fields

Bit	Name	Description	Access	Reset
7	FILTBYTEALWAYSCHAINABLEEN	When set to 0, filters are mapped to all statistic counters when counting bytes or enabled bytes. Therefore, only filter events mapped to even counters can be counted using a pair of chained counters.When set to 1, filters are mapped only to even statistic counters when counting bytes or enabled bytes. Thus events from any filter can be counted using a pair of chained counters.	RW	0x0
6	INTRUSIVEMODE	When set to 1, register field IntrusiveMode enables trace operation in Intrusive flow-control mode. When set to 0, the register enables trace operation in Overflow flow-control mode	RO	0x0
5	STATCONDDUMP	When set, register field StatCond-Dump enables the dump of a statistics frame to the range of counter values set for registers StatAlarmMin, StatAlarmMax, and AlarmMode. This field also renders register StatAlarmStatus inopera-tive. When parameter statisticsCoun-terAlarm is set to False, the StatCondDump register bit is reserved.	RW	0x0
4	ALARMEN	When set, register field AlarmEn enables the probe to collect alarm-related information. When the register field bit is null, both TraceAlarm and StatAlarm outputs are driven to 0.	RW	0x0
3	STATEN	When set to 1, register field StatEn enables statistics profiling. The probe sendS statistics results to the output for signal ObsTx. All statistics counters are cleared when the StatEn bit goes from 0 to 1. When set to 0, counters are disabled.	RW	0x0

Bit	Name	Description	Access	Reset
2	PAYLOADEN	Register field PayloadEn, when set to 1, enables traces to contain headers and payload. When set ot 0, only headers are reported.	RW	0x0
1	TRACEEN	Register field TraceEn enables the probe to send filtered packets (Trace) on the ObsTx observation output.	RW	0x0
0	ERREN	Register field ErrEn enables the probe to send on the ObsTx output any packet with Error status, independently of filtering mechanisms, thus constituting a simple supplementary global filter.	RW	0x0

mpu_m0_l_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
11:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x6AA

Reserved					BANDWIDTH RW 0x280										

fpga2soc_axi32_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x280

fpga2soc_axi128_l_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
12:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0xC80

emac0_m_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x100

emac2_m_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x100

Reserved					BANDWIDTH RW 0x100										

usb1_m_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x100

usb1_m_I_main_QosGenerator_Saturation

Module Instance	Base Address	Register Address
i_noc_mpu_m0_usb1_m_I_main_QosGenerator	0xFFD16500	0xFFD16514

sdmmc_m_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
10:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0x100

Reserved			BANDWIDTH RW 0xC80												

fpga2sdram2_axi128_I_main_QosGenerator_Bandwidth Fields

Bit	Name	Description	Access	Reset
12:0	BANDWIDTH	In Bandwidth Limiter or Bandwidth Regulator mode, the bandwidth threshold is in units of 1/256th bytes per cycle. The formula to calculate this value is: Bandwidth = Throughput (Mbsp) * 256 / Clock Frequency. For example, 80 MBps on a 250 MHz interface has the value 0x0052 (BW = 80Mbps * 256/ 250MHz = 81.92, which is rounded to 0x0052).	RW	0xC80

fpga2sdram2_axi128_I_main_QosGenerator_Saturation

Module Instance	Base Address	Register Address
i_noc_mpu_m0_fpga2sdram2_axi128_I_main_QosGenerator	0xFFD17000	0xFFD17014

HPS-FPGA Bridges 8

2016.10.28

a10_5v4 Subscribe Send Feedback

This chapter describes the bridges in the hard processor system (HPS) used to communicate data between the FPGA fabric and HPS logic.

These bridges make use of Advanced Microcontroller Bus Architecture (AMBA®) Advanced eXtensible Interface (AXI™) protocol, based on Arteris FlexNoC™ network-on-chip (NOC) interconnect IP.

The HPS contains the following HPS-FPGA bridges:

- FPGA-to-HPS Bridge
- HPS-to-FPGA Bridge
- Lightweight HPS-to-FPGA Bridge

Related Information

- **www.arteris.com**
  For detailed information about the FlexNoC Network-on-Chip Interconnect, refer to the Arteris website.
- **SoC Security** on page 6-1
  Information about security features in the HPS-FPGA bridges

  Additional information is available in the AMBA AXI Protocol Specification v1.0, which you can download from the ARM Infocenter website.

Features of the HPS-FPGA Bridges

The HPS-FPGA bridges allow masters in the FPGA fabric to communicate with slaves in the HPS logic and vice versa. For example, if you implement memories or peripherals in the FPGA fabric, HPS components such as the MPU can access them. Components implemented in the FPGA fabric, such as the Nios® II processor, can also access memories and peripherals in the HPS logic.

Table 8-1: HPS-FPGA Bridge Features

Feature	FPGA-to-HPS Bridge	HPS-to-FPGA Bridge	Lightweight HPS-to-FPGA Bridge
Supports the AMBA AXI3 interface and FlexNoC low latency interface protocols	Y	Y	Y
Implements clock crossing and manages the transfer of data across the clock domains in the HPS logic and the FPGA fabric	Y	Y	Y
Performs data width conversion between the HPS logic and the FPGA fabric	Y	Y	Y
Allows configuration of FPGA interface widths at instantiation time	Y	Y	N

Each bridge consists of a master-slave pair with one interface exposed to the FPGA fabric and the other exposed to the HPS logic. The FPGA-to-HPS bridge exposes an AXI slave interface that you can connect to AXI or Avalon-MM master interfaces in the FPGA fabric. The HPS-to-FPGA and lightweight HPS-to-FPGA bridges expose an AXI master interface that you can connect to AXI or Avalon-MM slave interfaces in the FPGA fabric.

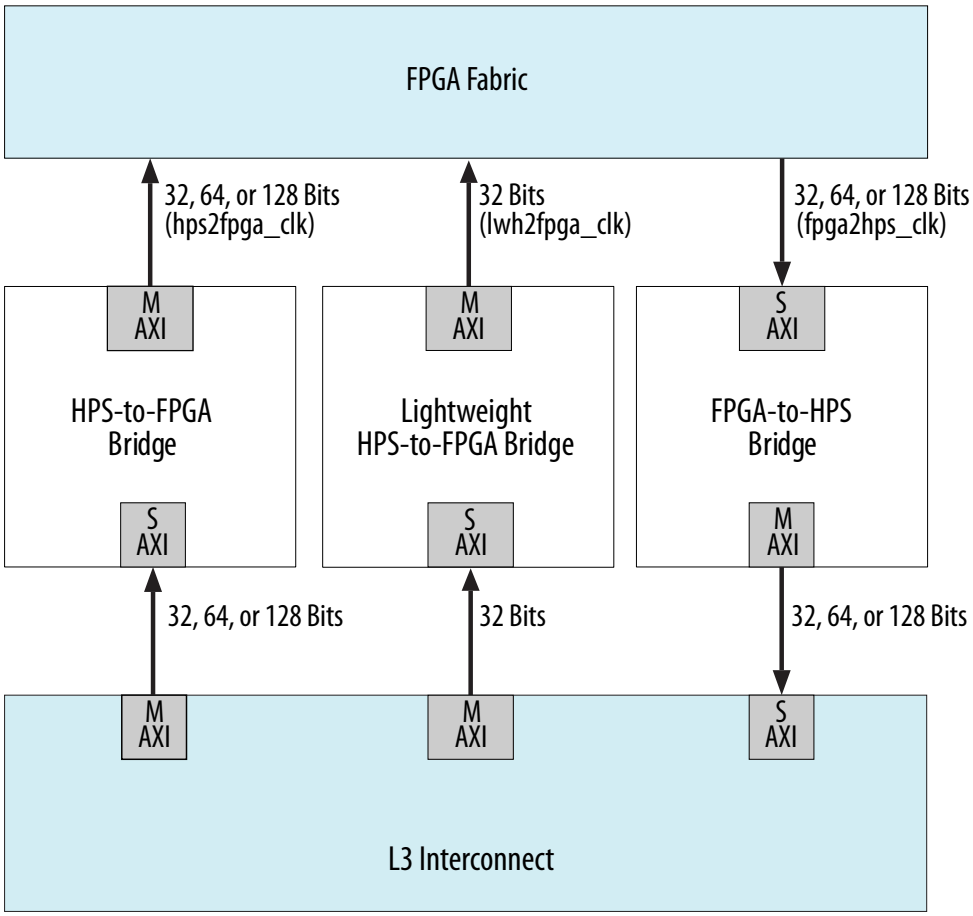
Arria 10 HPS-FPGA Bridges Block Diagram and System Integration

Figure 8-1: HPS-FPGA Bridge Connectivity

The following figure shows the HPS-FPGA bridges in the context of the FPGA fabric and the L3 interconnect to the HPS. Each master (M) and slave (S) interface is shown with its data width(s). The clock domain for each interconnect is shown in parentheses.



The HPS-to-FPGA and lightweight HPS-to-FPGA bridges are both mastered by the level 3 (L3) interconnect. The FPGA-to-HPS bridge masters the L3 interconnect. This arrangement allows any master implemented in the FPGA fabric to access most slaves in the HPS. For example, the FPGA-to-HPS bridge can access the accelerator coherency port (ACP) of the MPU subsystem to perform cache-coherent accesses to the SDRAM subsystem.

Functional Description of the HPS-FPGA Bridges

Functional Description of the FPGA-to-HPS Bridge

The FPGA-to-HPS bridge provides access to the peripherals in the HPS from the FPGA. This access is available to any master implemented in the FPGA fabric. You can configure the bridge slave, which is

exposed to the FPGA fabric, to support the AXI protocol, with a data width of 32, 64 or 128 bits. The FPGA-to-HPS bridge multiplexes the configured data width from the L3 interconnect to the FPGA interface.

Table 8-2: FPGA-to-HPS Bridge Properties

The following table lists the properties of the FPGA-to-HPS bridge, including the configurable slave interface exposed to the FPGA fabric.

Bridge Property	Value
Data width[17]	32, 64, or 128 bits
Clock domain	`fpga2hps_clk`
Byte address width	32 bits
ID width	4 bits
Read acceptance	8 transactions
Write acceptance	8 transactions
Total acceptance	16 transactions

The FPGA-to-HPS bridge is configurable in the HPS component parameter editor, available in Qsys and the IP Catalog. The HPS component parameter editor allows you to set the data path width and the bridge protocol, according to the FPGA bitstream.

Warning: To avoid memory aliasing issues, ensure that Avalon-MM burst transactions into the HPS do not cross the 4 KB address boundary restriction specified by the AXI protocol.

FPGA-to-HPS Access to ACP

When the error correction code (ECC) option is enabled in the level 2 (L2) cache controller, all accesses from the FPGA-to-HPS bridge to the ACP must be 64 bits wide and aligned on 8-byte boundaries after up- or downsizing takes place. Ensure that the address alignment is a multiple of 8 bytes and that (burst size) × (burst length) is a multiple of 8 bytes.

FPGA-to-HPS Bridge Slave Signals

The FPGA-to-HPS bridge slave address channels support user-sideband signals, routed to the ACP in the MPU subsystem. All the signals have a fixed width except the data and write strobes for the read and write data channels. The variable width signals depend on the data width setting of the bridge.

The FPGA-to-HPS bridge incorporates ARM's TrustZone technology by providing the `ARPROT[1]` and `AWPROT[1]` signals, which specify whether a transaction is secure or nonsecure. The firewall logic uses the `AxPROT` signals to determine if a bus transaction matches the security level allowed. You can program security values in the Secure Configuration Registers of the system interconnect.

All peripheral slaves and memories in the SoC are secure when they are released from reset.

[17] The bridge slave data width is user-configurable at the time you instantiate the HPS component in your system.

The following tables list all the signals exposed by the FPGA-to-HPS slave interface to the FPGA fabric.

Table 8-3: FPGA-to-HPS Bridge Slave Write Address Channel Signals

Signal	Width	Direction	Description
AWID	8 bits	Input	Write address ID
AWADDR	32 bits	Input	Write address
AWLEN	4 bits	Input	Burst length
AWSIZE	3 bits	Input	Burst size
AWBURST	2 bits	Input	Burst type
AWLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Input	Cache policy type
AWPROT	3 bits	Input	Protection type
AWVALID	1 bit	Input	Write address channel valid
AWREADY	1 bit	Output	Write address channel ready
AWUSER	5 bits	Input	User sideband signals

Table 8-4: FPGA-to-HPS Bridge Slave Write Data Channel Signals

Signal	Width	Direction	Description
WID	8 bits	Input	Write ID
WDATA	32, 64, or 128 bits	Input	Write data
WSTRB	4, 8, or 16 bits	Input	Write data strobes
WLAST	1 bit	Input	Write last data identifier
WVALID	1 bit	Input	Write data channel valid
WREADY	1 bit	Output	Write data channel ready

Table 8-5: FPGA-to-HPS Bridge Slave Write Response Channel Signals

Signal	Width	Direction	Description
BID	8 bits	Output	Write response ID
BRESP	2 bits	Output	Write response
BVALID	1 bit	Output	Write response channel valid
BREADY	1 bit	Input	Write response channel ready

Table 8-6: FPGA-to-HPS Bridge Slave Read Address Channel Signals

Signal	Width	Direction	Description
ARID	8 bits	Input	Read address ID
ARADDR	32 bits	Input	Read address
ARLEN	4 bits	Input	Burst length
ARSIZE	3 bits	Input	Burst size
ARBURST	2 bits	Input	Burst type
ARLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
ARCACHE	4 bits	Input	Cache policy type
ARPROT	3 bits	Input	Protection type
ARVALID	1 bit	Input	Read address channel valid
ARREADY	1 bit	Output	Read address channel ready
ARUSER	5 bits	Input	Read user sideband signals

Table 8-7: FPGA-to-HPS Bridge Slave Read Data Channel Signals

Signal	Width	Direction	Description
RID	8 bits	Output	Read ID
RDATA	32, 64, or 128 bits	Output	Read data
RRESP	2 bits	Output	Read response
RLAST	1 bit	Output	Read last data identifier

Functional Description of the HPS-to-FPGA Bridge

The HPS-to-FPGA bridge provides a configurable-width, high-performance master interface to the FPGA fabric. The bridge provides most masters in the HPS with access to logic and peripherals implemented in the FPGA. The effective size of the address space is 0x3FFF0000, or 1 gigabyte (GB) minus the 64 megabytes (MB) occupied by peripherals, lightweight HPS-to-FPGA bridge, and on-chip RAM in the HPS. You can configure the bridge master exposed to the FPGA fabric for 32-, 64-, or 128-bit data. The amount of address space exposed to the MPU subsystem can also be reduced through the L2 cache address filtering mechanism.

The HPS-to-FPGA bridge multiplexes the configured data width from the L3 interconnect to the FPGA interface. The bridge provides width adaptation and clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

Warning: The HPS-to-FPGA bridge is accessed if the MPU boots from the FPGA. Before the MPU boots from the FPGA, the FPGA portion of the SoC device must be configured, and the HPS-to-FPGA bridge must be remapped into addressable space. Otherwise, access to the HPS-to-FPGA bridge during the boot process results in a bus error.

Table 8-8: HPS-to-FPGA Bridge Properties

The following table lists the properties of the HPS-to-FPGA bridge, including the configurable master interface exposed to the FPGA fabric.

Bridge Property	Value
Data width [18]	32, 64, or 128 bits
Clock domain	hps2fpga_clk
Byte address width	30 bits
ID width	4 bits
Read acceptance	16 transactions
Write acceptance	16 transactions
Total acceptance	16 transactions

[18] The bridge master data width is user-configurable at the time you instantiate the HPS component in your system.

The HPS-to-FPGA bridge is configurable in the HPS component parameter editor, available in Qsys and the IP Catalog. The HPS component parameter editor allows you to set the data path width and the bridge protocol, according to the FPGA bitstream.

Functional Description of the Lightweight HPS-to-FPGA Bridge

The lightweight HPS-to-FPGA bridge provides a lower-performance interface to the FPGA fabric. This interface is useful for accessing the control and status registers of soft peripherals. The bridge provides a 2 MB address space and access to logic, peripherals, and memory implemented in the FPGA fabric. The MPU subsystem, direct memory access (DMA) controller, and debug access port (DAP) can use the lightweight HPS-to-FPGA bridge to access the FPGA fabric or NoC registers.

The lightweight HPS-to-FPGA bridge has a fixed data width of 32 bits.

Use the lightweight HPS-to-FPGA bridge as a secondary, lower-performance master interface to the FPGA fabric. With a fixed width and a smaller address space, the lightweight bridge is useful for low-bandwidth traffic, such as memory-mapped register accesses to FPGA peripherals. This approach diverts traffic from the high-performance HPS-to-FPGA bridge, and can improve both register access latency and overall system performance.

Warning: Before the lightweight HPS-to-FPGA bridge can be accessed, the FPGA portion of the SoC device must be configured, and the lightweight HPS-to-FPGA bridge must be remapped into addressable space. Otherwise, accesses to the lightweight HPS-to-FPGA bridge will result in a bus error.

Table 8-14: Lightweight HPS-to-FPGA Bridge Properties

This table lists the properties of the lightweight HPS-to-FPGA bridge, including the master interface exposed to the FPGA fabric.

Bridge Property	Value
Data width	32 bits
Clock domain	lwh2fpga_clk
Byte address width	21 bits
ID width	4 bits
Read acceptance	16 transactions
Write acceptance	16 transactions
Total acceptance	16 transactions

The lightweight HPS-to-FPGA bridge is configurable in the HPS component parameter editor, available in Qsys and the IP Catalog. The HPS component parameter editor allows you to set the bridge protocol, according to the FPGA bitstream.

Lightweight HPS-to-FPGA Bridge Master Signals

All the lightweight HPS-to-FPGA bridge master signals have a fixed width.

The lightweight HPS-to-FPGA bridge incorporates ARM's TrustZone technology by providing the ARPROT[1] and AWPROT[1] signals, which specify whether a transaction is secure or nonsecure. The firewall logic uses the AxPROT signals to determine if a bus transaction matches the security level allowed. You can program security values in the Secure Configuration Registers of the system interconnect.

All peripheral slaves and memories in the SoC are secure when they are released from reset.

The following tables list all the signals exposed by the lightweight HPS-to-FPGA master interface to the FPGA fabric.

Clocks and Resets

FPGA-to-HPS Bridge Clocks and Resets

The master interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The slave interface exposed to the FPGA fabric operates in the `fpga2hps_clk` clock domain provided by the user logic. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The FPGA-to-HPS bridge has one reset signal, `fpga2hps_bridge_rst_n`. The reset manager drives this signal to the FPGA-to-HPS bridge on a cold or warm reset.

Related Information

- **Clock Manager** on page 2-1
- **HPS Component Interfaces** on page 28-1
  Information about the HPS-FPGA bridge clock interfaces

HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `hps2fpga_clk` clock domain. The clock is provided by user logic. The slave interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The HPS-to-FPGA bridge has one reset signal, `hps2fpga_bridge_rst_n`. The reset manager drives this signal to the HPS-to-FPGA bridge on a cold or warm reset.

Related Information

- **Clock Manager** on page 2-1

  Information about the HPS-FPGA bridge clock interfaces

Lightweight HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `lwh2fpga_clk` clock domain. The clock is provided by custom logic in the FPGA fabric. The slave interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The lightweight HPS-to-FPGA bridge has one reset signal, `lwhps2fpga_bridge_rst_n`. The reset manager drives this signal to the lightweight HPS-to-FPGA bridge on a cold or warm reset.

Related Information

- **Clock Manager** on page 2-1
- **HPS Component Interfaces** on page 28-1
  Information about the HPS-FPGA bridge clock interfaces

Taking HPS-FPGA Bridges Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Modules Requiring Software Deassert on page 3-13
Reset register names

Data Width Sizing

The HPS-to-FPGA and FPGA-to-HPS bridges allow 32-, 64-, and 128-bit interfaces to be exposed to the FPGA fabric. For 32-bit and 128-bit interfaces, the bridge performs data width conversion to the fixed 64-bit interface within the HPS. This conversion is called *upsizing* in the case of data being converted from a 64-bit interface to a 128-bit interface. It is called *downsizing* in the case of data being converted from a 64-bit interface to a 32-bit interface. If an exclusive access is split into multiple transactions, the transactions lose their exclusive access information.

During the upsizing or downsizing process, transactions can also be resized using a data merging technique. For example, in the case of a 32-bit to 64-bit upsizing, if the size of each beat entering the bridge's 32-bit interface is only two bytes, the bridge can merge up to four beats to form a single 64-bit beat. Similarly, in the case of a 128-bit to 64-bit downsizing, if the size of each beat entering the bridge's 128-bit interface is only four bytes, the bridge can merge two beats to form a single 64-bit beat.

Ready Latency Support

The HPS-to-FPGA and FPGA-to-HPS bridges support an optional ready latency feature, which allows your design to run at a higher F_{MAX}. When enabled, this feature adds a pipeline stage between the HPS and the FPGA fabric to improve ready/valid handshake timing. Enabling this feature entails a minimal increase in bridge latency.

You can enable this feature when you instantiate the HPS component in Qsys.

