SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
12:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance Release
May 2016	2016.05.27	Maintenance Release
May 2016	2016.05.03	Maintenance Release
November 2015	2015.11.02	• Added "ECC Bits Required Based on Data Width" table to "Error Checking and Correction Algorithm" section • Added 136-bit Hamming Matrix figure to "Error Checking and Correction Algorithm" section

Date	Version	Changes
May 2015	2015.05.04	• Added 35-bit Hamming Matrix figure to "Error Checking and Correction Algorithm" section • Added "ECC Controller Address Map and Register Definitions" section
December 2014	2014.12.15	Added the "RAM and ECC Memory Organization Example" subsection to the "ECC Structure" section Added the following subsections in the "Indirect Memory Access" section: • "Watchdog Timer" • "Data Correction" • "Error Injection" • "Memory Testing" • "Error Checking and Correction Algorithm"
August 2014	2014.08.18	Initial Release

On-Chip Memory 12

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) contains two types of on-chip memory. The on-chip memory types are:

- On-chip RAM—The on-chip RAM provides 256 KB of general-purpose single-port RAM
- Boot ROM—The boot ROM provides 128 KB and is available to store the code required to boot the HPS from cold or warm reset

Both on-chip memories connect to the level 3 (L3) interconnect.

Related Information

- **On-Chip RAM** on page 12-1
- **Boot ROM** on page 12-4

On-Chip RAM

Features of the On-Chip RAM

The on-chip RAM offers the following features:

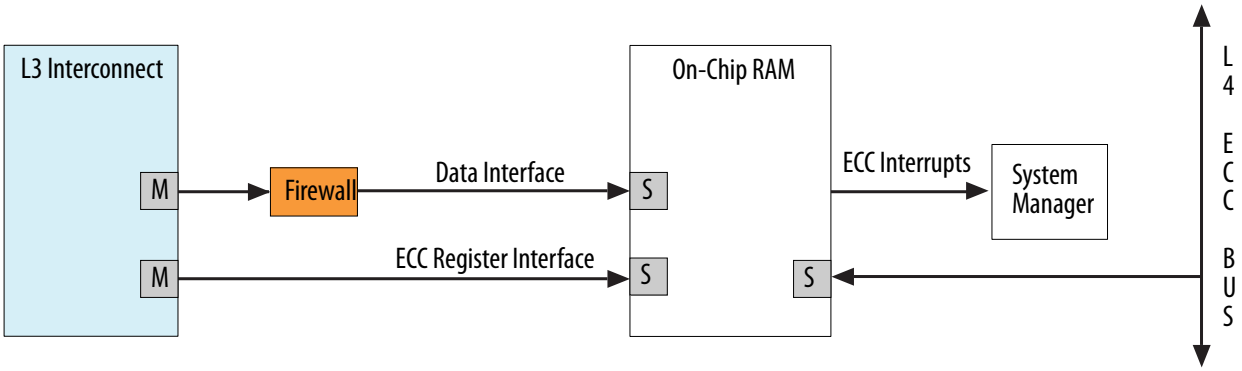
- 64-bit slave interface
- 256 KB of single-ported RAM
- Error correction code (ECC) support
- Capable of data transfers for every clock cycle
- Security firewall
- Supports scrambling and reset of memory on detection of a tamper event

Related Information

Clock Manager on page 2-1

On-Chip RAM Block Diagram and System Integration

Figure 12-1: On-Chip RAM Block Diagram



The on-chip RAM and L3 interconnect transfers data through a 64-bit interface that passes through a firewall, operating at the `l3_main_free_clk` interconnect clock frequency. For memory, read acceptance is two, write acceptance is two, and total acceptance is two with a round-robin arbitration.

Related Information

- **Error Checking and Correction Controller** on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).
- **SoC Security** on page 6-1

Functional Description of the On-Chip RAM

The on-chip RAM uses a 64-bit slave interface. The slave interface supports transfers between memory and the L3 interconnect. All reads and writes are serviced in order.

The on-chip RAM has an exclusive monitor, as well. To ensure mutually exclusive access to shared data, use the exclusive access support built into the on-chip RAM. The on-chip RAM contains five monitors. Each monitor can be used by any of the following:

- CPU and CPU1
- FPGA2SOC
- FPGA2SDRAM0
- FPGA2SDRAM1
- FPGA2SDRAM2

Note: The on-chip RAM exclusive monitor for the MPU does not differentiate between individual CPUs.

Related Information

Clock Manager on page 2-1

On-Chip RAM Clocks

The on-chip RAM is driven by the `l3_main_clk` interconnect clock.

There are two clocks to the on-chip RAM that must be enabled. The first clock is for the memory bus and the second clock is for the ECC register interface. The ECC register interface clock is the `l4_mp_clk`.

On-Chip RAM Resets

The contents of the RAM remain unchanged on a cold or warm reset. Reset only clears the state associated with the slave interface.

However, when a reset is initiated because the Security Manager receives a tamper detection assertion, the memory is scrambled and cleared.

Related Information

- **Error Checking and Correction Controller** on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).
- **SoC Security** on page 6-1

On-Chip RAM Initialization

You must initialize the on-chip RAM before you enable the ECC. Failure to do so triggers spurious interrupts.

The on-chip RAM can be initialized by setting the `INITA` bit in the ECC Control Register (CTRL). After the Initialization Status (`INITSTAT`) register indicates the initialization has completed, the ECC Controller can be enabled and ECC interrupts can be configured.

Related Information

Error Checking and Correction Controller on page 11-1
For more information about ECC, refer to the *Error Checking and Correction Controller* chapter of the Arria 10 Device Handbook.

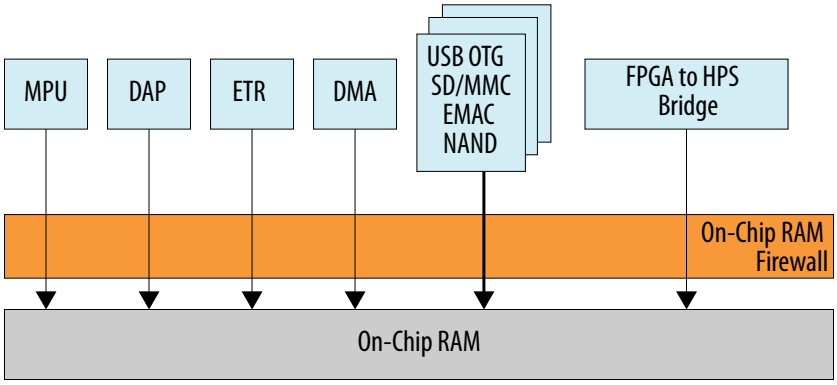
On-Chip RAM Firewall

At reset all memories are secure. Out of reset, regions of memories can be configured for non-secure accesses.

The on-chip RAM is divided into six regions of 4 KB. Within each region, a non-secure or shared memory region can be assigned by programming a `base` and `limit` value in the corresponding `regionNaddr` register, with `N` denoting the region number. Each of these regions can be enabled by writing to the `enable` register or setting the corresponding bit in the `enable_set` register.

When an incoming transaction falls within any enabled non-secure regions, the firewall allows both secure and non-secure packets. When the transaction is outside of any enabled regions, the firewall only allows secure packets.

Figure 12-2: On-Chip RAM Firewall



ECC Protection

The ECC controller operation and functionality is programmable through the ECC register slave interface, as shown in the **On-Chip RAM Block Diagram** in the "On-Chip RAM Block Diagram and System Integration" section. The ECC controller's register interface provides host access to configure the ECC logic as well as inject bit errors into the memory for testing purposes. It also provides host access to memory initialization hardware used to clear the memory contents, including the ECC bits. The ECC controller generates interrupts upon occurrences of single- and double-bit errors, and the interrupt signals are connected to the system manager.

Related Information

- **Error Checking and Correction Controller** on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).
- **SoC Security** on page 6-1

Boot ROM

Features of the Boot ROM

The boot ROM offers the following features:

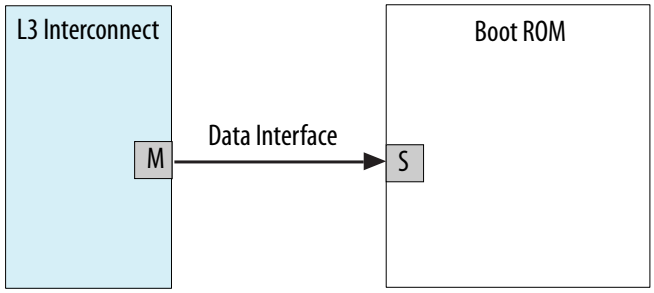
- 32-bit interface
- 128 KB size
- Capable of data transfers for every clock cycle
- Secure initialization

Related Information

Clock Manager on page 2-1

Boot ROM Block Diagram and System Integration

Figure 12-3: Block diagram of On-Chip ROM



Boot ROM and L3 interconnect transfers data through a 32-bit data interface that passes through a firewall, operating at the `l3_main_free_clk` interconnect clock frequency. The memory has a read acceptance of one, a write acceptance of one, and a total acceptance of two with round-robin arbitration.

Related Information

SoC Security on page 6-1

Functional Description of the Boot ROM

The boot ROM is used only for booting the system.

The boot ROM contains the execution code that identifies if there is a secure or non-secure boot, initializes the system to bring it out of reset, finds bootloader and can decrypt and/or authenticate it based on user fuses.

On a cold or warm reset of the microprocessor unit (MPU) subsystem, MPU0 executes the Preloader code stored in the boot ROM. The Preloader occurs after the initial boot stage, which is the boot ROM. It is loaded by the boot ROM and copied to the on-chip RAM. However, if you choose to boot the Preloader from the FPGA, or if a failure occurred at boot ROM, then as a fallback boot device, the Preloader can then run directly on the FPGA without the need to copy to on-chip RAM.

The boot ROM uses an 32-bit slave interface. The slave interface supports transfers between memory and the L3 interconnect. All writes return an error response.

Related Information

- **Clock Manager** on page 2-1
- **SoC Security** on page 6-1
- **Booting and Configuration** on page 30-1

Boot ROM Clocks

The boot ROM is driven by the `l3_main_clk` interconnect clock.

The boot ROM needs to set up the Main PLL and make sure it sources all of the system's clocks. The sequence applied for both Warm and Cold resets is similar. The PLL's are not set up on an FPGA boot, a successful RAM boot, or if the user selects a bypass mode.

Related Information

- **Clock Manager** on page 2-1
- **SoC Security** on page 6-1

Boot ROM Resets

Reset to on-chip ROM does not need to distinguish between warm and cold reset. Therefore, the content of the ROM will remain unchanged on a cold or warm reset.

On-Chip Memory Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved						ECC_SLVERR_DIS 0x1	ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
1	ECC_SLVERR_DIS	Enable to prevent double-bit ECC error from triggering SLVERR at ONCHIP_RAM AXI Interface RRESP output. Enable = 1'b1 Disable = 1'b0	RW	0x1
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C300C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_registerBlock	0xFF8C3000	0xFF8C3010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C301C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C302C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

DERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C3030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	Address 0x0														

SERRADDRA Fields

Bit	Name	Description	Access	Reset
14:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_onchip_ram_ecc_register-Block	0xFF8C3000	0xFF8C303C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0

NAND Flash Controller 13

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides a NAND flash controller to interface with external NAND flash memory in Altera system-on-a-chip (SoC) systems. You can use external flash memory to store software, or as extra storage capacity for large applications or user data. The HPS NAND flash controller is based on the Cadence Design IP® NAND Flash Memory Controller.

NAND Flash Controller Features

The NAND flash controller provides the following functionality and features:

- Supports one x8 or x16 NAND flash device

  Note: The HPS supports booting only from a x8 NAND flash device.
- Supports Open NAND Flash Interface (ONFI) 1.0
- Supports NAND flash memories from Hynix, Samsung, Toshiba, Micron, and STMicroelectronics
- Supports error correction codes (ECCs) providing single-bit error correction and double-bit error detection, with:
  - Sector size programmable 512 byte (4-, 8-, or 16-bit correction) or 1024 byte (24-bit correction)
  - Three NAND FIFOs - ECC Buffer, write FIFO and read FIFO
- Supports pipeline read-ahead and write commands for enhanced read and write throughput
- Supports devices with 32, 64, 128, 256, 384, or 512 pages per block
- Supports multiplane devices
- Supports page sizes of 512 bytes, 2 kilobytes (KB), 4 KB, or 8 KB
- Supports single layer cell (SLC) and multiple layer cell (MLC) devices with programmable correction capabilities
- Provides internal direct memory access (DMA)
- Provides programmable access timing

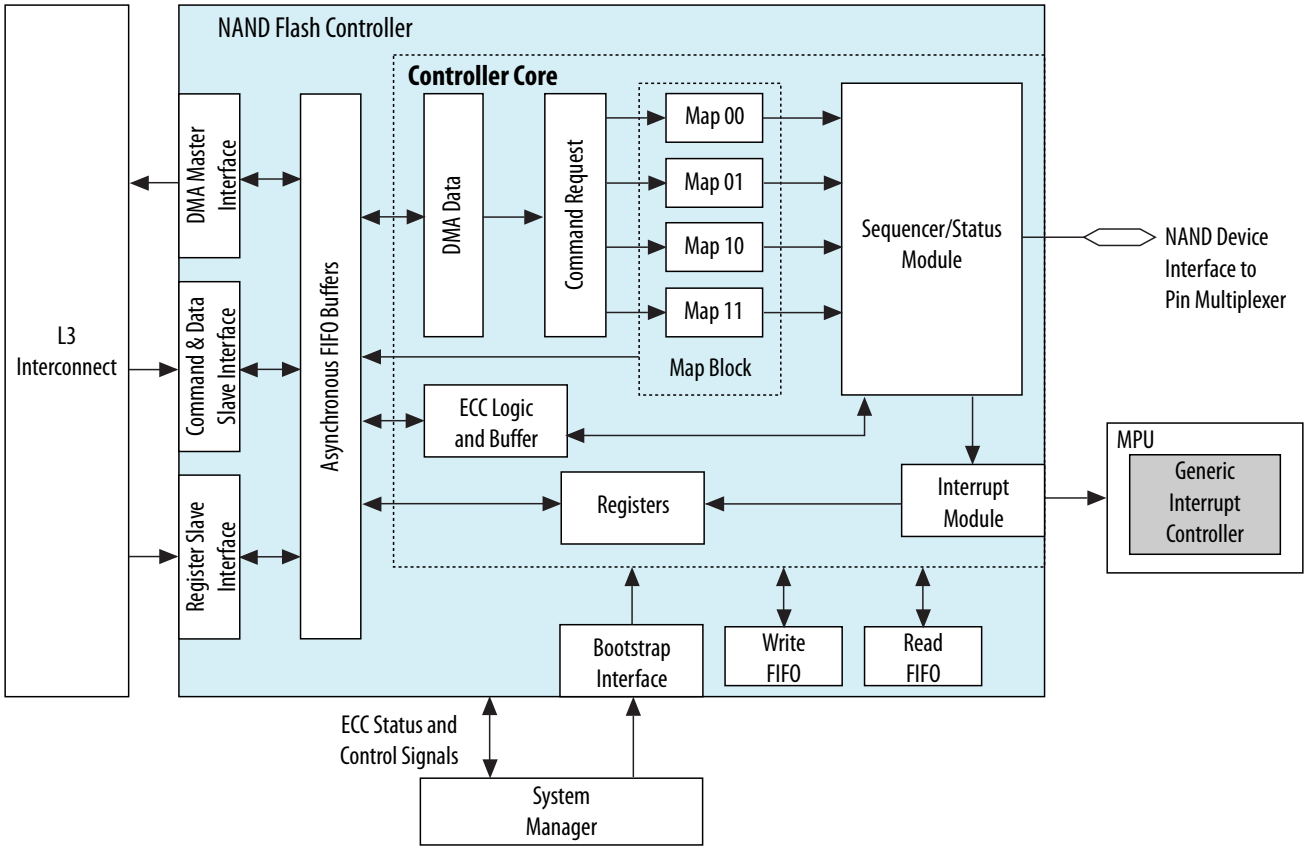
NAND Flash Controller Block Diagram and System Integration

Figure 13-1: NAND Flash Controller Block Diagram

The following figure shows integration of the NAND flash controller in the HPS.



Features of the flash controller:

- Receives commands and data from the host through memory-mapped control and data registers connected to the command and data slave interface
- The host accesses the flash controller's control and status registers (CSRs) through the register slave interface.
- Handles all command sequencing and flash device interactions
- Generates interrupts to the HPS Cortex-A9 MPCore
- The DMA master interface provides accesses to and from the flash controller through the controller's built-in DMA.

NAND Flash Controller Signal Descriptions

All NAND pins have to be from one of the following categories:

- HPS Dedicated
- Shared
- FPGA

The following table lists all NAND Flash Interface signals available to both the HPS and FPGA.

Pins	Supported Data Width	Supported Number of CE and R/B
HPS Dedicated Pins	x8	1
Shared Pins	x8/x16	1
FPGA Pins	x8/x16	1 – 4

The type of pins you use determines the number of Chip Enable (CE) and Ready/Busy (RB) pairs available to you for use. For example, if you use HPS dedicated pins or shared pins, you can only use one CE and R/B pair. If you use FPGA pins, you can use multiple CE and R/B pairs.

Note: The options are mutually exclusive, which means you cannot use HPS dedicated pins, and route the CE and R/B signals to FPGA dedicated pins.

For more information on which signals route to the FPGA and HPS I/O, please refer to the *HPS Component Interface* chapter.

Table 13-1: NAND Flash Interface Signals

Qsys Port Name	Connected to FPGA	Connected to HPS I/O	HPS Pin Name
nand_adq_i[15:0]	Yes	Yes	NAND_ADQ[15:0]
nand_adq_oe	Yes	Yes	
nand_adq_o[15:0]	Yes	Yes	
nand_ale_o	Yes	Yes	NAND_ALE
nand_ce_o[3:0]	Yes, 4 chip enables	Yes, 1 chip enable	NAND_CE_N
nand_cle_o	Yes	Yes	NAND_CLE
nand_re_o	Yes	Yes	NAND_RE_N
nand_rdy_busy_i[3:0]	Yes, 4 ready/busy signals	Yes, 1 ready/busy signal	NAND_RB
nand_we_o	Yes	Yes	NAND_WE_N
nand_wp_o	Yes	Yes	NAND_WP_N

Functional Description of the NAND Flash Controller

This section describes the functionality of the NAND flash controller.

Discovery and Initialization

The NAND flash controller performs a specific initialization sequence after the HPS receives power and the flash device is stable. During initialization, the flash controller queries the flash device and configures itself according to one of the following flash device types:

- ONFI 1.0-compliant devices
- Legacy (non-ONFI) NAND devices

The NAND flash controller identifies ONFI-compliant connected devices using ONFI discovery protocol, by sending the `Read ID` command. For devices that do not recognize this command (especially for 512-byte page size devices), software must write to the system manager to assert the `bootstrap_512B_device` signal to identify the device type before releasing the NAND controller from reset.

To support booting and initialization, the `rdy_busy_in` pin must be connected.

The NAND flash controller performs the following initialization steps:

1. If the system manager is asserting `bootstrap_inhibit_init`, the flash controller goes directly to **step 7**.
2. When the device is ready, the flash controller sends the "Read ID" command to read the ONFI signature from the memory device, to determine whether an ONFI or a legacy device is connected.
3. If the data returned by the memory device has an ONFI signature, the flash controller then reads the device parameter page. The flash controller stores the relevant device feature information in internal memory control registers, enabling it to correctly program other registers in the flash device, and goes to **step 5**.
4. If the data does not have a valid ONFI signature, the flash controller assumes that it is a legacy (non-ONFI) device. The flash controller then performs the following steps:
   a. Sends the `reset` command to the device
   b. Reads the device signature information
   c. Stores the relevant values into internal memory controller registers
5. The flash controller resets the memory device. At the same time, it verifies the width of the memory interface. The HPS supports one 8-bit or 16-bit NAND flash device. The flash controller detects the memory interface width.
6. The flash controller sends the `Page Load` command to block 0, page 0 of the device, configuring direct read access, so the processor can boot from that page. The processor can start reading from the first page of the flash memory, which is the expected location of the pre-loader software.

   Note: The system manager can bypass this step by asserting `bootstrap_inhibit_b0p0_load` before reset is de-asserted.
7. The flash controller sends the `reset` command to the flash.
8. The flash controller clears the `rst_comp` bit in the `intr_status0` register in the `status` group to indicate to software that the flash reset is complete.

Bootstrap Interface

The NAND flash controller provides a bootstrap interface that allows software to override the default behavior of the flash controller. The bootstrap interface contains four bits, which when set appropriately, allows the flash controller to skip the initialization phase and begin loading from flash memory immediately after reset. These bits are driven by software through the system manager. They are sampled by the NAND flash controller when the controller is released from reset.

Related Information

System Manager on page 5-1
For more information about the bootstrap interface control bits.

Bootstrap Setting Bits

The following table lists the relevant bootstrap setting bits, found in the system manager's NAND flash controller register group. As an example, this table also lists recommended bootstrap settings for a 512-byte page device.

Table 13-2: Bootstrap Setting Bits

Bit	Example Value for 512-Byte Page
`noinit`	1[24]
`page512`	1
`noloadb0p0`	1
`tworowaddr`	• 1—flash device supports two-cycle addressing • 0—flash device support three-cycle addressing

Related Information

Configuration by Host on page 13-5

Configuration by Host

If the system manager sets `bootstrap_inhibit_init` to 1, the NAND flash controller does not perform the process described in "Discovery and Initialization". In this case, the host processor must configure the flash controller.

When performance is not a concern in the design, the timing registers can be left unprogrammed.

Related Information

- **Bootstrap Setting Bits** on page 13-5
  For recommended configuration-by-host settings to enable the basic read, write, and erase operations for a single-plane, 512 bytes/page device.
- **Discovery and Initialization** on page 13-4

[24] When this register is set, the NAND flash controller expects the host to program the related device parameter registers. For more information, refer to "Configuration by Host".

Recommended Bootstrap Settings for 512-Byte Page Device

Table 13-3: Recommended Bootstrap Settings for an 8-bit, 512-Byte Page Device

Register	Value
devices_connected	1
device_width	0 indicating an 8-bit NAND flash device
number_of_planes	1 indicating a single-plane device
device_main_area_size	The value of this register must reflect the flash device's page main area size.
device_spare_area_size	The value of this register must reflect the flash device's page spare area size.
pages_per_block	The value of this register must reflect number of pages per block in the flash device.

NAND Page Main and Spare Areas

Each NAND page has a main area and a spare area. The main area is intended for data storage. The spare area is intended for ECC and maintenance data, such as wear leveling information. Each block consists of a group of pages.

The sizes of the main and spare areas, and the number of blocks in a page, depend on the specific NAND device connected to the NAND flash controller. Therefore, the device-dependent registers, `device_main_area_size`, `device_spare_area_size`, and `pages_per_block`, must be programmed to match the characteristics of the device.