The hard processor system (HPS) in the Altera SoC device includes a stand-alone, full-featured ARM Cortex-A9, dual-core 32-bit application processor. The Cortex-A9 microprocessor unit (MPU) subsystem is composed of a Cortex-A9 MPCore, a level 2 (L2) cache, and debugging modules.

Features of the Cortex-A9 MPU Subsystem

The Altera Cortex-A9 MPU subsystem provides the following features:

- Two ARM Cortex-A9 processors, each with the following support modules:
  - ARM NEON single instruction, multiple data (SIMD) coprocesoor
  - Memory Management Unit (MMU)
  - 32 KB instruction cache
  - 32 KB data cache
  - Private interval timer
  - Private watchdog timer
- Interrupt controller
- Global timer
- Snoop control unit (SCU)
- Accelerator Coherency Port (ACP)
- ARM L2 cache controller
- TrustZone system security extensions
- Symmetric multiprocessing (SMP) and asymmetric multiprocessing (AMP) modes
- Debugging modules

The Cortex-A9 MPU incorporates the following core and L2 cache versions:

Table 9-1: Cortex-A9 MPU Module Versions

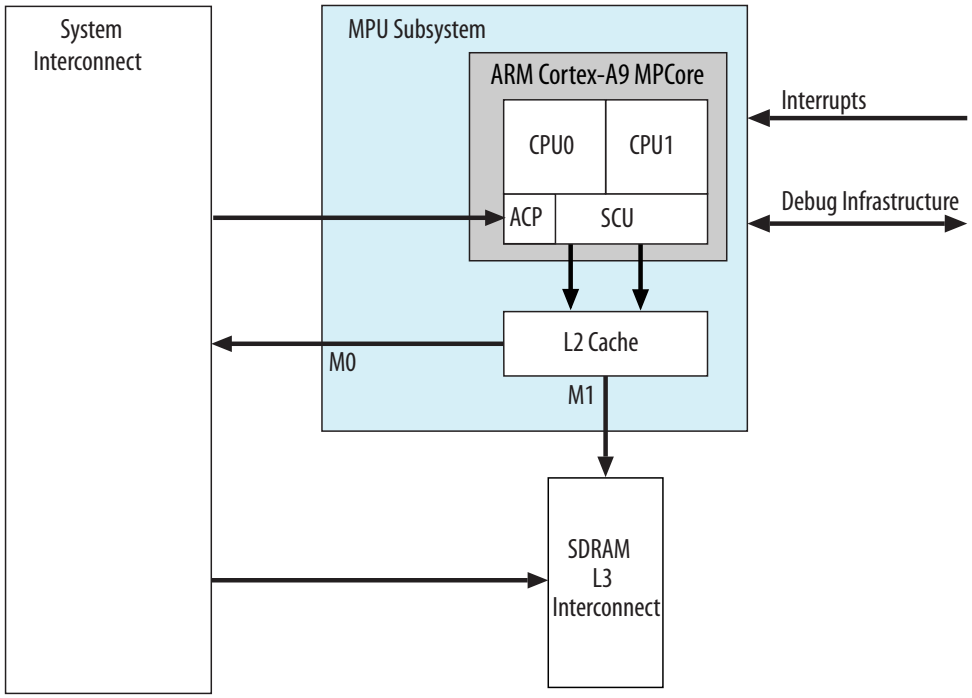
Feature	Version
Cortex-A9 Core	r4p1
L2-310 Level 2 Cache Controller	r3p3

Cortex-A9 MPU Subsystem Block Diagram and System Integration

Cortex-A9 MPU Subsystem with System Interconnect

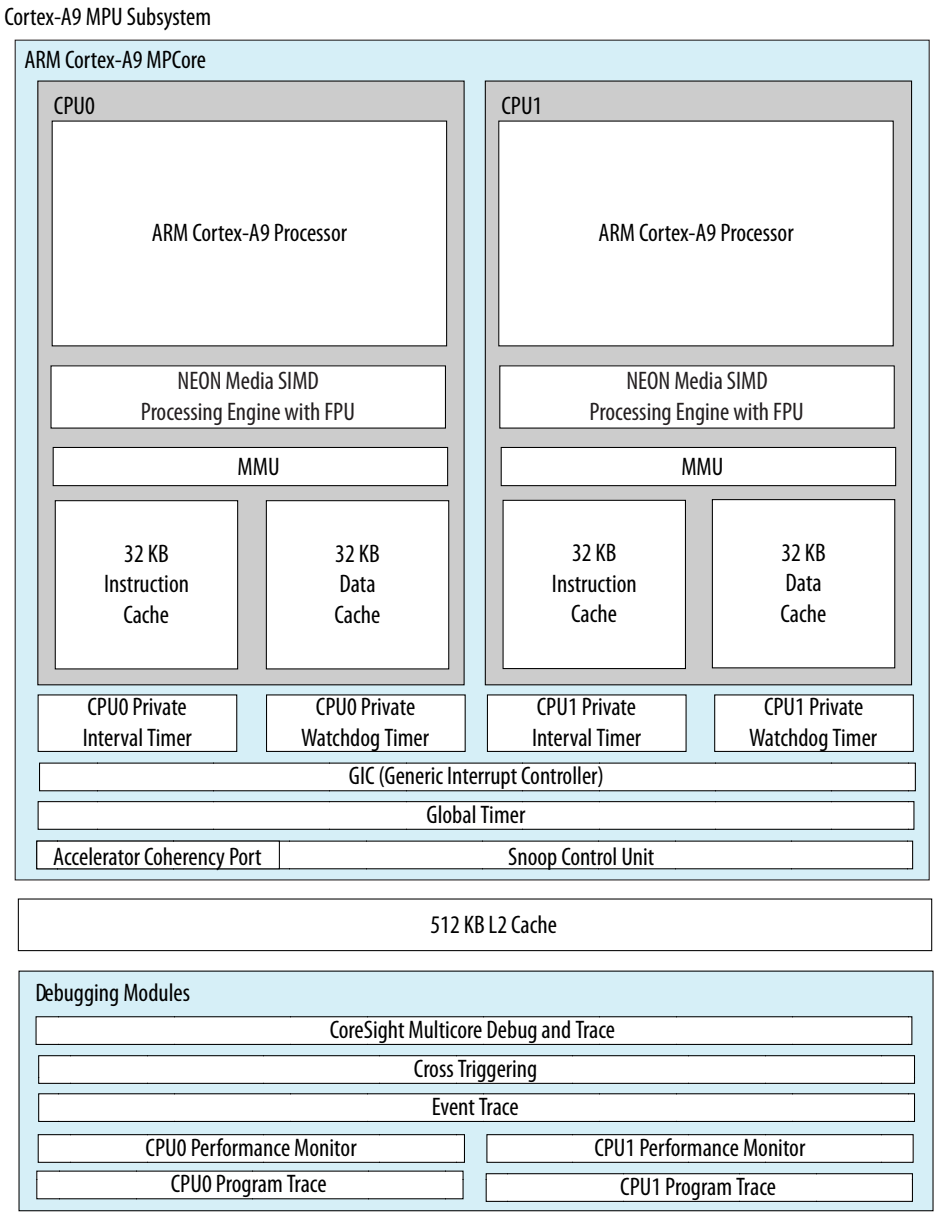
This block diagram shows a dual-core MPU subsystem in the context of the HPS, with the L2 cache. The L2 cache can access either the system interconnect or the SDRAM L3 Interconnect.

Figure 9-1: Cortex-A9 MPU Subsystem with Interconnect Block Diagram



Cortex-A9 MPU Subsystem Internals

Figure 9-2: Cortex-A9 MPU Subsystem Block Diagram



Cortex-A9 MPCore

The MPU subsystem includes a stand-alone, full-featured ARM Cortex-A9 MPCore dual-core 32-bit application processor. The processor, like other HPS masters, can access soft IP in the FPGA fabric through the HPS-to-FPGA bridges.

Functional Description

The ARM Cortex-A9 MPCore contains the following sub-modules:

- Two Cortex-A9 Revision r4p1 processors operating in SMP or AMP mode
- Snoop control unit (SCU)
- Private interval timer for each processor core
- Private watchdog timer for each processor core
- Global timer
- Interrupt controller

Each transaction originating from the Altera Cortex-A9 MPU subsystem can be flagged as secure or non-secure.

Implementation Details

Table 9-2: Cortex-A9 MPCore Processor Configuration

This table shows the parameter settings for the Altera Cortex-A9 MPCore.

Feature	Options
Cortex-A9 processors	2
Instruction cache size per Cortex-A9 processor	32 KB
Data cache size per Cortex-A9 processor	32 KB
TLB size per Cortex-A9 processor	512 entries
Media Processing Engine with NEON™ technology per Cortex-A9 processor(19)	Included
Preload Engine per Cortex-A9 processor	Included
Number of entries in the Preload Engine FIFO per Cortex-A9 processor	16
Jazelle DBX extension per Cortex-A9 processor	Full
Program Trace Macrocell (PTM) interface per Cortex-A9 processor	Included
Support for parity error detection (20)	Included
Master ports	Two
Accelerator Coherency Port	Included

Related Information

(19) Includes support for floating-point operations.

(20) For a description of the parity error scheme and parity error signals, refer to the Cortex-A9 Technical Reference Manual, available on the ARM website (infocenter.arm.com).

Cortex-A9 Processor

Each Cortex-A9 processor includes the following hardware blocks:

- ARM NEON™ single instruction, multiple data (SIMD) coprocessor with vector floating-point (VFP) v3 double-precision floating point unit for media and signal processing acceleration
  - Single- and double-precision IEEE-754 floating point math support
  - Integer and polynomial math support
- Level 1 (L1) cache with parity checking
  - 32 KB four-way set-associative instruction cache
  - 32 KB four-way set-associative data cache
- CoreSight™ Program Trace Macrocell (PTM) supporting instruction trace

Each Cortex-A9 processor supports the following features:

- Dual-issue superscalar pipeline with advanced branch prediction
- Out-of-order (OoO) dispatch and speculative instruction execution
- 2.5 million instructions per second (MIPS) per MHz, based on the Dhrystone 2.1 benchmark
- 2048-entry Branch Target Address Cache (BTAC)
- 512-entry translation lookaside buffer (TLB)
- 64-entry instruction micro-TLB
- TrustZone security extensions
- Configurable data endianness
- Jazelle® DBX Extensions for byte-code dynamic compiler support
- The Cortex-A9 processor architecture supports the following instruction sets:
  - The ARMv7-A performance-optimized instruction set
  - The memory-optimized Thumb®-2 mixed instruction set
    - Improves energy efficiency
    - 31% smaller memory footprint
    - 38% faster than the original Thumb instruction set
  - The Thumb instruction set—supported for legacy applications
- Each processor core in the Altera HPS includes an MMU to support the memory management requirements of common modern operating systems.

The Cortex-A9 processors are designated CPU0 and CPU1.

Related Information

ARM Infocenter

Detailed documentation of ARM Cortex-A9 series processors is available on the ARM Infocenter website.

Reset

When a cold or warm reset is issued in the MPU, CPU0 is released from reset automatically. If CPU1 is present, then its reset signals are left asserted when a cold or warm reset is issued. After CPU0 comes out of reset, it can deassert CPU1's reset signals by clearing the `CPU1` bit in the MPU Module Reset (`mpumodrst`) register in the Reset Manager.

Related Information

Reset Manager on page 3-1

Interactive Debugging Features

Each Cortex-A9 processor has built-in debugging capabilities, including six hardware breakpoints (two with Context ID comparison capability) and four watchpoints. The interactive debugging features can be controlled by external JTAG tools or by processor-based monitor code.

Related Information

ARM Infocenter

For more information about the interactive debugging system, refer to the *Debug* chapter of the Cortex-A9 Technical Reference Manual, available on the ARM Infocenter website.

L1 Caches

Cache memory that is closely coupled with an associated processor is called level 1, or L1 cache. Each Cortex-A9 processor has two independent 32 KB L1 caches—one for instructions and one for data—allowing simultaneous instruction fetches and data access. Each L1 cache is four-way set associative, with 32 bytes per line, and supports parity checking.

Note: A parity error cannot be recovered and is indicated by one of the parity error interrupt signals. On a parity error interrupt, you can reset the system or perform further actions depending on the indication of the interrupt signals.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

Preload Engine

The preload engine (PLE) is a hardware block that enables the L2 cache to preload selected regions of memory.

The PLE signals the L2 cache when a cache line is needed in the L2 cache, by making the processor data master port start fetching the data. The processor data master does not complete the fetch or return the data to the processor. However, the L2 cache can then proceed to load the cache line. The data is only loaded to the L2 cache, not to the L1 cache or processor registers.

The preload functionality is under software control. The following PLE control parameters must be programmed:

- Programmed parameters, including the following:
  - Base address
  - Length of stride
  - Number of blocks
- A valid bit
- TrustZone memory protection for the cache memory, with an NS (non-secure) state bit
- A translation table base (TTB) address
- An Address Space Identifier (ASID) value

Related Information

ARM Infocenter

For more information about the PLE, refer to the *Preload Engine* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

Floating Point Unit

Each ARM Cortex-A9 processor includes full support for IEEE-754 floating point operations.

The floating-point unit (FPU) can execute half-, single-, and double-precision variants of the following operations:

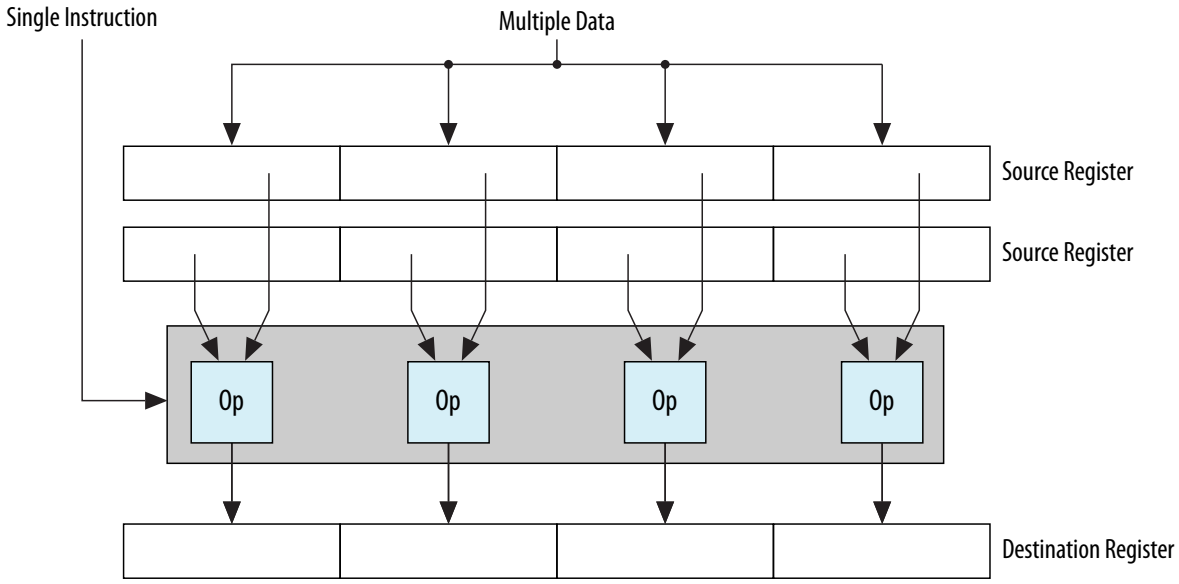
- Add
- Subtract
- Multiply
- Divide
- Multiply and accumulate (MAC)
- Square root

The FPU also converts between floating-point data formats and integers, including special operations to round towards zero required by high-level languages.

NEON Multimedia Processing Engine

The NEON multimedia processing engine (MPE) provides hardware acceleration for media and signal processing applications. Each CPU includes an ARM NEON MPE that supports SIMD processing.

Single Instruction, Multiple Data (SIMD) Processing



Features of the NEON MPE

The NEON processing engine accelerates multimedia and signal processing algorithms such as video encoding and decoding, 2-D and 3-D graphics, audio and speech processing, image processing, telephony, and sound synthesis.

The Cortex-A9 NEON MPE performs the following types of operations:

- SIMD and scalar single-precision floating-point computations
- Scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- 8-, 16-, 32-, and 64-bit signed and unsigned integer SIMD computation
- 8-bit or 16-bit polynomial computation for single-bit coefficients

The following operations are available:

- Addition and subtraction
- Multiplication with optional accumulation (MAC)
- Maximum- or minimum-value driven lane selection operations
- Inverse square root approximation
- Comprehensive data-structure load instructions, including register-bank-resident table lookup

Related Information

ARM Infocenter
For more information about the Cortex-A9 NEON MPE, refer to the Cortex-A9 NEON™ Media Processing Engine Technical Reference Manual, which you can download from the ARM Infocenter website.

Memory Management Unit

The MMU is used in conjunction with the L1 and L2 caches to translate virtual addresses used by software to physical addresses used by hardware. Each processor has a private MMU.

TLBs Supported By the MMU

TLB Type	Memory Type	Number of Entries	Associativity
Micro TLB	Instruction	64	Fully associative
Micro TLB	Data	64	Fully associative
Main TLB	Instruction and Data	512	Two-way associative

TLB Features

The main TLB has the following features:

- Lockable entries using the lock-by-entry model
- Supports hardware page table walks to perform look-ups in the L1 data cache

The MPU address map is divided into the following regions:

- The boot region
- The SDRAM region
- The FPGA slaves region
- The HPS peripherals region

Note: The `SMP` bit in the `ACTLR` register must be set before enabling the MMU.

Related Information

- **ARM Infocenter**
  For more information about the MMU, refer to the *Memory Management Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.
- **Cortex-A9 MPCore Technical Reference Manual**
  For more further information about the `ACTLR register`, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

The Boot Region

The boot region is 1 MB in size, based at address 0. After power-on, or after reset of the system interconnect, the boot region is occupied by the boot ROM, allowing the Cortex-A9 MPCore to boot. Although the boot region size is 1 MB, accesses beyond 128 KB are illegal because the boot ROM is only 128 KB.

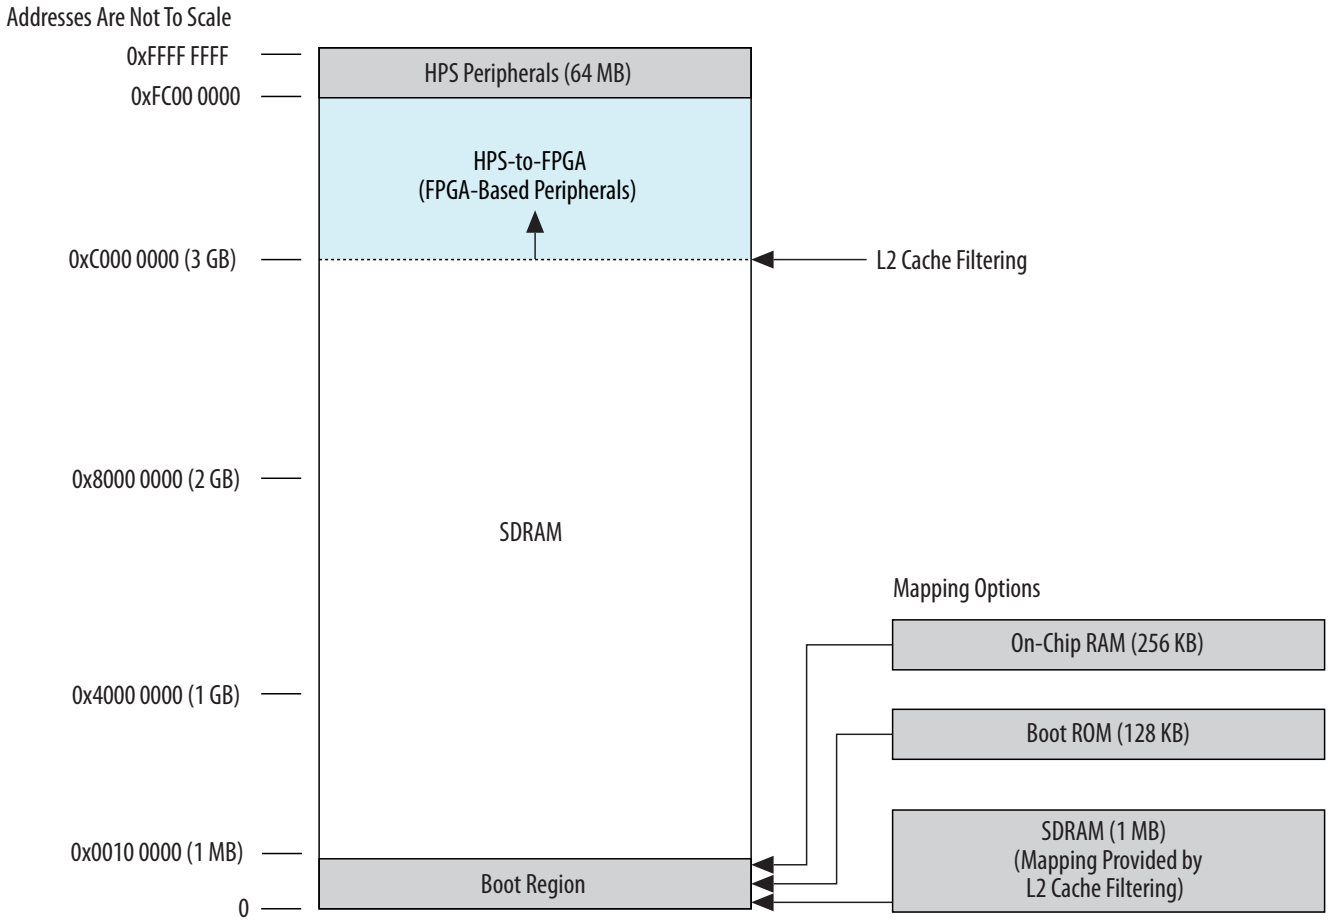
The 1 MB boot region can be subsequently remapped to the bottom 1 MB of SDRAM region by adjusting the L2 cache address filter.