If your software does not perform the discovery and initialization sequence, the software must include an alternative method to determine the correct value of the device-dependent registers. The HPS boot ROM code enables discovery and initialization by default (that is, `bootstrap_inhibit_init = 0`).

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

Each of these memories is protected by ECC, and by interrupts for single and double-bit errors. The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows injection of single- and double-bit errors for test purposes. It must be initialized to enable the ECC function.

Related Information

Error Checking and Correction Controller on page 11-1
For more information about ECC, refer to the *Error Checking and Correction Controller* chapter of the Arria 10 Device Handbook.

Clocks

The NAND clock runs synchronously from the NOC clocks, which is always active. To minimize the number of clocks, Clock Manager outputs software managed enables to the USB, SPI Masters, QSPI and NAND peripherals. The software enable for NAND is `nand_clk_en` and is set to ENABLE by default. Also, in Boot Mode, `nand_clk_en` is active to ensure that all clocks are active if RAM is cleared for security.

Table 13-4: Clock Inputs to NAND Flash Controller

Clock Signal	Description
`nand_x_clk`	Clock for master and slave interfaces and the ECC sector buffer.
`nand_clk`	Clock for the NAND flash controller.

The frequency of `nand_x_clk` is four times the frequency of `nand_clk`.

Clock Generation

The clock manager sends the top level clock from the HPS.

The clock manager sends the 200 MHz clock, `l4_mp_clk`, to the NAND Flash Controller. This clock becomes the NAND reference clock called `nand_mp_clk`. The `nand_mp_clk` is divided by four and is used for input and output. Since the NAND places a 200 MHz limit on the clock, each of these four generated clocks are 50 MHz and called `nand_clk`.

Clock Enable

The `nand_mp_clk` and `nand_clk` clocks have enables.

Clock Switching

When you use clock switching, you must follow the following requirements:

- Ensure that there is no activity.
- Software must disable this module during the frequency switch and re-enable it after the frequency has changed.
- When clock switching is complete, the software must reconfigure the NAND initialization registers according to the new frequency before triggering any new transactions onto the flash interface.

Resets

When a tamper is detected, the reset manager sends a special signal to the NAND data RAM. This scrambles and clears the RAM. In addition, the RAM can be cleared during a cold or warm reset, depending on how fuse bits are programmed in the device.

Before the NAND flash controller comes out of the reset state, the pin multiplexers for the flash external interface must be configured.

Related Information

Reset Manager on page 3-1

Taking the NAND Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

- **Module Reset Signals** on page 3-8
- **Modules Requiring Software Deassert** on page 3-13

Indexed Addressing

The NAND flash controller uses indexed addressing to reduce the address span consumed by the flash controller.

Indirect addressing is implemented by two registers, accessed through the `nanddata` region, as described in the "Register Map for Indexed Addressing" section.

Register Map for Indexed Addressing

Indexed addressing uses registers in the nanddata region of the HPS memory map. The nanddata region consists of a control register and a variable-size register that allows direct access to flash memory, as detailed in the following table.

Table 13-5: Register Map for Indexed Addressing

Register Name	Offset Address	Usage
`Control`	0x0	Identifies the page of flash memory to be read or written. Software writes the 32-bit control information consisting of **map** command type, block, and page address. The upper four bits must be set to 0. For specific usage of the `Control` register, refer to "Command Mapping".
`Data`	0x10	The `Data` register is a page-size window into the NAND flash. By reading from or writing to locations starting at this offset, the software reads directly from or writes directly to the page and block of NAND flash memory specified by the `Control` register. The Data register is always addressed on 32-bit word boundaries, although the physical flash device has an 8-bit-wide data path.

Related Information

- **Command Mapping** on page 13-9
- **HPS Peripheral Region Address Map** on page 1-20

Indexed Addressing Host Usage

The host uses indexed addressing as follows:

1. Program the 32-bit index-address field into the `Control` register in the `nanddata` region. This action provides the flash address parameters to the NAND flash controller.
2. Perform a 32-bit read or write in the `Data` register.
3. Perform additional 32-bit reads and writes if they are in the same page and block in flash memory.

It is unnecessary to write to the control register for every data transfer if a group of data transfers targets the same page and block address. For example, you can write the control register at the beginning of a page with the block and page address, and then read or write the entire page by directing consecutive transactions to the `Data` register.

Command Mapping

The NAND flash controller supports several flash controller-specific MAP commands, providing an abstraction level for programming a NAND flash device. By using the MAP commands, you can avoid directly programming device-specific commands. Using this abstraction layer provides enhanced performance. Commands take multiple cycles to send off-chip. The MAP commands let you initiate commands and let the flash controller sequence them off-chip to the NAND device.

The NAND flash controller supports the following flash controller-specific MAP commands:

- MAP00 commands—boot-read or buffer read/write during read-modify-write operations
- MAP01 commands—memory arrays read/write
- MAP10 commands—NAND flash controller commands
- MAP11 commands—low-level direct access

MAP00 Commands

MAP00 commands access a page buffer in the NAND flash device. Addressing always begins at 0x0 and extends to the page size specified by the `device_main_area_size` and `device_spare_area_size` registers in the `config` group. You can use this command to perform a boot read. Use MAP00 commands in read-modify-write (RMW) operations to read or write any word in the buffer. MAP00 commands allow a direct data path to the page buffer in the device.

The host can access the page buffer directly using the MAP00 commands only if there are no other MAP01 or MAP10 commands active on the NAND flash controller.

MAP00 Command Format

Table 13-6: MAP00 Command Format with Address Mapping

The following table shows the format of a MAP00 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	`CMD_MAP`	Set to 0
25:13	(reserved)	Set to 0

Address Bits	Name	Description
12:2	BUFF_ADDR	Data width-aligned buffer address on the memory device. Maximum page access is 8 KB.
1:0	(reserved)	Set to 0

MAP00 Usage Limitations

The usage of these commands under normal operations is limited to the following situations:

- They can be used to perform an Execute-in-Place (XIP) boot from the device; reading directly from the page buffer while booting directly from the device.
- MAP00 commands can be used to perform RMW operations where MAP00 writes are used to modify a read page in the device page buffer. Because the NAND flash controller does not perform ECC correction during such an operation, Altera does not recommend this method in an MLC device.
- In association with MAP11 commands, MAP00 commands provide a way for the host to directly access the device bypassing the hardware abstractions provided by NAND flash controller with MAP01 and MAP10 commands. This method is also used for debugging, or for issuing an operation that the flash controller might not support with MAP01 or MAP10 commands.

Restrictions:

- MAP00 commands cannot be used with MAP01 commands to read part of a page. Accesses using MAP01 commands must perform a complete page transfer.
- No ECC is performed during a MAP00 data access.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while performing MAP00 operations.

MAP01 Commands

MAP01 commands transfer complete pages between the host memory and a specific page of the NAND flash device. Because the MAP01 commands support only page addresses, the entire page must be read or written at once. The actual number of commands required depends on the size of the data transfer. The Command register points to the first page and block in the transfer. You do not change the Command register when you initiate subsequent transactions in the transfer, but only when the entire page is transferred.

When the NAND flash controller receives a read command, it issues a load operation on the device, waits for the load to complete, and then returns read data. Read data must be read from the start of the page to the end of the page.

Write data must be written from the start of the page to the end of the page. When the NAND flash controller receives confirmation of the transfer, it issues commands to program the data into the device.

The flash controller ignores the byte enables for read and write commands and transfers the entire data width.

MAP01 Command Format

Table 13-7: MAP01 Command Format with Address Mapping

The following table shows the format of a MAP01 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 1
25:24	(reserved)	Set to 0
23:<*M*>	BLK_ADDR	Block address in the device
(<*M*>-1):0	PAGE_ADDR	Page address in the device

Note: <*M*> depends on the number of pages per block in the device. <*M*> = ceil(log2(<*device pages per block*>)). Therefore, use the following values:

- 32 pages per block: <*M*>=5
- 64 pages per block: <*M*>=6
- 128 pages per block: <*M*>=7
- 256 pages per block: <*M*>=8
- 384 pages per block: <*M*>=9
- 512 pages per block: <*M*>=9

MAP01 Usage Limitations

Use the MAP01 command as follows:

- A complete page must be read or written using a MAP01 command. During such transfers, every transaction from the host must have the same block and page address. The NAND flash controller internally keeps track of how much data it reads or writes.
- MAP00 commands cannot be used in between using MAP01 commands for reading or writing a page.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while the host is performing MAP01 operations directly. If the host issues MAP01 commands to the NAND flash controller while DMA is enabled, the flash controller discards the request and generates an `unsup_cmd` interrupt.

MAP10 Commands

MAP10 commands provide an interface to the control plane of the NAND flash controller. MAP10 commands control special functions of the flash device, such as erase, lock, unlock, copy back, and page spare area access. Data passed in this command pathway targets the NAND flash controller rather than the flash device. Unlike other command types, the data (input or output) related to these transactions does not affect the contents of the flash device. Rather, this data specifies and performs the exact commands of the flash controller. Only the lower 16 bits of the `Data` register contain the relevant information.

MAP10 Command Format

Table 13-8: MAP10 Command Format with Address Mapping

The following table shows the format of a MAP10 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 2
25:24	(reserved)	Set to 0
23:<*M*>	BLK_ADDR	Block address in the device
(<*M*>-1):0	PAGE_ADDR	Page address in the device

Note: <*M*> depends on the number of pages per block in the device, as follows:

- 32 pages per block: <*M*>=5
- 64 pages per block: <*M*>=6
- 128 pages per block: <*M*>=7
- 256 pages per block: <*M*>=8
- 384 pages per block: <*M*>=9
- 512 pages per block: <*M*>=9

MAP10 Operations

Table 13-9: MAP10 Operations

Command	Function
0x01	Sets block address for erase and initiates operation
0x10	Sets unlock start address
0x11	Sets unlock end address and initiates unlock
0x21	Initiates a lock of all blocks
0x31	Initiates a lock-tight of all blocks
0x41	Sets up for spare area access
0x42	Sets up for default area access
0x43	Sets up for main+spare area access
0x60	Loads page to the buffer for a RMW operation
0x61	Sets the destination address for the page buffer in RMW operation

Command	Function
0x62	Writes the page buffer for a RMW operation
0x1000	Sets copy source address
0x11<*PP*>	Sets copy destination address and initiates a copy of <*PP*> pages
0x20<*PP*>	Sets up a pipeline read-ahead of <*PP*> pages
0x21<*PP*>	Sets up a pipeline write of <*PP*> pages

MAP10 Usage Limitations

Use the MAP10 commands as follows:

- MAP10 commands should be used to issue commands to the controller, such as erase, copy-back, lock, or unlock.
- MAP10 pipeline commands should also be used to read or write consecutive multiple pages from the flash device within a device block boundary. The host must first issue a MAP10 pipeline read or write command and then issue MAP01 commands to do the actual data transfers. The MAP10 pipeline read or write command instructs the NAND flash controller to use high-performance commands such as cache or multiplane because the flash controller has knowledge of multiple consecutive pages to be read. The pages must not cross a block boundary. If a block boundary is crossed, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Up to four pipeline read or write commands, at the same time, can be issued to the NAND flash controller.
- While the NAND flash controller is performing MAP10 pipeline read or write commands, DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0). DMA must be disabled because the host is directly transferring data from and to the flash device through the flash controller.

MAP11 Commands

MAP11 commands provide direct access to the NAND flash controller's address and control cycles, allowing software to issue the commands directly to the flash device using the Command and Data registers. The MAP11 command is useful if the flash device supports a device-specific command not included with standard flash commands. It can also be useful for low-level debugging.

MAP11 commands provide a direct control path to the flash device. These commands execute command, address, and data read and write cycles directly on the NAND device interface. The host can issue only single-beat accesses to the `nanddata` region while using MAP11 commands. The following are the usage requirements:

- Command, address, and write data values are placed in the `Data` register.
- Command and address cycles to the device must be a write transaction on the host bus.
- For data cycles, the type of transaction on the host bus (read/write) determines the data cycle type on the device interface.
- On a read, the returned data also appears in the `Data` register.
- The Control register encodes the control operation type.

MAP11 Control Format

Table 13-10: MAP11 Control Format with Address Mapping

The following table shows the format of a MAP11 command. This command is written to the Command register in the `nanddata` region.

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	`CMD_MAP`	Set to 3
25:2	(reserved)	Set to 0
1:0	`TYPE`	Sets the control type as follows: • 0 = Command cycle • 1 = Address cycle • 2 = Data Read/Write Cycle

MAP11 Usage Limitations

Use the MAP11 commands as follows:

- Use MAP11 commands only in special cases, for debugging or sending device-specific commands that are not supported by the NAND flash controller.
- DMA must be disabled before you use MAP11 operations.
- The host can use only single beat access transfers when using MAP11 commands.

Note: MAP11 commands provide direct, unstructured access to the NAND flash device. Incorrect use can lead to unpredictable behavior.

Data DMA

The DMA transfers data with minimal host involvement. Software initiates data DMA with the MAP10 command.

The `flag` bit of the `dma_enable` register in the `dma` group enables data DMA functionality. Only enable or disable this functionality when there are no active transactions pending in the NAND flash controller. When the DMA is enabled, the flash controller initiates one DMA transfer per MAP10 command over the DMA master interface. When the DMA is disabled, all operations with the flash controller occur through the memory-mapped `nanddata` region.

The NAND flash controller supports up to four outstanding DMA commands, and ignores additional DMA commands. If software issues more than four outstanding DMA commands, the flash controller issues the `unsup_cmd` interrupt. On receipt of a DMA command, the flash controller performs command sequencing to transfer the number of pages requested in the DMA command. The DMA master reads or writes page data from the system memory in programmed burst-length chunks. After the DMA command completes, the flash controller issues an interrupt, and starts working on the next queued DMA command.

Pipelining allows the NAND flash controller to optimize its performance while executing back-to-back commands of the same type.

With certain restrictions, non-DMA MAP10 commands can be issued to the NAND flash controller while the flash controller is servicing DMA transactions. MAP00, MAP01, and MAP11 commands cannot be issued while DMA mode is enabled because the flash controller is operating in an extremely tightly-coupled, high-performance data transfer mode. On receipt of erroneous commands (MAP00, MAP01 or MAP11), the flash controller issues an `unsup_cmd` interrupt to inform the host about the violating command.

Consider the following points when using the DMA:

- A data DMA command is a type of MAP10 command. This command is interpreted by the data DMA engine and not by the flash controller core.
- No MAP01, MAP00, or MAP11 commands are allowed when DMA is enabled.
- Before the flash controller can accept data DMA commands, DMA must be enabled by setting the `flag` bit of the `dma_enable` register in the `dma` group.
- When DMA is enabled and the DMA engine initiates data transfers, ECC can be enabled for as-needed data correction concurrent with the data transfer.
- MAP10 commands are used along with data movements similar to MAP01 commands.
- With the exception of data DMA commands and MAP10 pipeline read and write commands, all other MAP10 commands such as erase, lock, unlock, and copy-back are forwarded to the flash controller.
- At any time, up to four outstanding data DMA commands can be handled by flash controller. During multi-page operations, the DMA transfer must not cross a flash block boundary. If it does, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Data DMA commands are typically multi-page read and write commands with an associated pointer in host memory. The multi-page data is transferred to or from the host memory starting from the host memory pointer.
- Data DMA uses the `flash_burst_length` register in the `dma` group to determine the burst length value to drive on the interconnect. The data DMA hardware does not account for the interconnect's boundary crossing restrictions. The host must initialize the starting host address so that the DMA master burst transaction does not cross a 4 KB boundary.

There are two methods for initiating a DMA transaction: the multitransaction DMA command, and the burst DMA command.

Multi-Transaction DMA Command

The NAND flash controller processes multitransaction DMA commands only if it receives all four command-data pairs in order. The flash controller responds to out-of-order commands with an `unsup_cmd` interrupt. The flash controller also responds with an `unsup_cmd` interrupt if sequenced commands are interleaved with other flash controller MAP commands.

To initiate DMA with a multitransaction DMA command, you send four command-data pairs to the NAND flash controller through the Control and Data registers in the `nanddata` region, as shown in "Command-Data Pair Formats".

Using Multi-Transaction DMA Commands

If you want the NAND flash controller DMA to perform cacheable accesses then you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to change its cache capabilities.

You can issue non-DMA MAP10 commands while the NAND flash controller is in DMA mode. For example, you might trigger a host-initiated page move between DMA commands, to achieve wear leveling. However, do not interleave non-DMA MAP10 commands between the command-data pairs in a set of multitransaction DMA commands. You must issue all four command-data pairs shown in the above tables before sending a different command.

Note: Do not issue MAP00, MAP01 or MAP11 commands while DMA is enabled.

MAP10 commands in multitransaction format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in increment four (INCR4) format (described in "Burst DMA Command").

Related Information

- **Indexed Addressing** on page 13-8
- **Burst DMA Command** on page 13-17
- **System Manager** on page 5-1

Burst DMA Command

You can initiate a DMA transfer by sending a command to the NAND flash controller as a burst transaction of four 16-bit accesses. This form of DMA command might be useful for initiating DMA transfers from custom IP in the FPGA fabric. Most processor cores cannot use this form of DMA command, because they cannot control the width of the burst.

When DMA is enabled, the NAND flash controller recognizes the MAP10 pipeline DMA command as an INCR4 command, in the format shown in the following table. The address decoding for MAP10 pipeline DMA command remains the same, as shown in "MAP10 Command Format".

(27) INT specifies the host interrupt to be generated at the end of the complete DMA transfer. For more information about INT, see the Note at the bottom of this table.

MAP10 commands in INCR4 format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in multitransaction format (described in the "Multi-Transaction DMA Command").

Table 13-15: MAP10 Burst DMA (INCR4) Command Structure

The following table lists the MAP10 burst DMA command structure. The burst DMA command carries the same information as the multi-transaction DMA command-data pairs, but in a very different format.

Data Beat	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Beat 0	0x2				0x0: read. 0x1: write.				<*PP*>=number of pages							
Beat 1[28]	Memory address high															
Beat 2[28]	Memory address low															
Beat 3	0x0							INT[29]	Burst length							

Note: INT controls the value of the `dma_cmd_comp` bit of the `intr_status0` register in the `status` group at the end of the DMA transfer. INT can take on one of the following values:

0—Do not interrupt host. The `dma_cmd_comp` bit is set to 0.

1—Interrupt host. The `dma_cmd_comp p` bit is set to 1.

You can optionally send the 16-bit fields in the above table to the NAND flash controller as four separate bursts of length 1 in sequential order. Altera recommends this method.

If you want the NAND flash controller DMA to perform cacheable accesses, you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to modify its cache capabilities.

ECC

The NAND flash controller incorporates ECC logic to calculate and correct bit errors. The flash controller uses a Bose-Chaudhuri-Hocquenghem (BCH) algorithm for detection of multiple errors in a page.

The NAND flash controller supports 512- and 1024-byte ECC sectors. The flash controller inserts ECC check bits for every 512 or 1024 bytes of data, depending on the selected sector size. After 512 or 1024 bytes, the flash controller writes the ECC check bit information to the device page.

ECC information is striped in between 512 or 1024 bytes of data across the page. The NAND flash controller reads ECC information in the same pattern and performs a calculation to check for the presence of errors.

[28] The buffer address in host memory, which must be aligned to 32 bits.

[29] INT specifies the host interrupt to be generated at the end of the complete DMA transfer. For more information about INT, see the Note at the bottom of this table.

Memory Data Initialization on page 11-5
For more information about clearing memory data before enabling ECC, refer to "Memory Data Initialization" in the Error Checking and Correction section.

Correction Capability, Sector Size, and Check Bit Size

Table 13-16: Correction Capability, Sector Size, and Check Bit Size

Correction	Sector Size in Bytes	Check Bit Size in Bytes
4	512	8
8	512	14
16	512	26
24	1024	46

ECC Programming Modes

The NAND flash controller provides the following ECC programming modes that software uses to format a page:

- Main Area Transfer Mode
- Spare Area Transfer Mode
- Main+Spare Area Transfer Mode

Related Information

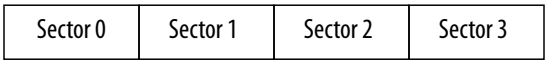
- **Main Area Transfer Mode** on page 13-19
- **Spare Area Transfer Mode** on page 13-19
- **Main+Spare Area Transfer Mode** on page 13-20

Main Area Transfer Mode

In main area transfer mode, when ECC is enabled, the NAND flash controller inserts ECC check bits in the data stream on writes and strips ECC check bits on reads. Software does not need to manage the ECC sectors when writing a page. ECC checking is performed by the flash controller, so software simply transfers the data.

If ECC is turned off, the NAND flash controller does not read or write ECC check bits.

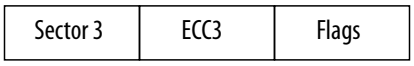
Figure 13-2: Main Area Transfer Mode for ECC



Spare Area Transfer Mode

The NAND flash controller does not introduce or interpret ECC check bits in spare area transfer mode, and acts as a pass-through for data transfer.

Figure 13-3: Spare Area Transfer Mode for ECC



Main+Spare Area Transfer Mode

In main+spare area transfer mode, the NAND flash controller expects software to format a page as shown in following figure. When ECC is enabled during a write operation, the flash controller-generated ECC check bits replace the ECC check bit data provided by software. During read operations, the flash controller forwards the ECC check bits from the device to the host. If ECC is disabled, page data received from the software is written to the device, and read data received from the device is forwarded to the host.

Figure 13-4: Main+Spare Area Transfer Mode for ECC

Preserving Bad Block Markers

When flash device manufacturers test their devices at the time of manufacture, they mark any bad device blocks that are found. Each bad block is marked at specific, known offsets, typically at the base of the spare area. A bad block marker is any byte value other than 0xFF (the normal state of erased flash).

Bad block markers can be overwritten by the last sector data in a page when ECC is enabled. This happens because the NAND flash controller also uses the main area of a page to store ECC information, which causes the last sector to spill over into the spare area. It is necessary for the system to preserve the bad block information prior to writing data, to ensure the correct identification of bad blocks in the flash device.

You can configure the NAND flash controller to skip over a specified number of bytes when it writes the last sector in a page to the spare area. This option allows the flash controller to preserve bad block markers. To use this option, write the desired offset to the `spare_area_skip_bytes` register in the `config` group. For example, if the device page size is 2 KB, and the device manufacturer stores the bad block markers in the first two bytes in the spare area, set the `spare_area_skip_bytes` register to 2. When the flash controller writes the last sector of the page that overlaps with the spare area, it starts at offset 2 in the spare area, skipping the bad block marker at offset 0. A value of 0 (default) specifies that no bytes are skipped. The value of `spare_area_skip_bytes` must be an even number. For example, if the bad block marker is a single byte, set `spare_area_skip_bytes` to 2.

In main area transfer mode, the NAND flash controller does not skip the bad block marker. Instead, it overrides the bad block marker with the value programmed in the `spare_area_marker` register in the `config` group. This 8-bit register is used in conjunction with the `spare_area_skip_bytes` register in the `config` group to determine which bytes in the spare area of a page should be written with a the new marker value. For example, to mark a block as good set the `spare_area_marker` register to 0xFF and set the `spare_area_skip_bytes` register to the number of bytes that the marker should be written to, starting from the base of the spare area.

In the spare area transfer mode, the NAND flash controller ignores the `spare_area_skip_bytes` and `spare_area_marker` registers. The flash controller transfers the data exactly as received from the host or device.

In the main+spare area transfer mode, the NAND flash controller starts writing the last sector in a page into the spare area, starting at the offset specified in the `spare_area_skip_bytes` register. However, the area containing the bad block identifier information is overwritten by the data the host writes into the page. The host writes both the data sectors and the bad block markers. The flash controller depends on the host software to set up the bad block markers properly before writing the data.

Figure 13-5: Bad Block Marker

The following figure shows an example of how the NAND flash controller can skip over a bad block marker. In this example, the flash device has a 2-KB page with a 64-byte spare area. A 14-byte sector ECC is shown, with 8 byte per sector correction.

Transfer Mode Operations on page 13-27
For detailed information about configuring the NAND flash controller for default, spare, or main+spare area transfer mode.

Error Correction Status

The ECC error correction information (`ECCCorInfo_b01`) register, in the `ecc` group, contains error correction information for each read or write that the NAND flash controller performs. The `ECCCorInfo_b01` register contains ECC error correction information in the `max_errors_b0` and `uncor_err_b0` fields.

At the end of data correction for the transaction in progress, `ECCCorInfo_b01` holds the maximum number of corrections applied to any ECC sector in the transaction. In addition, this register indicates whether the transaction as a whole has correctable errors, uncorrectable errors, or no errors at all. A transaction has no errors when none of the ECC sectors in the transaction has any errors. The transaction is marked as uncorrectable if any one of the sectors is uncorrectable. The transaction is marked as correctable if any one sector has correctable errors and none is uncorrectable.

At the end of each transaction, the host must read this register. The value of this register provides error data to the host about the block. The host can take corrective action after the number of correctable errors encountered reaches a particular threshold value.

NAND Flash Controller Programming Model

This section describes how the NAND flash controller is to be programmed by software running on the microprocessor unit (MPU).

Note: If you write a configuration register and follow it up with a data operation that is dependent on the value of this configuration register, Altera recommends that you read the value of the register before performing the data operation. This read operation ensures that the posted write of the register is completed and takes effect before the data operation is issued to the NAND flash controller.

Basic Flash Programming

This section describes the steps that must be taken by the software to access and control the NAND flash controller.

NAND Flash Controller Optimization Sequence

The software must configure the flash device for interrupt or polling mode, using the `bank0` bit of the `rb_pin_enabled` register in the `config` group. If the device is in polling mode, the software must also program the additional registers, to select the times and frequencies of the polling. Program the following registers in the `config` group:

- Set the `rb_pin_enabled` register to the desired mode of operation for each flash device.
- For polling mode, set the `load_wait_cnt` register to the appropriate value depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `program_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `erase_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `int_mon_cyccnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.

At any time, the software can change any flash device from interrupt mode to polling mode or vice-versa, using the `bank0` bit of the `rb_pin_enabled` register.

The software must ensure that the particular flash device does not have any outstanding transactions before changing the mode of operation for that particular flash device.

Device Initialization Sequence

At initialization, the host software must program the following registers in the `config` group:

- Set the `devices_connected` register to 1.
- Set the `device_width` register to 8.
- Set the `device_main_area_size` register to the appropriate value.
- Set the `device_spare_area_size` register to the appropriate value.
- Set the `pages_per_block` register according to the parameters of the flash device.
- Set the `number_of_planes` register according to the parameters of the flash device.
- If the device allows two ROW address cycles, the `flag` bit of the `two_row_addr_cycles` register must be set to 1. The host program can ensure this condition either of the following ways:
  - Set the `flag` bit of the `bootstrap_two_row_addr_cycles` register to 1 prior to the NAND flash controller's reset initialization sequence, causing the flash controller to initialize the bit automatically.
  - Set the `flag` bit of the `two_row_addr_cycles` register directly to 1.
- Clear the `chip_enable_dont_care` register in the `config` group to 0.

The NAND flash controller can identify the flash device features, allowing you to initialize the flash controller registers to interface correctly with the device, as described in *Discovery and Initialization*.

However, a few NAND devices do not follow any universally accepted identification protocol. If connected to such a device, the NAND flash controller cannot identify it correctly. If you are using such a device, your software must use other means to ensure that the initialization registers are set up correctly.

Discovery and Initialization on page 13-4

Device Operation Control

This section provides a list of registers that you need to program while choosing to use multi-plane or cache operations on the device. If the device does not support multi-plane operations or cache operations, then these registers can be left at their power-on reset values with no impact on the functionality of the NAND flash controller. Even if the device supports these sequences, the software does not need to use them. Software can leave these registers at their power-on reset values.

Program the following registers in the `config` group to achieve the best performance from a given device:

- Set `flag` bit in the `multiplane_operation` register in the `config` group to 1 if the device supports multi-plane operations to access the data on the flash device connected to the NAND flash controller. If the flash controller is set up for multi-plane operations, the number of pages to be accessed is always a multiple of the number of planes in the device.
- If the NAND flash controller is configured for multi-plane operation, and if the device has support for multi-plane read command sequence, set the `multiplane_read_enable` register in the `config` group.
- If the device implements multiplane address restrictions, set the `flag` bit in the `multiplane_addr_restrict` register to 1.
- Initialize the `die_mask` and `first_block_of_next_plane` registers as per device requirements.
- If the device supports cache command sequences, enable the `cache_write_enable` and `cache_read_enable` registers in the `config` group.
- Clear the `flag` bit of the `copyback_disable` register in the `config` group to 0 if the device does not support the copyback command sequences. The register defaults to enabled state.
- The `read_mode`, `write_mode` and `copyback_mode` registers, in the `config` group, currently need not be written by software, because the NAND flash controller is capable of using the correct sequences based on a combination of some multi-plane or cache-related settings of the NAND flash controller and the manufacturer ID. If at some future time these settings change, program the registers to accommodate the change.

ECC Enabling

Before you start any data operation on the flash device, you must decide whether you want the ECC enabled or disabled.

To prevent spurious ECC errors, software must use the memory initialization block in the ECC controller to clear the entire memory data and initialize the ECC bits. The initialization block clears the memory data. Initializing the memory with the initialization block is independent of enabling the ECC.

If the ECC needs enabling, set up the appropriate correction level depending on the page size and the spare area available on the device.

Set the flag bit in the ecc_enable register in the config group to 1 to enable ECC. If enabled, the following registers in the config group must be programmed accordingly, else they can be ignored:

- Initialize the ecc_correction register to the appropriate correction level.
- Program the spare_area_skip_bytes and spare_area_marker registers in the config group if the software needs to preserve the bad block marker.

Related Information

ECC on page 13-18

NAND Flash Controller Performance Registers

These registers specify the size of the bursts on the device interface, which maximizes the overall performance on the NAND flash controller.

Initialize the flash_burst_length register in the dma group to a value which maximizes the performance of the device interface by minimizing the number of bursts required to transfer a page.

Interrupt and DMA Enabling

Prior to initiating any data operation on the NAND flash controller, the software must set appropriate interrupt status register bits. If the software uses the DMA logic in the flash controller, then the appropriate DMA enable and interrupts bits in the register space must be set.

1. Set the flag bit in the global_int_enable register in the config group to 1, to enable global interrupt.
2. Set the relevant bits of the intr_en0 register in the status group to 1 before initiating any operations if the flash controller is in interrupt mode. Altera recommends that the software reads back this register to ensure clearing an interrupt status. This recommendation applies also to an interrupt service routine.
3. Enable DMA if your application needs DMA mode. Enable DMA by setting the flag bit of the dma_enable register in the dma group. Altera recommends that the software reads back this register to ensure that the mode change is accepted before sending a DMA command to the flash controller.
4. If the DMA is enabled, then set up the appropriate bits of the dma_intr_en register in the dma group.

Order of Interrupt Status Bits Assertion

The following interrupt status bits, in the intr_status0 register in the status group, are listed in the order of interrupt bit setting:

1. time_out—All other interrupt bits are set to 0 when the watchdog time_out bit is asserted.
2. dma_cmd_comp—This bit signifies the completion of data transfer sequence.(30)
3. pipe_cpybck_cmd_comp—This bit is asserted when a copyback command or the last page of a pipeline command completes.
4. locked_blk—This bit is asserted when a program (or erase) is performed on a locked block.
5. INT_act—No relationship with other interrupt status bits. Indicates a transition from 0 to 1 on the ready_busy pin value for that flash device.
6. rst_comp—No relationship with other interrupt status bits. Occurs after a reset command has completed.
7. For an erase command:

(30) This interrupt status bit is the last to be asserted during a DMA operation to transfer data.

a. `erase_fail` (if failure)
b. `erase_comp`

8. For a program command:
   a. `locked_blk` (if performed on a locked block)
   b. `pipe_cmd_err` (if the pipeline sequence is broken by a MAP01 command)
   c. `page_xfer_inc` (at the end of each page data transfer)
   d. `program_fail` (if failure)
   e. `pipe_cpybck_cmd_comp`
   f. `program_comp`
   g. `dma_cmd_comp` (If DMA enabled)
9. For a read command:
   a. `pipe_cmd_err` (if the pipeline sequence is broken by a MAP01 command)
   b. `page_xfer_inc` (at the end of each page data transfer)
   c. `pipe_cpybck_cmd_comp`
   d. `load_comp`
   e. `ecc_uncor_error` (if failure)
   f. `dma_cmd_comp` (If DMA enabled)

Timing Registers

You must optimize the following registers for your flash device's speed grade and clock frequency. The NAND flash controller operates correctly with the power-on reset values. However, functioning with power-on reset values is a non-optimal mode that provides loose timing (large margins to the signals).

Set the following registers in the `config` group to optimize the NAND flash controller for the speed grade of the connected device and frequency of operation of the flash controller:

- `twhr2_and_we_2_re`
- `tcwaw_and_addr_2_data`
- `re_2_we`
- `acc_clks`
- `rdwr_en_lo_cnt`
- `rdwr_en_hi_cnt`
- `max_rd_delay`
- `cs_setup_cnt`
- `re_2_re`

Registers to Ignore

You do not need to initialize the following registers in the `config` group:

- The `transfer_spare_reg` register—Data transfer mode can be initialized using MAP10 commands.
- The `write_protect` register—Does not need initializing unless you are testing the write protection feature.

Flash-Related Special Function Operations

This section describes all the special functions that can be performed on the flash memory.

The functions are defined by MAP10 commands as described in *Command Mapping*.

Related Information

Command Mapping on page 13-9

Erase Operations

Before data can be written to flash, an erase cycle must occur. The NAND flash memory controller supports single block and multi-plane erases.

The controller decodes the block address from the indirect addressing shown in "MAP10 Command Format".

Related Information

MAP10 Command Format on page 13-11

Single Block Erase

A single command is needed to complete a single-block erase, as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For a single block erase, the register `multiplane_operation` in the `config` group must be reset.

After the device completes the erase operation, the controller generates an `erase_comp` interrupt. If the erase operation fails, the `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Multi-Plane Erase

For multi-plane erases, the `number_of_planes` register in the `config` group holds the number of planes in the flash device, and the block address specified must be aligned to the number of planes in the device. The NAND flash controller consecutively erases each block of the memory, up to the number of planes available. Issue this command as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For multi-plane erase, the register `multiplane_operation` in the `config` group must be set.

After the device completes erase operation on all planes, the NAND flash controller generates an `erase_comp` interrupt. If the erase operation fails on any of the blocks in a multi-plane erase command, an `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Lock Operations

The NAND flash controller supports the following features:

- Flash locking—The NAND flash controller supports all flash locking operations.

  The flash device itself might have limited support for these functions. If the device does not support locking functions, the flash controller ignores these commands.
- Lock-tight—With the lock-tight feature, the NAND flash controller can prevent lock status from being changed. After the memory is locked tight, the flash controller must be reset before any flash area can be locked or unlocked.

Unlocking a Span of Memory Blocks

To unlock several blocks of memory, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to unlock.
2. Write 0x10 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the ending address of the area to unlock.
4. Write 0x11 to the `Data` register.

When unlocking a range of blocks, the start block address must be less than the end block address. Otherwise, the NAND flash controller exhibits undetermined behavior.

Locking All Memory Blocks

To lock the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x21 to the `Data` register.

Setting Lock-Tight on All Memory Blocks

After the lock-tight is applied, unlocked areas cannot be locked, and locked areas cannot be unlocked. To lock-tight the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x31 to the `Data` register.

To disable the lock-tight, reset the memory controller.

Transfer Mode Operations

You can configure the NAND flash controller in one of the following modes of data transfer:

- Default area transfer mode
- Spare area transfer mode
- Main+spare area transfer mode

The NAND flash controller determines the default transfer mode from the setting of `transfer_spare_reg` register in the `config` group. Use MAP10 commands to dynamically change the transfer mode from the existing mode to the new mode. All subsequent commands are in the new mode of transfer. You must consider that transfer modes can be changed at logical data transfer boundaries. For example:

- At the beginning or end of a page in case of single page read or write.
- At the beginning or end of a complete multi-page pipeline read or write command.

transfer_spare_reg and MAP10 Transfer Mode Commands

The following table lists the functionality of the MAP10 transfer mode commands, and their mappings to the `transfer_spare_reg` register in the `config` group.

Table 13-17: transfer_spare_reg and MAP10 Transfer Mode Commands

transfer_spare_reg	MAP10 Transfer Mode Commands	Resulting NAND Flash Controller Mode
0	0x42	Main(31)
0	0x41	Spare
0	0x43	Main+spare
1	0x42	Main+spare(31)
1	0x41	Spare
1	0x43	Main+spare

Related Information

MAP10 Commands on page 13-11

Configure for Default Area Access

You only need to configure for default area access if the transfer mode was previously changed to spare area or main+spare area. To configure default area access:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any block.
2. Write 0x42 to the `Data` register.

The NAND flash controller determines the default area transfer mode from the setting of the `transfer_spare_reg` register in the `config` group. If it is set to 1, then the transfer mode becomes main +spare area, otherwise it is main area.

Configure for Spare Area Access

To access only the spare area of the flash device, use the MAP10 command to set up the NAND flash controller to read or write only the spare area on the device. After the flash controller is set up, use MAP01 read and write commands to access the spare area of the appropriate block and page addresses. To configure the NAND flash controller to access the spare area only, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the target block.
2. Write 0x41 to the `Data` register.

Configure for Main+Spare Area Access

To configure the NAND flash controller to access the main+spare area:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ ADDR` field to the target block.
2. Write 0x43 to the `Data` register.

(31) Default access mode (0x42) maps to either main (only) or main+spare mode, depending on the value of `transfer_spare_reg`.

Read-Modify-Write Operations

To read a specific page or modify a few words, bytes, or bits in a page, use the RMW operations. A read command copies the desired data from flash memory to a page buffer. You can then modify the information in the buffer using MAP00 buffer read and write commands and issue another command to write that information back to the memory.

The read-modify-write command operates on an entire page. This command is also useful for a copy type operation, where most of a page is saved to a new location. In this type of operation, the NAND flash controller reads the data, modifies a specified number of words in the page, and then writes the modified page to a new location.

Note: Because the data is modified within the page buffer of the flash device, the NAND flash controller ECC hardware is not used in RMW operations. Software must update the ECC during RMW operations.

Note: For a read-modify-write command to work with hardware ECC, the entire page must be read into system memory, modified, then written back to flash without relying on the RMW feature.

Read-Modify-Write Operation Flow

1. Start the flow by reading a page from the memory:
   - Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the desired block.
   - Write 0x60 to the `Data` register.

   This step makes the page available to you in the page buffer in the flash device.
2. Provide the destination page address:
   - Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the destination address of the desired block.
   - Write 0x61 to the `Data` register.

   This step initiates the page program and provides the destination address to the device.
3. Use the MAP00 page buffer read and write commands to modify the data in the page buffer.
4. Write the page buffer data back to memory:
   - Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the same destination address.
   - Write 0x62 to the `Data` register.

   This step performs the write.

After the device completes the load operation, the NAND flash controller issues a `load_comp` interrupt. A `program_comp` interrupt is issued when the host issues the write command and the device completes the program operation.

If the page program operation (as a part of an RMW operation) results in a program failure in the device, `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copy-Back Operations

The NAND flash controller supports copy back operations. However, the flash device might have limited support for this function. If you attempt to perform a copy-back operation on a device that does not support copy-back, the NAND flash controller triggers an interrupt. An interrupt is also triggered if the

source block is not specified before the destination block is specified, or if the destination block is not specified in the next command following a source block specification.

The NAND flash controller cannot do ECC validation in case of copy-back commands. The flash controller copies the ECC data, but does not check it during the copy operation.

Note: Altera recommends that you use copy-back only if the ECC implemented in the flash controller is strong enough so that the next access can correct accumulated errors.

The 8-bit value <*PP*> specifies the number of pages for copy-back. With this feature, the NAND flash controller can copy multiple consecutive pages with a single command. When you issue a copy-back command, the flash controller performs the operation in the background. The flash controller puts other commands on hold until the current copy-back completes.

For a multi-plane device, if the `flag` bit in the `multiplane_operation` register in the `config` group is set to 1, multi-plane copy-back is available as an option. In this case, the block address specified must be plane-aligned and the value <*PP*> must specify the total number of pages to copy as a multiple of the number of planes. The block address continues incrementing, keeping the page address fixed, for the total number of planes in the device before incrementing the page address.

A `pipe_cpyback_cmd_comp` interrupt is generated when the flash controller has completed copy-back operation of all <*PP*> pages. If any page program operation (as a part of copy back operation) results in a program failure in the device, the `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copying a Memory Area (Single Plane)

To copy <*PP*> pages from one memory location to another:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied.
2. Write 0x1000 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written.
4. Write 0x11<*PP*> to the `Data` register, where <*PP*> is the number of pages to copy.

Copying a Memory Area (Multi-Plane)

To copy <*PP*> pages from one memory location to another:

1. Set the `flag` bit of the `multiplane_operation` register in the `config` group to 1.
2. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied. The address must be plane-aligned.
3. Write 0x1000 to the `Data` register.
4. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written. This address must also be plane-aligned.
5. Write 0x11<*PP*> to the `Data` register, where <*PP*> is the number of pages to copy.

The parameter <*PP*> must be a multiple of the number of planes in the device.

Pipeline Read-Ahead and Write-Ahead Operations

The NAND flash controller supports pipeline read-ahead and write-ahead operations. However, the flash device might have limited support for this function. If the device does not support pipeline read-ahead or write-ahead, the flash controller processes these commands as standard reads or writes.

The NAND flash controller can handle at the most four outstanding pipeline commands, queued up in the order in which the flash controller received the commands. The flash controller operates on the pipeline command at the head of the queue until all the pages corresponding to the pipeline command are executed. The flash controller then pops the pipeline command at the head of the queue and proceeds to work on the next pipeline command in the queue.

Pipeline Read-Ahead Function

The pipeline read-ahead function allows for a continuous reading of the flash memory. On receiving a pipeline read command, the flash controller immediately issues a load command to the device. While data is read out with MAP01 commands in a consecutive or multi-plane address pattern, the flash controller maintains additional cache or multi-plane read command sequencing for continuous streaming of data from the flash device.

Pipeline read-ahead commands can read data from the queue in this interleaved fashion. The parameter <PP> denotes the total number of pages in multiples of the number of planes available, and the block address must be plane-aligned, which keeps the page address constant while incrementing the block address for each page-size chunk of data. After reading from every plane, the NAND flash controller increments the page address and resets the block address to the initial address. You can also use pipeline write-ahead commands in multi-plane mode. The write operation works similarly to the read operation, holding the page address constant while incrementing the block address until all planes are written.

Note: The same four-entry queue is used to queue the address and page count for pipeline read-ahead and write-ahead commands. This commonality requires that you use MAP01 commands to read out all pages for a pipeline read-ahead command before the next pipeline command can be processed. Similarly, you must write to all pages pertaining to pipeline write-ahead command before the next pipeline command can be processed.

Because the value of the `flag` bit of the `multiplane_operation` register in the `config` group determines pipeline read-ahead or write-ahead behavior, it can only be changed when the pipeline registers are empty.

When the host issues a pipeline read-ahead command, and the flash controller is idle, the load operation occurs immediately.

Note: The read-ahead command does not return the data to the host, and the write-ahead command does not write data to the flash address. The NAND flash controller loads the read data. The read data is returned to the host only when the host issues MAP01 commands to read the data. Similarly, the flash controller loads the write data, and writes it to the flash only when the host issues MAP01 commands to write the data.

Set Up a Single Area for Pipeline Read-Ahead

To set up an area for pipeline read-ahead, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-read.
2. Write 0x20<*PP*> to the `Data` register, where the 0 sets this command as a read-ahead and <*PP*> is the number of pages to pre-read. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

The read-ahead command is a hint to the flash device to start loading the next page in the page buffer as soon as the previous page buffer operation has completed. After you set up the read-ahead, use a MAP01

command to actually read the data. In the MAP01 command, specify the same starting address as in the read-ahead.

If the read command received following a pipeline read-ahead request is not to a pre-read page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline read-ahead request to re-load the same data. You must use MAP01 commands to read all of the data that is pre-read before the NAND flash controller returns to the idle state.

Pipeline Write-Ahead Function

The pipeline write-ahead function allows for a continuous writing of the flash memory. While data is written with MAP01 commands in a consecutive or multi-plane address pattern, the NAND flash controller maintains cache or multi-plane command sequences for continuous streaming of data into the flash device.

For pipeline write commands, if any page program results in a failure in the device, a `program_fail` interrupt is issued. The failing page's block and page addresses are updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Set Up a Single Area for Pipeline Write-Ahead

To set up an area for pipeline write-ahead:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-write.
2. Write 0x21<PP> to the `Data` register, where the value 1 sets this command as a write-ahead and <PP> is the number of pages to pre-write. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

After you set up the write-ahead, use a MAP01 command to write the data. In the MAP01 command, specify the same starting address as in the write-ahead.

If the write command received following a pipeline write-ahead request is not to a pre-written page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline write-ahead request to configure the write logic.

You must use MAP01 commands to write all of the data that is pre-written before the NAND flash controller returns to the idle state.

Other Supported Commands

MAP01 commands must read or write pages in the same sequence that the pipelined commands were issued to the NAND flash controller. If the host issues multiple pipeline commands, pages must be read or written in the order the pipeline commands were issued. It is not possible to read or write pages for a second pipeline command before completing the first pipeline command. If the pipeline sequence is broken by a MAP01 command, the `pipe_cmd_err` interrupt is issued, and the flash controller clears the pipeline command queue. The flash controller services the violating incoming MAP01 read or write request with a normal page read or write sequence.