Note: Alternatively, the boot region can be mapped to the 256 KB on-chip RAM.

Related Information

- **Address Remapping** on page 7-19
  For more information about address remapping
- **System Interconnect** on page 7-1

Boot ROM Mapping



The SDRAM Region

The SDRAM region starts at address `0x100000` (1 MB). The top of the region is determined by the L2 cache filter.

The L2 cache contains a filtering mechanism that routes accesses to the SDRAM L3 interconnect and system interconnect. The filter defines a filter range with start and end addresses. Any access within this filter range is routed to the SDRAM L3 interconnect. Accesses outside of this filter range are routed to the system interconnect.

The start and end addresses are specified in the following register fields:

- `reg12_addr_filtering_start.address_filtering_start`
- `reg12_address_filtering_end.address_filtering_end`

To remap the lower 1MB of SDRAM into the boot region, set the filter start address to `0x0` to ensure accesses between `0x0` and `0xFFFFF` are routed to the SDRAM. Independently, you can set the filter end address in 1 MB increments above `0xC0000000` to extend the upper bounds of the SDRAM region. However, you achieve this extended range at the expense of the FPGA peripheral address span. Depending on the address filter settings in the L2 cache, the top of the SDRAM region can range from `0xBFFFFFFF` to `0xFBFFFFFF`.

Related Information

L2 Cache on page 9-34

The FPGA Slaves Region

The Cortex-A9 MPU subsystem supports the variable-sized FPGA slaves region to communicate with FPGA-based peripherals. This region can start as low as `0xC0000000`, depending on the L2 cache filter settings. The top of the FPGA slaves region is located at `0xFBFFFFFF`. As a result, the size of the FPGA slaves region can range from 0 to `0x3C000000` bytes.

The HPS Peripherals Region

The HPS peripherals region is the top 64 MB in the address space, starting at `0xFC000000` and extending to `0xFFFFFFFF`. The HPS peripherals region is always allocated to the HPS dedicated peripherals for the Altera Cortex-A9 MPU subsystem.

Performance Monitoring Unit

Each Cortex-A9 processor has a Performance Monitoring Unit (PMU). The PMU supports 58 events to gather statistics on the operation of the processor and memory system. Six counters in the PMU accumulate the events in real time. The PMU counters are accessible either from the processor itself, using the Coprocessor 14 (CP14) interface, or from an external debugger. The events are also supplied to the PTM and can be used for trigger or trace.

Related Information

ARM Infocenter

For more information about the PMU, refer to the *Performance Monitoring Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

ARM Cortex-A9 MPCore Timers

There is one interval timer and one watchdog timer for each processor.

Functional Description

Each timer is private, meaning that only its associated processor can access it. If the watchdog timer is not needed, it can be configured as a second interval timer.

Each private interval and watchdog timer has the following features:

- A 32-bit counter that optionally generates an interrupt when it reaches zero
- Configurable starting values for the counter
- An eight-bit prescaler value to qualify the clock period

Implementation Details

The timers are configurable to either single-shot or auto-reload mode. The timer blocks are clocked by `mpu_periph_clk` running at ¼ the rate of the `mpu_clk`.

Related Information

ARM Infocenter
For more information about private timers, refer to "About the private timer and watchdog blocks" in the *Global timer, Private timers, and Watchdog registers* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

Generic Interrupt Controller

Functional Description

The PL390 Generic Interrupt Controller (GIC) supports up to 128 interrupt sources, including dedicated peripherals and IP implemented in the FPGA fabric. In a dual-core system, the GIC is shared by both Cortex-A9 processors. Each processor also has 16 banked software-generated interrupts and 16 banked private peripheral interrupts, which occupy GIC interrupt numbers 0 to 31.

Implementation Details

The configuration and control for the GIC is memory-mapped and accessed through the SCU. The GIC are clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Global Timer

The MPU features a global 64-bit, auto-incrementing timer, which is primarily used by the operating system.

Functional Description

The global timer is accessible by the processors using memory-mapped access through the SCU. The global timer has the following features:

- 64-bit incrementing counter with an auto-incrementing feature. It continues incrementing after sending interrupts.
- Memory-mapped in the private memory region.
- Accessed at reset in Secure State only. It can only be set once, but secure code can read it at any time.
- Accessible to both Cortex-A9 processors in the MPCore.
- Clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Implementation Details

Each Cortex-A9 processor has a private 64-bit comparator that generates a private interrupt when the counter reaches the specified value. Each Cortex-A9 processor uses the banked ID, ID27, for this interrupt. ID27 is sent to the GIC as a Private Peripheral Interrupt (PPI).

The global timer is clocked by mpu_periph_clk, running at ¼ the rate of mpu_clk.

Related Information

ARM Infocenter

For more information about the global timer, refer to "About the Global Timer" in the *Global timer, Private timers, and Watchdog registers* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

Snoop Control Unit

The SCU manages data traffic for the Cortex-A9 processors and the memory system, including the L2 cache. In a multi-master system, the processors and other masters can operate on shared data. The SCU ensures that each processor operates on the most up-to-date copy of data, maintaining cache coherency.

Functional Description

The SCU is used to connect the Cortex-A9 processors and the ACP to the L2 cache controller. The SCU performs the following functions:

- When the processors are set to SMP mode, the SCU maintains data cache coherency between the processors.

  Note: The SCU does not maintain coherency of the instruction caches.
- Initiates L2 cache memory accesses
- Arbitrates between processors requesting L2 access
- Manages ACP access with cache coherency capabilities.

Related Information

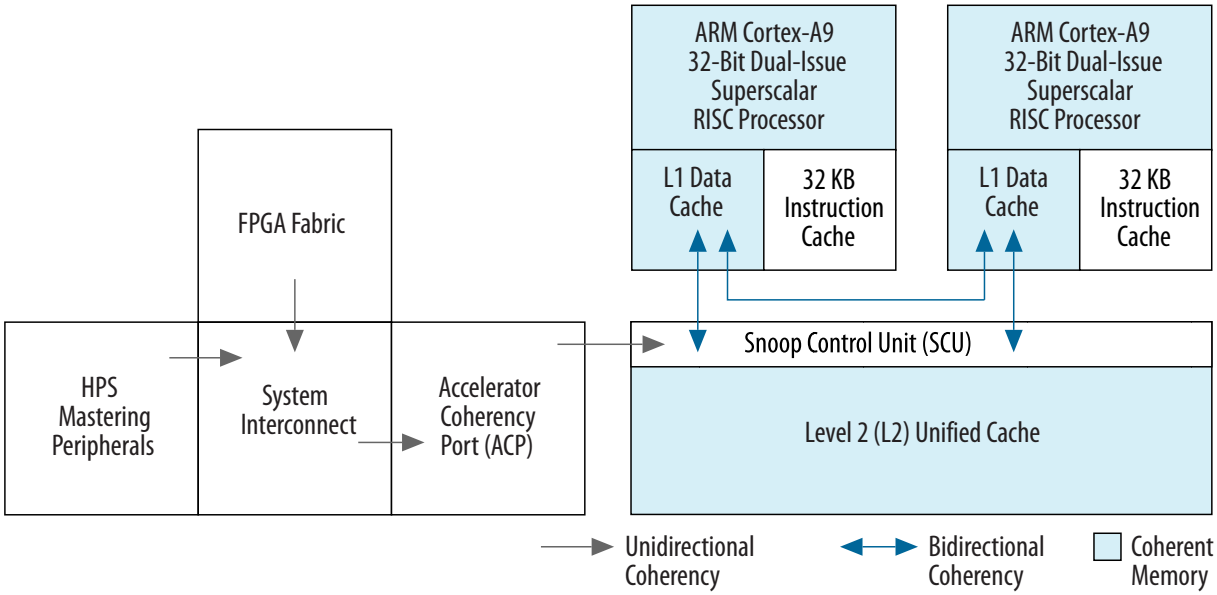
ARM Infocenter

For more information about the SCU, refer to the *Snoop Control Unit* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

Coherent Memory, Snoop Control Unit, and Accelerator Coherency Port

Figure 9-3: Data Flow Between L1 Caches and SCU

This diagram illustrates the flow of data among the L1 data caches and the SCU.



Related Information

Accelerator Coherency Port on page 9-29

Implementation Details

When the processor writes to any coherent memory location, the SCU ensures that the relevant data is coherent (updated, tagged or invalidated). Similarly, the SCU monitors read operations from a coherent memory location. If the required data is already stored within the other processor's L1 cache, the data is returned directly to the requesting processor. If the data is not in L1 cache, the SCU issues a read to the L2 cache. If the data is not in the L2 cache memory, the read is finally forwarded to main memory. The primary goal is to maximize overall memory performance and minimize power consumption.

The SCU maintains bidirectional coherency between the L1 data caches belonging to the processors. When one processor performs a cacheable write, if the same location is cached in the other L1 cache, the SCU updates it.

Non-coherent data passes through as a standard read or write operation.

The SCU also arbitrates between the Cortex-A9 processors if both attempt simultaneous access to the L2 cache, and manages accesses from the ACP.

Accelerator Coherency Port

The ACP allows master peripherals—including FPGA-based master peripherals—to maintain data coherency with the Cortex-A9 MPCore processors and the SCU. Dedicated master peripherals in the HPS,

and those built in FPGA logic, access the coherent memory through the ACP. Cacheable master accesses from the system interconnect are redirected to the ACP.

The ACP port allows one-way coherency. One-way coherency allows an external ACP master to see the coherent memory of the Cortex-A9 processors but does not allow the Cortex-A9 processors to see memory changes outside of the cache.

A master on the ACP port can read coherent memory directly from the L1 and L2 caches, but cannot write directly to the L1 cache. The possible ACP master read and write scenarios are as follows:

- ACP master read with coherent data in the L1 cache: The ACP gets data directly from the L1 cache and the read is interleaved with a processor access to the L1 cache.
- ACP master read with coherent data in L2 cache: The ACP request is queued in the SCU and the transaction is sent to the L2 cache.
- ACP master read with coherent data not in L1 or L2 cache: Depending on the previous state of the data, the L1 or L2 cache may request the data from the L3 system interconnect. The ACP is stalled until data is available, however ACP support of multiple outstanding transactions minimizes bottlenecks.
- ACP master write with coherent data in the L1 cache: The L1 cache data is marked as invalid in the Cortex-A9 MPU and the line is evicted from the L1 cache and sent to L2 memory. The ACP write data is scheduled in the SCU and is eventually written to the L2 cache. Later, when the Cortex-A9 processor accesses the same memory location, a cache miss in the L1 occurs.
- ACP master write, with coherent data in the L2 cache: The ACP write is scheduled in the SCU and then is written into the L2 cache.
- ACP master write, with coherent data not in L1 or L2 cache: ACP write is scheduled.

An ACP transaction is generated when a master on the system interconnect has its `AxCACHE[1]` attribute signal set to 1, which indicates a coherent request. All transactions that are set as cacheable are routed to the ACP instead of the normal mapping and are treated as coherent by the cache controllers of the MPU subsystem. The ACP ID generation follows an allocation mechanism that ensures that requests with the same master initiator flow and sequence identifiers always allocate the same local sequence ID and that requests with different identifiers always have different IDs. In addition, if an allocator runs out of sequence IDs, the ACP stalls requests until the reception of responses makes new sequence IDs available. Therefore, the guaranteed number of pending transactions that the interconnect can have is up to four pending transactions, with the allowed AXI ID[2:0] values of 0x4 through 0x7. AxID[2:0] values of 0x0 and 0x1 are assigned to CPU0 and CPU1, respectively.

Note: The entire 4 GB address space can be accessed coherently through the ACP.

Note: Refer to the Arria 10 SoC device errata for details on ARM errata that directly affect the ACP.

AxUSER and AxCACHE Attributes

ARUSER[0] and AWUSER[0] Bits

The ACP distinguishes between shared and non-shared requests with the `ARUSER[0]` and `AWUSER[0]` signals. The other AxUSER signals, `AxUSER[4:1]` are not interpreted by the SCU and are simply forwarded to the L2 cache. They are typically set to `AxUSER[4:1]` = b'1111.The `AxCACHE[1]` attribute signals must

also be set to allow L1 caches to be snooped. Sideband signals ARUSER[4:1] and AWUSER[4:1] convey the inner cache attributes.

The table below shows how the AxUSER[0] bit determines whether a request is shared or non-shared. ARUSER[0] applies to read transactions, and AWUSER[0] applies to write transactions.

Table 9-4: ARUSER[0] or AWUSER[0] Sideband Signal Information

ARUSER[0] or AWUSER[0]	Sideband Signal Information
1	Shared request
0	Non-shared request

Other AxUSER bits from the ACP are not interpreted by the SCU but are forwarded to the L2 cache.

ARCACHE[4:0] and AWCACHE[4:0] Bits

The Cortex-A9 MPU only interprets ARCACHE[1] and AWCACHE[1] from ACP requests. All other attributes are forwarded to the L2 cache. AxCACHE[1] is used in combination with AxUSER[0] to detect a coherent access. If AxCACHE[1]=0x1, (normal memory) and AxUSER[0]=0x1, then the access is considered coherent. All ACP requests with AxCACHE[1]=0x0 or AxUSER[0]=0x0 are seen as non-coherent requests.

Table 9-5: ARUSER[0] or AWUSER[0] Sideband Signal Information

ARCACHE[1] or AWCACHE[1]	ARUSER[0] or AWUSER[0]	Access Type
1	1	Coherent request
0	0	Non-coherent request

Cache Coherency for ACP Shared Requests

When a shared access is received on the ACP, caches are checked for coherency of the requested address. A shared access occurs when two masters access the same memory space.

This coherency check is performed by the SCU. If a cache hit occurs during a write access, the affected cache lines are cleaned and invalidated. This event may cause an eviction from the L1 cache to be sent to L2 memory if the L1 cache line is dirty. Once the invalidation and possible eviction is completed, the ACP write request is written to L2 memory. If an eviction was executed from L1 cache, then two consecutive writes to L2 memory occur over the AXI bus: the write from the eviction and the write from the ACP.

For a cache hit during a read access, the L1 cache line is provided by the CPU and is returned to the ACP.

For a cache miss during a write access, the invalidation is considered as complete and the ACP request is sent to L2 memory.

For a cache miss during a read access, the request is forwarded to L2 memory, which returns the data directly to the ACP.

Note: Shared write requests are always transferred to the L2 memory once the cache line is potentially clean and invalidated in the L1 cache memory. Reads are observed on the L2 only if they miss in the L1 cache.

AXI Master Configuration for ACP Access

To use the ACP for coherent accesses, the following configurations apply:

ACP master configurations must be as follows:

- For coherent ACP read accesses, the AXI bits must be programmed as follows to avoid compromising coherency:
  - `AxCACHE[3:0]` attributes must match the properties defined in the Cortex-A9 MPCore MMU page tables for the relevant memory region.
  - Shareable attribute `AxUSER[0]` must be set to 0x1

The Cortex-A9 MPCore configuration for ACP use should be as follows:

- The Snoop Control Unit must be enabled (by setting the SCU enable bit in the SCU Control Register at 0xFFFFC000).
- Coherent memory must be marked cacheable and shareable.
- The `SMP` bit of the `ACTLR` register must be set in the Cortex-A9 processor that shares data over the ACP.

Note: To achieve maximum performance on the ACP, avoid switching from shared to non-shared requests and vice-versa. When a shared request is latched in the ACP and there are non-shared requests still pending, the non-shared requests must be completed before the shared request can proceed.

The following sections detail the attribute configurations necessary to support coherency.

Configuring AxCACHE[3:0] Sideband Signals for Coherent Accesses

The following list highlights how to correctly derive and apply the correct `AxCACHE` settings for coherent accesses.

- The correct `AxCACHE[3:0]` setting is dependent on the MMU page table settings. However, for coherent accesses, `AxCACHE[1]` must be set to 0x1.
- For HPS masters, `AxCACHE[3:0]` is static and applied to the relevant master port through the System Manager.
- For FPGA masters, `AxCACHE[3:0]` is applied in the FPGA fabric and can be set for each access.

Related Information

- **System Manager** on page 5-1
  For more information about programming AxCACHE[3:0] through the System Manager
- **Cortex-A9 MPCore Technical Reference Manual**
  For more information about the Accelerator Coherency Port.

Configuring AxUSER[4:0] Sideband Signals

The following list highlights how to correctly derive and apply the correct `AxUSER` settings for coherent accesses.

- AxUSER[0] (shared attribute) must be set to 0x1 for coherent accesses.
- Because the ACP has no inner cache policy, AxUSER[3:1] is not interpreted by the SCU. AxUSER[3:1] attributes pass to the L2 cache controller and are used when the cache is operating in exclusive mode.
- For FPGA masters, AxUSER[4:0] is applied in the FPGA fabric and can be set for each access.

Related Information

Cortex-A9 MPCore Technical Reference Manual
For more information about the Accelerator Coherency Port.

Burst Sizes and Byte Strobes

The ACP improves system performance for hardware accelerators in the FPGA fabric. However, in order to achieve high levels of performance, you must use the one of the optimized burst types. Other burst configurations have significantly lower performance.

Recommended Burst Types

Table 9-6: Recommended Burst Types for Optimized Bursts

Burst Type	Beats	Width (Bits)	Address Type	Byte Strobes
Wrapping	4	64	64-bit aligned	Asserted
Incrementing	4	64	32-bit aligned	Asserted

Note: If the slave port of the FPGA-to-HPS bridge is not 64 bits wide, you must supply bursts to the FPGA-to-HPS bridge that are upsized or downsized to the burst types above. For example, if the slave data width of the FPGA-to-HPS bridge is 32 bits, then bursts of eight beats by 32 bits are required to access the ACP efficiently.

Note: If the address and burst size of the transaction to the ACP matches either of the conditions shown in the table "Recommended Burst Types for Optimized Bursts", the logic in the MPU assumes the transaction has all its byte strobes set. If the byte strobes are not all set, then the write does not actually overwrite all the bytes in the word. Instead, the cache assumes the whole cache line is valid. If this line is dirty (and therefore gets written out to SDRAM), data corruption might occur.

In addition to optimizing performance, using a 64-bit access width will allow you to use ECC. ECC is only supported for 64-bit accesses that are 64-bit aligned..

Related Information

Single Event Upset Protection on page 9-37

Exclusive and Locked Accesses

The ACP does not support exclusive accesses to coherent memory. To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM L3 interconnect scheduler. The AXI buses that interface to the scheduler provide ARLOCK[0] and AWLOCK[0] signals which are used by the

scheduler to arbitrate for exclusive access to a memory location. The SDRAM L3 scheduler contains one monitor for each of the following exclusive-capable masters:

- CPU0
- CPU1
- FPGA-to-HPS
- FPGA-to-SDRAM0
- FPGA-to-SDRAM1
- FPGA-to-SDRAM2

Each monitor only tracks one exclusive address.

Related Information

System Interconnect on page 7-1
To learn more about Exclusive Monitors in the System Interconnect, refer to the System Interconnect Chapter.

L2 Cache

The MPU subsystem includes a secondary 512 KB L2 shared, unified cache memory.

Functional Description

The L2 cache is much larger than the L1 cache. The L2 cache has significantly lower latency than external memory. The L2 cache is up to eight-way associative, configurable down to one-way (direct mapped). Like the L1 cache, the L2 cache can be locked by cache line, locked by way, or locked by master (CPU and ACP masters).

The L2 cache implements error correction codes (ECCs) and ECC error reporting. The cache can report a number of events to the processor and operating system.

Related Information

Cortex-A9 MPU Subsystem Register Implementation on page 9-46
For more information regarding the L2 Cache Controller Address Map, refer to the *Cortex-A9 MPU Subsystem Register Implementation* section.

Cache Controller Configuration

The L2 cache consists of the ARM L2C-310 L2 cache controller configured as follows:

- 512 KB total memory
- Eight-way associativity
- Physically addressed, physically tagged
- Line length of 32 bytes
- Critical first word linefills

- Support for all AXI cache modes
  - Write-through
  - Write-back
  - Read allocate
  - Write allocate
  - Read and write allocate
- Single event upset (SEU) protection
  - Parity on Tag RAM
  - ECC on L2 Data RAM
- Two slave ports mastered by the SCU
- Two master ports connected to the following slave ports:
  - SDRAM L3 interconnect, 64-bit slave port width
  - L3 interconnect, 64-bit slave port width
- Cache lockdown capabilities as follows:
  - Line lockdown
  - Lockdown by way
  - Lockdown by master (both processors and ACP masters)
- TrustZone support
- Cache event monitoring

Related Information

- **L2 Cache Event Monitoring** on page 9-36
- **System Manager** on page 5-1
  For more information about SEU errors, refer to the *System Manager* chapter.
- **ARM Infocenter**
  For more information about AXI user sideband signals, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, which you can download from the ARM Infocenter website.

Implementation Details

The following table shows the parameter settings for the cache controller.

Table 9-7: Cache Controller Configuration

Feature	Meaning
Cache way size	64 KB
Number of cache ways	8 ways
Tag RAM write latency	1
Tag RAM read latency	1
Tag RAM setup latency	1
Data RAM write latency	1

Feature	Meaning
Data RAM read latency	2
Data RAM setup latency	1
Parity logic	Parity logic enabled
Lockdown by master	Lockdown by master enabled
Lockdown by line	Lockdown by line enabled
AXI ID width on slave ports	6 AXI ID bits on slave ports
Address filtering	Address filtering logic enabled
Speculative read	Logic for supporting speculative read enabled
Presence of ARUSERMx and AWUSERMx sideband signals	Sideband signals enabled

Related Information

ARM Infocenter

For further information about cache controller configurable options, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available on the ARM Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 9-8: L2 Cache Events

Event	Description
`CO`	Eviction (cast out) of a line from the L2 cache.
`DRHIT`	Data read hit in the L2 cache.
`DRREQ`	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
`DWHIT`	Data write hit in the L2 cache.
`DWREQ`	Data write lookup to the L2 cache. Subsequently results in a hit or miss.

Event	Description
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
SRCONFS1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

ARM Infocenter

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

Single Event Upset Protection

The L2 cache has the option of using ECCs to protect against Single Event Upset (SEU) errors in the cache RAM.

The L2 cache has two types of protection:

- The L2 cache tag RAMs are protected by parity.
- The L2 cache data RAMs are protected using single error correction, double error detection (SECDED) ECC Hamming code.

Enabling ECCs does not affect the performance of the L2 cache. The ECC bits are calculated only for writes to the data RAM that are 64 bits wide (8 bytes, or one-quarter of the cache line length). The ECC logic does not perform a read-modify-write when calculating the ECC bits.

The ECC protection bits are not valid in the following cases:

- Data is written that is not 64-bit aligned in memory
- Data is written that is less than 64 bits in width

In these cases the Byte Write Error interrupt is asserted. Cache data is still written when such an error occurs. However, the ECC error detection and correction continues to function. Therefore, the cache data is likely to be incorrect on subsequent reads.

To use ECCs, the software and system must meet the following requirements:

- L1 and L2 cache must be configured as write-back and write-allocate for any cacheable memory region
- Level 3 interconnect masters using the ACP must only perform the following types of data writes:
  - 64-bit aligned in memory
  - 64-bit wide accesses

  Note that system interconnect masters can include masters in the FPGA accessing the FPGA-to-HPS bridge.

If a correctable ECC error occurs, the ECC corrects the read data in parallel to asserting a correctable error signal on the AXI bus. If an uncorrectable error occurs in the L2 cache, the uncorrected data remains in the L2 cache and an AXI slave error (SLVERR) is sent to the L1 memory system. In addition, interrupts can be enabled for correctable and uncorrectable ECC errors through the GIC.

Related Information

System Manager on page 5-1
For more information about SEU errors, refer to the *System Manager* chapter.

L2 Cache Parity

Because the L2 data RAM is ECC-protected, parity checking on the data RAM is not required. However, because the tag RAM is not ECC protected, it requires parity checking. Because parity cannot be configured independently, parity checking for both the data RAM and tag RAM must be enabled.

Ideally, parity should be enabled before the L2 cache is enabled. If the cache is already enabled, you must clean the cache and disable it before parity is enabled. After enabling parity, the cache is invalidated and enabled. To enable parity:

1. Set the `Parity_on` bit in the L2 `Auxiliary Control register`.
2. Invalidate the L2 cache through the `Cache Maintenance Operations` registers.
3. Enable the cache through the `L2_Cache_enable bit` of the L2 `Control register`.

Note: If you would like the parity errors to be reported you must enable the parity interrupts in the `L2 Interrupt Mask` register along with the corresponding interrupts in the general interrupt controller (GIC).

Refer to the ARM Infocenter website for more information regarding L2 cache registers and programming.

Parity Error Handling

If a parity error occurs in the tag or data RAM during AXI read transactions, a SLVERR response is reported through the event bus and interrupt signals. If a parity error occurs on tag or data RAM during AXI write transactions, a SLVERR response is reported back through a SLVERRINTR interrupt signal. For cache maintenance operations, if a parity error occurs on tag or data RAM, the error is reported back through the interrupt lines only. In addition, the L2 Cache cannot refill a line from external memory due to a parity error.

Related Information

ARM Infocenter

L2 Cache Lockdown Capabilities

The L2 cache has three methods to lock data in the cache RAMs:

- Lockdown by line—Used to lock lines in the cache. This is commonly used for loading critical sections of software into the cache temporarily.
- Lockdown by way—Allows any or all of the eight cache ways to be locked. This is commonly used for loading critical data or code into the cache.
- Lockdown by master-- allows cache ways to be dedicated to a single master port. This allows a large cache to look like smaller caches to multiple master ports. The L2 cache can be mastered by any of the L3 masters (including the FPGA fabric). When using lockdown by master, AXI ID0 and 1 represent CPU0 and CPU1 respectively and AXI IDs 0x4 through 0x7 can be used for the L3 interconnect masters.

Related Information

ARM Infocenter

For more information about L2 cache lockdown capabilities, refer to "Cache operation" in the *Functional Overview* chapter of the *CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual*, available on the ARM Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 9-9: L2 Cache Events

Event	Description
`CO`	Eviction (cast out) of a line from the L2 cache.
`DRHIT`	Data read hit in the L2 cache.

Event	Description
DRREQ	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
DWHIT	Data write hit in the L2 cache.
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
SRCONFS1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

ARM Infocenter
For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

L2 Cache Address Filtering

The L2 cache can access either the system interconnect fabric or the SDRAM L3 interconnect. The L2 cache address filtering determines how much address space is allocated to the HPS-to-FPGA bridge and how much is allocated to SDRAM, depending on the configuration of the memory management unit.

Related Information

- **Cortex-A9 MPU Subsystem with System Interconnect** on page 9-2
- **Memory Management Unit** on page 9-10
  Information about how the address space is set based on L2 cache address filtering.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

CPU Prefetch

The Cortex-A9 performs instruction and data prefetches regardless of the state of the MMU.

A prefetch occurs when any address that is 4 KB above the current instruction pointer is accessed. The system has been designed to ensure that the system bus does not lock on prefetches. Any prefetches to unmapped memory space produce a decode error on the system interconnect.

TrustZone

As platforms allow more outside application downloads and as sensitive data is shared on devices, risks of hardware or data asset attacks rise. The Cortex-A9 MPU subsystem has integrated TrustZone technology which provides a system solution to protect application platforms from malicious attack. The TrustZone hardware and supporting software are designed to provide a strong security solution regardless of the operating environment. TrustZone creates a separation between the secure and non-secure areas of the SoC and allows the designer to choose which assets in a design are designated as secure and non-secure.

TrustZone security is implemented in the Cortex-A9 MPU subsystem in three ways:

- Hardware partitioning: Resources can be assigned and identified as secure or non-secure.
- Virtual processor execution: Each core can context switch between secure and non-secure operation.
- Secure debug control: The MPU subsystem provides both secure and non-secure hardware debug features. The type of debug allowed can be configured by the user.

Related Information

TrustZone
For more information about the use of the TrustZone, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

Secure Partitioning

System interconnect and cache accesses as well as processor execution can be securely partitioned using the TrustZone infrastructure.

Secure Bus Accesses

The Cortex-A9 MPCore and other masters that utilize the system interconnect can be configured for secure or non-secure accesses.

Master accesses drive a protection signal, `AxPROT[1]`, to communicate the security level of the attempted transaction. The Cortex-A9 drives this signal low for secure accesses and high for non-secure accesses. The secure firewalls determine whether the access is allowed or not. A slave access type defaults to secure if no other configuration is programmed. Users can define whether a bus error is generated or if a bus failure occurs when a secure access is violated.

Note: Secure processor configuration is programmed through the `CP15` register.

Related Information

- **Arria 10 HPS Secure Firewalls** on page 6-24
  For more detailed information about secure bus accesses, refer to the "Secure Firewall" section.
- **SoC Security** on page 6-1
  For more information about SoC Security, refer to the *SoC Security* Chapter.

Secure Cache Accesses

Secure and non-secure partitioning also extends to the L1 and L2 caches.

There is a 32-bit physical address space for secure and non-secure transactions and a 33rd bit is provided to indicate security. The cache is able to store both secure and non-secure lines.

The Accelerator Coherency Port (ACP) in the ARM Cortex-A9 MPCore can be used with TrustZone technology. The security state of the masters using the ACP must be the same as the Cortex-A9 processor.

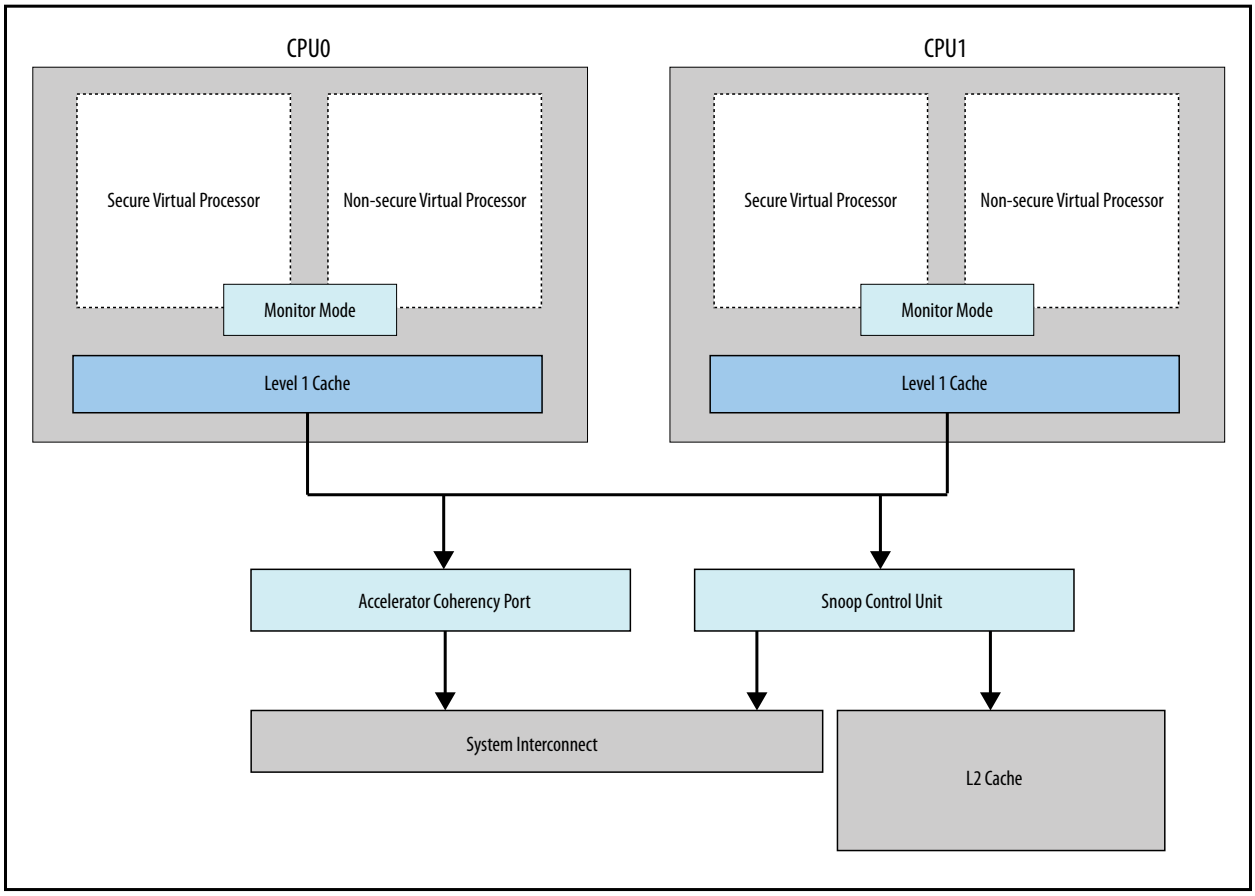
Related Information

- **ARM TrustZone**
  Refer to this location for information about virtual core operation.
- **SoC Security** on page 6-1
  For more information about SoC Security, refer to the *SoC Security* Chapter.

Virtual Processor Operation

Two virtual processors (secure and non-secure) with context switch capability (monitor mode) exist for each Cortex-A9 processor core. The secure virtual processor only accesses secure resources and the non-secure virtual processor only accesses non-secure resources.

Figure 9-4: Virtual Processor Environment with Monitor Mode



A context switch to secure operation is achieved through a secure monitor call (SMC) instruction or the following hardware exceptions (if configured to do so):

- IRQ interrupt
- Faster Interrupt Request (FIQ) interrupt
- External data abort
- External prefetch abort

When a context switch occurs, the state of the current mode is saved and restored on the next context switch or on a return from exception.

Exception Vector Tables

Three exception vector tables are provided for the MPU with TrustZone:

1. Non-secure
2. Secure
3. Monitor mode

Typically IRQs are used for non-secure interrupts and FIQs are used for secure interrupts. The location of each of the three vector tables can be moved at runtime.

The Generic Interrupt Controller (GIC) can handle secure and non-secure interrupts and prevent non-secure accesses from reading or modifying the configuration of a secure interrupt. An interrupt can be made secure by programming the appropriate bits in the Interrupt Security Register. Secure interrupts are always given a higher priority than non-secure interrupts.

Secure Debug

Debug security extensions exist for the MPU subsystem and the system SoC. Secure privileged and user processor debug access can be controlled by two input pins to the core logic. Depending on the configuration of these pins, secure privileged or user JTAG or trace can be used. In addition, normal user debug visibility can be allowed while preventing all secure world debug. To disable all visibility to the core, both secure and non-secure, a global debug pin, `NIDEN`, is provided to the core. Each Cortex-A9 processor in an MPU subsystem has its own dedicated debug visibility signals.

Related Information

CoreSight Debug and Trace on page 10-1

Debugging Modules

The MPU subsystem includes debugging resources through ARM CoreSight on-chip debugging and trace. The following functionality is included:

- Individual program trace for each processor
- Event trace for the Cortex-A9 MPCore
- Cross triggering between processors and other HPS debugging features

Program Trace

Each processor has an independent program trace monitor (PTM) that provides real-time instruction flow trace. The PTM is compatible with a number of third-party debugging tools.

The PTM provides trace data in a highly compressed format. The trace data includes tags for specific points in the program execution flow, called waypoints. Waypoints are specific events or changes in the program flow.

The PTM recognizes and tags the waypoints listed in **Table 9-10**.

Table 9-10: Waypoints Supported by the PTM

Type	Additional Waypoint Information
Indirect branches	Target address and condition code
Direct branches	Condition code
Instruction barrier instructions	—
Exceptions	Location where the exception occurred
Changes in processor instruction set state	—
Changes in processor security state	—
Context ID changes	—
Entry to and return from debug state when Halting debug mode is enabled	—

The PTM optionally provides additional information for waypoints, including the following:

- Processor cycle count between waypoints
- Global timestamp values
- Target addresses for direct branches

Related Information

- **CoreSight Debug and Trace** on page 10-1
- **ARM Infocenter**
  For more information about the PTM, refer to the CoreSight PTM-A9 Technical Reference Manual, available on the ARM Infocenter website.

Event Trace

Events from each processor can be used as inputs to the PTM. The PTM can use these events as trace and trigger conditions.

Related Information

- **Performance Monitoring Unit** on page 9-12
- **ARM Infocenter**
  For more information about the trigger and trace capabilities, refer to the CoreSight PTM-A9 Technical Reference Manual, Revision r1p0, available on the ARM Infocenter website.

Cross-Triggering

The PTM can export trigger events and perform actions on trigger inputs. The cross-trigger signals interface with other HPS debugging components including the FPGA fabric. Also, a breakpoint in one processor can trigger a break in the other.

Related Information

CoreSight Debug and Trace on page 10-1
For detailed information about cross-triggering and about debugging hardware in the MPU, refer to the *CoreSight Debug and Trace* chapter.

Clocks

Three synchronous clocks and two debug clocks are provided to the MPU subsystem.

Table 9-11: MPU Subsystem Clocks

System Clock Name	Use
`mpu_clk`	Main clock for the MPU subsystem
`mpu_periph_clk`	Clock for peripherals inside the MPU subsystem
`mpu_l2_ram_clk`	Clock for L2 cache and AXI interface clocks to and from the system interconnect
`dbg_at_clk`	Trace bus clock
`dbg_clk`	Debug clock

Related Information

Clock Manager on page 2-1

Cortex-A9 MPU Subsystem Register Implementation

The following configurations are available through registers in the Cortex-A9 subsystem:

- All processor-related controls, including the MMU and L1 caches, are controlled using the Coprocessor 15 (CP15) registers of each individual processor.
- All SCU registers, including control for the timers and GIC, are memory mapped.
- All L2 cache registers are memory-mapped.

Related Information

ARM Infocenter
For detailed definitions of the registers for the Altera Cortex-A9 MPU subsystem, refer to the Cortex-A9 MPCore Technical Reference Manual, Revision r4p1 and the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision r3p3, available on the ARM Infocenter website.

Cortex-A9 MPU Subsystem Address Map for Arria 10

The Cortex-A9 MPU subsystem registers reside within the address range from 0xFFFFC000 to 0xFFFFEFFF.

mpu_regs_MPUSCU Address Map

This address space is allocated for the Snoop Control Unit (SCU) registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUSCU	0xFFFFC000	0xFFFFC0FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

mpu_regs_MPUGIC Address Map

This address space is allocated for the General Interrupt Controller (GIC) registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUGIC	0xFFFFC100	0xFFFFC1FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

mpu_regs_MPUGLOBALTIMER Address Map

This address space is allocated for the Global Timer registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUGLOBALTIMER	0xFFFFC200	0xFFFFC5FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

mpu_regs_MPUPRIVATETIMER Address Map

This address space is allocated for the Private Timers and Watchdog registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUPRIVATETIMER	0xFFFFC600	0xFFFFCFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

mpu_regs_MPUINTRDIST Address Map

This address space is allocated for the Interrupt Distributor registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the Cortex-A9 MPCore.

Module Instance	Base Address	End Address
mpu_regs_MPUINTRDIST	0xFFFFD000	0xFFFFEFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

L2 Cache Controller Address Map for Arria 10

The register space for the L2 cache controller ranges from 0xFFFFF000 to 0xFFFFFFFF

l2_regs_L2TYPE Address Map

This address space is allocated for the Cache ID and Cache Type registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2TYPE	0xFFFFF000	0xFFFFF0FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2CONTROL Address Map

This address space is allocated for the Control registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2CONTROL	0xFFFFF100	0xFFFFF1FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2INTERRUPT Address Map

This address space is allocated for the Interrupt and Counter Control registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2INTERRUPT	0xFFFFF200	0xFFFFF6FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2MAINTENANCE Address Map

This address space is allocated for the Cache Maintenance registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2MAINTENANCE	0xFFFFF700	0xFFFFF8FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2LOCKDOWN Address Map

This address space is allocated for the Cache Lockdown registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2LOCKDOWN	0xFFFFF900	0xFFFFFBFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2ADDRESSFILTER Address Map

This address space is allocated for the Address Filtering registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2ADDRESSFILTER	0xFFFFFC00	0xFFFFFEFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

l2_regs_L2DEBUG Address Map

This address space is allocated for the Debug, Prefecth and Power registers. For detailed information about the use of this address space, go to the **ARM Infocenter** to access the ARM documentation for the L2C-301.

Module Instance	Base Address	End Address
l2_regs_L2DEBUG	0xFFFFFF00	0xFFFFFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Document Revision History

Date	Version	Changes
October 2016	2016.10.28	• Added "Configuring AxCACHE[3:0] Sideband Signals" and "Configuring AxUser[4:0] Sideband Signals" subsections to the "AXI Master configuration for ACP Access" section
May 2016	2016.05.27	Maintenance release
May 2016	2016.05.03	Maintenance release
November 2015	2015.11.02	• Reordered "L2 Cache" subsections • Renamed "ECC Support" L2 subsection to be "Single Event Upset Protection" • Added "L2 Cache Parity" subsection in "L2 Cache" section
May 2015	2015.05.04	• Corrected allowed AxID values in "Accelerator Coherency Port" section • Added address maps for the Cortex-A9 MPU subsystem and the L2 cache controller

Date	Version	Changes
December 2014	2014.12.15	• Added bus transaction scenarios in the "Accelerator Coherency Port" section • Added the "AxUSER and AxCACHE" subsection to the "Accelerator Coherency Port" section • Added the "Shared Requests on ACP" subsection to the "Accelerator Coherency Port" section • Added the "Configuration for ACP Use" subsection to the "Accelerator Coherency Port" section • Added parity error handling information to the "L1 Caches" section and the "Cache Controller Configuration" topic of the "L2 Cache" section.
August 2014	2014.08.18	Initial Release

CoreSight Debug and Trace 10

2016.10.28

a10_5v4 Subscribe Send Feedback

CoreSight systems provide all the infrastructure you require to debug, monitor, and optimize the performance of a complete HPS design. CoreSight technology addresses the requirement for a multicore debug and trace solution with high bandwidth for whole systems beyond the processor core.