For a multi-plane device that supports multi-plane programming, you must set the `flag` bit of the `multiplane_operation` register in the `config` group to 1. In this case, the data is interleaved into page-size chunks to consecutive blocks.

A `pipe_cpyback_cmd_comp` interrupt is generated when the NAND flash controller has finished processing a pipeline command and has discarded that command from its queue. At this point of time, the

host can send another pipeline command. A pipeline command is popped from the queue, and an interrupt is issued when the flash controller has started processing the last page of pipeline command. Hence, the `pipe_cpyback_cmd_comp` interrupt is issued prior to the last page load in the case of a pipeline read command and start of data transfer of the last page to be programmed, in the case of a pipeline write command.

An additional `program_comp` interrupt is generated when the last page program operation completes in the case of a pipeline write command.

If the device command set requires the NAND flash controller to issue a load command for the last page in the pipeline read command, a `load_comp` interrupt is generated after the last page load operation completes.

The pipeline commands sequence advanced commands in the device, such as cache and multi-plane. When the NAND flash controller receives a multi-page read or write pipeline command, it sequences commands sent to the device depending on settings in the following registers in the `config` group:

- `cache_read_enable`
- `cache_write_enable`
- `multiplane_operation`

For a device that supports cache read sequences, the `flag` bit of the `cache_read_enable` register must be set to 1. The NAND flash controller sequences each multi-page pipeline read command as a cache read sequence. For a device that supports cache program command sequences, `cache_write_enable` must be set. The flash controller sequences each multi-page write pipeline command as a cache write sequence.

For a device that has multi-planes and supports multi-plane program commands, the NAND flash controller register `multiplane_operation`, in the `config` group, must be set. On receiving the multi-page pipeline write command, the flash controller sequences the device with multi-plane program commands and expects that the host transfers data to the flash controller in an even-odd block increment addressing mode.

NAND Flash Controller Address Map and Register Definitions

For complete HPS address map and register definitions, refer to the **Arria 10 HPS Address Map and Register Definitions**.

IP_REV_ID

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2000

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C200C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C201C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C202C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C203C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						ECC_AddrBUS 0x0									

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
9:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2044

Offset: 0x44

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2078

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C207C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2080

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandecc_ecc_registerBlock	0xFF8C2000	0xFF8C2090

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

nandr_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C27FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-149	0x0	32	RO	0x0	
CTRL on page 11-150	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-150	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-151	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-152	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-153	0x18	32	RW	0x0	Error Interrupt reset.

Register	Offset	Width	Access	Reset Value	Description
INTMODE on page 11-154	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-154	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-155	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-156	0x28	32	RW	0x0	Counter feature status flag
DERRADDRA on page 11-157	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-157	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-158	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-159	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-160	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-160	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-161	0x4C	32	RO	0x0	Data will be read to this register field.

Register	Offset	Width	Access	Reset Value	Description
ECC_RData3bus on page 11-162	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-162	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-163	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-164	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-164	0x60	32	WO	0x0	Data from the register will be written to the RAM.
ECC_RDataecc0bus on page 11-165	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-166	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-167	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-168	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Register	Offset	Width	Access	Reset Value	Description
ECC_dbytectrl on page 11-169	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-170	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-170	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-171	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-172	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2414

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2418

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C241C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2420

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2424

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2428

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C242C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

DERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2430

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address 0x0				

SERRADDRA Fields

Bit	Name	Description	Access	Reset
4:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C243C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C247C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2480

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandr_ecc_registerBlock	0xFF8C2400	0xFF8C2490

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											Address RO 0x0				

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
4:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

nandw_ecc Address Map

Module Instance	Base Address	End Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2BFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-181	0x0	32	RO	0x0	
CTRL on page 11-182	0x8	32	RW	0x0	ECC Control Register

Register	Offset	Width	Access	Reset Value	Description
INITSTAT on page 11-183	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-184	0x10	32	RW	0x0	Error Interrupt enable

SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2808

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C280C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOM-PLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2810

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2814

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2818

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C281C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2820

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2824

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2828

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C282C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

DERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2830

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

SERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C283C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2840

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECC_WData3bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_WDataBUS	ECC_WDataBUS[127-96].	WO	0x0

ECC_RDataecc0bus

The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2864

Offset: 0x64

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

14:8	ECC_WDataecc5BUS	Eccdata from the register will be written to the RAM.	WO	0x0
6:0	ECC_WDataecc4BUS	Eccdata from the register will be written to the RAM.	WO	0x0

ECC_dbytectrl

ECC Data Byte Control. The maximum number of implemented byte enables equals the data width of the RAM divided by 8.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2874

Offset: 0x74

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2878

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C287C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2880

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_nandw_ecc_registerBlock	0xFF8C2800	0xFF8C2890

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address RO 0x0						

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
6:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

nand_config Address Map

Module Instance	Base Address	End Address
i_nand_config	0xFFB80000	0xFFB802FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
transfer_spare_reg on page 13-142	0x10	32	RW	0x0	Default data transfer mode. (Ignored during Spare only mode)
load_wait_cnt on page 13-142	0x20	32	RW	0x1F4	Wait count value for Load operation
program_wait_cnt on page 13-144	0x30	32	RW	0x1F40	Wait count value for Program operation
erase_wait_cnt on page 13-145	0x40	32	RW	0x1F40	Wait count value for Erase operation
int_mon_cyccnt on page 13-146	0x50	32	RW	0x1F4	Interrupt monitor cycle count value

Register	Offset	Width	Access	Reset Value	Description
rb_pin_enabled on page 13-147	0x60	32	RW	0x1	Interrupt or polling mode. Ready/Busy pin is enabled from device.
multiplane_operation on page 13-149	0x70	32	RW	0x0	Multiplane transfer mode. Pipelined read, copyback, erase and program commands are transfered in multiplane mode
multiplane_read_enable on page 13-150	0x80	32	RW	0x0	Device supports multiplane read command sequence
copyback_disable on page 13-151	0x90	32	RW	0x0	Device does not support copyback command sequence
cache_write_enable on page 13-152	0xA0	32	RW	0x0	Device supports cache write command sequence
cache_read_enable on page 13-153	0xB0	32	RW	0x0	Device supports cache read command sequence
prefetch_mode on page 13-153	0xC0	32	RW	0x1	Enables read data prefetching to faster performance
chip_enable_dont_care on page 13-155	0xD0	32	RW	0x0	Device can work in the chip enable dont care mode
ecc_enable on page 13-155	0xE0	32	RW	0x1	Enable controller ECC check bit generation and correction
global_int_enable on page 13-156	0xF0	32	RW	0x0	Global Interrupt enable and Error/ Timeout disable.
twhr2_and_we_2_re on page 13-157	0x100	32	RW	0x1432	
tcwaw_and_addr_2_data on page 13-158	0x110	32	RW	0x1432	

Register	Offset	Width	Access	Reset Value	Description
re_2_we on page 13-159	0x120	32	RW	0x32	Timing parameter between re high to we low (Trhw)
acc_clks on page 13-160	0x130	32	RW	0x0	Timing parameter from read enable going low to capture read data
number_of_planes on page 13-161	0x140	32	RW	0x0	Number of planes in the device
pages_per_block on page 13-162	0x150	32	RW	0x0	Number of pages in a block
device_width on page 13-163	0x160	32	RW	0x3	I/O width of attached devices
device_main_area_size on page 13-164	0x170	32	RW	0x0	Page main area size of device in bytes
device_spare_area_size on page 13-165	0x180	32	RW	0x0	Page spare area size of device in bytes
two_row_addr_cycles on page 13-166	0x190	32	RW	0x0	Attached device has only 2 ROW address cycles
multiplane_addr_restrict on page 13-167	0x1A0	32	RW	0x0	Address restriction for multiplane commands
ecc_correction on page 13-168	0x1B0	32	RW	0x8	Correction capability required and the Erase threshold value.
read_mode on page 13-171	0x1C0	32	RW	0x0	The type of read sequence that the controller will follow for pipe read commands.
write_mode on page 13-173	0x1D0	32	RW	0x0	The type of write sequence that the controller will follow for pipe write commands.
copyback_mode on page 13-174	0x1E0	32	RW	0x0	The type of copyback sequence that the controller will follow.

Register	Offset	Width	Access	Reset Value	Description
rdwr_en_lo_cnt on page 13-176	0x1F0	32	RW	0x12	Read/Write Enable low pulse width
rdwr_en_hi_cnt on page 13-177	0x200	32	RW	0xC	Read/Write Enable high pulse width
max_rd_delay on page 13-178	0x210	32	RW	0x0	Max round trip read data delay for data capture
cs_setup_cnt on page 13-179	0x220	32	RW	0xA003	Chip select setup/tWB time
spare_area_skip_bytes on page 13-180	0x230	32	RW	0x0	Spare area skip bytes
spare_area_marker on page 13-181	0x240	32	RW	0xFFFF	Spare area marker value
devices_connected on page 13-182	0x250	32	RW	0x0	Number of Devices connected on one bank
die_mask on page 13-183	0x260	32	RW	0x0	Indicates the die differentiator in case of NAND devices with stacked dies.
first_block_of_next_plane on page 13-184	0x270	32	RW	0x1	The starting block address of the next plane in a multi plane device.
write_protect on page 13-185	0x280	32	RW	0x1	This register is used to control the assertion/de-assertion of the WP# pin to the device.
re_2_re on page 13-186	0x290	32	RW	0x32	Timing parameter between re high to re low (Trhz) for the next bank
por_reset_count on page 13-187	0x2A0	32	RW	0x13B	The number of cycles the controller waits after POR to issue the first RESET command to the device.

Register	Offset	Width	Access	Reset Value	Description
watchdog_reset_count on page 13-188	0x2B0	32	RW	0x5B9A	The number of cycles the controller waits before flagging a watchdog timeout interrupt.
device_reset on page 13-189	0x0	32	RW	0x0	Device reset. Controller sends a RESET command to device. Controller resets bit after sending command to device

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x0

transfer_spare_reg Fields

Bit	Name	Description	Access	Reset
0	flag	On all read or write commands through Map 01, if this bit is set, data in spare area of memory will be transfered to host along with main area of data. The main area will be transfered followed by spare area.[list][*]1 - MAIN+SPARE [*]0 - MAIN[/list]	RW	0x0

load_wait_cnt

Wait count value for Load operation

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x1F4															

load_wait_cnt Fields

Bit	Name	Description	Access	Reset
15:0	value	Number of clock cycles after issue of load operation before Cadence NAND Flash Controller polls for status. This values is of relevance for status polling mode of operation and has been provided to minimize redundant polling after issuing a command. After a load command, the first polling will happen after this many number of cycles have elapsed and then on polling will happen every intmon_cyc_cnt cycles. The default values is equal to the default value of intmon_cyc_cnt.	RW	0x1F4

program_wait_cnt

Wait count value for Program operation

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80030

Offset: 0x30

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x1F40															

program_wait_cnt Fields

Bit	Name	Description	Access	Reset
15:0	value	Number of clock cycles after issue of program operation before Cadence NAND Flash Controller polls for status. This values is of relevance for status polling mode of operation and has been provided to minimize redundant polling after issuing a command. After a program command, the first polling will happen after this many number of cycles have elapsed and then on polling will happen every intmon_cyc_cnt cycles. The default values is equal to the default value of intmon_cyc_cnt. The controller internally multiplies the value programmed into this register by 16 to provide a wider range for polling.	RW	0x1F40

erase_wait_cnt

Wait count value for Erase operation

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Bit	Name	Description	Access	Reset
13:8	twhr2	Signifies the number of controller clocks that should be introduced between the last command of a random data output command to the start of the data transfer.	RW	0x14
5:0	we_2_re	Signifies the number of bus interface clk_x clocks that should be introduced between write enable going high to read enable going low. The number of clocks is the function of device parameter Twhr and controller clock frequency.	RW	0x32

tcwaw_and_addr_2_data

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80110

Offset: 0x110

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		tcwaw RW 0x14						Reserved	addr_2_data RW 0x32						

tcwaw_and_addr_2_data Fields

Bit	Name	Description	Access	Reset
13:8	tcwaw	Signifies the number of controller clocks that should be introduced between the command cycle of a random data input command to the address cycle of the random data input command.	RW	0x14
6:0	addr_2_data	Signifies the number of bus interface clk_x clocks that should be introduced between an address to a data input cycle. The number of clocks is the function of device parameter Tadl and controller clock frequency.	RW	0x32

re_2_we

Timing parameter between re high to we low (Trhw)

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80120

Offset: 0x120

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RW 0x32					

re_2_we Fields

Bit	Name	Description	Access	Reset
5:0	value	Signifies the number of bus interface clk_x clocks that should be introduced between read enable going high to write enable going low. The number of clocks is the function of device parameter Trhw and controller clock frequency.	RW	0x32

acc_clks

Timing parameter from read enable going low to capture read data

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80130

Offset: 0x130

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0x0			

acc_clks Fields

Bit	Name	Description	Access	Reset
3:0	value	Signifies the number of bus interface clk_x clock cycles, controller should wait from read enable going low to sending out a strobe of clk_x for capturing of incoming data.	RW	0x0

number_of_planes

Number of planes in the device

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80140

Offset: 0x140

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													value RW 0x0		

number_of_planes Fields

Bit	Name	Description	Access	Reset
2:0	value	Controller will read Electronic Signature of devices and populate this field as the number of planes information is present in the signature. For 512B device, this information needs to be programmed by software. Software could also choose to override the populated value. The values in the fields should be as follows[list] [*]3'h0 - Monoplane device [*]3'h1 - Two plane device [*]3'h3 - 4 plane device [*]3'h7 - 8 plane device [*]All other values - Reserved[/list]	RW	0x0

pages_per_block

Number of pages in a block

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80150

Offset: 0x150

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

pages_per_block Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. For 512B devices, bootstrap_512B_device will determine the value of this field to be of 32. Software could also choose to override the populated value.	RW	0x0

device_width

I/O width of attached devices

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80160

Offset: 0x160

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														value RW 0x3	

device_width Fields

Bit	Name	Description	Access	Reset
1:0	value	Controller will read Electronic Signature of devices and populate this field. For 512B devices, bootstrap_x16_device will determine the value of this field. Software could also choose to override the populated value. The values in this field should be as follows[list][*]2'h00 - 8bit device[*] 2'h01 - 16bit device[*]All other values - Reserved[/list]	RW	0x3

device_main_area_size

Page main area size of device in bytes

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80170

Offset: 0x170

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

device_main_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. For 512B devices, bootstrap_512B_device will determine the value of this field to be 512. Software could also choose to override the populated value.	RW	0x0

device_spare_area_size

Page spare area size of device in bytes

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80180

Offset: 0x180

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

device_spare_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. For 512B devices, bootstrap_512B_device will determine the value of this field to be 16. Software could also choose to override the populated value.	RW	0x0

two_row_addr_cycles

Attached device has only 2 ROW address cycles

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80190

Offset: 0x190

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											four RW 0x0	Reserved			flag RW 0x0

two_row_addr_cycles Fields

Bit	Name	Description	Access	Reset
4	four	This flag must be set for devices which allow for 4 ROW address cycles instead of the usual 3.	RW	0x0
0	flag	This flag must be set for devices which allow for 2 ROW address cycles instead of the usual 3. Alternatively, bootstrap_two_row_addr_cycles when asserted will set this flag.	RW	0x0

multiplane_addr_restrict

Address restriction for multiplane commands

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB801A0

Offset: 0x1A0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x0

multiplane_addr_restrict Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which require that during multiplane operations all but the address for the last plane should have their address cycles tied low. The last plane address cycles has proper values. This ensures multiplane address restrictions in the device.	RW	0x0

ecc_correction

Correction capability required and the Erase threshold value.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB801B0

Offset: 0x1B0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
erase_threshold RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x8							

ecc_correction Fields

Bit	Name	Description	Access	Reset
31:16	erase_threshold	This value informs the ECC logic of the number of 0's to count in a page before considering it as Erased. If the number of 0's in the page being read is less than the value in this register, an erased page is inferred and no un-correctable error will be flagged for that page. If ECC is disabled, the erased_page interrupt shall be set as explained above. If ECC is enabled, in addition to the above condition, only when the ECC logic detects an un-correctable error for that page will the erased_ page interrupt be flagged. If the ECC logic detects a no-error or correct-able error page, this erased page interrupt will not be set. A value of ZERO in this register will disabled checking for erased pages. Erased page detection logic will be activated only in MAIN or MAIN+SPARE or META-DATA(if available) modes of operation.	RW	0x0

Bit	Name	Description	Access	Reset
7:0	value	The required correction capability. A smaller correction capability will lead to lesser number of ECC check-bits being written per ECC sector. The supported ECC correction levels are - [list] [*] 16,8,4 over 512 bytes. [*] 24 over 1024 bytes. [*] All other values will cause the correction value in the controller to fall back to the previously selected value. [/list]	RW	0x8

read_mode

The type of read sequence that the controller will follow for pipe read commands.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB801C0

Offset: 0x1C0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0x0			

read_mode Fields

Bit	Name	Description	Access	Reset
3:0	value	The values in the field should be as follows: 4'h0 - This value informs the controller that the pipe read sequence to follow is of a normal read. For 512 byte page devices, Normal read sequence is, C00, Address, Data, ... For devices with page size greater that 512 bytes, the sequence is, C00, Address, C30, Data..... 4'h1 - This value informs the controller that the pipe read sequence to follow is of a Cache Read with the following sequence, C00, Address, C30, C31, Data, C31, Data, ..., C3F, Data. 4'h2 - This value informs the controller that the pipe read sequence to follow is of a Cache Read with the following sequence, C00, Address, C31, Data, Data, ..., C34. 4'h3 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Read with the following sequence, C00, Address, C00, Address, C30, Data, C06, Address, CE0, Data..... 4'h4 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Read with the following sequence, C60, Address, C60, Address, C30, C00, Address, C05, Address, CE0, Data, C00, Address, C05, Address, CE0, Data..... 4'h5 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Cache Read with the following sequence, C60, Address, C60, Address, C30, C31, C00, Address, C05, Address, CE0, Data, C00, Address, C05, Address, CE0, Data, ..., C3F, C00, Address, C05, Address, CE0, Data, C00, Address, C05, Address, CE0, Data 4'h6 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Read with the following sequence, C00, Address, C32, .., C00,	RW	0x0

Bit	Name	Description	Access	Reset
		Address, C30, C06, Address, CE0, Data, C06, Address, CE0, Data,.... 4'h7 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Cache Read with the following sequence, C00, Address, C32,..., C00, Address, C30, C31,C06, Address, CE0, Data, C31, C06, Address, CE0, Data, C3F, C06, Address, CE0, Data.... 4'h8 - This value informs the controller that the pipe read sequence to follow is of a 'N' Plane Cache Read with the following sequence, C60, Address, C60, Address, C33, C31, C00, Address, C05, Address, CE0, Data, C00, Address, C05, Address, CE0, Data, ..., C3F, C00, Address, C05, Address, CE0, Data, C00, Address, C05, Address, CE0, Data 4'h9 - 4'h15 - Reserved. ..... indicates that the previous sequence is repeated till the last page.		

write_mode

```
        The type of write sequence that the controller will follow
for pipe write commands.
```

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB801D0

Offset: 0x1D0

		4'h7 - This value informs the controller that the copyback sequence to follow is of a two plane copyback sequence, C60, Address, C60, Address, C30, C8C, Address, C11, C8C, Address, C10. 4'h8 - 4'h15 - Reserved.		

rdwr_en_lo_cnt

Read/Write Enable low pulse width

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB801F0

Offset: 0x1F0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x12				

rdwr_en_lo_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of clk_x cycles that read or write enable will kept low to meet the min Trp/Twp parameter of the device. The value in this register plus rdwr_en_hi_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max clk_x time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/5x clocking scheme.	RW	0x12

rdwr_en_hi_cnt

Read/Write Enable high pulse width

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80200

Offset: 0x200

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0xC				

rdwr_en_hi_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of clk_x cycles that read or write enable will kept high to meet the min Treh/Tweh parameter of the device. The value in this register plus rdwr_en_lo_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max clk_x time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/5x clocking scheme.	RW	0xC

max_rd_delay

Max round trip read data delay for data capture

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80210

Offset: 0x210

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0x0			

max_rd_delay Fields

Bit	Name	Description	Access	Reset
3:0	value	Number of clk_x cycles after generation of feedback clk_x_out pulse when it is safe to synchronize received data to clk_x domain. Data should have been registered with clk_x_in and stable by the time max_rd_delay cycles has elapsed. Please see timing diagram in bus interface timing section of this guide for further elaboration. A default value of zero will mean a value of clk_x multiple minus one.	RW	0x0

cs_setup_cnt

Chip select setup/tWB time

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80220

Offset: 0x220

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

spare_area_skip_bytes Fields

Bit	Name	Description	Access	Reset
5:0	value	Number of bytes to skip from start of spare area before last ECC sector data starts. The bytes will be written with the value programmed in the spare_area_marker register. This register could be potentially used to preserve the bad block marker in the spare area by marking it good. The default value is zero which means no bytes will be skipped and last ECC sector will start from the beginning of spare area. This value should be an even number.	RW	0x0

spare_area_marker

Spare area marker value

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80240

Offset: 0x240

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0xFFFF															

spare_area_marker Fields

Bit	Name	Description	Access	Reset
15:0	value	A 16bit value that will be written in the spare area skip bytes. This value will be used by controller while in the MAIN mode of data transfer.	RW	0xFFFF

devices_connected

Number of Devices connected on one bank

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80250

Offset: 0x250

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													value RW 0x0		

devices_connected Fields

Bit	Name	Description	Access	Reset
2:0	value	Indicates the number of devices connected to a bank. At POR, the value loaded is the maximum possible devices that could be connected in this configuration.	RW	0x0

die_mask

Indicates the die differentiator in case of NAND devices with stacked dies.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80260

Offset: 0x260

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x0															

die_mask Fields

Bit	Name	Description	Access	Reset
15:0	value	The die_mask register information will be used for devices having address restrictions. For example, in certain Samsung devices, when the first address in a two-plane command is being sent, it is expected that the address is all zeros. But if the NAND device internally has multiple dies stacked, the die information (MSB of final row address) has to be sent. The value programmed in this register will be used to mask the address while sending out the last row address.	RW	0x0

first_block_of_next_plane

The starting block address of the next plane in a multi plane device.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80270

Offset: 0x270

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x1															

first_block_of_next_plane Fields

Bit	Name	Description	Access	Reset
15:0	value	This values informs the controller of the plane structure of the device. In case the device is a multi plane device and the value here is 1, the controller understands that the next plane starts from Block number 1 and in conjunction with the number of planes parameter can decide upon the distribution of blocks in a plane in the device.	RW	0x1

write_protect

This register is used to control the assertion/de-assertion of the WP# pin to the device.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80280

Offset: 0x280

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x1

write_protect Fields

Bit	Name	Description	Access	Reset
0	flag	When the controller is in reset, the WP# pin is always asserted to the device. Once the reset is removed, the WP# is de-asserted. The software will then have to come and program this bit to assert/de-assert the same. [list][*]1 - Write protect de-assert [*]0 - Write protect assert[/list]	RW	0x1

re_2_re

Timing parameter between re high to re low (Trhz) for the next bank

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80290

Offset: 0x290

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RW 0x32					

re_2_re Fields

Bit	Name	Description	Access	Reset
5:0	value	Signifies the number of bus interface clk_x clocks that should be introduced between read enable going high to a bank to the read enable going low to the next bank. The number of clocks is the function of device parameter Trhz and controller clock frequency.	RW	0x32

por_reset_count

The number of cycles the controller waits after POR to issue the first RESET command to the device.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB802A0

Offset: 0x2A0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x13B															

por_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing the first RESET command to the device. The number in this register is multiplied internally by 16 in the controller to form the final reset wait count.	RW	0x13B

watchdog_reset_count

The number of cycles the controller waits before flagging a watchdog timeout interrupt.