CoreSight technology provides the following features:

- Cross-trigger support between SoC subsystems
- High data compression
- Multi-source trace in a single stream
- Standard programming models for standard tool support

The hard processor system (HPS) debug infrastructure provides visibility and control of the HPS modules, the ARM Cortex-A9 microprocessor unit (MPU) subsystem, and user logic implemented in the FPGA fabric. The debug system design incorporates ARM CoreSight components.

Details of the ARM CoreSight debug components can be viewed by clicking on the following related information links:

Features of CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate Program Trace Macrocell (PTM) for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP generation of triggers and system trace messages
- External trace interface through Trace Port Interface Unit (TPIU) for trace analysis tools
- Custom message injection through the System Trace Macrocell (STM) into the trace stream for delivery to a host debugger
- STM, PTM, and level 3 (L3) trace sources multiplexed into a single stream through the Trace Funnel
- Capability to route trace data to any slave accessible to the Embedded Trace Router (ETR) AXI master connected to the L3 interconnect
- Capability for the following components to trigger each other through the embedded cross-trigger system:
  - Cortex-A9 PTM-0
  - Cortex-A9 PTM-1
  - STM
  - Embedded Trace FIFO (ETF)
  - ETR
  - TPIU
  - Cross Trigger Interface (CTI)
  - FPGA-CTI
  - Cross Trigger Matrix (CTM)

Related Information

Cross Trigger Interface on page 10-9

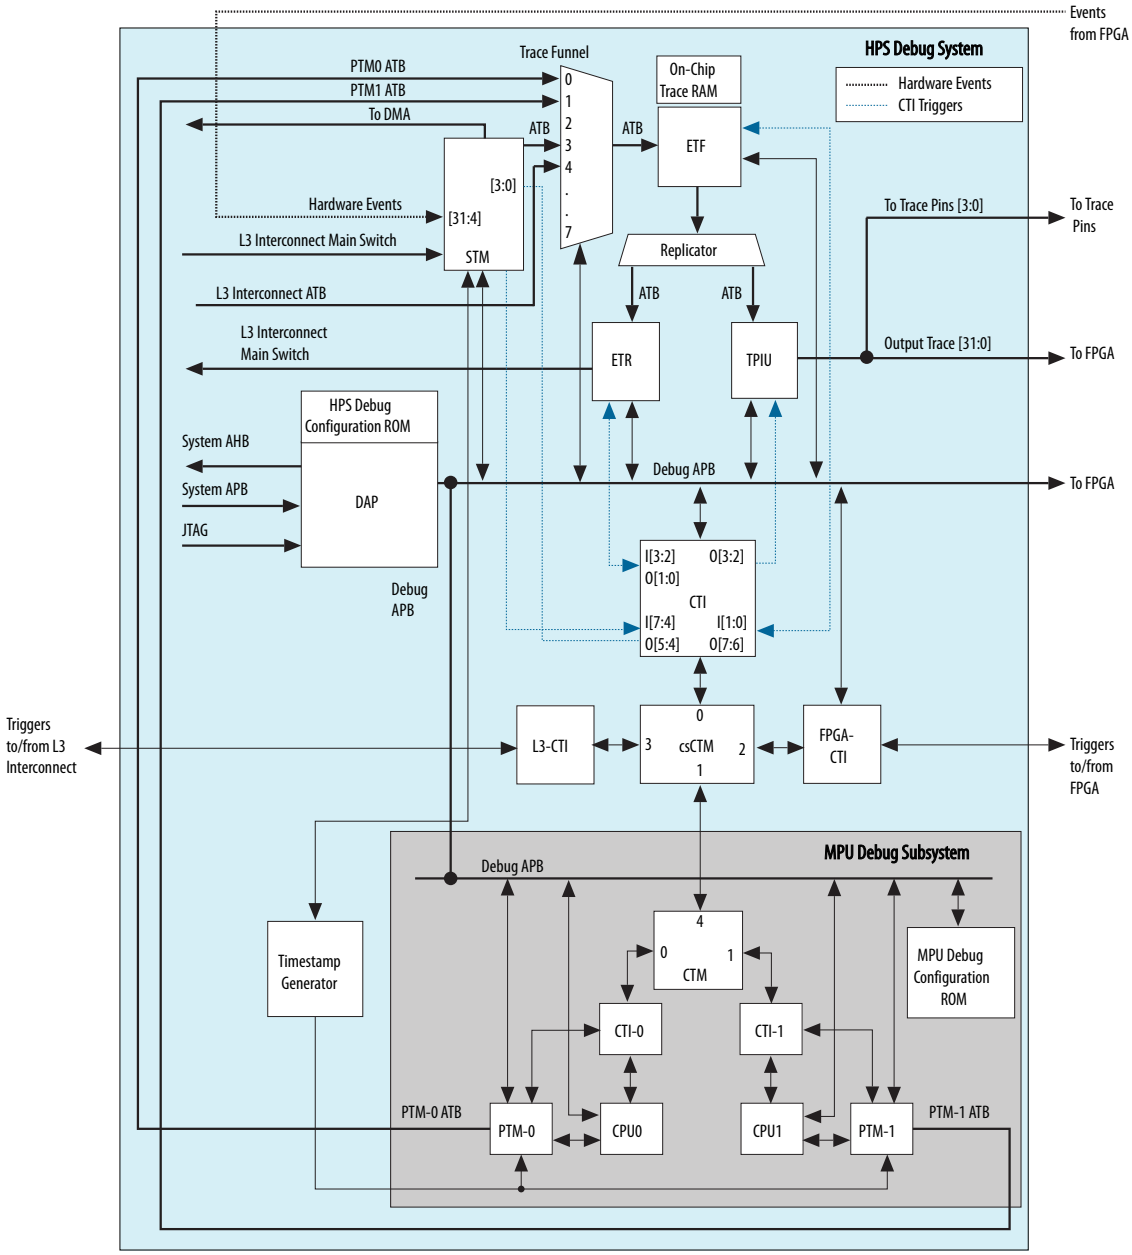
CoreSight Debug and Trace Block Diagram and System Integration

Figure 10-1: HPS CoreSight Debug and Trace System Block Diagram



Functional Description of CoreSight Debug and Trace

Debug Access Port

The Debug Access Port (DAP) provides the necessary ports for a host debugger to connect to and communicate with the HPS through a JTAG interface, which is connected to the FPGA JTAG chain. The JTAG interface provided with the DAP allows a host debugger to access various modules inside the HPS. Additionally, a debug monitor executing on either processor can access different HPS components by interfacing with the system Advanced Microcontroller Bus Architecture (AMBA) Advanced Peripheral Bus (APB) slave port of the DAP.

The system APB slave port occupies 2 MB of address space in the HPS. Both the JTAG port and system APB port have access to the debug APB master port of the DAP.

A host debugger can access any HPS memory-mapped resource in the system through the DAP system master port. Requests made over the DAP system master port are impacted by reads and writes to peripheral registers.

Note: The HPS JTAG interface does not support boundary scan tests (BST).

Related Information

- **CoreSight Debug and Trace Block Diagram and System Integration** on page 10-3
  Shows CoreSight components connected to the debug APB

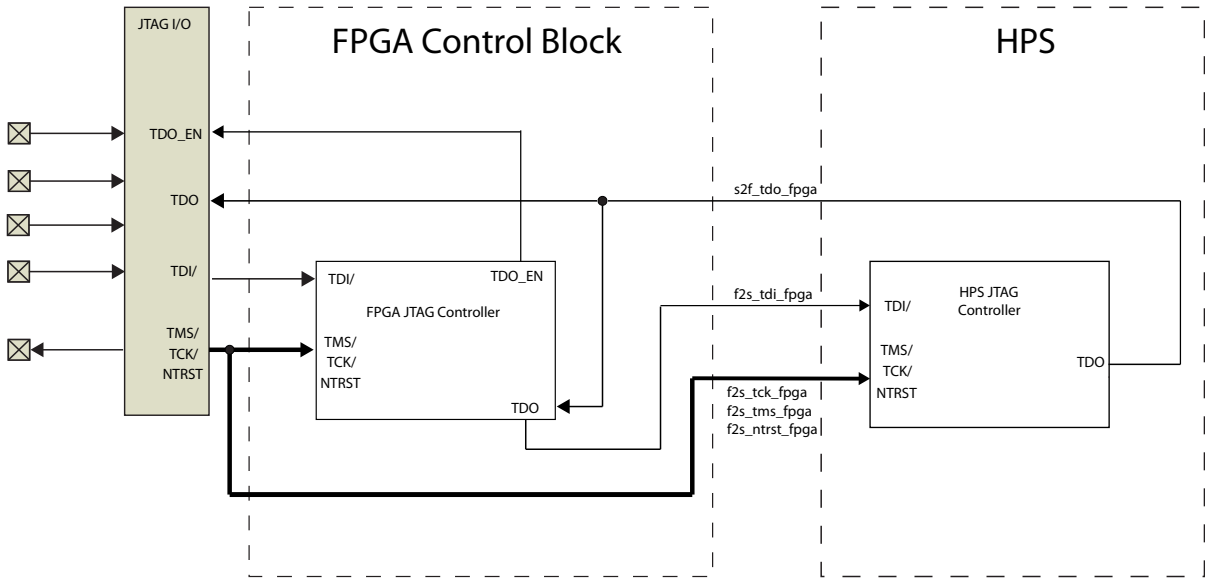
  For more information about boundary scan tests, refer to the "JTAG Boundary-Scan Testing in Arria 10 Devices" chapter.
- **ARM Infocenter**
  Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

JTAG Connection

The SoC device has two JTAG controllers: the FPGA JTAG (located in the configuration sub-system (CSS)) and the HPS JTAG (located in the HPS). The controllers have separate instruction sets and work independently. To share the same external JTAG port between the two controllers, they are internally daisy-chained, where the FPGA appears before the HPS on the chain.

The following figure shows how the two test access port (TAP) controllers are connected:



System Trace Macrocell

The STM allows messages to be injected into the trace stream for delivery to the host debugger receiving the trace data. These messages can be sent through stimulus ports or the hardware EVENT interface. The STM allows these messages to be time stamped.

The STM provides an AMBA Advanced eXtensible Interface (AXI) slave interface used to create trace events. The interface can be accessed by the MPU subsystem, direct memory access (DMA) controller, and masters implemented as soft logic in the FPGA fabric through the FPGA-to-HPS bridge. The AXI slave interface supports three address segments, where each address segment is 16 MB and each segment supports up to 65536 channels. Each channel occupies 256 bytes of address space.

The STM also provides 32 hardware EVENT pins. The higher-order 28 pins (31:4) are connected to the FPGA fabric, allowing logic inside FPGA to insert messages into the trace stream. When the STM detects a rising edge on an EVENT pin, a message identifying the EVENT is inserted into the stream. The lower four EVENT pins (3:0) are connected to CTI.

- **ARM Infocenter**
  For more information, refer to the *CoreSight System Trace Macrocell Technical Reference Manual* on the ARM Infocenter website.
- **CTI** on page 10-21

Trace Funnel

The Trace Funnel is used to combine multiple trace streams into one trace stream. There are four trace streams that use the following funnel ports:

Table 10-1: Trace Stream Connections

Funnel Port	Description
0	The trace stream coming from the PTM connected to CPU0 uses this port.
1	The trace stream coming from the PTM connected to CPU1 uses this port.
2	Not connected.
3	The trace stream coming from the STM uses this port.
4	NoC trace data uses this port.
5 .. 7	Not connected.

Related Information

- **ARM Infocenter**
  Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.
- **Program Trace Macrocell** on page 10-12

CoreSight Trace Memory Controller

The CoreSight Trace Memory Controller (TMC) has three possible configurations:

- Embedded Trace FIFO (ETF)
- Embedded Trace Router (ETR)
- Embedded Trace Buffer (ETB)

ETB is not used in this device.

Related Information

ARM Infocenter
For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

Embedded Trace FIFO

The Trace Funnel output is sent to the ETF. The ETF is used as an elastic buffer between trace generators (STM, PTM, L3 interconnect) and trace destinations. The ETF stores up to 32 KB of trace data in the on-chip trace RAM.

Related Information

ARM Infocenter
For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

Embedded Trace Router

The ETR can route trace data to the HPS on-chip RAM, the HPS SDRAM, and any memory in the FPGA fabric connected to the HPS-to-FPGA bridge. The ETR receives trace data from the AMBA Trace Bus Replicator. By default, the buffer to receive the trace data resides in SDRAM at offset 0x00100000 and is 32 KB. You can override this default configuration by programming registers in the ETR.

Related Information

- **HPS-FPGA Bridges** on page 8-1
- **CoreSight Debug and Trace Programming Model** on page 10-18
- **ARM Infocenter**
  For more information, refer to the *CoreSight System Trace Memory Controller Technical Reference Manual* on the ARM Infocenter website.

AMBA Trace Bus Replicator

The AMBA Trace Bus Replicator broadcasts trace data from the ETF to the ETR and TPIU.

Related Information

ARM Infocenter
Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and an off-chip trace port. The TPIU receives trace data from the Trace Bus Replicator (Replicator) and drives the trace data to a trace port analyzer.

The trace output is routed to a 32-bit interface to the FPGA fabric. The trace data sent to the FPGA fabric can be transported off-chip using available serializer/deserializer (SERDES) resources in the FPGA.

Related Information

ARM Infocenter
Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

Embedded Cross Trigger System

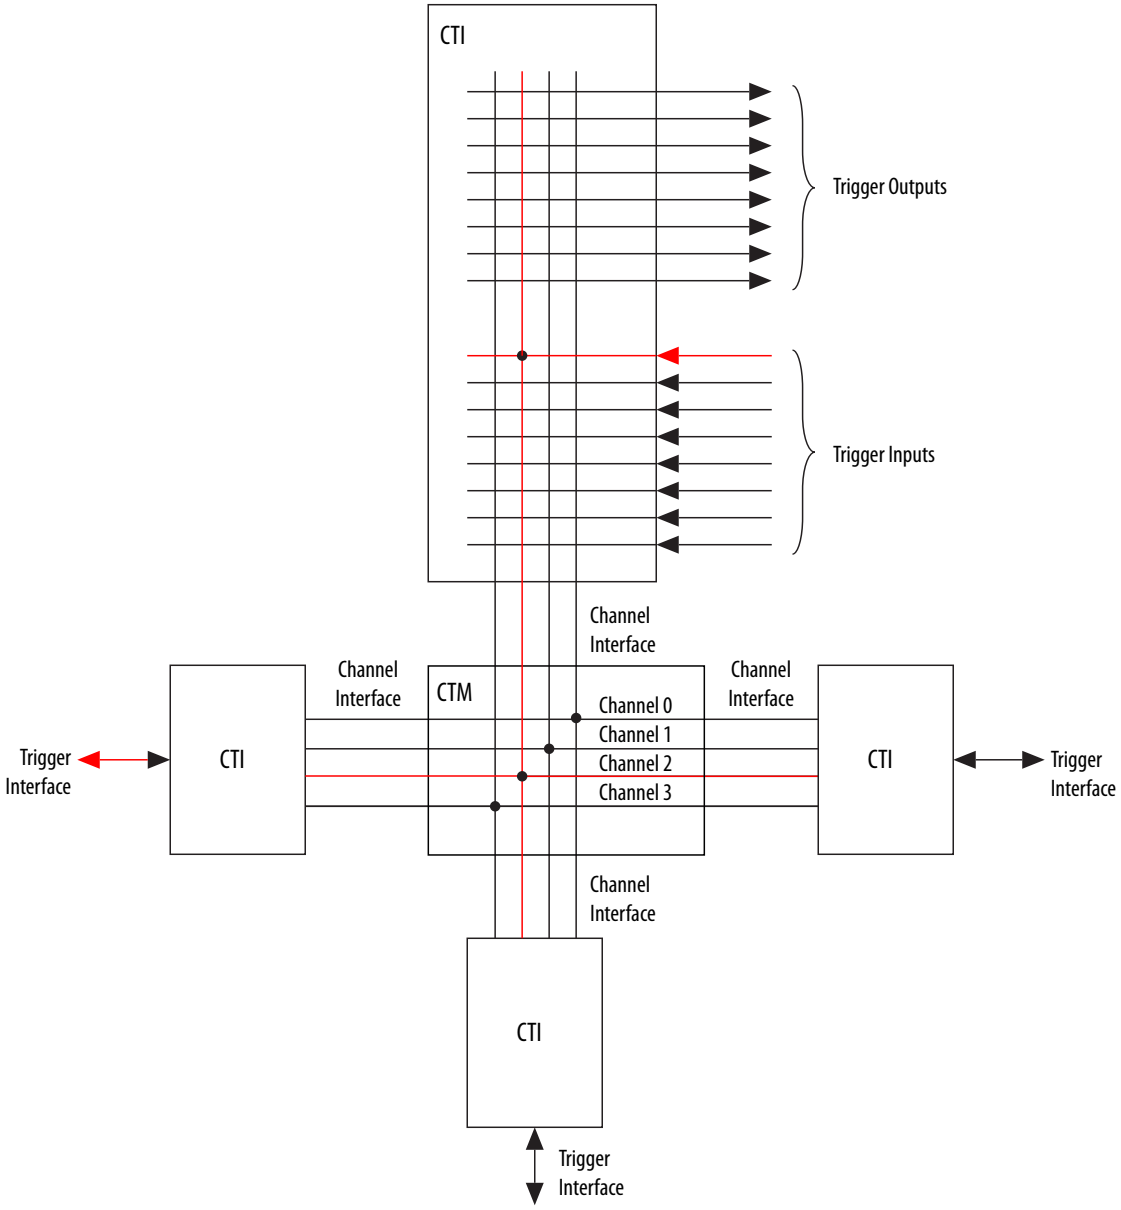
The ECT system provides a mechanism for the components listed in "Features of the CoreSight Debug and Trace" to trigger each other. The ECT consists of the following modules:

- Cross Trigger Interface (CTI)
- Cross Trigger Matrix (CTM)

Figure 10-2: Generic ECT System

The following figure shows an example of how CTIs and CTMs are used in a generic ECT setup. Though the signal travels through channel 2, it only enters and exits through trigger inputs and outputs you configure.

Note: The red line depicts an trigger input to one CTI generating a trigger output in another CTI.



Related Information

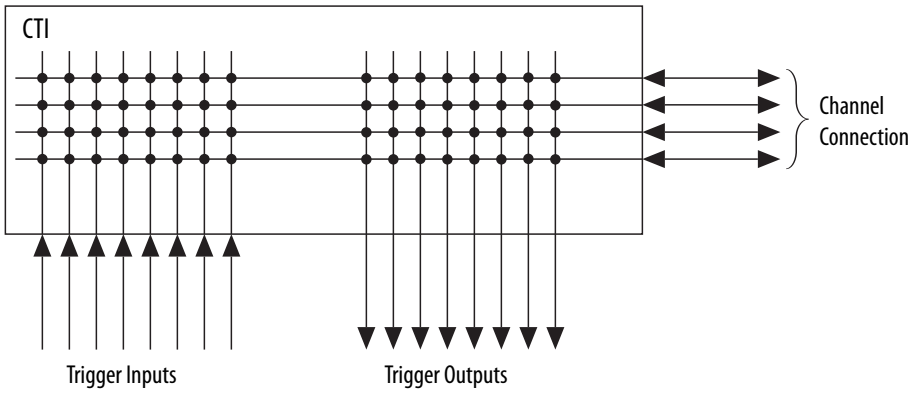
- **Cross Trigger Interface** on page 10-9
- **Features of CoreSight Debug and Trace** on page 10-2
- **Cross Trigger Matrix** on page 10-9

Cross Trigger Interface

CTIs allow trigger sources and sinks to interface with the ECT. Each CTI supports up to eight trigger inputs and eight trigger outputs, and is connected to a CTM. **Figure 10-5** shows the relationship of trigger inputs, trigger outputs, and CTM channels of a CTI.

Figure 10-3: CTI Connections

The following figure shows the eight potential trigger input and trigger output connections that are supported.



The HPS debug system contains the following CTIs:

- CTI—performs cross triggering between the STM, ETF, ETR, and TPIU.
- FPGA-CTI—exposes the cross-triggering system to the FPGA fabric.
- CTI-0 and CTI-1—reside in the MPU debug subsystem. Each CTI is associated with a processor and the processor's PTM.
- L3-CTI—allows cross triggering with L3 interconnect.

Cross Trigger Matrix

A CTM is a transport mechanism for triggers traveling from one CTI to one or more CTIs or CTMs. The HPS contains two CTMs. One CTM connects CTI and FPGA-CTI; the other connects CTI-0 and CTI-1. The two CTMs are connected together, allowing triggers to be transmitted between the MPU debug subsystem, the debug system, and the FPGA fabric.

Each CTM has four ports and each port has four channels. Each CTM port can be connected to a CTI or another CTM.

Figure 10-4: CTM Channel Structure

The following figure shows the structure of a CTM channel. Paths inside the CTM are purely combinatorial.