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB802B0

Offset: 0x2B0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x5B9A															

watchdog_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing a watchdog timeout interrupt. The value in this register is multiplied internally by 32 in the controller to form the final watchdog counter.	RW	0x5B9A

device_reset

Device reset. Controller sends a RESET command to device. Controller resets bit after sending command to device

Module Instance	Base Address	Register Address
i_nand_config	0xFFB80000	0xFFB80000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												bank3 RW 0x0	bank2 RW 0x0	bank1 RW 0x0	bank0 RW 0x0

device_reset Fields

Bit	Name	Description	Access	Reset
3	bank3	Issues reset to bank 3. Controller resets the bit after reset command is issued to device.	RW	0x0
2	bank2	Issues reset to bank 2. Controller resets the bit after reset command is issued to device.	RW	0x0
1	bank1	Issues reset to bank 1. Controller resets the bit after reset command is issued to device.	RW	0x0
0	bank0	Issues reset to bank 0. Controller resets the bit after reset command is issued to device.	RW	0x0

nand_param Address Map

Module Instance	Base Address	End Address
i_nand_param	0xFFB80300	0xFFB803FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RO 0x0															

onfi_device_features Fields

Bit	Name	Description	Access	Reset
15:0	value	The values in the field should be interpreted as follows[list] [*]Bit 0 - Supports 16 bit data bus width. [*]Bit 1 - Supports multiple LUN operations. [*]Bit 2 - Supports non-sequential page programming. [*]Bit 3 - Supports interleaved program and erase operations. [*]Bit 4 - Supports odd to even page copyback. [*]Bit 5 - Supports source synchro-nous. [*]Bit 6 - Supports interleaved read operations. [*]Bit 7 - Supports extended parameter page. [*]Bit 8 - Supports program page register clear enhancement. [*]Bit 9 - Supports EZNAND. [*]Bit 10 - Supports NV-DDR2. [*]Bit 11 - Supports Volume Addressing. [*]Bit 12 - Supports External Vpp. [*]Bit 13-15 - Reserved.[/list]	RO	0x0

onfi_optional_commands

Optional commands supported by the connected ONFI device

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB80390

Offset: 0x90

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RO 0x0															

onfi_optional_commands Fields

Bit	Name	Description	Access	Reset
15:0	value	The values in the field should be interpreted as follows[list] [*]Bit 0 - Supports page cache program command. [*]Bit 1 - Supports read cache commands. [*]Bit 2 - Supports get and set features. [*]Bit 3 - Supports read status enhanced commands. [*]Bit 4 - Supports copyback. [*]Bit 5 - Supports Read Unique Id. [*]Bit 6 - Supports Change Read Column Enhanced. [*]Bit 7 - Supports change row address. [*]Bit 8 - Supports Change small data move. [*]Bit 9 - Supports RESET LUN. [*]Bit 10 - Supports Volume Select. [*]Bit 11 - Supports ODT Configure. [*]Bit 12-15 - Reserved.[/list]	RO	0x0

onfi_timing_mode

Asynchronous Timing modes supported by the connected ONFI device

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803A0

Offset: 0xA0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RO 0x0					

onfi_timing_mode Fields

Bit	Name	Description	Access	Reset
5:0	value	The values in the field should be interpreted as follows[list] [*]Bit 0 - Supports Timing mode 0. [*]Bit 1 - Supports Timing mode 1. [*]Bit 2 - Supports Timing mode 2. [*]Bit 3 - Supports Timing mode 3. [*]Bit 4 - Supports Timing mode 4. [*]Bit 5 - Supports Timing mode 5.[/list]	RO	0x0

onfi_pgm_cache_timing_mode

Asynchronous Program Cache Timing modes supported by the connected ONFI device

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803B0

Offset: 0xB0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RO 0x0					

onfi_pgm_cache_timing_mode Fields

Bit	Name	Description	Access	Reset
5:0	value	The values in the field should be interpreted as follows[list] [*]Bit 0 - Supports Timing mode 0. [*]Bit 1 - Supports Timing mode 1. [*]Bit 2 - Supports Timing mode 2. [*]Bit 3 - Supports Timing mode 3. [*]Bit 4 - Supports Timing mode 4. [*]Bit 5 - Supports Timing mode 5.[/list]	RO	0x0

onfi_device_no_of_luns

Indicates if the device is an ONFI compliant device and the number of LUNS present in the device

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803C0

Offset: 0xC0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved											ce_reduction_volume_addr_and_change RW 0x0	Reserved			onfi_jedec_multiplane_erase_seq RW 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			prog_page_reg_clear_enhancement RW 0x0	Reserved			onfi_device RW 0x0	no_of_luns RO 0x0							

onfi_device_no_of_luns Fields

Bit	Name	Description	Access	Reset
20	ce_reduction_volume_addr_and_change	Device supports CE pin reduction with volume assignments,volume addressing and volume change command sequence.For any device configured by host to be used in volume addressing mode, this bit must be set to 1. [list][*]1 - supported [*]0 - Not supported[/list]	RW	0x0

Bit	Name	Description	Access	Reset
16	onfi_jedec_multiplane_erase_seq	Device supports ONFI JEDEC Multiplane erase sequence.(Only valid for Onfi devices) [list][*]1 - ONFI JEDEC Multiplane erase sequence supported [*]0 - ONFI JEDEC Multiplane erase sequence not supported[/list]	RW	0x0
12	prog_page_reg_clear_enhancement	Device supports program page register clear enhancement.In such a device, a program can be initiated in a LUN even if a read command is ongoing in another LUN in the device. [list][*]1 - Program page register clear enhancement supported [*]0 - Program page register clear enhancement not supported[/list]	RW	0x0
8	onfi_device	Indicates if the device is an ONFI compliant device.[list] [*]0 - Non-ONFI compliant device [*]1 - ONFI compliant device[/list]	RW	0x0
7:0	no_of_luns	Indicates the number of LUNS present in the device	RO	0x0

onfi_device_no_of_blocks_per_lun_l

Lower bits of number of blocks per LUN present in the ONFI complaint device.

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803D0

Offset: 0xD0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RO 0x0															

onfi_device_no_of_blocks_per_lun_l Fields

Bit	Name	Description	Access	Reset
15:0	value	Indicates the lower bits of number of blocks per LUN present in the ONFI complaint device.	RO	0x0

onfi_device_no_of_blocks_per_lun_u

Upper bits of number of blocks per LUN present in the ONFI complaint device.

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803E0

Offset: 0xE0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RO 0x0															

onfi_device_no_of_blocks_per_lun_u Fields

Bit	Name	Description	Access	Reset
15:0	value	Indicates the upper bits of number of blocks per LUN present in the ONFI complaint device.	RO	0x0

features

Shows Available hardware features or attributes

Module Instance	Base Address	Register Address
i_nand_param	0xFFB80300	0xFFB803F0

Offset: 0xF0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

flash_burst_length Fields

Bit	Name	Description	Access	Reset
31:8	polling_sync_counter_value	Number of cycles CMDDMA channel has to wait before polling the SYNC Pointer again. If this counter value is 0, no polling is done.	RW	0x0
4	continous_burst	When this bit is set, the Data DMA will burst the entire page from/to the flash device. Please make sure that the host system can provide/sink data at a fast pace to avoid unnecessary pausing of data on the device interface.	RW	0x0

Bit	Name	Description	Access	Reset
1:0	value	Sets the burst used by data dma for transferring data to/from flash device. This burst length is different and is larger than the burst length on the host bus so that larger amount of data can be transferred to/from device, descreasing controller data transfer overhead in the process. 00 - 64 bytes, 01 - 128 bytes, 10 - 256 bytes, 11 - 512 bytes. The host burst size multiplied by the number of outstanding requests on the host side should be greater than equal to this value. If not, the device side burst length will be equal to host side burst length.	RW	0x1

chip_interleave_enable_and_allow_int_reads

Module Instance	Base Address	Register Address
i_nand_dma	0xFFB80700	0xFFB80780

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							cmd_dma_error_enable RW 0x1	Reserved			allow_int_reads_within_luns RW 0x1	Reserved			chip_interleave_enable RW 0x0

chip_interleave_enable_and_allow_int_reads Fields

Bit	Name	Description	Access	Reset
8	cmd_dma_error_enable	This bit informs the CDMA channels to stop working on any new MAP10 Command DMAcommands from the host after encountering an error situation till the error bit for that corresponding channel is cleared in the cmd_dma_channel_error register by f/w. When the CDMA channel encounters an error, it will set the corresponding error bit in cmd_dma_channel_error register If this bit is set, the channel will stop executing any further commands till f/w comes and clears the error bit in the cmd_dma_channel_error_register. If this bit is not set, controller will still keep on executing new commands issued from f/w.	RW	0x1

Bit	Name	Description	Access	Reset
4	allow_int_reads_ within_luns	This bit informs the controller to enable or disable simultaneous read accesses to different LUNS in the same bank. This bit is of importance only if the controller supports interleaved operations among LUNs and if the device has multiple LUNS. If the bit is disabled, the controller will send read commands to different LUNS of of the same bank only sequentially and if enabled, the controller will issue simulta-neous read accesses to LUNS of same bank if required. [list][*]1 - Enable [*]0 - Disable[/list]	RW	0x1
0	chip_interleave_ enable	This bit informs the controller to enable or disable interleaving among banks/LUNS to increase the net performance of the controller. [list][*]1 - Enable interleaving [*]0 - Disable Interleaving[/list]	RW	0x0

no_of_blocks_per_lun

Module Instance	Base Address	Register Address
i_nand_dma	0xFFB80700	0xFFB807A0

Offset: 0xA0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved			issue_read_before_sync RW 0x0	Reserved			update_sync_before_prog_comp RW 0x0	Reserved							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0xF			

no_of_blocks_per_lun Fields

Bit	Name	Description	Access	Reset
28	issue_read_before_sync	Issue LOAD cmd to flash core even if SYNC condition is not satisfied. But the data is read from the device (for this load) only after the SYNC condition has been satisfied. If this value is 0, CMD DMA waits for SYNC before issuing a READ command. This bit should be set to 0 if the controller is being accessed in non-Command DMA mode.	RW	0x0
24	update_sync_before_prog_comp	Update SYNC Pointer after the data is written to flash and dont wait for program to complete. If this value is 0, CMD DMA waits for page program to get over before updating the sync pointer. This bit should be set to 0 if the controller is being accessed in non-Command DMA mode.	RW	0x0

Bit	Name	Description	Access	Reset
3:0	value	Indicates the first block of next LUN. This information is used for extracting the target LUN during LUN interleaving. After Initialization, if the controller detects an ONFi device, this field is automatically updated by the controller. For other devices, software will need to write to this register for proper interleaving. The value in this register is interpreted as follows- [list][*]0 - Next LUN starts from 1024. [*]1 - Next LUN starts from 2048. [*]2 - Next LUN starts from 4096 and so on... [/list]	RW	0xF

lun_status_cmd

Indicates the command to be sent while checking status of the next LUN.

Module Instance	Base Address	Register Address
i_nand_dma	0xFFB80700	0xFFB807B0

Offset: 0xB0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

cmd_dma_channel_error Fields

Bit	Name	Description	Access	Reset
3	channel3	CMD-DMA channel 3 received an error.	RW	0x0
2	channel2	CMD-DMA channel 2 received an error.	RW	0x0
1	channel1	CMD-DMA channel 1 received an error.	RW	0x0
0	channel0	CMD-DMA channel 0 received an error.	RW	0x0

cmd_dma_channel_error_en

Enable bits indicating CMD-DMA channel receiving an error condition. To get more information on the error, s/w needs to read the status field of the descriptor.

Module Instance	Base Address	Register Address
i_nand_dma	0xFFB80700	0xFFB807D0

Offset: 0xD0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												channel3 RW 0x0	channel2 RW 0x0	channel1 RW 0x0	channel0 RW 0x0

cmd_dma_channel_error_en Fields

Bit	Name	Description	Access	Reset
3	channel3	enable bit for CMD-DMA channel 3 receiving an error	RW	0x0
2	channel2	enable bit for CMD-DMA channel 2 receiving an error	RW	0x0
1	channel1	enable bit for CMD-DMA channel 1 receiving an error	RW	0x0
0	channel0	enable bit for CMD-DMA channel 0 receiving an error	RW	0x0

rescan_buffer_flag

Rescan buffer flag.

Module Instance	Base Address	Register Address
i_nand_dma	0xFFB80700	0xFFB80790

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												flag RW 0x0			

rescan_buffer_flag Fields

Bit	Name	Description	Access	Reset
3:0	flag	This register can be used to force rescan of buffer flags in any of the cmd-dma channels. The bit index decides the Channel number. Cmd-dma would rescan the buffer flag for matching condition and it executes the descriptor if it is ready. Hardware clears this register after generating the trigger event.	RW	0x0

nand_NANDDATA Address Map

This address space is allocated for indexed addressing by the NAND flash controller. For more information, please refer to the NAND Flash Controller chapter of the Arria 10 Hard Processor System Technical Reference Manual.

Module Instance	Base Address	End Address
i_nand_NANDDATA	0xFFB90000	0xFFC01FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Document Revision History

Table 13-18: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
May 2016	2016.05.27	Added a link to the *Supported Flash Devices for Arria 10 SoC* webpage.
May 2016	2016.05.03	Added information about determining how many CE/RB signals are available based on the selected pins.
November 2015	2015.11.02	• Updated the Interrupt and DMA Enabling section to recommend reading back a register to ensure clearing an interrupt status. • Removed the reference to a missing figure from the `cs_setup_cnt` description. • Documented the behavior of the `wp_n` bit for when it will or will not be available.
May 2015	2015.05.04	Added information about clearing out the ECC before the feature is enabled
December 2014	2014.12.15	Maintenance release
August 2014	2014.08.18	Initial release

SD/MMC Controller 14

2016.10.28

a10_5v4

The hard processor system (HPS) provides a Secure Digital/Multimedia Card (SD/MMC) controller for interfacing to external SD and MMC flash cards, secure digital I/O (SDIO) devices, and Consumer Electronics Advanced Transport Architecture (CE-ATA) hard drives. The SD/MMC controller enables you to store boot images and boot the processor system from the removable flash card. You can also use the flash card to expand the on-board storage capacity for larger applications or user data. Other applications include interfacing to embedded SD (eSD) and embedded MMC (eMMC) non-removable flash devices.

The SD/MMC controller is based on the Synopsys DesignWare Mobile Storage Host (SD/MMC controller) controller.[32]

This document refers to SD/SDIO commands, which are documented in detail in the *Physical Layer Simplified Specification, Version 3.01* and the *SDIO Simplified Specification, Version 2.00* described on the SD Association website.

Related Information

SD Association

To learn more about how SD technology works, visit the SD Association website (www.sdcard.org).

Features of the SD/MMC Controller

The HPS SD/MMC controller offers the following features:

[32] Portions © 2016 Synopsys, Inc. Used with permission. All rights reserved. Synopsys & DesignWare are registered trademarks of Synopsys, Inc. All documentation is provided "as is" and without any warranty. Synopsys expressly disclaims any and all warranties, express, implied, or otherwise, including the implied warranties of merchantability, fitness for a particular purpose, and non-infringement, and any warranties arising out of a course of dealing or usage of trade.

†Paragraphs marked with the dagger (†) symbol are Synopsys Proprietary. Used with permission.

- Supports HPS boot from mobile storage
- Supports the following standards or card types:[33]
  - SD, including eSD—version 3.0
  - SDIO, including embedded SDIO (eSDIO)—version 3.0
  - CE-ATA—version 1.1
- Supports various types of multimedia cards (MMC version 4.41 and eMMC version 4.5[34])[35]
  - MMC: 1-bit data bus
  - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
  - MMCPlus: 1-bit, 4-bit, and 8-bit data bus
  - MMCMobile: 1-bit data bus
  - Embedded MMC (eMMC) version 4.5: 1-bit, 4-bit, and 8-bit data bus
- Supports the Micron MTFC16GJDDQ-4M IT (16 GB) eMMC flash memory that is verified to work with the HPS.
- Supports the Kingston® 4 GB SD Micro flash card
- Integrated descriptor-based direct memory access (DMA)
- Internal 4 KB receive and transmit FIFO buffer

Unsupported Features

- Card Detect is only supported on interfaces routed via the FPGA fabric. The Card Detect Interface signals are not included if the interface is pinned out to HPS I/O.
- The SD/MMC controller does not directly support voltage switching, card interrupts, or back-end power control of eSDIO card devices. However, you can connect these signals to general-purpose I/Os (GPIOs).
- The SD/MMC controller does not contain a reset output as part of the external card interface. To reset the flash card device, consider using a general purpose output pin.

Related Information

- **MMC Support Matrix** on page 14-3
  For more information on what is supported, refer to the MMC Support Matrix table.
- **Supported Flash Devices for Arria 10 SoC**
  For more information, refer to the supported SD/SDHC/SDXC/MMC/eMMC flash devices section on this page.

(33) SD and SDIO do not support SDR50, SDR104, and DDR50 modes.
(34) This is a new bus mode for Arria 10.
(35) The MMC and RSMMC does not support DDR. However, the MMCPlus, MMCMobile, and eMMC do support DDR, but not by the HPS.

SD Card Support Matrix

Table 14-1: SD Card Support Matrix

Device Card Type	Voltages Supported[36]		Bus Modes Supported			Bus Speed Modes Supported			
						Default Speed	High Speed	SDR12	SDR25[37]
	3.0 V	1.8 V[38]	1 bit	4 bit	8 bit	12.5 MBps 25 MHz	25 MBps 50 MHz	12.5 MBps 25 MHz	25 MBps 50 MHz
SDSC (SD)	√		√			√	√		
SDHC	√	√	√	√		√	√	√	√
SDXC	√	√	√	√		√	√	√	√
eSD	√	√	√	√		√	√	√	√
SDIO	√	√	√	√		√	√	√	√
eSDIO	√	√	√	√	√	√	√	√	√

Note: Card form factors (such as mini and micro) are not enumerated in the above table because they do not impact the card interface functionality.

MMC Support Matrix

Table 14-2: MMC Support Matrix

Card Device Type	Max Clock Speed (MHz)	Max Data Rate (MBps)	Voltages Supported		Bus Modes Supported			Bus Speed Modes Supported	
			3.3 V	1.8 V	1 bit	4 bit	8 bit	Default Speed	High Speed
MMC	20	2.5	√		√			√	
RSMMC	20	10	√		√	√		√	√
MMCPlus	50[39]	25	√		√	√	√	√	√
MMCMobile	50	6.5	√	√	√			√	√
eMMC	50	25	√	√	√	√	√	√	√

[36] Because SD cards initially operate at 3.0 V and can switch to 1.8V after power-up and the BSEL values are constant during the boot process, transceivers are required to support level-shifting and isolation.

[37] SDR25 speed mode requires 1.8-V signaling. Note that even if a card supports UHS-I modes (for example SDR50, SDR104, DDR50) it can still communicate at the lower speeds (for example SDR12, SDR25).

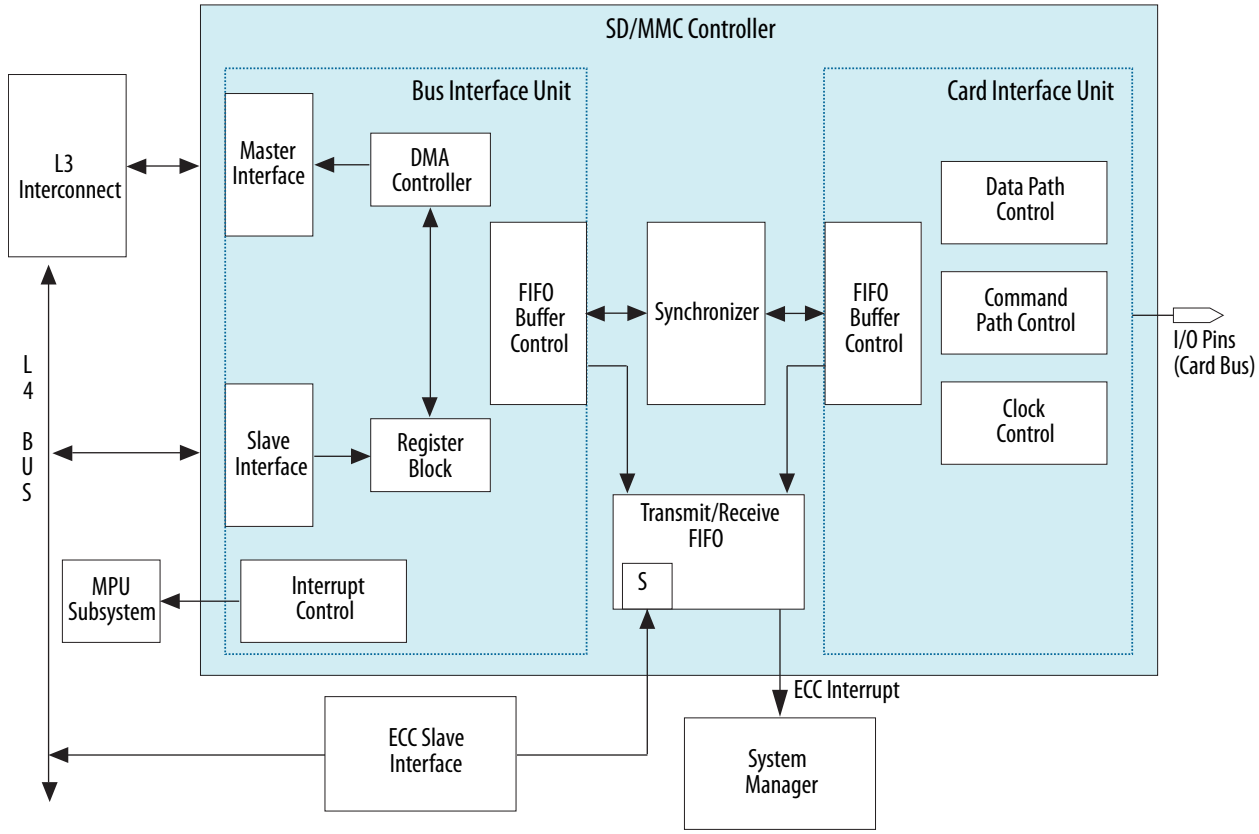
[38] Where supported, external transceivers are needed to switch the voltage.

[39] Supports a maximum clock rate of 50 MHz instead of 52 MHz (specified in MMC specification).

SD/MMC Controller Block Diagram and System Integration

The SD/MMC controller includes a bus interface unit (BIU) and a card interface unit (CIU). The BIU provides a slave interface for a host to access the control and status registers (CSRs). Additionally, this unit also provides independent FIFO buffer access through a DMA interface. The DMA controller is responsible for exchanging data between the system memory and FIFO buffer. The DMA registers are accessible by the host to control the DMA operation. The CIU supports the SD, MMC, and CE-ATA protocols on the controller, and provides clock management through the clock control block. The interrupt control block for generating an interrupt connects to the generic interrupt controller in the ARM Cortex-A9 microprocessor unit (MPU) subsystem.

Figure 14-1: SD/MMC Controller Connectivity



SD/MMC Controller Signal Description

The following table shows the SD/MMC controller signals that are routed to the FPGA and the HPS I/O.

Note: The last five signals in the table are not routed to HPS I/O, but only to the FPGA. For more information on how each of the signals are routed to the FPGA and HPS I/O pins, refer to the *HPS Component Interfaces* chapter.

Table 14-3: SD/MMC Controller Interface I/O Pins

Signal	Width	Direction	Description
sdmmc_cclk_out	1	Out	Clock from controller to the card
sdmmc_cmd_i	1	In	Card command
sdmmc_cmd_o	1	Out	
sdmmc_cmd_oe		Out	
sdmmc_pwr_ena_o	1	Out	External device power enable
sdmmc_data_i	8	In	Card data
sdmmc_data_o	8	Out	
sdmmc_data_oe	1	Out	
sdmmc_cdn_i	1	In	Card detect signal
sdmmc_wp_i	1	In	Card write protect signal
sdmmc_vs_o	1	Out	Voltage switching between 3.3V and 1.8V
sdmmc_rstn_o	1	Out	Card reset signal used in MMC mode
sdmmc_card_intn_i	1	In	Card interrupt signal

Functional Description of the SD/MMC Controller

This section describes the SD/MMC controller components and how the controller operates.

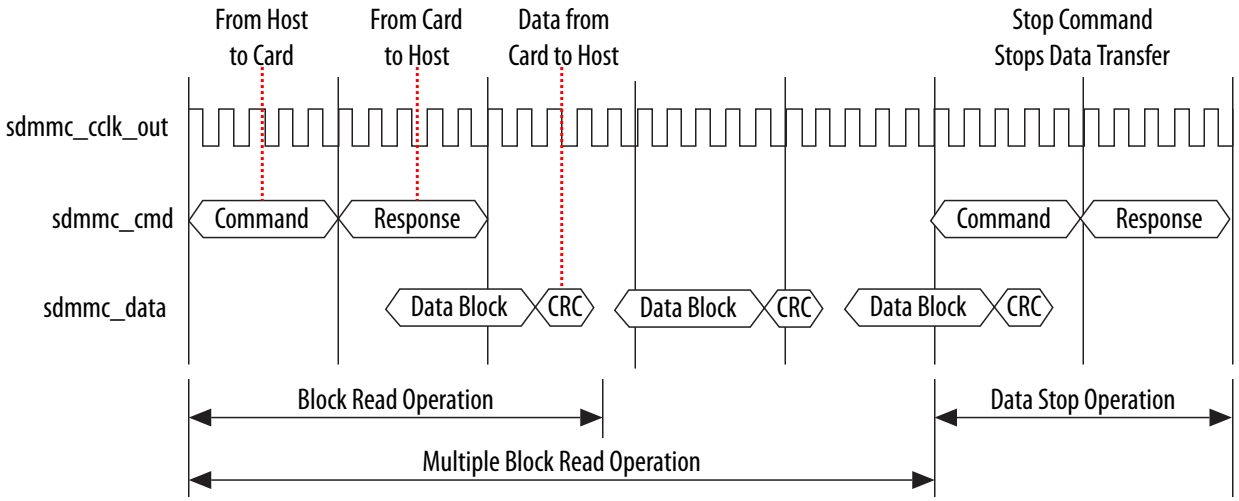
SD/MMC/CE-ATA Protocol

The SD/MMC/CE-ATA protocol is based on command and data bit streams that are initiated by a start bit and terminated by a stop bit. Additionally, the SD/MMC controller provides a reference clock and is the only master interface that can initiate a transaction.†

- Command—a token transmitted serially on the CMD pin that starts an operation.†
- Response—a token from the card transmitted serially on the CMD pin in response to certain commands.†
- Data—transferred serially using the data pins for data movement commands.†

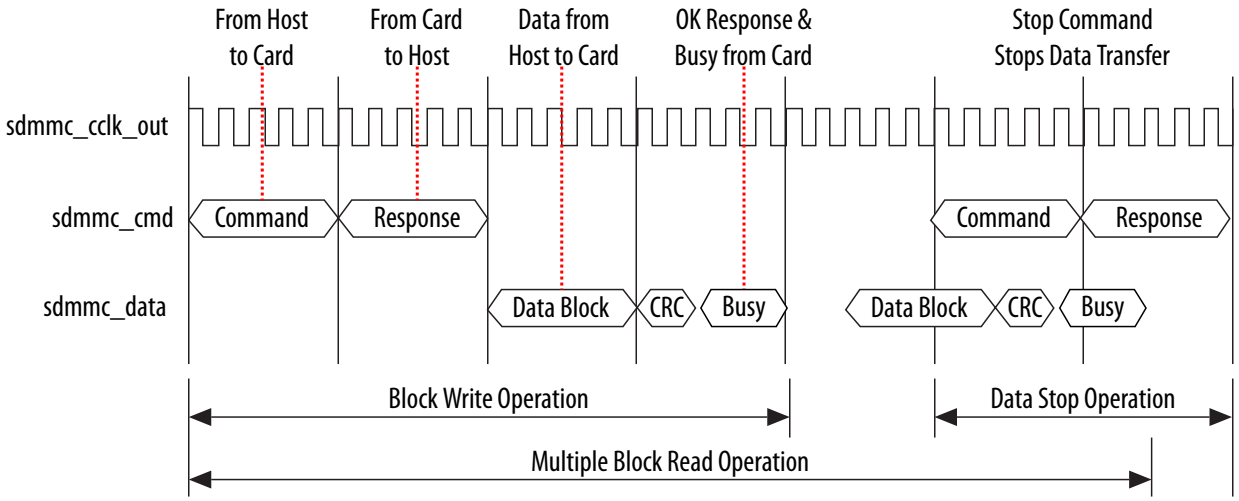
In the following figure, the clock is a representative only and does not show the exact number of clock cycles.

Figure 14-2: Multiple–Block Read Operation†



The following figure illustrates an example of a command token sent by the host in a multiple-block write operation.

Figure 14-3: Multiple-–Block Write Operation†



BIU

The Bus Interface Unit (BIU) interfaces with the Card Interface Unit (CIU), and is connected to the level 3 (L3) interconnect and level 4 (L4) peripheral buses. The BIU consists of the following primary functional blocks, which are defined in the following sections:

- Slave interface
- Register block
- FIFO buffer
- Interrupt control
- Internal DMA controller

Slave Interface

The host processor accesses the SD/MMC controller registers and data FIFO buffers through the slave interface.

Register Block

The register block is part of the BIU and provides read and write access to the CSRs.

All registers reside in the BIU clock domain, `l4_mp_clk`. When a command is sent to a card by setting the start command bit (`start_cmd`) of the command register (`cmd`) to 1, all relevant registers needed for the CIU operation are copied to the CIU block. During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to reset the `start_cmd` bit to 0 before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.

Registers Locked Out Pending Command Acceptance

After a command start is issued by setting the `start_cmd` bit of the `cmd` register, the following registers cannot be rewritten until the command is accepted by the CIU:†

- Command (`cmd`)†
- Command argument (`cmdarg`)†
- Byte count (`bytcnt`)†
- Block size (`blksiz`)†
- Clock divider (`clkdiv`)†
- Clock enable (`clkena`)†
- Clock source (`clksrc`)†
- Timeout (`tmout`)†
- Card type (`ctype`)†

The hardware resets the `start_cmd` bit after the CIU accepts the command. If a host write to any of these registers is attempted during this locked time, the write is ignored and the hardware lock write error bit (`hle`) is set to 1 in the raw interrupt status register (`rintsts`). Additionally, if the interrupt is enabled and not masked for a hardware lock error, an interrupt is sent to the host.†

Once a command is accepted, you can send another command to the CIU—which has a one-deep command queue—under the following conditions:†

- If the previous command is not a data transfer command, the new command is sent to the SD/MMC/CE-ATA card once the previous command completes.†
- If the previous command is a data transfer command and if the wait previous data complete bit (`wait_prvdata_complete`) of the `cmd` register is set to 1 for the new command, the new command is sent to the SD/MMC/CE-ATA card only when the data transfer completes.†
- If the `wait_prvdata_complete` bit is 0, the new command is sent to the SD/MMC/CE-ATA card as soon as the previous command is sent. Typically, use this feature to stop or abort a previous data transfer or query the card status in the middle of a data transfer.†

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the `rintsts` register, the interrupt mask register (`intmask`), and the interrupt enable bit (`int_enable`) of the control register (`ctrl`). Once an interrupt condition is detected, the controller sets the corresponding interrupt bit in the `rintsts` register. The bit in the `rintsts` register remains set until the software clears the bit by writing a 1 to the interrupt bit; writing a 0 leaves the bit untouched.

The interrupt controller unit generates active high, level sensitive interrupts that are asserted only when at least one bit in the `rintsts` register is set to 1, the corresponding `intmask` register bit is 1, and the `int_enable` bit of the `ctrl` register is 1.

The `int_enable` bit of the `ctrl` register is cleared during a power-on reset, and the `intmask` register bits are set to 0x0000000, which masks all the interrupts.

Table 14-4: Interrupt Status Register Bits†

Bits	Interrupt	Description
16	SDIO Interrupts†	Interrupts from SDIO cards.†
15	End Bit Error (read)/Write no CRC (EBE)†	Error in end-bit during read operation, or no data CRC received during write operation.† **Note:** For MMC CMD19, there may be no CRC status returned by the card. Hence, EBE is set for CMD19. The application should not treat this as an error. †
14	Auto Command Done (ACD)†	Stop/abort commands automatically sent by card unit and not initiated by host; similar to Command Done (CD) interrupt. † **Recommendation:** Software typically need not enable this for non CE-ATA accesses; Data Transfer Over (DTO) interrupt that comes after this interrupt determines whether data transfer has correctly competed. For CE-ATA accesses, if the software sets `send_auto_stop_ccsd` bit in the control register, then software should enable this bit.†
13	Start Bit Error (SBE)	Error in data start bit when data is read from a card. In 4-bit mode, if all data bits do not have start bit, then this error is set.
12	Hardware Locked write Error (HLE)†	During hardware-lock period, write attempted to one of locked registers. †

Bits	Interrupt	Description
11	FIFO Underrun/Overrun Error (FRUN)†	Host tried to push data when FIFO was full, or host tried to read data when FIFO was empty. Typically this should not happen, except due to error in software. † Card unit never pushes data into FIFO when FIFO is full, and pop data when FIFO is empty. † If IDMAC (Internal Direct Memory Access Controller) is enabled, FIFO underrun/overrun can occur due to a programming error on MSIZE and watermark values in FIFOTH register; for more information, refer to *Internal Direct Memory Access Controller (IDMAC)* section in the "Synopsys DesignWare Cores Mobile Storage Host Databook".†
10	Data Starvation by Host Timeout (HTO)†	To avoid data loss, card clock out (`cclk_out`) is stopped if FIFO is empty when writing to card, or FIFO is full when reading from card. Whenever card clock is stopped to avoid data loss, data-starvation timeout counter is started with data-timeout value. This interrupt is set if host does not fill data into FIFO during write to card, or does not read from FIFO during read from card before timeout period. † Even after timeout, card clock stays in stopped state, with CIU state machines waiting. It is responsibility of host to push or pop data into FIFO upon interrupt, which automatically restarts `cclk_out` and card state machines. † Even if host wants to send stop/abort command, it still must ensure to push or pop FIFO so that clock starts in order for stop/abort command to send on cmd signal along with data that is sent or received on data line. †
9	Data Read Timeout (DRTO)/Boot Data Start (BDS)†	• In Normal functioning mode: Data read timeout (DRTO) Data timeout occurred. Data Transfer Over (DTO) also set if data timeout occurs. † • In Boot Mode: Boot Data Start (BDS) When set, indicates that SD/MMC controller has started to receive boot data from the card. A write to this register with a value of 1 clears this interrupt.†

Bits	Interrupt	Description
8	Response Timeout (RTO)/ Boot Ack Received (BAR)†	• In Normal functioning mode: Response timeout (RTO) Response timeout occurred. Command Done (CD) also set if response timeout occurs. If command involves data transfer and when response times out, no data transfer is attempted by SD/MMC controller.† • In Boot Mode: Boot Ack Received (BAR) When expect_boot_ack is set, on reception of a boot acknowledge pattern—0-1-0—this interrupt is asserted. A write to this register with a value of 1 clears this interrupt.†
7	Data CRC Error (DCRC)†	Received Data CRC does not match with locally-generated CRC in CIU; expected when a negative CRC is received. †
6	Response CRC Error (RCRC)†	Response CRC does not match with locally-generated CRC in CIU.†
5	Receive FIFO Data Request (RXDR)†	Interrupt set during read operation from card when FIFO level is greater than Receive-Threshold level.† **Recommendation:** In DMA modes, this interrupt should not be enabled.† ISR, in non-DMA mode: `pop RX_WMark + 1 data from FIFO` †

4	Transmit FIFO Data Request (TXDR)†	Interrupt set during write operation to card when FIFO level reaches less than or equal to Transmit-Threshold level.†
		Recommendation: In DMA modes, this interrupt should not be enabled.†
		ISR in non-DMA mode: †
		`if (pending_bytes > \†`
		`(FIFO_DEPTH - TX_WMark))†`
		`push (FIFO_DEPTH - \†`
		`TX_WMark) data into FIFO†`
		`else†`
		`push pending_bytes data \†`
		`into FIFO†`

Bits	Interrupt	Description
3	Data Transfer (DTO)†	Data transfer completed, even if there is Start Bit Error or CRC error. This bit is also set when "read data-timeout" occurs or CCS is sampled from CE-ATA device.† **Recommendation:** In non-DMA mode, when data is read from card, on seeing interrupt, host should read any pending data from FIFO. In DMA mode, DMA controllers guarantee FIFO is flushed before interrupt.† **Note:** DTO bit is set at the end of the last data block, even if the device asserts MMC busy after the last data block.†
2	Command Done (CD)†	Command sent to card and received response from card, even if Response Error or CRC error occurs. Also set when response timeout occurs or CCSD sent to CE-ATA device.†
1	Response Error (RE)†	Error in received response set if one of following occurs:† • Transmission bit != 0† • Command index mismatch† • End-bit != 1†
0	Card-Detect (CDT)†	When one or more cards inserted or removed, this interrupt occurs. Software should read card-detect register (CDETECT, 0x50) to determine current card status.† **Recommendation:** After power-on and before enabling interrupts, software should read card detect register and store it in memory. When interrupt occurs, it should read card detect register and compare it with value stored in memory to determine which card(s) were removed/inserted. Before exiting ISR, software should update memory with new card-detect value.†

Interrupt Setting and Clearing

The SDIO Interrupts, Receive FIFO Data Request, and Transmit FIFO Data Request interrupts are set by level-sensitive interrupt sources. Therefore, the interrupt source must be first cleared before you can reset the interrupt's corresponding bit in the `rintsts` register to 0.†

For example, on receiving the Receive FIFO Data Request interrupt, the FIFO buffer must be emptied so that the FIFO buffer count is not greater than the RX watermark, which causes the interrupt to be triggered.†

The rest of the interrupts are triggered by single clock-pulse-width sources.†

FIFO Buffer

The SD/MMC controller has a 4 KB data FIFO buffer for storing transmit and receive data.

The FIFO has an ECC controller built-in to provide ECC protection. The ECC controller is able to detect single-bit and double-bit errors, and correct the single-bit errors. The ECC operation and functionality is programmable through the ECC register slave interface. The ECC register slave interface provides host access to configure the ECC logic as well as inject bit errors into the memory. It also provides the host access to memory initialization hardware used to clear out the memory contents including the ECC bits. The ECC controller generates interrupts upon occurrences of single- and double-bit errors, and the interrupt signals are connected to the system manager.

Note: Since SD/MMC has multiple memories, it must initialize both memories explicitly. Initialization is controlled by software through the ECC Control (CTRL) register. This process cannot be interrupted or stopped once it starts; hence software must wait for the initialization complete bit to be set in the Initialization Status (`INITSTAT`) register. Memory accesses are allowed after the initialization process is complete.

Internal DMA Controller

Internal DMA controller (AHB Master) enables the core to act as a Master on the AHB to transfer data to and from the AHB.

- Supports 32-bit data
- Supports split, retry, and error AHB responses, but does not support wrap
- Configurable for little-endian or big-endian mode
- Allows the selection of AHB burst type through software

The internal DMA controller has a CSR and a single transmit or receive engine, which transfers data from system memory to the card and vice versa. The controller uses a descriptor mechanism to efficiently move data from source to destination with minimal host processor intervention. You can configure the controller to interrupt the host processor in situations such as transmit and receive data transfer completion from the card, as well as other normal or error conditions. The DMA controller and the host driver communicate through a single data structure.†

The internal DMA controller transfers the data received from the card to the data buffer in the system memory, and transfers transmit data from the data buffer in the memory to the controller's FIFO buffer. Descriptors that reside in the system memory act as pointers to these buffers.†

A data buffer resides in the physical memory space of the system memory and consists of complete or partial data. The buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data buffers.†

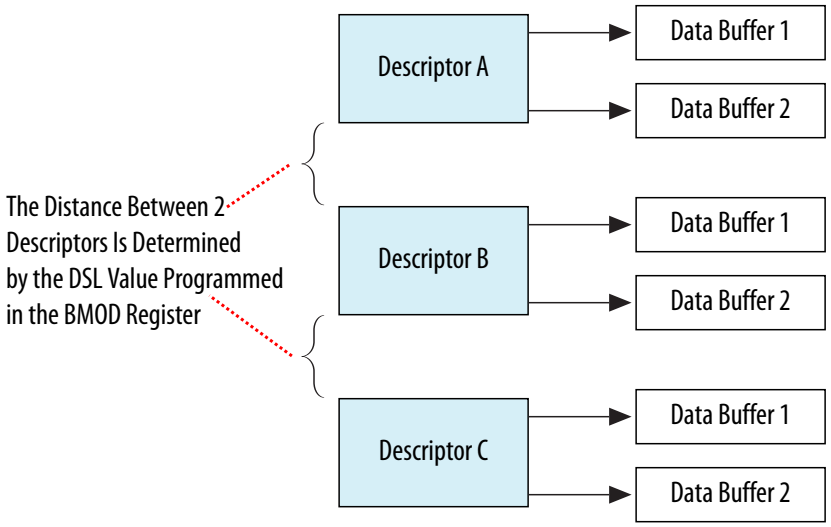
A single descriptor is used for both reception and transmission. The base address of the list is written into the descriptor list base address register (`dbaddr`). A descriptor list is forward linked. The last descriptor can point back to the first entry to create a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.†

Internal DMA Controller Descriptors

The internal DMA controller uses these types of descriptor structures:†

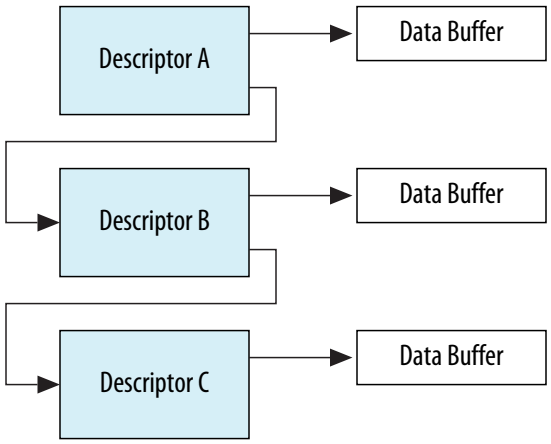
- Dual-buffer structure—The distance between two descriptors is determined by the skip length value written to the descriptor skip length field (`dsl`) of the bus mode register (`bmod`).†

Figure 14-4: Dual-Buffer Descriptor Structure†



- Chain structure—Each descriptor points to a unique buffer, and to the next descriptor in a linked list.†

Figure 14-5: Chain Descriptor Structure†



Internal DMA Controller Descriptor Address

The descriptor address must be aligned to the 32-bit bus. Each descriptor contains 16 bytes of control and status information.†

Table 14-5: Descriptor Format

Name	Off-set	31	30	29:27	26	25:14	13	12:7	6	5	4	3	2	1	0
DES0	0	OWN	CES	—						ER	CH	FS	LD	DIC	—
DES1	4	—				BS2		BS1							
DES2	8	BAP1													
DES3	12	BAP2 or Next Descriptor Address													

Related Information

Internal DMA Controller Descriptor Fields on page 14-14
Refer to this table for information about each of the bits of the descriptor.

Internal DMA Controller Descriptor Fields

The DES0 field in the internal DMA controller descriptor contains control and status information.

Table 14-6: Internal DMA Controller DES0 Descriptor Field†

Bits	Name	Description
31	OWN	When set to 1, this bit indicates that the descriptor is owned by the internal DMA controller. When this bit is set to 0, it indicates that the descriptor is owned by the host. The internal DMA controller resets this bit to 0 when it completes the data transfer.
30	Card Error Summary (CES)	The CES bit indicates whether a transaction error occurred. The CES bit is the logical OR of the following error bits in the `rintsts` register. • End-bit error (`ebe`) • Response timeout (`rto`) • Response CRC (`rcrc`) • Start-bit error (`sbe`) • Data read timeout (`drto`) • Data CRC for receive (`dcrc`) • Response error (`re`)
29:6	Reserved	—

Bits	Name	Description
5	End of Ring (ER)	When set to 1, this bit indicates that the descriptor list reached its final descriptor. The internal DMA controller returns to the base address of the list, creating a descriptor ring. ER is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set to 1, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set to 1, BS2 (DES1[25:13]) must be all zeros.
3	First Descriptor (FD)	When set to 1, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.
2	Last Descriptor (LD)	When set to 1, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the data.
1	Disable Interrupt on Completion (DIC)	When set to 1, this bit prevents the setting of the TI/RI bit of the internal DMA controller status register (`idsts`) for the data that ends in the buffer pointed to by this descriptor.
0	Reserved	—

Table 14-7: Internal DMA Controller DES1 Descriptor Field†

The DES1 descriptor field contains the buffer size.