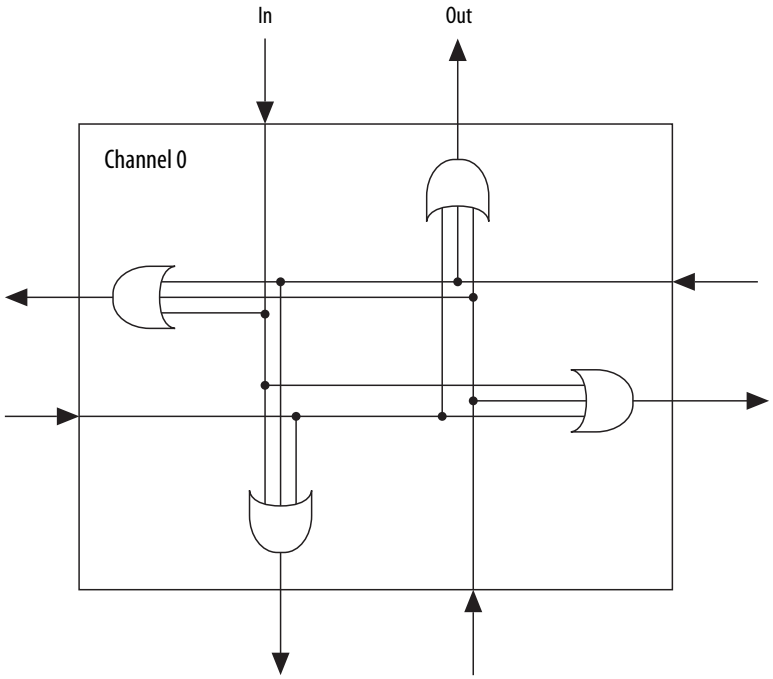


Figure 10-5: CTI Trigger Connections

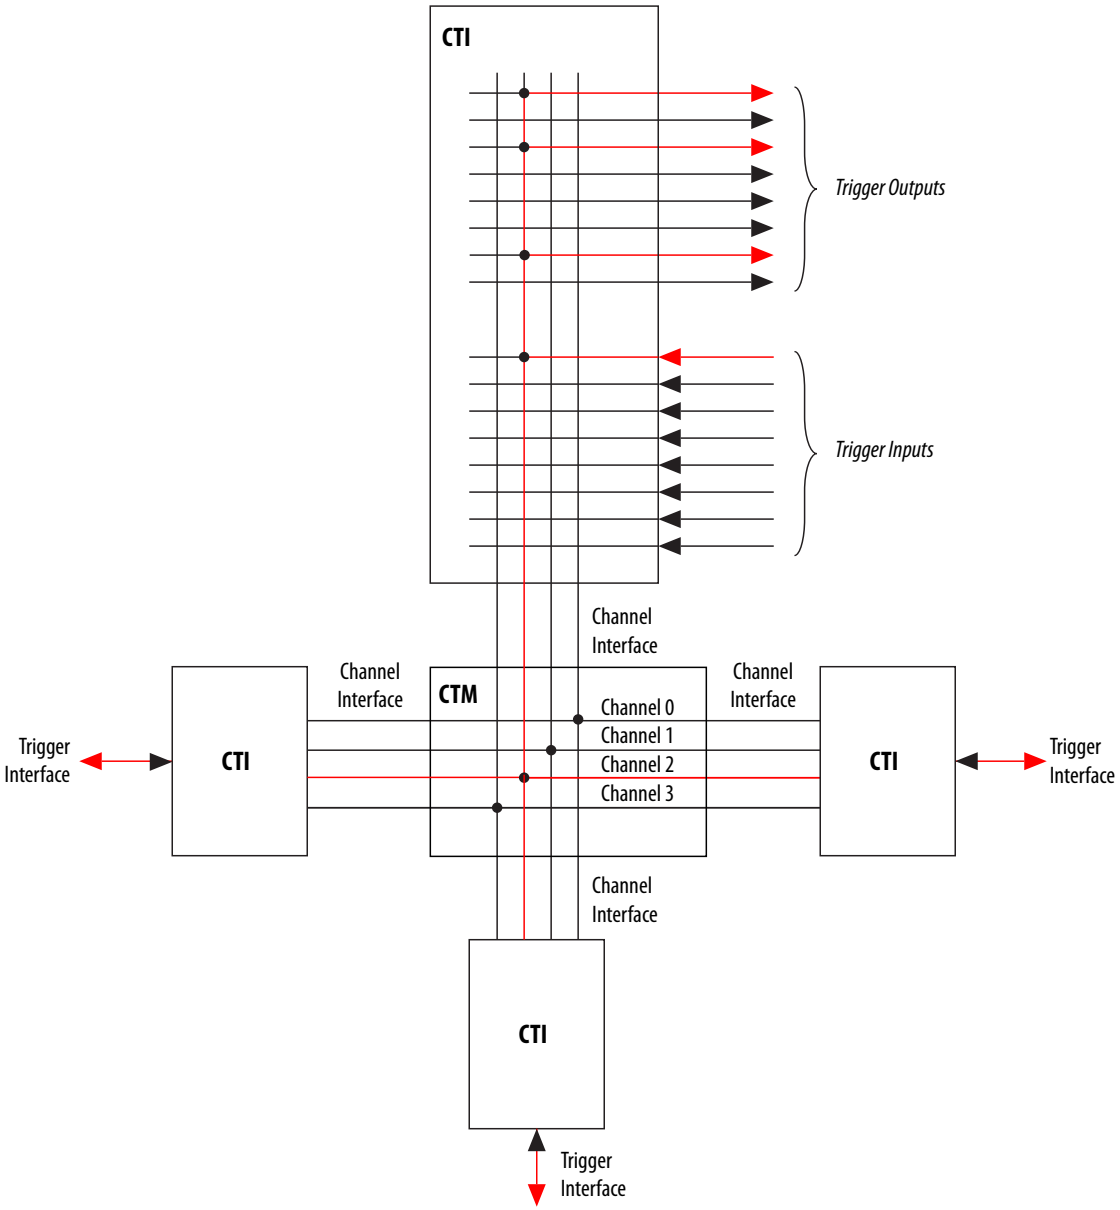
Each CTI trigger input can be connected through a CTM to one or more trigger outputs under control by a debugger. The following figure shows an example of CTI trigger connections.

Note: The red lines depict the impact one trigger input can have on the entire system.



Related Information

ARM Infocenter

Refer to the *CoreSight Components Technical Reference Manual* on the ARM Infocenter website.

Program Trace Macrocell

The PTM performs real-time program flow instruction tracing and provides a variety of filters and triggers that can be used to trace specific portions of code.

The HPS contains two PTMs. Each PTM is paired with a processor and CTI. Trace data generated from the PTM can be transmitted off-chip using HPS pins, or to the FPGA fabric, where it can be pre-processed and transmitted off-chip using high-speed FPGA pins.

Related Information

ARM Infocenter
For more information, refer to the *CoreSight PTM-A9 Technical Reference Manual* .

HPS Debug APB Interface

The HPS can extend the CoreSight debug control bus into the FPGA fabric. The debug interface is an APB-compatible interface with built-in clock crossing.

Related Information

- **FPGA Interface** on page 10-12
- **HPS Component Interfaces** on page 28-1

FPGA Interface

The following components connect to the FPGA fabric. This section lists the signals from the debug system to the FPGA.

DAP

The DAP uses the system APB port to connect to the FPGA.

Table 10-2: DAP

The following table shows the signal description between DAP and FPGA.

Signal	Description
h2f_dbg_apb_PADDR	Address bus to system APB port, when PADDR
h2f_dbg_apb_PADDR31	Address bus to system APB port, when PADDR31
h2f_dbg_apb_PENABLE	Enable signal from system APB port
h2f_dbg_apb_PRDATA[32]	32-bit system APB port read data bus
h2f_dbg_apb_PREADY	Ready signal to system APB port
h2f_dbg_apb_PSEL	Select signal from system APB port
h2f_dbg_apb_PSLVERR	Error signal to system APB port
h2f_dbg_apb_PWDATA[32]	32-bit system APB port write data bus

Signal	Description
h2f_dbg_apb_PWRITE	Select whether read or write to system APB port • 0 - System APB port read from DAP • 1 - System APB Port write to DAP

STM

The STM has 28 event pins, f2h_stm_hw_events[28], for FPGA to trigger events to STM.

FPGA-CTI

The FPGA-CTI allows the FPGA to send and receive triggers from the debug system.

Table 10-3: FPGA-CTI Signal Description Table

The following table lists the signal descriptions between the FPGA-CTI and FPGA.

Signal	Description
h2f_cti_trig_in[8]	Trigger input from FPGA
h2f_cti_trig_in_ack[8]	ACK signal to FPGA
h2f_cti_trig_out[8]	Trigger output to FPGA
h2f_cti_trig_out_ack[8]	ACK signal from FPGA
h2f_cti_clk	Clock input from FPGA
h2f_cti_fpga_clk_en	Clock enable driven by FPGA

Related Information

ARM Infocenter

For more information about the cross-trigger interface

CTI-NoC

The CTI is used for receiving triggers from device that can generate triggers and for sending triggers to devices that can receive triggers. This instance of CTI is used exclusively by NoC and allows NoC probe units to send and receive triggers.

Table 10-4: Trigger Input Interface

Name	Input/Output	Description
CTITRIGIN	Input	Trigger In Connected to noc_CTITRIGIN

Name	Input/Output	Description
TISBYPASSIN	Input	8'b0000_0000 —Trigger In synchronization bypass (Static value) Enable synchronizers for all 8 inputs. CTI runs off cs_at_clk
CTITRIGINACK	Output	Trigger In acknowledge Connected to noc_CTITRIGINACK

Table 10-5: Trigger Output Interface

Name	Input/Output	Description
CTITRIGOUT	Output	Trigger Out Connected to noc_CTITRIGOUT
CTITRIGOUTACK	Input	Trigger Out acknowledge Connected to noc_CTITRIGOUTACK
TISBYPASSACK	Input	8'b0000_0000—Trigger Out acknowledge synchronization bypass (Static value) Enable synchronizers for all 8 inputs
TIHSBYPASS	Input	8'b0000_0000—Trigger interface handshake bypass (Static value) Hand shaking is enabled

TPIU

Figure 10-6: Trace Clock and Trace Data Width

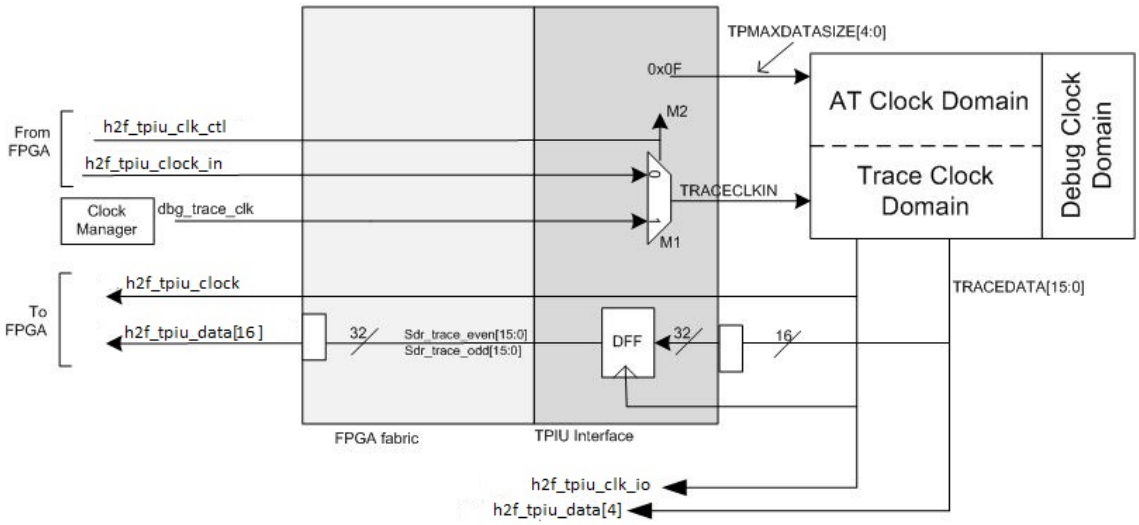


Table 10-6: TPIU Signals

The following table lists the signal descriptions between the TPIU and FPGA.

Signal	Description
h2f_tpiu_clk_ctl	Selects whether trace data is captured using the internal TPIU clock, which is the dbg_trace_clk signal from the clock manager; or an external clock provided as an input to the TPIU from the FPGA. 0 - use h2f_tpiu_clock_in 1 - use internal clock **Note**: When the FPGA is powered down or not configured the TPIU uses the internal clock.
h2f_tpiu_data[16]	16-bit trace data bus. Trace data changes on both edges of h2f_tpiu_clock.
h2f_tpiu_clock_in	Clock from the FPGA used to capture trace data.
h2f_tpiu_clock	Clock output from TPIU

Debug Clocks

Table 10-7: CoreSight Clocks

Port Name	Clock Source	Signal Name	Description
ATCLK	Clock manager	cs_at_clk	Trace bus clock.
CTICLK (for CTI)	Clock manager	cs_at_clk	Cross trigger interface clock for CTI. It can be synchronous or asynchronous to CTMCLK.
CTICLK (for FPGA-CTI)	FPGA fabric	cs_at_clk	Cross trigger interface clock for FPGA-CTI.
CTICLK (for CTI-0 and CTI-1)	Clock manager	mpu_clk	Cross trigger interface clock for CTI-0 and CTI-1. It can be synchronous or asynchronous to CTMCLK.
CTMCLK (for csCTM)	Clock manager	cs_pdbg_clk	Cross trigger matrix clock for csCTM. It can be synchronous or asynchronous to CTICLK.
CTMCLK (for CTM)	Clock manager	mpu_clk	Cross trigger matrix clock for CTM. It can be synchronous or asynchronous to CTICLK.
DAPCLK	Clock manager	cs_pdbg_clk	DAP internal clock. It must be equivalent to PCLKDBG.
PCLKDBG	Clock manager	cs_pdbg_clk	Debug APB (DAPB) clock.
HCLK	Clock manager	cs_pdbg_clk	Used by the AHB-Lite master inside the DAP. It is asynchronous to DAPCLK. In the HPS, the AHB-Lite port uses same clock as DAPCLK.
PCLKSYS	Clock manager	cs_pdbg_clk	Used by the APB slave port inside the DAP. It is asynchronous to DAPCLK.
SWCLKTCK	JTAG interface	dap_tck	The SWJ-DP clock driven by the external debugger through the JTAG interface. It is asynchronous to DAPCLK. When through the JTAG interface, this clock is the same as TCK of the JTAG interface.

Port Name	Clock Source	Signal Name	Description
TRACECLKIN	Clock manager	cs_trace_clk	TPIU trace clock input. It is asynchronous to ATCLK. In the HPS, this clock can come from the clock manager or the FPGA fabric.

Related Information

ARM Infocenter

For more information about the CoreSight port names, refer to the *CoreSight Technology System Design Guide*.

Debug Resets

The CoreSight system uses several resets.

Table 10-8: CoreSight Resets

ARM Reset Name	Clock Source	HPS Reset Signal Name	Description
ATRESETn	Reset manager	dbg_rst_n	Trace bus reset. It resets all registers in the ATCLK domain.
nCTIRESET	Reset manager	dbg_rst_n	CTI reset signal. It resets all registers in the CTICLK domain. In the HPS, there are four instances of CTI. All four use the same reset signal.
DAPRESETn	Reset manager	dbg_rst_n	DAP internal reset. It is connected to PRESETDBGn.
PRESETDBGn	Reset manager	dbg_rst_n	Debug APB reset. Resets all registers clocked by PCLKDBG.
HRESETn	Reset manager	sys_dbg_rst_n	SoC-provided reset signal that resets all of the AMBA on-chip interconnect. Use this signal to reset the DAP AHB-Lite master port.
PRESETSYSn	Reset manager	sys_dbg_rst_n	Resets system APB slave port of DAP.
nCTMRESET	Reset manager	dbg_rst_n	CTM reset signal. It resets all signals clocked by CTMCLK.

ARM Reset Name	Clock Source	HPS Reset Signal Name	Description
nPOTRST	Reset manager	tap_cold_rst_n	True power on reset signal to the DAP SWJ-DP. It must only reset at power-on.
nTRST	JTAG interface	nTRST pin	Resets the DAP TAP controller inside the SWJ-DP. This signal is driven by the host using the JTAG connector.
TRESETn	Reset manager	dbg_rst_n	Reset signal for TPIU. Resets all registers in the TRACECLKIN domain.

The ETR stall enable field (etrstallen) of the ctrl register in the reset manager controls whether the ETR is requested to stall its AXI master interface to the L3 interconnect before a warm or debug reset.

The level 4 (L4) watchdog timers can be paused during debugging to prevent reset while the processor is stopped at a breakpoint.

CoreSight Debug and Trace Programming Model

This section describes programming model details specific to Altera's implementation of the ARM CoreSight technology.

The debug components can be configured to cause triggers when certain events occur. For example, soft logic in the FPGA fabric can signal an event which triggers an STM message injection into the trace stream.

Related Information

ARM Infocenter
Programming interface details of each CoreSight component.

Coresight Component Address

CoreSight components are configured through memory-mapped registers, located at offsets relative to the CoreSight component base address. CoreSight component base addresses are accessible through the component address table in the DAP ROM.

Table 10-9: Coresight Component Address Table

The following table is located in the ROM table portion of the DAP.

ROM Entry	Offset[30:12]	Description
0x0	0x00001	ETF Component Base Address
0x1	0x00002	CTI Component Base Address
0x2	0x00003	TPIU Component Base Address
0x3	0x00004	Trace Funnel Component Base Address
0x4	0x00005	STM Component Base Address
0x5	0x00006	ETR Component Base Address
0x6	0x00007	FPGA-CTI Component Base Address
0x7	0x00100	A9 ROM
0x8	0x00080	FPGA ROM
0x9	0x00008	L3-CTI

A host debugger can access this table at 0x80000000 through the DAP. HPS masters can access this ROM at 0xFF000000. Registers for a particular CoreSight component are accessed by adding the register offset to the CoreSight component base address, and adding that total to the base address of the ROM table.

The base address of the ROM table is different when accessed from the debugger (at 0x8000_0000) than when accessed from any HPS master (at 0xFF000000). For example, the CTI output enable (CTIOUTEN) register, `CTIOUTEN[2]` at offset 0xA8, can be accessed by the host debugger at 0x800020A8. To derive that value, add the host debugger access address to the ROM table of 0x80000000, to the CTI component base address of 0x00002000, to the `CTIOUTEN[2]` register offset of 0xA8.

STM Channels

The STM AXI slave is connected to the MPU, DMA, and FPGA-to-HPS bridge masters. Each master has up to 65536 channels where each channel occupies 256 bytes of address space, for a total of 16 MB per master. The HPS address map allocates 48 MB of consecutive address space to the STM AXI slave port, divided in three 16 MB segments.

Table 10-10: STM AXI Slave Port Address Allocation

Segment	Start Address	End Address
0	0xFC000000	0xFCFFFFFF
1	0xFD000000	0xFDFFFFFF

Segment	Start Address	End Address
2	0xFE000000	0xFEFFFFFF

Each of the three masters can access any one of the three address segments. Your software design determines which master uses which segment, based on the value of bits 24 and 25 in the write address, `AWADDRS[25:24]`. Software must restrict each master to use only one of the three segments.

Table 10-11: STM AXI Address Fields

STM receives trace data over an AXI slave port. This table contains a list of signals associated with this interface.

AXI Signal Fields	Description
`AWADDRS[7:0]`	These bits index the 256 bytes of the stimulus port.
`AWADDRS[23:8]`	These bits identify the 65536 stimulus ports associated with a master.
`AWADDRS[25:24]`	These bits identify the three masters. Only 0, 1, and 2 are valid values.
`AWADDRS[31:26]`	Always 0x3F. Bits 24 to 31 combine to access 0xFC000000 through 0xFEFFFFFF.

Each STM message contains a master ID that tells the host debugger which master is associated with the message. The STM master ID is determined by combining a portion of the `AWADDRS` signal and the `AWPROT` protection bit. In the following table, `MasterID[6]` identifies the

Table 10-12: STM Master ID Calculation

Master ID Bits	AXI Signal Bits	Notes
Master ID[5:0]	`AWADDRS[29:24]`	The lowest two bits are sufficient to determine which master, but CoreSight uses a six-bit master ID.
Master ID[6]	`AWPROT[1]`	0 indicates a secure master; 1 indicates a nonsecure master.

In addition to access through STM channels, the higher-order 28 (31:4) of the 32 event signals are attached to the FPGA through the FPGA-CTI. These event signals allow the FPGA fabric to send additional messages using the STM.

CTI Trigger Connections to Outside the Debug System

The following CTIs in the HPS debug system connect to outside the debug system:

- CTI
- FPGA-CTI
- L3-CTI

CTI

This section lists the trigger input, output, and output acknowledge pin connections implemented for CTI in the debug system. The trigger input acknowledge signals are not connected to pins.

Table 10-13: CTI Trigger Input Signals

The following table lists the trigger input pin connections implemented for CTI .

Number	Signal	Source
7	ASYNCOUT	STM
6	TRIGOUTHETE	STM
5	TRIGOUTSW	STM
4	TRIGOUTSPTE	STM
3	ACQCOMP	ETR
2	FULL	ETR
1	ACQCOMP	ETF
0	FULL	ETF

Table 10-14: CTI Trigger Output Signals

FPGA-CTI

FPGA-CTI connects the debug system to the FPGA fabric. FPGA-CTI has all of its triggers available to the FPGA fabric.