Bits	Name	Description
31:26	Reserved	—
25:13	Buffer 2 Size (BS2)	This field indicates the second data buffer byte size. The buffer size must be a multiple of four. When the buffer size is not a multiple of four, the resulting behavior is undefined. This field is not valid if DES0[4] is set to 1.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of four bytes. When the buffer size is not a multiple of four, the resulting behavior is undefined. If this field is 0, the DMA ignores the buffer and proceeds to the next descriptor for a chain structure, or to the next buffer for a dual-buffer structure. If there is only one descriptor and only one buffer to be programmed, you need to use only buffer 1 and not buffer 2.

Table 14-8: Internal DMA Controller DES2 Descriptor Field†

The DES2 descriptor field contains the address pointer to the data buffer.

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The internal DMA controller ignores DES2 [1:0], because it only performs 32-bit aligned accesses.

Table 14-9: Internal DMA Controller DES3 Descriptor Field†

The DES3 descriptor field contains the address pointer to the next descriptor if the present descriptor is not the last descriptor in a chained descriptor structure or the second buffer address for a dual-buffer structure.†

Bits	Name	Description
31:0	Buffer Address Pointer 2 (BAP2) or Next Descriptor Address	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set to 1, this address contains the pointer to the physical memory where the next descriptor is present. If this is not the last descriptor, the next descriptor address pointer must be aligned to 32 bits. Bits 1 and 0 are ignored.

Host Bus Burst Access

The internal DMA controller attempts to issue fixed-length burst transfers on the master interface if configured using the fixed burst bit (`fb`) of the `bmod` register. The maximum burst length is indicated and limited by the programmable burst length (`pbl`) field of the `bmod` register. When descriptors are being fetched, the master interface always presents a burst size of four to the interconnect.†

The internal DMA controller initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO buffer or the number of bytes to the end of transfer is less than the configured burst-length. When the DMA master interface is configured for fixed-length bursts, it transfers data using the most efficient combination of INCR4, INCR8 or INCR16 and SINGLE transactions. If the DMA master interface is not configured for fixed length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.†

Host Data Buffer Alignment

The transmit and receive data buffers in system memory must be aligned to a 32-bit boundary.

Buffer Size Calculations

The driver knows the amount of data to transmit or receive. For transmitting to the card, the internal DMA controller transfers the exact number of bytes from the FIFO buffer, indicated by the buffer size field of the DES1 descriptor field.†

If a descriptor is not marked as last (with the LD bit of the DES0 field set to 0) then the corresponding buffer(s) of the descriptor are considered full, and the amount of valid data in a buffer is accurately indicated by its buffer size field. If a descriptor is marked as last, the buffer might or might not be full, as indicated by the buffer size in the DES1 field. The driver is aware of the number of locations that are valid.† The driver is expected to ignore the remaining, invalid bytes.

Internal DMA Controller Interrupts

Interrupts can be generated as a result of various events. The `idsts` register contains all the bits that might cause an interrupt. The internal DMA controller interrupt enable register (`idinten`) contains an enable bit for each of the events that can cause an interrupt to occur.†

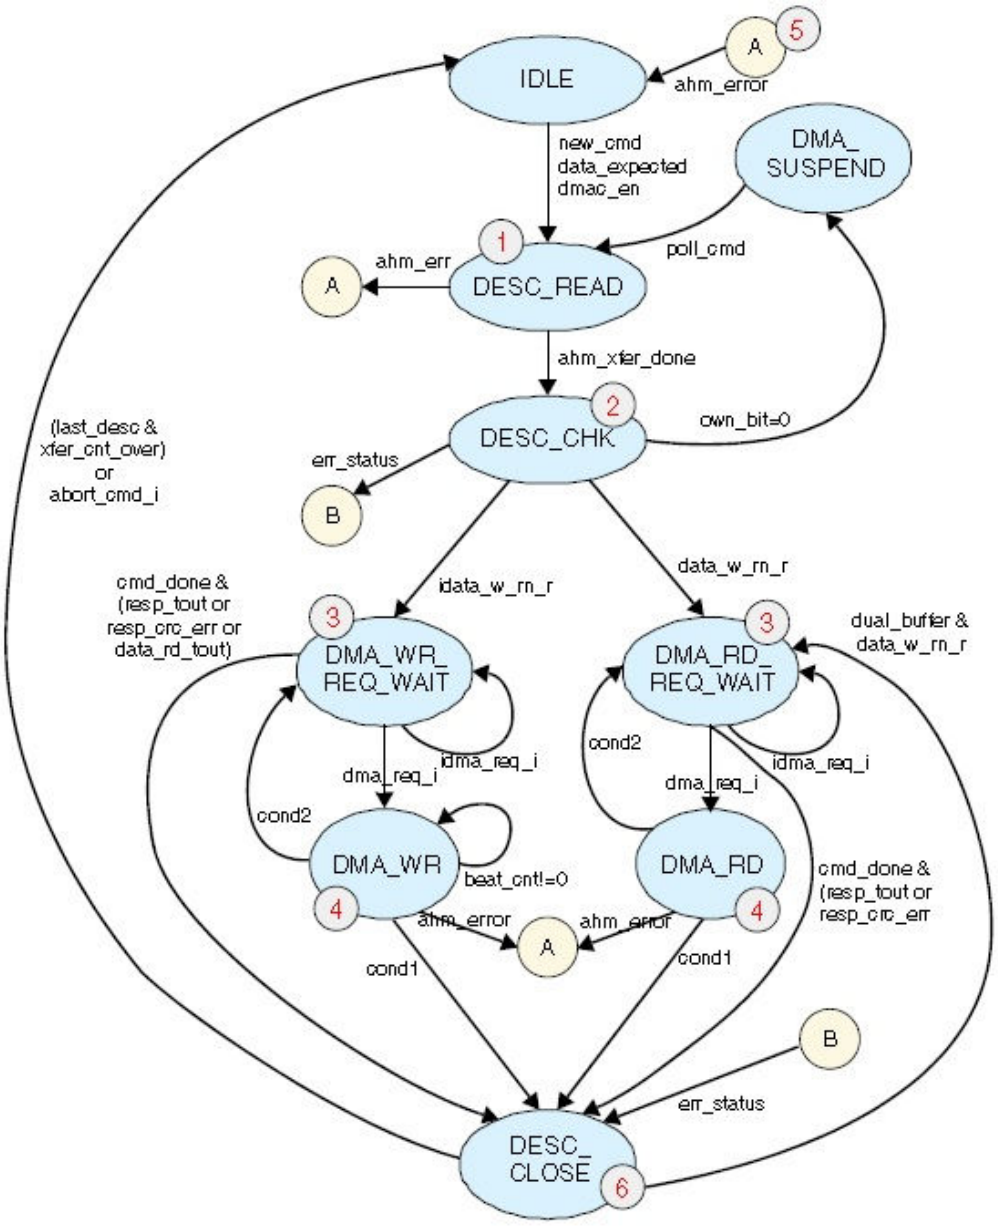
There are two summary interrupts—the normal interrupt summary bit (`nis`) and the abnormal interrupt summary bit (`ais`)—in the `idsts` register.† The `nis` bit results from a logical OR of the transmit interrupt (`ti`) and receive interrupt (`ri`) bits in the `idsts` register. The `ais` bit is a logical OR result of the fatal bus error interrupt (`fbe`), descriptor unavailable interrupt (`du`), and card error summary interrupt (`ces`) bits in the `idsts` register.

Interrupts are cleared by writing a 1 to the corresponding bit position.† If a 0 is written to an interrupt's bit position, the write is ignored, and does not clear the interrupt. When all the enabled interrupts within a group are cleared, the corresponding summary bit is set to 0. When both the summary bits are set to 0, the interrupt signal is de-asserted.†

Interrupts are not queued. If another interrupt event occurs before the driver has responded to the previous interrupt, no additional interrupts are generated. For example, the `ri` bit of the `idsts` register indicates that one or more data has been transferred to the host buffer.†

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the `idsts` register for the interrupt cause.† The final interrupt signal from the controller is a logical OR of the interrupts from the BIU and internal DMA controller.

Internal DMA Controller Functional State Machine†



The following list explains each state of the functional state machine:†

1. The internal DMA controller performs four accesses to fetch a descriptor.†
2. The DMA controller stores the descriptor information internally. If it is the first descriptor, the controller issues a FIFO buffer reset and waits until the reset is complete.†
3. The internal DMA controller checks each bit of the descriptor for the correctness. If bit mismatches are found, the appropriate error bit is set to 1 and the descriptor is closed by setting the OWN bit in the DES0 field to 1.†

The `rintsts` register indicates one of the following conditions:†

- Response timeout†
- Response CRC error†
- Data receive timeout†
- Response error†

4. The DMA waits for the RX watermark to be reached before writing data to system memory, or the TX watermark to be reached before reading data from system memory. The RX watermark represents the number of bytes to be locally stored in the FIFO buffer before the DMA writes to memory. The TX watermark represents the number of free bytes in the local FIFO buffer before the DMA reads data from memory.†
5. If the value of the programmable burst length (PBL) field is larger than the remaining amount of data in the buffer, single transfers are initiated. If dual buffers are being used, and the second buffer contains no data (buffer size = 0), the buffer is skipped and the descriptor is closed.†
6. The OWN bit in descriptor is set to 0 by the internal DMA controller after the data transfer for one descriptor is completed. If the transfer spans more than one descriptor, the DMA controller fetches the next descriptor. If the transfer ends with the current descriptor, the internal DMA controller goes to idle state after setting the `ri` bit or the `ti` bit of the `idsts` register. Depending on the descriptor structure (dual buffer or chained), the appropriate starting address of descriptor is loaded. If it is the second data buffer of dual buffer descriptor, the descriptor is not fetched again.†

Abort During Internal DMA Transfer

If the host issues an SD/SDIO STOP_TRANSMISSION command (CMD12) to the card while data transfer is in progress, the internal DMA controller closes the present descriptor after completing the data transfer until a Data Transfer Over (DTO) interrupt is asserted. Once a STOP_TRANSMISSION command is issued, the DMA controller performs single burst transfers.†

- For a card write operation, the internal DMA controller keeps writing data to the FIFO buffer after fetching it from the system memory until a DTO interrupt is asserted. This is done to keep the card clock running so that the STOP_TRANSMISSION command is reliably sent to the card.†
- For a card read operation, the internal DMA controller keeps reading data from the FIFO buffer and writes to the system memory until a DTO interrupt is generated. This is required because DTO interrupt is not generated until and unless all the FIFO buffer data is emptied.†

Note: For a card write abort, only the current descriptor during which a STOP_TRANSMISSION command is issued is closed by the internal DMA controller. The remaining unread descriptors are not closed by the internal DMA controller.†

Note: For a card read abort, the internal DMA controller reads the data out of the FIFO buffer and writes them to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.†

Fatal Bus Error Scenarios

A fatal bus error occurs when the master interface issues an error response. This error is a system error, so the software driver must not perform any further setup on the controller. The only recovery mechanism from such scenarios is to perform one of the following tasks:†

- Issue a reset to the controller through the reset manager.†
- Issue a program controller reset by writing to the controller reset bit (`controller_reset`) of the `ctrl` register.†

FIFO Buffer Overflow and Underflow

During normal data transfer conditions, FIFO buffer overflow and underflow does not occur. However, if there is a programming error, a FIFO buffer overflow or underflow can result. For example, consider the following scenarios.†

For transmit:†

- PBL=4†
- TX watermark = 1†

For these programming values, if the FIFO buffer has only one location empty, the DMA attempts to read four words from memory even though there is only one word of storage available. This results in a FIFO Buffer Overflow interrupt.†

For receive:†

- PBL=4†
- RX watermark = 1†

For these programming values, if the FIFO buffer has only one location filled, the DMA attempts to write four words, even though only one word is available. This results in a FIFO Buffer Underflow interrupt.†

The driver must ensure that the number of bytes to be transferred, as indicated in the descriptor, is a multiple of four bytes. For example, if the `bytcnt` register = 13, the number of bytes indicated in the descriptor must be rounded up to 16 because the length field must always be a multiple of four bytes.†

PBL and Watermark Levels

This table shows legal PBL and FIFO buffer watermark values for internal DMA controller data transfer operations.†

Table 14-10: PBL and Watermark Levels†

PBL (Number of transfers)	TX/RX FIFO Buffer Watermark Value
1	greater than or equal to 1
4	greater than or equal to 4
8	greater than or equal to 8
16	greater than or equal to 16
32	greater than or equal to 32
64	greater than or equal to 64
128	greater than or equal to 128
256	greater than or equal to 256

CIU

The Card Interface Unit (CIU) interfaces with the BIU and SD/MMC cards or devices. The host processor writes command parameters to the SD/MMC controller's BIU control registers and these parameters are then passed to the CIU. Depending on control register values, the CIU generates SD/MMC command and data traffic on the card bus according to the SD/MMC protocol. The control register values also decide whether the command and data traffic is directed to the CE-ATA card, and the SD/MMC controller controls the command and data path accordingly.†

The following list describes the CIU operation restrictions:†

- After a command is issued, the CIU accepts another command only to check read status or to stop the transfer.†
- Only one data transfer command can be issued at a time.†
- During an open-ended card write operation, if the card clock is stopped because the FIFO buffer is empty, the software must first fill the data into the FIFO buffer and start the card clock. It can then issue only an SD/SDIO STOP_TRANSMISSION (CMD12) command to the card.†
- During an SDIO/COMBO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO buffer and start the resume command as if it were a new data transfer command.†
- When issuing SD/SDIO card reset commands (GO_IDLE_STATE, GO_INACTIVE_STATE or CMD52_reset) while a card data transfer is in progress, the software must set the stop abort command bit (`stop_abort_cmd`) in the `cmd` register to 1 so that the controller can stop the data transfer after issuing the card reset command.†
- If the card clock is stopped because the FIFO buffer is full during a card read, the software must read at least two FIFO buffer locations to start the card clock.†
- If CE-ATA card device interrupts are enabled (the `nIEN` bit is set to 0 in the ATA control register), a new RW_BLK command must not be sent to the same card device if there is a pending RW_BLK command in progress (the RW_BLK command used in this document is the RW_MULTIPLE_BLOCK MMC command defined by the CE-ATA specification). Only the Command Completion Signal Disable (CCSD) command can be sent while waiting for the Command Completion Signal (CCS).†
- For the same card device, a new command is allowed for reading status information, if interrupts are disabled in the CE-ATA card (the `nIEN` bit is set to 1 in the ATA control register).†
- Open-ended transfers are not supported for the CE-ATA card devices.†
- The `send_auto_stop` signal is not supported (software must not set the `send_auto_stop` bit in the `cmd` register) for CE-ATA transfers.†

The CIU consists of the following primary functional blocks:†

- Command path†
- Data path†
- Clock control†

Command Path

The command path performs the following functions:†

- Load card command parameters†
- Send commands to card bus†
- Receive responses from card bus†
- Send responses to BIU†
- Load clock parameters†
- Drives the P-bit on command pin†

A new command is issued to the controller by writing to the BIU registers and setting the `start_cmd` bit in the `cmd` register. The command path loads the new command (command, command argument, timeout) and sends an acknowledgement to the BIU.†

After the new command is loaded, the command path state machine sends a command to the card bus—including the internally generated seven-term CRC (CRC-7)—and receives a response, if any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command. In CE-ATA data payload transfer (RW_MULTIPLE_BLOCK) commands, if the card device interrupts are enabled (the nIEN bit is set to 0

in the ATA control register), the state machine performs the following actions after receiving the response:†

- Does not drive the P-bit; it waits for CCS, decodes and goes back to idle state, and then drives the P-bit.†
- If the host wants to send the CCSD command and if eight clock cycles are expired after the response, it sends the CCSD pattern on the command pin.†

Load Command Parameters

Commands or responses are loaded in the command path in the following situations:†

- New command from BIU—When the BIU sends a new command to the CIU, the `start_cmd` bit is set to 1 in the `cmd` register.†
- Internally-generated `send_auto_stop`—When the data path ends, the SD/SDIO STOP command request is loaded.†
- Interrupt request (IRQ) response with relative card address (RCA) 0x000—When the command path is waiting for an IRQ response from the MMC and a "send irq response" request is signaled by the BIU, the send IRQ request bit (`send_irq_response`) is set to 1 in the `ctrl` register.†

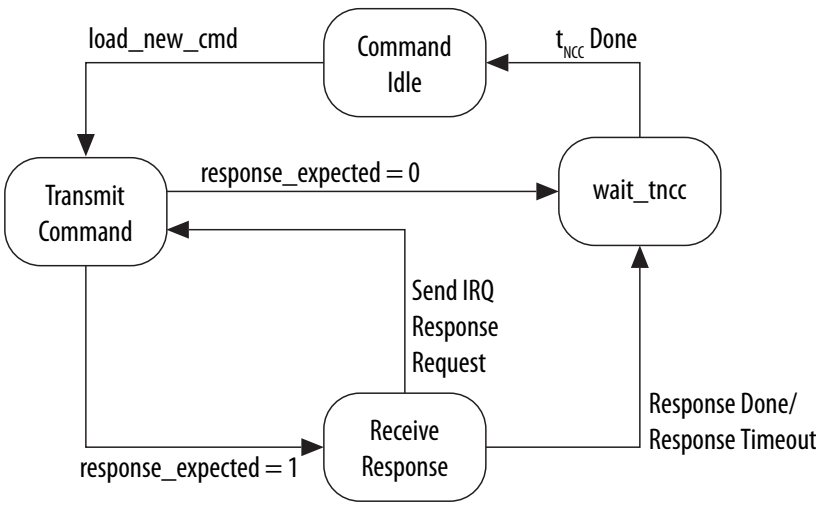
Loading a new command from the BIU in the command path depends on the following `cmd` register bit settings:†

- `update_clock_registers_only`—If this bit is set to 1 in the `cmd` register, the command path updates only the `clkena`, `clkdiv`, and `clksrc` registers. If this bit is set to 0, the command path loads the `cmd`, `cmdarg`, and `tmout` registers. It then processes the new command, which is sent to the card.†
- `wait_prvdata_complete`—If this bit is set to 1, the command path loads the new command under one of the following conditions:†
  - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (`bytcnt` = 0).†
  - After completion of the current data transfer, if a predefined data transfer is in progress.†

Send Command and Receive Response

After a new command is loaded in the command path (the `update_clock_registers_only` bit in the `cmd` register is set to 0), the command path state machine sends out a command on the card bus.†

Figure 14-6: Command Path State Machine†



The command path state machine performs the following functions, according to cmd register bit values:†

1. send_initialization—Initialization sequence of 80 clock cycles is sent before sending the command.†
2. response_expected—A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start bit of the card response is not received within the number of clock cycles (as set up in the tmout register), the rto bit and command done (CD) bit are set to 1 in the rintsts register, to signal to the BIU. If the response-expected bit is set to 0, the command path sends out a command and signals a response done to the BIU, which causes the cmd bit to be set to 1 in the rintsts register.†
3. response_length—If this bit is set to 1, a 136-bit long response is received; if it is set to 0, a 48-bit short response is received.†
4. check_response_crc—If this bit is set to 1, the command path compares CRC-7 received in the response with the internally-generated CRC-7. If the two do not match, the response CRC error is signaled to the BIU, that is, the rcrc bit is set to 1 in the rintsts register.†

Send Response to BIU

If the response_expected bit is set to 1 in the cmd register, the received response is sent to the BIU. Response register 0 (resp0) is updated for a short response, and the response register 3 (resp3), response register 2 (resp2), response register 1 (resp1), and resp0 registers are updated on a long response, after which the cmd bit is set to 1 in the rintsts register. If the response is for an AUTO_STOP command sent by the CIU, the response is written to the resp1 register, after which the auto command done bit (acd) is set to 1 in the rintsts register.†

The command path verifies the contents of the card response.

Table 14-11: Card Response Fields†

Field	Contents
Response transmission bit	0
Command index	Command index of the sent command
End bit	1

The command index is not checked for a 136-bit response or if the check_response_crc bit in the cmd register is set to 0. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved, that is, 0b111111.†

Related Information

SD Association

For more information about response values, refer to Physical Layer Simplified Specification, Version 3.01 as described on the SD Association website.