Related Information

Configuring Embedded Cross-Trigger Connections on page 10-22
For more information about the triggers, refer to the "Configuring Embedded Cross-Trigger Connections" chapter.

L3-CTI

L3-CTI has all of its triggers available to the L3 interconnect.

Configuring Embedded Cross-Trigger Connections

CTI interfaces are programmable through a memory-mapped register interface.

The specific registers are described in the *CoreSight Components Technical Reference Manual*, which you can download from the ARM Infocenter.

To access registers in any CoreSight component through the debugger, the register offsets must be added to the CoreSight component's base address. That combined value must then be added to the address at which the ROM table is visible to the debugger (0x80000000).

Each CTI has two interfaces, the trigger interface and the channel interface. The trigger interface is the interface between the CTI and other components. It has eight trigger signals, which are hardwired to other components. The channel interface is the interface between a CTI and its CTM, with four bidirectional channels. The mapping of trigger interface to channel interface (and vice versa) in a CTI is dynamically configured. You can enable or disable each CTI trigger output and CTI trigger input connection individually.

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, and multiple-to-multiple.

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in the CTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in the CTI.

Another soft logic signal in the FPGA connected to trigger input T2 in the FPGA-CTI can be configured to trigger a STM message. The CTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in the CTI; and then configure trigger input T2 to channel 1 in FPGA-CTI.

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

Related Information

- **Coresight Component Address** on page 10-18
- **ARM Infocenter**
  For more information about the cross-trigger interface

Configuring Trigger Input 0

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-tomultiple, multiple-to-single, and multiple-to-multiple.

Triggering a Flush of Trace Data to the TPIU

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in CTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in CTI.

Triggering an STM message

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. CTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in CTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

Triggering a Breakpoint on CPU 1

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the external debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

Error Checking and Correction Controller 11

2016.10.28

a10_5v4

Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

ECC Controller Features

The features supported by each ECC controller are:

- Hamming code-based ECC calculations
- Single-bit error detection and correction
- Double-bit error detection
- Dedicated hardware block for memory data initialization
- Indirect memory access for:
  - Data correction on the corrupted memory address
  - Data and ECC syndrome bit error injection
- Watchdog timeout for indirect access to prevent bus stall
- Display of the current single or double-bit error memory address
- Single-bit error occurrence counter
- Look-up table (LUT) for logging single-bit error memory address
- Interrupt generated upon single and double-bit errors
- User-controllable interrupt assertion for test purposes

ECC Supported Memories

In addition to the 256 KB on-chip RAM, the peripherals that have integrated memories with ECC controllers are:

- USB OTG 0/1
- SD/MMC controller
- Ethernet MAC 0/1/2
- DMA controller
- NAND flash controller
- QSPI flash controller

Note: The L2 cache and the SDRAM interface have their own dedicated ECC support.

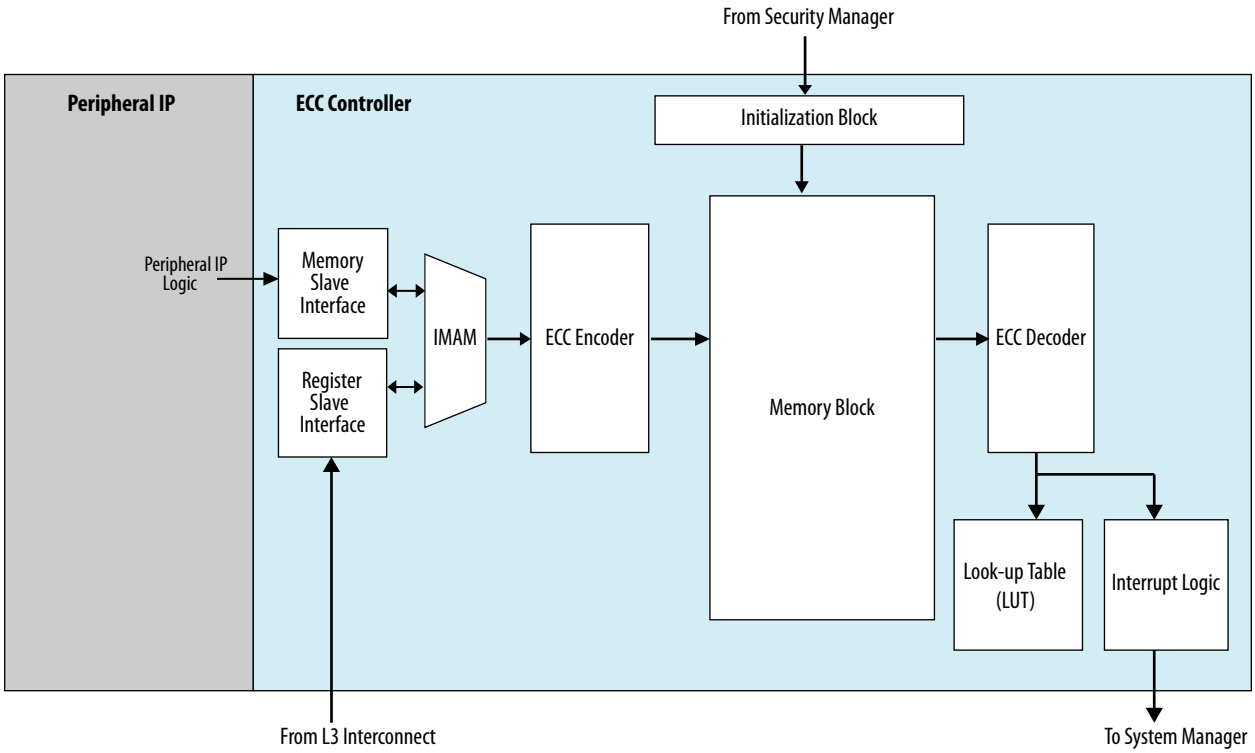
ECC Controller Block Diagram and System Integration

The figure below shows the ECC controller components and the ECC controller communication with other HPS peripherals.

Figure 11-1: ECC Block Diagram and System Integration

This figure applies to any of the peripheral IP that have ECC-supported memories.



Each peripheral accesses its memory block through the memory slave interface. The register slave interface allows the Microprocessor Unit (MPU) subsystem to access registers in the ECC controller for software configuration of the ECC controller. The register slave interface also allows the MPU subsystem to indirectly access the memory block through the indirect memory access MUX (IMAM).

Before the peripheral writes data to its memory block, it is encoded in the ECC controller. Before memory sends read data to a peripheral, it is decoded by the ECC controller. The initialization block initializes the memory data content, as well as the ECC syndrome bits, to known values. This block is controlled by the

register slave interface and also by the Security Manager when memory clearing is required during a tamper event.

When enabled, the look-up table (LUT) records the memory address of all single-bit errors, allowing you to analyze the error rate history.

The interrupt logic provides interrupt capability for single- and double-bit errors.

Related Information

Indirect Memory Access on page 11-6

ECC Controller Functional Description

Overview

An ECC controller can be enabled or disabled by programming the ECC Control (`CTRL`) register. The controller is disabled by default when the HPS is released from reset. When the ECC controller is disabled, data written to the memory block is not encoded, and data read from the memory block does not require ECC decoding. When the ECC controller is enabled, single-bit errors can be detected and corrected by the ECC controller. Double-bit errors are detected but not corrected.

ECC Structure

The ECC is calculated based on a Hamming code for the corresponding data word length.

Table 11-1: ECC Bits Required Based on Data Width

Data Bus Width	ECC Bits
8 to 15 bits	5
16 to 31 bits	6
32 to 63 bits	7
64 to 127 bits	8
128 to 255 bits	9
256 bits	10

Table 11-2: ECC Memory Characteristics

This table shows the memory data size and the Hamming code word length for each of the ECC-protected memories in the HPS, as well as the memory type. The Hamming code word length is calculated based on the full data width and whether the memory is byte- or word- addressable.

Notice that the on-chip RAM and DMA are byte-addressable. For each byte of data, five syndrome bits are used. For a data size of 64 bits (8 bytes), a total of `8 bytes*(8-bit data + 5-bit ECC)` bits are used for a Hamming code word.

Peripheral Memory	Data Size	Memory	ECC Bits	Data Width + ECC Bits	Hamming Code Word (length in bits)	Type [21]
On-chip RAM	64 x 32768	Byte-addressable	5 per byte lane	64+40[22]	104	Single port
USB RAM	35 x 8192	Word-addressable	7	35+7	42	Single port
SD/MMC FIFO	32 x 1024	Word-addressable	7	32+7	39	True dual port
EMAC Rx FIFO	35 x 4096	Word-addressable	7	35+7	42	Simple dual port
EMAC Tx FIFO	35 x 1024	Word-addressable	7	35+7	42	Simple dual port
DMA FIFO	64 x 512	Byte-addressable	5 per byte lane	64+40[22]	104	Simple dual port
NAND ECC Buffer	16 x 768	Word-addressable	6	16+6	22	Simple dual port
NAND Write FIFO	32 x 128	Word-addressable	7	32+7	39	Simple dual port
NAND Read FIFO	32 x 32	Word-addressable	7	32+7	39	Simple dual port
QSPI RAM	32 x 128	Word-addressable	7	32+7	39	Single port

RAM and ECC Memory Organization Example

The on-chip RAM and DMA have a memory organization that is byte-writeable, where every byte of data requires 5 bits of ECC.

The tables below shows the memory organization of the byte-writable memory with a 64-bit data size and 5 bits of ECC data.

[21] True dual-port memory has two writeable and two readable ports. Simple dual port memory has one write-only port and one read-only port.

[22] This is the same as 8 byte lanes with 5 ECC bits per lane.

Table 11-3: Organization of Byte-Writeable Memory with 64-bit Data Size

Address	RAM Bits							
	[63:56]	[55:48]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]
0x0	data[7]	data[6]	data[5]	data[4]	data[3]	data[2]	data[1]	data[0]
0x8	data[15]	data[14]	data[13]	data[12]	data[11]	data[10]	data[9]	data[8]

Table 11-4: Memory Organization of 5-Bit ECC Data

Address	ECC Memory Bits							
	[31:29]	[28:24]	[23:21]	[20:16]	[15:13]	[12:8]	[7:5]	[4:0]
0x0	0x0	ecc_data[3]	0x0	ecc_data[2]	0x0	ecc_data[1]	0x0	ecc_data[0]
0x4	0x0	ecc_data[7]	0x0	ecc_data[6]	0x0	ecc_data[5]	0x0	ecc_data[4]
0x8	0x0	ecc_data[11]	0x0	ecc_ data[10]	0x0	ecc_data[9]	0x0	ecc_data[8]
0xC	0x0	ecc_ data[15]	0x0	ecc_ data[14]	0x0	ecc_ data[13]	0x0	ecc_data[12]

Memory Data Initialization

When an ECC controller is enabled, the memory data must be written first before any data read occurs. If the memory is not written, the ECC syndrome bits are random, potentially causing false single- or double-bit errors when the memory data is read.

Every byte of data in the RAM is protected with ECC. This protection can lead to spurious ECC errors under the following conditions:

- When the MPU prefetches any uninitialized locations.
- When the MPU (or any master) reads from an uninitialized byte.

To prevent spurious ECC errors, software must use the memory initialization block in the ECC controller to initialize the entire memory data and ECC bits. The initialization block clears the memory data. Enabling initialization in the ECC Control (`CTRL`) register is independent of enabling the ECC.

Note: Peripherals with true dual-port memories, such as SD/MMC, must initialize both memories explicitly.

Software controls initialization through the ECC Control (`CTRL`) register. This process cannot be interrupted or stopped after it starts, therefore software must wait for the initialization complete (`INITCOMPLETE*`) bit to be set in the Initialization Status (`INITSTAT`) register. Memory accesses are allowed after the initialization process is complete.

The initialization block is accessed through the register slave interface. Additionally, the Security Manager can access the initialization block. If there is an unauthorized access to the memory or a tamper attempt, the Security Manager signals the Reset Manager to begin scrambling the on-chip memories through the initialization block. After scrambling, the initialization block clears the memory data to zero. This security feature is useful in applications that require secure boot, configuration and authentication.

The Security Manager can also be configured to scramble and clear memory on a cold or warm reset, or both a cold and warm reset. This feature is configured through a combination of user fuses and configuration registers within the Security Manager.

In the Security Manager, you can also select whether the memory is cleared in series or parallel. If time savings is required, memories can be initialized in parallel. If power integrity and savings are required, memories can be initialized in series.

Related Information

SoC Security on page 6-1
For more information regarding Security Manager functions, refer to the *SoC Security* chapter.

Indirect Memory Access

The register slave interface on an ECC controller allows software to access the memory block indirectly.

Through this interface, software can alter the memory data content and the stored ECC syndrome bits. By directly altering the data and syndrome bits, software can manually correct corrupted data, and run tests and diagnostics on the ECC controller.

Accesses to syndrome bits are not supported by the conventional memory access through the memory slave interface and instead, the ECC encoder handles them automatically.

Watchdog Timer

To prevent stalled indirect memory accesses, each ECC controller has a watchdog timer.

For example, if the clock to the memory block is stopped, the watchdog timer can assert an interrupt indicating that memory failed to respond within the expected interval. The watchdog timer is in a separate clock domain from the memory, enabling it to continue running independently of any problem with the memory clock.

The watchdog timer can be enabled or disabled in the ECC Watchdog Control (`ECC_wdcrtl`) register. The watchdog timeout is 2048 clock cycles of the clock domain that is connected to the ECC control slave port. The watchdog timeout interval is not software-programmable.

Data Correction

The data in the memory block can be overwritten through an indirect memory access. This feature is particularly useful when a double-bit error is detected on the data. The ECC controller provides the memory address of the current double-bit error. The data can be corrected by writing to the given memory address using an indirect memory access.

Error Injection

The ECC controller allows you to explicitly inject errors into the memory block for testing purposes. You can alter the memory data or ECC syndrome bits to manually introduce errors. If you change one bit of the memory data to the opposite value, a single-bit error is detected and corrected by the ECC controller. You can also alter ECC syndrome bits to test if the ECC controller triggers an error detection signal as expected.

Memory Testing

Testing methods can include both direct and indirect methods of memory access through the peripheral slave interface and the register slave interface. You can use both paths to test the syndrome bits and the

single-bit and double-bit error logic. However, you can only control ECC syndrome bits by injecting them through the register slave interface.

Peripheral Slave Interface Tests

Data and ECC overwrite bits in the `ECC_accctrl` register are provided to test the functionality of the peripheral interface to the ECC-protected RAM.

ECC-Enabled Test

The following sequence can be used to test if the ECC decoder works correctly.

1. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
2. Write data to any ECC-protected RAM memory location. This action generates an ECC value that can be read through the `ECC_Rdataecc0bus` and `ECC_Rdataecc1bus` registers.
3. Read back the memory data. The data read back is expected to match the data originally written (with or without a single-bit error) or generate a double-bit error. Refer to the "Error Logging" section for more details about identifying errors.

ECC-Disabled Test

This sequence can be used to test that the ECC decoder does not produce output when disabled.

1. Disable the ECC by clearing the `ECC_EN` bit in the `CTRL` register.
2. Write to any ECC-protected RAM memory location. No ECC value is expected to be generated and no interrupt or error logging occurs.
3. The ECC value can be read through the `ECC_Rdataecc0bus` and `ECC_Rdataecc1bus` registers to verify that the ECC values do not correspond to the read memory data.

ECC Disable/Enable Test

This sequence shows that memory data written when the ECC controller is disabled generates an error if the ECC controller is subsequently enabled and the same memory data location is read.

1. Disable the ECC by clearing the `ECC_EN` bit in the `CTRL` register.
2. Write to any ECC-protected RAM memory location. No ECC value is expected to be generated and no interrupt or error logging occurs.
3. Enable the ECC by setting the `ECC_EN` bit in the `CTRL` register.
4. Read the data from ECC-protected RAM memory location you wrote in step 2.
5. Expect an error to be generated because the ECC value corresponding to the memory data is not correct. Refer to the "Error Logging" section for more details about identifying errors.

Related Information

- **Error Logging** on page 11-11
  For more information about error logging.

Register Interface Tests

You can correct memory errors and test the memory register interface through registers in the ECC Controller.

The following registers can be used to test and correct memory:

- ECC_Addrbus: Holds the address of the memory and ECC data.
- ECC_RData3bus through ECC_RData0bus: Holds memory data from a read access.
- ECC_WData3bus through ECC_WData0bus: Holds the data to be written to memory.
- ECC_RDataecc1bus and ECC_RDataecc0bus: Holds the ECC data from a read access.
- ECC_WDataecc1bus and ECC_WDataecc0bus: Holds the ECC data to be written to memory.
- ECC_accctrl: Configures the access as a read or a write and enables memory and ECC data overwrites.
- ECC_startacc: Initiates the register interface access of memory data or ECC data.

Single-Bit Error Test

This sequence tests the single-bit error detection and correction in the ECC decoder.

1. Enable the ECC by setting the ECC_EN bit in the CTRL register.
2. Set the Data Override (DATAOVR) bit in the ECC_accctrl register.
3. Write data to an address location in memory using a normal memory write. Expect the correct ECC data to be generated.
4. Write a data value that has one bit altered in the ECC_WData3bus through ECC_WData0bus registers and write the address of the memory location in the ECC_Addrbus.
5. Configure the ECC_accctrl register to a write and set the ENBUSA bit of the ECC_startacc register to initiate the write. If the memory is dual-ported, an ENBUSB bit could optionally be enabled depending on the port access.
6. Read the same memory location using a normal memory read access. Expect a single-bit error to be logged but the data read to be correct. Refer to the "Error Logging" section for more details about identifying errors.

Double-Bit Error Test

This sequence tests the double-bit error detection in the ECC decoder.

1. Enable the ECC by setting the ECC_EN bit in the CTRL register.
2. Set the Data override (DATAOVR) bit in the ECC_accctrl register.
3. Write data to an address location in memory using a normal memory write. Expect the correct ECC data to be generated.
4. Write a data value that has two bits altered in the ECC_WData3bus through ECC_WData0bus registers and write the address of the memory location in the ECC_Addrbus.
5. Configure the ECC_accctrl register to a write and set the ENBUSA bit of the ECC_startacc register to initiate the write. If the memory is dual-ported, an ENBUSB bit could optionally be enabled depending on the port access.
6. Read the same memory location using a normal memory read access. Expect a double-bit error to be logged with no data correction. Refer to the "Error Logging" section for more details about identifying errors.

  For more information about error logging.

Error Checking and Correction Algorithm

The HPS error checking algorithm is based on an extended Hamming code, which is single-error correcting and double-error detecting (SECDED).

The computation can be understood by a given data (d) and a calculation of the check bits (c) through the equation:

$c = d \times H_d^T$

where H is the parity check matrix, $H = \{H_d, H_c\}$.

If the code word, designated by v and calculated by:

$v = \{d, c\}$

transmits to a noisy channel (for example in a RAM that is subjected to soft errors by cosmic rays) and becomes a contaminated code word, v', we can recover or discover the errors from its syndrome, s, by using the equation:

$s = v' \times H^T$

Errors are indicated when s does not equal 0. The syndrome shows the position of the error in the data.

The following examples show the parity check matrix for different data sizes.

Error Logging

The ECC controller logs the errors that are detected in the memory block. This logging is useful for diagnosing the error and possibly recovering the correct memory data.

Recent Error Address Registers

Each ECC controller logs the most recent single-bit and double-bit error memory addresses.

These address values are stored in the ECC Single-Bit Error Address (SERRADDRx) and Double-Bit Error Address (DERRADDRx) registers and can be read by software. These registers store the most recent memory

error address. The logged address is a word address, rather than a byte address value, so that software must shift the address left to obtain the true address corresponding to the address width. For example, a 16-bit address must be shifted left by one to represent the true address. For a 32-bit address the value must be shifted left by two; and for a 64-bit address, the value must be shifted left by three bits.

For a single-bit error, the SERRADDRx register logs the error address only if the single-bit error interrupt generation is enabled. Every double-bit error is logged if the ECC controller is enabled.

For true dual-port memory, two sets of recent error address registers are present. Each register shows the address of the error that has occurred on its corresponding memory port.

Related Information

ECC Structure on page 11-3
Refer to the "ECC Structure" section for more information regarding ECC Structure and Hamming Code word lengths.

Single-Bit Error Occurrence

The ECC controller has a 32-bit wide counter that increments on every occurrence of a single-bit error.

You can program the ECC controller to trigger an interrupt when the single-bit error counter has reached a specific value, which is configured in the Single-Bit Error Count (SERRCNTREG) register. You can reset the counter by clearing the CNT_RSTA bit in the ECC Control (CTRL) register.

For true dual-port memory, such as SD/MMC, two internal single-bit error counters are present in its ECC controller. Each counter counts the errors on its own memory port. However, both counters refer to the same user-configurable threshold for interrupt generation. In this case, program the counter threshold value in the SERRCNTREG register to represent the average number of errors of both memories.

Single-Bit Error Look-Up Table

The ECC controller of each memory port has a look-up table (LUT) that logs the memory addresses of all unique single-bit error occurrences. Repeated errors at the same memory address are not stored. The LUT keeps track of single-bit errors, but not double-bit errors.

The most significant bit (MSB) of each entry in the LUT is the valid bit. Whenever a single-bit error occurs and is logged by the LUT, the valid bit is set. The rest of the bits in a single LUT entry contain the memory address of the data error. After the memory address has been read from the LUT, software can clear the entry by writing a 1 to the valid bit in the entry. If all of the LUT entries are occupied and valid bits have not been cleared, overflow occurs on the next single-bit error. An interrupt can be generated on a LUT overflow. For more information about interrupts, refer to the "ECC Controller Interrupts" section.

The table below lists the LUT depth for every ECC-protected memory in the HPS.

Table 11-5: LUT Depth for HPS ECC Memories

Peripheral	LUT Depth (entries)
On-chip RAM	16
USB	8
SD/MMC	4 x 2 (23)
Ethernet MAC (Rx FIFO)	4

Peripheral	LUT Depth (entries)
Ethernet MAC (Tx FIFO)	4
DMA	4
NAND (ECC Buffer)	4
NAND (Write FIFO)	4
NAND (Read FIFO)	4
QSPI	4

The LUT entries are located in the ECC controller register map. Software can read the LUT error address and clear the valid bits. For more information, refer to the *ECC Controller Address Map and Register Description* section.

ECC Controller Interrupts

The ECC controller has the ability to generate single- and double-bit error interrupts to the System Manager.

The ECC controller interrupt mechanism involves the System Manager, generic interrupt controller (GIC) and the ARM Cortex-A9 . The following steps outline the interrupt generation process when interrupts have been enabled through the Error Interrupt Enable (`ERRINTEN`) register.

1. The ECC controller generates an interrupt when an error occurs and notifies the System Manager.
2. The System Manager updates its interrupt status register and sends the interrupt to the GIC.
3. The GIC sends the interrupt to the MPU.
4. The MPU services the interrupt and clears the interrupt in the ECC controller.
5. The System Manager clears the interrupt to the GIC and the corresponding interrupt status bit.

Single-Bit Error Interrupts

The Single-Bit Error Interrupt Enable (`ERRINTEN`) register must be configured for single-bit error interrupt generation.

For true dual port memory, a separate interrupt is generated for errors on each memory port.

(23) The ECC controller for SD/MMC peripheral has two LUTs, 4-entries deep, because the memory used for the SD/MMC controller is a true dual-port type, where both ports can perform read operations. Reading either of the ports can trigger a single-bit error and so, a LUT is required for each of the ports.

The ECC controller can generate a single-bit error interrupt for:

- All single-bit errors
- LUT overflow
- Single-bit error counter match

The address of the most recent single-bit error is logged in the Single-Bit Error Address (SERRADDRx) register.

The interrrupt status (INSTAT) register indicates if a single-bit error is pending in the ECC controller. All single-bit interrupts are cleared by clearing the single-bit error pending bit of the INTSTAT register. The single-bit interrupt generation can be disabled by setting the error interrupt reset bit of the Error Interrupt Reset (ERRINTENR) register.

ECC Controller Address Map and Register Descriptions on page 11-18

All Single-Bit Error Interrupt

To generate an interrupt for every single-bit error that occurs, regardless of whether it is with a new or repeated memory address access, you must:

- Clear the INTMODE bit in the Interrupt Mode (INTMODE) register
- Enable the interrupt by setting the SERRINTEN bit of the Error Interrupt Enable (ERRINTEN) register

This mode generates the most frequent interrupts and therefore, consumes greater processor cycle resources to service all the interrupts.

Note: Overflow data is not logged in this interrupt configuration.

LUT Overflow Interrupt

The LUT table can be used to generate two types of interrupts.

On every single-bit error detection and correction, the address of the error is logged in the LUT. Each address logged is unique and is at the data word boundary of its RAM bank. Coherency of the address table is maintained by a valid bit.

An interrupt can be generated for each new LUT entry or only when the LUT overflows. The following table describes the interrupt result based on the INTMODE and INTONOVF values in the INTMODE register. In this table, it is assumed that interrupts have been enabled by setting the SERRINTEN bit of the Error Interrupt Enable (ERRINTEN) register.

Note: If the INTMODE bit is clear, then all errors generate an interrupt and no overflow data is logged. The INTMODE bit must be set to 1 for the LUT to log entries.

Table 11-6: LUT Overflow Interrupt Configuration Options

INTMODE value	INTONOVF value	Result
0	X = Don't care	All errors generate an interrupt. No overflow data is logged.

INTMODE value	INTONOVF value	Result
1	0	An interrupt is generated for each new LUT entry. Overflow detection is disabled. Example: For a four-entry LUT, an interrupt asserts for each unique address entered in the LUT.
1	1	An interrupt is generated only when the LUT overflows. Example: If the LUT depth is four, the occurrence of the fifth unique address causes an interrupt to assert.

Counter Match Interrupt

The counter match interrupt allows you to set a threshold for the number of single-bit errors captured before an interrupt flag is set.

The INTONCMP bit in the INTMODE register enables the internal counter to count and compare against the SERRCNT value in the Single-Bit Error Count (SERRCNTREG) register. The internal counter increments on every single-bit error, regardless of whether it is a new or repeated address. The INTONCMP bit has no influence on the INTMODE and INTONOVF bits of the INTMODE register. As long as the internal counter is less than the Single-Bit Error Count (SERRCNTREG) register value, no interrupt is generated. When the internal counter is greater than or equal to the SERRCNTREG value, a single-bit interrupt request is asserted, the CMPFLGx bit is set in the Mode Status (MODSTAT) register, and the SERRPENx bit is set in the Interrupt Status (INTSTAT) register. When the match occurs, additional errors do not increment the counter until the CMPFLGx bit is cleared in the MODSTAT register.

This resultant match can be handled in three ways:

- Reset the error counter without restarting it. The ECC controller does not count single-bit errors until you restart the counter. Set the CNT_RSTx bit in the CTRL register to 1, which clears the counter. The CMPFLGx bit remains set. The counter does not increment until the CMPFLGx bit is cleared.
- Reset and restart the counter and clear the compare flag. Set CNT_RSTx bit in the CTRL register to 1, which clears the counter. Write a 1 to the CMPFLGx bit, which clears it. The internal counter begins counting from zero.
- Set the count to a higher value and clear the compare flag. Write the SERRCNTREG value to a higher value than the initial compare match value. Write a 1 to the CMPFLGx bit. This clears the CMPFLGx bit, but the internal counter is not reset and the count continues from where it left off until it reaches the new SERRCNTREG value.

If you allow the counter to resume during your interrupt service routine (ISR), it is possible that the error counter could run out again before the ISR exits. If this happens, and you clear the interrupt and exit the ISR, you will never detect the new counter match condition. To avoid this problem, check the CMPFLGx bit in the MODSTAT register prior to exiting the ISR. If CMPFLGx indicates another counter match condition, ensure that you handle it.

To clear the single-bit error interrupt, set the SERRPENx bit in the INTSTAT register.

Related Information

ECC Controller Address Map and Register Descriptions on page 11-18

Double-Bit Error Interrupt

All double-bit errors generate interrupts and the error memory address is logged into the recent double-bit error (DERRADDRx) register.

The Interrupt Status (INTSTAT) register indicates if a double-bit error has occured. The double-bit error interrupt generation cannot be disabled. The interrupt is de-asserted by writing to the double-bit error pending bit of the INTSTAT register.

Related Information

ECC Controller Address Map and Register Descriptions on page 11-18

Interrupt Testing

The ECC controller allows you to test the interrupt assertion and de-assertion to check if the interrupt logic is functioning properly. Set the single-or double-bit error test bits in the Interrupt Test (INTTEST) register to assert the corresponding interrupt. To clear the interrupt, set the single- or double-bit error pending bits in the Interrupt Status (INTSTAT) register.

ECC Controller Initialization and Configuration

The steps for initializing and configuring an ECC controller are as follows:

1. Turn off ECC interrupts by setting interrupt masks in the ecc_intmask_set register in the System Manager and disabling interrupts in the ERRINTEN register of the ECC Controller.
2. Ensure the ECC detection and correction logic is disabled by clearing the ECC_EN bit in the CTRL register.
3. Enable memory initialization through the ECC controller's memory initialization block by setting the INITx bit in the CTRL register. If the memory is dual-ported, initialization must be performed on both ports. Refer to the *ECC Structure* section to identify what type of memory you are initializing.
4. When the INITCOMPLETEx bit in the INITSTAT register is set, configure any single-bit, count, or compare match interrupts that are required. Enable ECC interrupts in the ECC controller and System Manager. Refer to the *ECC Controller Interrupts* section and the System Manager chapter for information on enabling interrupts.
5. (Optional) Test the ECC to see if it is functioning as expected. You can perform tests with or without the ECC controller enabled.

   Software can write to the control, data, and address registers provided in the ECC controller and then set the ENBUSx bit of the ECC_startacc register to initiate memory accesses. Alternatively, software can enable the ECC controller by setting the ECC_EN bit in the CTRL register and test the memory slave interface. Please refer to the *Memory Testing* section for more information on how to test the ECC controller.

   If optional testing is completed, clear the test memory.

After these steps are complete, normal accesses can occur.

When an ECC controller is enabled:

- The ECC controller writes the ECC bits whenever data is written to the RAM.
- Error interrupt requests can be enabled in the Interrupt Mode (INTMODE) register.
- Data errors are detected and correction is attempted.

The ECC calculation can only be performed when there is a valid RAM access.

ECC Controller Clocks

The ECC controller for each ECC-protected memory operates at the same clock frequency as its associated RAM port.

The ECC register interface, however, is in the `l4_mp_clk` domain. The clock source names for each ECC controller and its RAM are determined by the specific peripheral.

Table 11-7: Clock Source for Each ECC Controller and Memory

ECC Memory	Functional Clock
On-chip RAM	`l3_main_free_clk`
USB	asynchronous `l4_mp_clk`
SD/MMC	Port A read and write: `cclk_in`
	Port B read and write: `l4_mp_clk`
Ethernet MAC (Rx FIFO)	Read: `ap_clk`
	Write: `clk_rx_int`
Ethernet MAC (Tx FIFO)	Read: `ap_clk`
	Write: `clk_tx_int`
DMA	`l4_main_clk`
NAND (ECC Buffer)	`nand_clk`
NAND (Write FIFO)	Write: `nand_x_clk`
	Read: `nand_clk`
NAND (Read FIFO)	Read: `nand_x_clk`
	Write: `nand_clk`
QSPI	`l4_mp_clk`

Related Information

Clock Manager on page 2-1
For details of the clock signals for each ECC controller.

ECC Controller Reset

The Reset Manager drives the reset signal to the ECC controllers on a cold or warm reset. This resets the logic in the ECC controllers. The Security Manager can also request the Reset Manager to send a signal to scramble and clear all of the memories if a security event occurs.

Related Information

- **Reset Manager** on page 3-1
  For more information regarding reset, refer to the *Reset Manager* chapter.

  For more information regarding Security Manager functions, refer to the *SoC Security* chapter.

ECC Controller Address Map and Register Descriptions

Each peripheral with ECC-supported memory has its own ECC Controller address space and registers. This section lists the individual peripheral's ECC Controller address maps and registers but this information can also be found within the peripheral chapters of this technical reference manual.

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C080C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C100C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C180C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0810
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1010
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1810

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0814
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1014
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1814

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0818
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1018
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1818

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C081C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C101C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C181C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0820
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1020
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0824
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1024

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C082C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C102C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C182C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address 0x0											

DERRADDRA Fields

Bit	Name	Description	Access	Reset
11:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0830
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1030
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1830

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address 0x0											

SERRADDRA Fields

Bit	Name	Description	Access	Reset
11:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C083C
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C103C
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C183C

Offset: 0x3C

Access: RW

Bit Fields

ECC_WDataecc0bus Fields

Bit	Name	Description	Access	Reset
30:24	ECC_WDataecc3BUS	Eccdata from the register will be written to the RAM.	WO	0x0
22:16	ECC_WDataecc2BUS	Eccdata from the register will be written to the RAM.	WO	0x0
14:8	ECC_WDataecc1BUS	Eccdata from the register will be written to the RAM.	WO	0x0
6:0	ECC_WDataecc0BUS	Eccdata from the register will be written to the RAM.	WO	0x0

ECC_WDataecc1bus

The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0870
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1070
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1870

Offset: 0x70

Access: WO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

ECC_dbytectrl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0874
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1074
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1874

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0878
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1078
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1878

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0880
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1080
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1880

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_emac0_rx_ecc_registerBlock	0xFF8C0800	0xFF8C0890
ecc_emac1_rx_ecc_registerBlock	0xFF8C1000	0xFF8C1090
ecc_emac2_rx_ecc_registerBlock	0xFF8C1800	0xFF8C1890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				Address RO 0x0											

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
11:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

emac_tx_ecc Address Map

Module Instance	Base Address	End Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0FFF
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C17FF
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-82	0x0	32	RO	0x0	
CTRL on page 11-83	0x8	32	RW	0x0	ECC Control Register

Register	Offset	Width	Access	Reset Value	Description
INITSTAT on page 11-84	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-85	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-86	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-87	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 11-87	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTTEST on page 11-88	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-89	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-90	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-91	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-91	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-92	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-93	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-94	0x48	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData2bus on page 11-94	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 11-95	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-96	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-97	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-97	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-98	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-99	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-100	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-101	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_WDataecc1bus on page 11-102	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 11-103	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-104	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-105	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-105	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-106	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.
INTSTAT on page 11-107	0x	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

ECC_dbytectrl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C74
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1474
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C74

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C78
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1478
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C78

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0

Bit	Name	Description	Access	Reset
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C7C
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C147C
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C7C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C80
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1480
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C80

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C90
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1490
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C90

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_emac0_tx_ecc_registerBlock	0xFF8C0C00	0xFF8C0C32
ecc_emac1_tx_ecc_registerBlock	0xFF8C1400	0xFF8C1432
ecc_emac2_tx_ecc_registerBlock	0xFF8C1C00	0xFF8C1C32

Offset: 0x32

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

nandecc_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C23FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-117	0x0	32	RO	0x0	
CTRL on page 11-117	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-118	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-119	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-120	0x14	32	RW	0x0	Error Interrupt set

Register	Offset	Width	Access	Reset Value	Description
ERRINTENR on page 11-120	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 11-121	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-122	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-123	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-124	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-124	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-125	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-126	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-127	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-127	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-128	0x48	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData2bus on page 11-129	0x4C	32	RO	0x0	Data will be read to this register field.

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C200C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C201C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C202C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C203C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

nandr_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C27FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-149	0x0	32	RO	0x0	
CTRL on page 11-150	0x8	32	RW	0x0	ECC Control Register

Register	Offset	Width	Access	Reset Value	Description
INITSTAT on page 11-150	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-151	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-152	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-153	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 11-154	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-154	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-155	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-156	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-157	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-157	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Register	Offset	Width	Access	Reset Value	Description
SERRCNTREG on page 11-158	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-159	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-160	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-160	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-161	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 11-162	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-162	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-163	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-164	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-164	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-165	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_RDataecc1bus on page 11-166	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-167	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-168	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 11-169	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-170	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-170	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2408

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C240C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2410

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2414

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2418

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C241C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2420

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2424

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2428

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C242C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

DERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2430

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

SERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C243C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2440

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											ECC_AddrBUS 0x0				

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
4:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address

8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C247C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2480

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2490

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address RO 0x0				

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
4:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

nandw_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2BFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-181	0x0	32	RO	0x0	
CTRL on page 11-182	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-183	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-184	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-185	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-185	0x18	32	RW	0x0	Error Interrupt reset.

Register	Offset	Width	Access	Reset Value	Description
INTMODE on page 11-186	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-187	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-188	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-189	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-189	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-190	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-191	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-192	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-192	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-193	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-194	0x4C	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData3bus on page 11-194	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-195	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-196	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-196	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-197	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-198	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-198	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-199	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-200	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_dbytectrl on page 11-201	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-202	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-203	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-204	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-204	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C281C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2824

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2828

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C282C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

DERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2830

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

SERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C283C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2840

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

INTMODE on page 11-220	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-220	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-221	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-222	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-223	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-224	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Register	Offset	Width	Access	Reset Value	Description
DERRADDRB on page 11-224	0x34	32	RO	0x0	This register shows the address of PORTB current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRB on page 11-225	0x38	32	RO	0x0	This register shows the address of PORTB current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-226	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-227	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-227	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-228	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-229	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 11-229	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-230	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-231	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-231	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-232	0x60	32	WO	0x0	Data from the register will be written to the RAM.

Register	Offset	Width	Access	Reset Value	Description
ECC_RDataecc0bus on page 11-233	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-233	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-234	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-235	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 11-236	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-237	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-238	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-239	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-239	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

Register	Offset	Width	Access	Reset Value	Description
SERRLKUPB0 on page 11-240	0xD0	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTB.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C08

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							INITB 0x0	Reserved							INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CNT_RSTB 0x0	CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
24	INITB	Enable for the hardware memory initialization PORTB.	RW	0x0
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
9	CNT_RSTB	Enable to reset internal single-bit error counter B value to zero	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C0C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INITCOMPLETEB 0x0	Reserved							INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
8	INITCOMPLETEB	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C10

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C14

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C18

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C1C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C20

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Reserved														CMPFLGB 0x0	CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
1	CMPFLGB	Port B compare status flag	RW	0x0
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

DERRADDRB

This register shows the address of PORTB current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C34

Offset: 0x34

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRB Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRB

This register shows the address of PORTB current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C38

Offset: 0x38

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SERRLKUPB0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

onchip_ram_ecc Address Map

Module Instance	Base Address	End Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C7FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-250	0x0	32	RO	0x0	
CTRL on page 11-251	0x8	32	RW	0x2	ECC Control Register

Register	Offset	Width	Access	Reset Value	Description
INITSTAT on page 11-252	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-252	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-253	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-254	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 11-255	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-255	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-256	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-257	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-258	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-258	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Register	Offset	Width	Access	Reset Value	Description
SERRCNTREG on page 11-259	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-260	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-261	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-261	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-262	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 11-263	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-263	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-264	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-265	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-265	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-266	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_RDataecc1bus on page 11-267	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-268	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-269	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 11-270	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-271	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-272	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-272	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-273	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C302C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

DERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

SERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C303C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	ECC_AddrBUS 0x0														

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
14:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3044

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[31:0].	RO	0x0

ECC_RData1bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3048

Offset: 0x48

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData1bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[63:32].	RO	0x0

ECC_RData2bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C304C

Offset: 0x4C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECC_dbytectrl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3074

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								DBEN 0x0							

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
7:0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C307C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address RO 0x0														

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
14:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

dmac_ecc Address Map

Module Instance	Base Address	End Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C83FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-282	0x0	32	RO	0x0	
CTRL on page 11-283	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-284	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-285	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-286	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-286	0x18	32	RW	0x0	Error Interrupt reset.

Register	Offset	Width	Access	Reset Value	Description
INTMODE on page 11-287	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-288	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-289	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-290	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-290	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-291	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-292	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-293	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-293	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-294	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-295	0x4C	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData3bus on page 11-295	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-296	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-297	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-297	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-298	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-299	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-299	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

IP_REV_ID

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8000

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C800C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C801C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C802C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

DERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

SERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C803C

Offset: 0x3C

Access: RW

Bit Fields

Reserved								DBEN 0x0							

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
7:0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C807C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address RO 0x0								

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
8:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

qspi_ecc Address Map

Module Instance	Base Address	End Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C87FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-315	0x0	32	RO	0x0	
CTRL on page 11-316	0x8	32	RW	0x0	ECC Control Register

Register	Offset	Width	Access	Reset Value	Description
INITSTAT on page 11-316	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-317	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-318	0x14	32	RW	0x0	Error Interrupt set

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8410

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8414

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8418

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C841C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8420

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8424

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8428

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C842C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

DERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8430

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

SERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C843C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8440

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8478

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C847C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8480

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8490

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address RO 0x0						

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
6:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

usb_ecc Address Map

Module Instance	Base Address	End Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8BFF
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF9FFFFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-353	0x0	32	RO	0x0	
CTRL on page 11-354	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-354	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-355	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-356	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-357	0x18	32	RW	0x0	Error Interrupt reset.

Register	Offset	Width	Access	Reset Value	Description
INTMODE on page 11-358	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-358	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-359	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-360	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-361	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-361	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-362	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-363	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-364	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-364	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-365	0x4C	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData3bus on page 11-366	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-367	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-367	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-368	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-369	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-369	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-370	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-371	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-372	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_dbytectrl on page 11-373	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-374	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-375	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-376	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-376	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8820
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C20

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8824
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C24

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8828
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C28

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C882C
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			Address 0x0												

DERRADDRA Fields

Bit	Name	Description	Access	Reset
12:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8830
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			Address 0x0												

SERRADDRA Fields

Bit	Name	Description	Access	Reset
12:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C883C
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C3C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8840
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C40

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			ECC_AddrBUS 0x0												

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
12:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_otg0_ecc_registerBlock	0xFF8C8800	0xFF8C8844
ecc_otg1_ecc_registerBlock	0xFF8C8C00	0xFF8C8C44

Offset: 0x44

Access: RO

Bit Fields