Driving P-bit to the CMD Pin

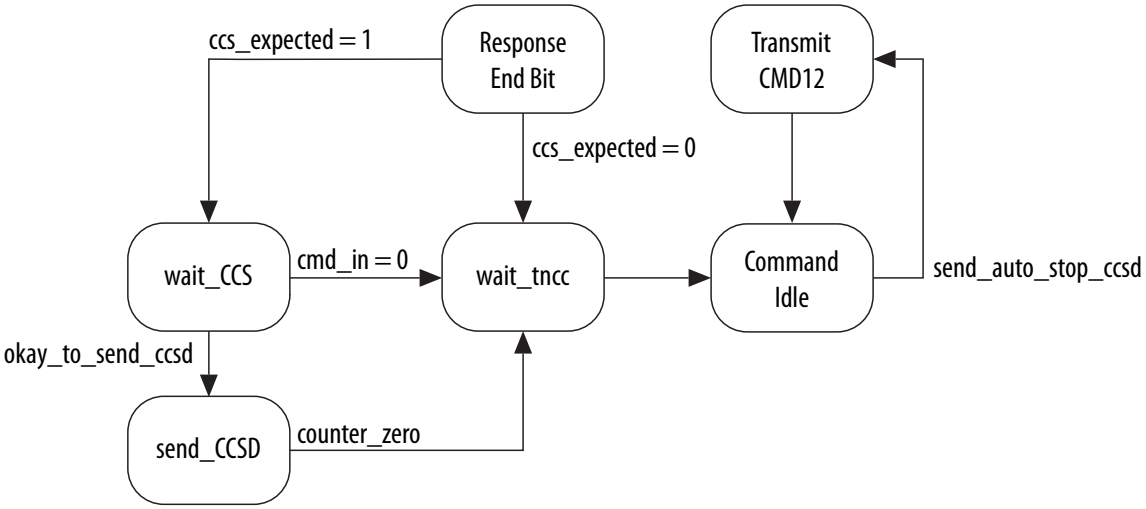
The command path drives a one-cycle pull-up bit (P-bit) to 1 on the CMD pin between two commands if a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command. While accessing a CE-ATA card device, for commands that expect a CCS, the P-bit is driven after the response only if the interrupts are disabled in the CE-ATA card (the nIEN

bit is set to 1 in the ATA control register), that is, the CCS expected bit (ccs_expected) in the cmd register is set to 0. If the command expects the CCS, the P-bit is driven only after receiving the CCS.†

Polling the CCS

CE-ATA card devices generate the CCS to notify the host controller of the normal ATA command completion or ATA command termination. After receiving the response from the card, the command path state machine performs the functions illustrated in the following figure according to cmd register bit values.†

Figure 14-7: CE-ATA Command Path State Machine†



The above figure illustrates:

- Response end bit state—The state machine receives the end bit of the response from the card device. If the ccs_expected bit of the cmd register is set to 1, the state machine enters the wait CCS state.†
- Wait CCS—The state machine waits for the CCS from the CE-ATA card device. While waiting for the CCS, the following events can happen:†
  1. Software sets the send CCSD bit (send_ccsd) in the ctrl register, indicating not to wait for CCS and to send the CCSD pattern on the command line.†
  2. Receive the CCS on the CMD line.†
- Send CCSD command—Sends the CCSD pattern (0b00001) on the CMD line.†

CCS Detection and Interrupt to Host Processor

If the ccs_expected bit in the cmd register is set to 1, the CCS from the CE-ATA card device is indicated by setting the data transfer over bit (dto) in the rintsts register. The controller generates a DTO interrupt if this interrupt is not masked.†

For the RW_MULTIPLE_BLOCK commands, if the CE-ATA card device interrupts are disabled (the nIEN bit is set to 1 in the ATA control register)— that is, the ccs_expected bit is set to 0 in the cmd register—there are no CCSs from the card. When the data transfer is over—that is, when the requested number of bytes are transferred—the dto bit in the rintsts register is set to 1.†

CCS Timeout

If the command expects a CCS from the card device (the `ccs_expected` bit is set to 1 in the `cmd` register), the command state machine waits for the CCS and remains in the wait CCS state. If the CE-ATA card fails to send out the CCS, the host software must implement a timeout mechanism to free the command and data path. The controller does not implement a hardware timer; it is the responsibility of the host software to maintain a software timer.†

In the event of a CCS timeout, the host must issue a CCSD command by setting the `send_ccsd` bit in the `ctrl` register. The controller command path state machine sends the CCSD command to the CE-ATA card device and exits to an idle state. After sending the CCSD command, the host must also send an SD/SDIO STOP_TRANSMISSION command to the CE-ATA card to abort the outstanding ATA command.†

Send CCSD Command

If the `send_ccsd` bit in the `ctrl` register is set to 1, the controller sends a CCSD pattern on the CMD line. The host can send the CCSD command while waiting for the CCS or after a CCS timeout happens.†

After sending the CCSD pattern, the controller sets the `cmd` bit in the `rintsts` register and also generates an interrupt to the host if the Command Done interrupt is not masked.†

Note: Within the CIU block, if the `send_ccsd` bit in the `ctrl` register is set to 1 on the same clock cycle as CCS is sampled, the CIU block does not send a CCSD pattern on the CMD line. In this case, the `dto` and `cmd` bits in the `rintsts` register are set to 1.†

Note: Due to asynchronous boundaries, the CCS might have already happened and the `send_ccsd` bit is set to 1. In this case, the CCSD command does not go to the CE-ATA card device and the `send_ccsd` bit is not set to 0. The host must reset the `send_ccsd` bit to 0 before the next command is issued.†

If the send auto stop CCSD (`send_auto_stop_ccsd`) bit in the `ctrl` register is set to 1, the controller sends an internally generated STOP_TRANSMISSION command (CMD12) after sending the CCSD pattern. The controller sets the `acd` bit in the `rintsts` register.†

I/O transmission delay (N_{ACIO} Timeout)

The host software maintains the timeout mechanism for handling the I/O transmission delay (N_{ACIO} cycles) time-outs while reading from the CE-ATA card device. The controller neither maintains any timeout mechanism nor indicates that N_{ACIO} cycles are elapsed while waiting for the start bit of a data token. The I/O transmission delay is applicable for read transfers using the RW_REG and RW_BLK commands; the RW_REG and RW_BLK commands used in this document refer to the RW_MULTIPLE_REGISTER and RW_MULTIPLE_BLOCK MMC commands defined by the CE-ATA specification.†

Note: After the N_{ACIO} timeout, the application must abort the command by sending the CCSD and STOP commands, or the STOP command. The Data Read Timeout (DRTO) interrupt might be set to 1 while a STOP_TRANSMISSION command is transmitted out of the controller, in which case the data read timeout boot data start bit (`bds`) and the `dto` bit in the `rintsts` register are set to 1.†

Data Path

The data path block reads the data FIFO buffer and transmits data on the card bus during a write data transfer, or receives data and writes it to the FIFO buffer during a read data transfer. The data path loads new data parameters—data expected, read/write data transfer, stream/block transfer, block size, byte count, card type, timeout registers—whenever a data transfer command is not in progress. If the data

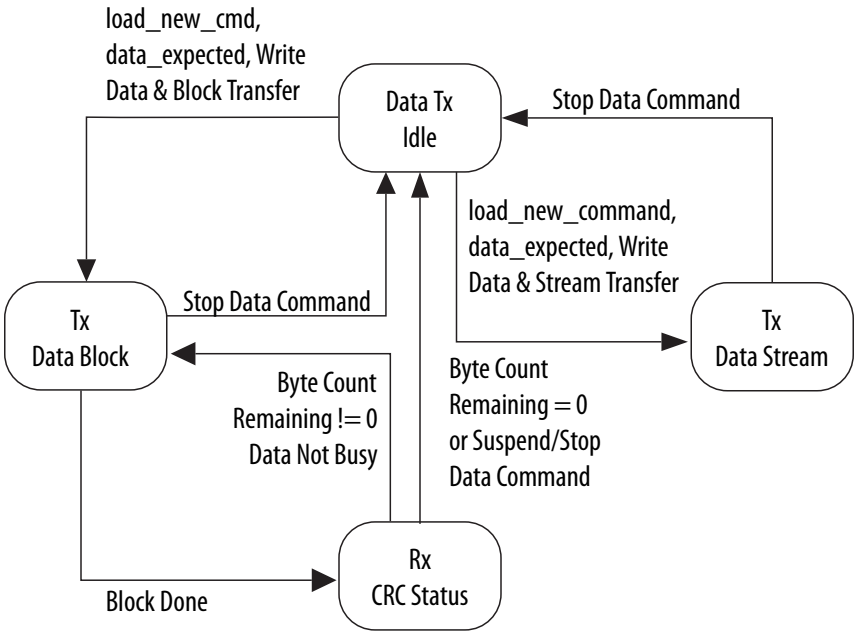
transfer expected bit (`data_expected`) in the `cmd` register is set to 1, the new command is a data transfer command and the data path starts one of the following actions:†

- Transmits data if the read/write bit = 1†
- Receives data if read/write bit = 0†

Data Transmit

The data transmit state machine starts data transmission two clock cycles after a response for the data write command is received. This occurs even if the command path detects a response error or response CRC error. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the transfer mode bit (`transfer_mode`) in the `cmd` register, the data transmit state machine puts data on the card data bus in a stream or in blocks.†

Figure 14-8: Data Transmit State Machine†



Stream Data Transmit

If the `transfer_mode` bit in the `cmd` register is set to 1, the transfer is a stream-write data transfer. The data path reads data from the FIFO buffer from the BIU and transmits in a stream to the card data bus. If the FIFO buffer becomes empty, the card clock is stopped and restarted once data is available in the FIFO buffer.†

If the `bytcnt` register is reset to 0, the transfer is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer is terminated when the end bit of the STOP command and end bit of the data match over two clock cycles.†

If the `bytcnt` register is written with a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, the STOP command is internally generated and loaded in the command path when the end bit of the STOP command occurs after the last byte of the stream write transfer matches. This data transfer can also terminate if the host issues a STOP command before all the data bytes are transferred to the card bus.†

Single Block Data

If the `transfer_mode` bit in the `cmd` register is set to 0 and the `bytcnt` register value is equal to the value of the `block_size` register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated 16-term CRC (CRC-16).†

If the `ctype` register is set for a 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.†

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This happens when the `dto` bit in the `rintsts` register is set to 1.†

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register.†

Additionally, if the start bit of the CRC status is not received by two clock cycles after the end of the data block, a CRC status start-bit error (SBE) is signaled to the BIU by setting the `sbe` bit in the `rintsts` register.†

Multiple Block Data

A multiple-block write-data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 0 and the value in the `bytcnt` register is not equal to the value of the `block_size` register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC-16 value.†

If the `ctype` register is set to 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1-, 4-, or 8-data lines, respectively, and CRC-16 is separately generated and transmitted on 1-, 4-, or 8-data lines, respectively.†

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining byte count becomes 0, the data path signals to the BIU that the data transfer is done. This happens when the `dto` bit in the `rintsts` register is set to 1.†

If the remaining data bytes are greater than zero, the data path state machine starts to transmit another data block.†

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register, and continues further data transmission until all the bytes are transmitted.†

If the CRC status start bit is not received by two clock cycles after the end of a data block, a CRC status SBE is signaled to the BIU by setting the `ebe` bit in the `rintsts` register and further data transfer is terminated.†

If the `send_auto_stop` bit is set to 1 in the `cmd` register, the SD/SDIO STOP command is internally generated during the transfer of the last data block, where no extra bytes are transferred to the card. The end bit of the STOP command might not exactly match the end bit of the CRC status in the last data block.†

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data is transferred, at which time the internally-generated STOP command is loaded in the command path.†

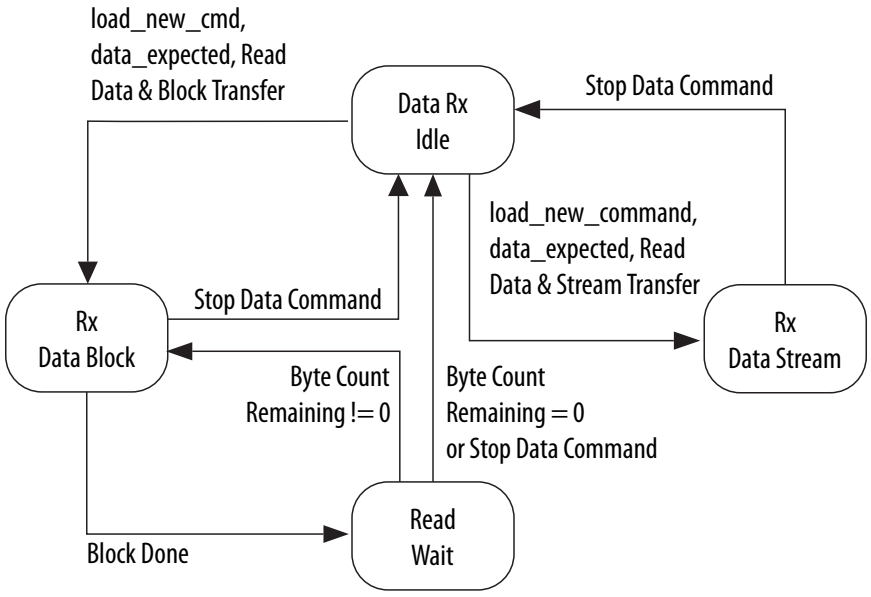
If the bytcnt is zero (the block size must be greater than zero) the transfer is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.†

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. If a response is not received from the card because a response timeout occurs, the BIU does not receive a signal that the data transfer is complete. This happens if the command sent by the controller is an illegal operation for the card, which keeps the card from starting a read data transfer.†

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the transfer_mode bit in the cmd register, the data-receive state machine gets data from the card data bus in a stream or block(s).†

Figure 14-9: Data Receive State Machine†



Stream Data Read

A stream-read data transfer occurs if the transfer_mode bit in the cmd register is set to 1, at which time the data path receives data from the card and writes it to the FIFO buffer. If the FIFO buffer becomes full, the card clock stops and restarts once the FIFO buffer is no longer full.†

An open-ended stream-read data transfer occurs if the bytcnt register is set to 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer terminates two clock cycles after the end bit of the STOP command.†

If the bytcnt register contains a nonzero value and the send_auto_stop bit in the cmd register is set to 1, a STOP command is internally generated and loaded into the command path, where the end bit of the STOP command occurs after the last byte of the stream data transfer is received. This data transfer can

terminate if the host issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command before all the data bytes are received from the card.†

Single-block Data Read

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there is a CRC-16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an End-bit Error (EBE).†

Multiple-block Data Read

If the `transfer_mode` bit in the `cmd` register is clear and the value of the `bytcnt` register is not equal to the value of the `block_size` register, the transfer is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC-16.†

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining byte count becomes zero, the data path signals a data transfer to the BIU.†

If the remaining data bytes are greater than zero, the data path state machine causes another data block to be received. If CRC-16 of a received data block does not match the internally-generated CRC-16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU and the data-receive state machine terminates data reception, waits for data timeout, and signals to the BIU that the data transfer is complete.†

If the `send_auto_stop` bit in the `cmd` register is set to 1, the SD/SDIO STOP command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the STOP command might not exactly match the end bit of the last data block.†

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data is transferred, at which point the internally-generated STOP command is loaded in the command path. Data received from the card after that are then ignored by the data path.†

If the `bytcnt` register is 0 (the block size must be greater than zero), the transfer is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.†

Auto-Stop

The controller internally generates an SD/SDIO STOP command and is loaded in the command path when the `send_auto_stop` bit in the `cmd` register is set to 1. The AUTO_STOP command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for SD memory transfer for SD cards. The software must set the `send_auto_stop` bit according to the following details: †

The following list describes conditions for the AUTO_STOP command:†

- Stream-read for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than six (48 bits), a few extra data bytes are received from the card before the end bit of the STOP command is sent.†
- Stream-write for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than six (48 bits), the data path transmits the data last to meet these condition.†
- Multiple-block read memory for SD card with byte count greater than zero—If the block size is less than four (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all the bytes are read. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the last data block is received.†
- Multiple-block write memory for SD card with byte count greater than zero—If the block size is less than three (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all data blocks are transmitted. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the end bit of the CRC status is received.†
- Precaution for host software during auto-stop—When an AUTO_STOP command is issued, the host software must not issue a new command to the controller until the AUTO_STOP command is sent by the controller and the data transfer is complete. If the host issues a new command during a data transfer with the AUTO_STOP command in progress, an AUTO_STOP command might be sent after the new command is sent and its response is received. This can delay sending the STOP command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command, in which case the controller does not generate an AUTO_STOP command.†

Auto-Stop Generation for MMC Cards

Table 14-12: Auto-Stop Generation for MMC Cards†

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Stream read	0	No	Open-ended stream
Stream read	>0	Yes	Auto-stop after all bytes transfer
Stream write	0	No	Open-ended stream
Stream write	>0	Yes	Auto-stop after all bytes transfer
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 is illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes (40) †	Pre-defined multiple block

(40) The condition under which the transfer mode is set to block transfer and byte_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n*block_size (n = 2, 3, …), the condition is treated as a predefined multiple-block data transfer command. In the case of

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes (40)†	Pre-defined multiple block

Auto-Stop Generation for SD Cards

Table 14-13: Auto-Stop Generation for SD Cards†

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes	Auto-stop after all bytes transfer

Auto-Stop Generation for SDIO Cards

Table 14-14: Auto-Stop Generation for SDIO Cards†

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	No	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	No	Pre-defined multiple block

Non-Data Transfer Commands that Use Data Path

Some SD/SDIO non-data transfer commands (commands other than read and write commands) also use the data path.

---

an MMC card, the host software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the send_auto_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send_auto_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.†

Clock Control Block

The clock control block provides different clock frequencies required for SD/MMC/CE-ATA cards. The clock control block has one clock divider, which is used to generate different card clock frequencies.†

The clock frequency of a card depends on the following clock `ctrl` register settings:†

- `clkdiv` register—Internal clock dividers are used to generate different clock frequencies required for the cards. The division factor for the clock divider can be set by writing to the `clkdiv` register. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510; a value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.†
- `clksrc` register—Set this register to 0 as clock is divided by clock divider 0.†
- `clkena` register—The `cclk_out` card output clock can be enabled or disabled under the following conditions:†
  - `cclk_out` is enabled when the `cclk_enable` bit in the `clkena` register is set to 1 and disabled when set to 0.†
  - Low-power mode can be enabled by setting the `cclk_low_power` bit of the `clkena` register to 1. If low-power mode is enabled to save card power, the `cclk_out` signal is disabled when the card is idle for at least eight card clock cycles. Low-power mode is enabled when a new command is loaded and the command path goes to a non-idle state.†

Under the following conditions, the card clock is stopped or disabled:†

(41) Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.†

(42) Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.†

- Clock can be disabled by writing to the `clkena` register.†
- When low-power mode is selected and the card is idle for at least eight clock cycles.†
- FIFO buffer is full, data path cannot accept more data from the card, and data transfer is incomplete—to avoid FIFO buffer overflow.†
- FIFO buffer is empty, data path cannot transmit more data to the card, and data transfer is incomplete —to avoid FIFO buffer underflow.†

Note: The card clock must be disabled through the `clkena` register before the host software changes the values of the `clkdiv` and `clksrc` registers.†

Error Detection

Errors can occur during card operations within the CIU in the following situations.

Response†

- Response timeout—did not receive the response expected with response start bit within the specified number of clock cycles in the timeout register.†
- Response CRC error—response is expected and check response CRC requested; response CRC-7 does not match with the internally-generated CRC-7.†
- Response error—response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.†

Data Transmit†

- No CRC status—during a write data transfer, if the CRC status start bit is not received for two clock cycles after the end bit of the data block is sent out, the data path performs the following actions:†
  - Signals no CRC status error to the BIU†
  - Terminates further data transfer†
  - Signals data transfer done to the BIU†
- Negative CRC—if the CRC status received after the write data block is negative (that is, not 0b010), the data path signals a data CRC error to the BIU and continues with the data transfer.†
- Data starvation due to empty FIFO buffer—if the FIFO buffer becomes empty during a write data transmission, or if the card clock stopped and the FIFO buffer remains empty for a data-timeout number of clock cycles, the data path signals a data-starvation error to the BIU and the data path continues to wait for data in the FIFO buffer.†

Data Receive

- Data timeout—during a read-data transfer, if the data start bit is not received before the number of clock cycles specified in the timeout register, the data path does the following action: †
  - Signals a data-timeout error to the BIU†
  - Terminates further data transfer†
  - Signals data transfer done to BIU†
- Data SBE—during a 4-bit or 8-bit read-data transfer, if the all-bit data line does not have a start bit, the data path signals a data SBE to the BIU and waits for a data timeout, after which it signals that the data transfer is done.†
- Data CRC error—during a read-data-block transfer, if the CRC-16 received does not match with the internally generated CRC-16, the data path signals a data CRC error to the BIU and continues with the data transfer.†
- Data EBE—during a read-data transfer, if the end bit of the received data is not 1, the data path signals an EBE to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.†
- Data starvation due to FIFO buffer full—during a read data transmission and when the FIFO buffer becomes full, the card clock stops. If the FIFO buffer remains full for a data-timeout number of clock cycles, the data path signals a data starvation error to the BIU, by setting the data starvation host timeout bit (`hto`) in `rintsts` register to 1, and the data path continues to wait for the FIFO buffer to empty.†

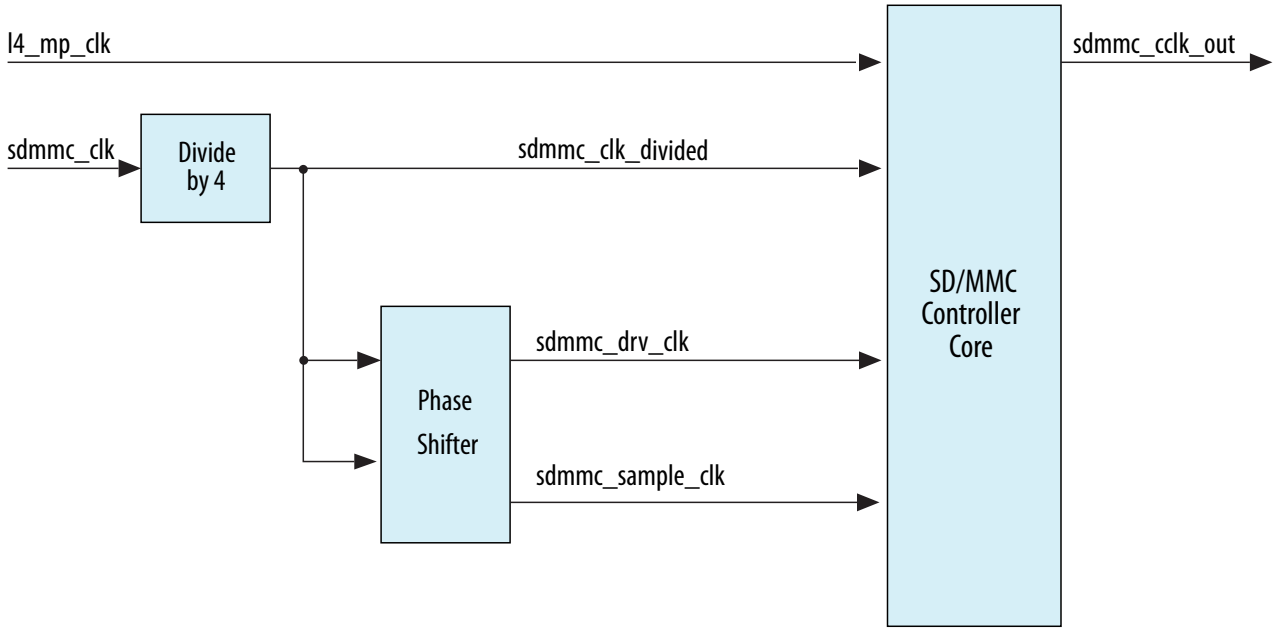
Clocks

Table 14-19: SD/MMC Controller Clocks

Clock Name	Direction	Description
`l4_mp_clk`	In	Clock for SD/MMC controller BIU
`sdmmc_clk`	In	Clock for SD/MMC controller
`sdmmc_cclk_out`	Out	Generated output clock for card
`sdmmc_clk_divided`	Internal	Divide-by-four clock of `sdmmc_clk`
`sdmmc_sample_clk`	Internal	Phase-shifted clock of `sdmmc_clk_divided` used to sample the command and data from the card
`sdmmc_drv_clk`	Internal	Phase-shifted clock of `sdmmc_clk_divided` for controller to drive command and data to the card to meet hold time requirements

Figure 14-10: SD/MMC Controller Clock Connections - HPS

This figure displays the controller clock connections from the HPS.



The `sdmmc_clk` clock from the clock manager is divided by four and becomes the `sdmmc_clk_divided` clock before passing to the phase shifters and the SD/MMC controller CIU. The phase shifters are used to generate the `sdmmc_drv_clk` and `sdmmc_sample_clk` clocks. These phase shifters provide up to eight phases shift which include 0, 45, 90, 135, 180, 225, 270, and 315 degrees. The `sdmmc_sample_clk` clock can be driven by the output from the phase shifter.

Note: The selections of phase shift degree and `sdmmc_sample_clk` source are done in the system manager. For information about setting the phase shift and selecting the source of the `sdmmc_sample_clk` clock, refer to the "Clock Setup" section within this document.

The controller generates the `sdmmc_cclk_out` clock, which is driven to the card. For more information about the generation of the `sdmmc_cclk_out` clock, refer to the "Clock Control Block" section within this document.

Related Information

  Refer to this section for information about the generation of the `sdmmc_cclk_out`clock.

Resets

The SD/MMC controller has one reset signal. The reset manager drives this signal to the SD/MMC controller on a cold or warm reset.

Related Information

Reset Manager on page 3-1

Taking the SD/MMC Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Module Reset Signals on page 3-8

Voltage Switching

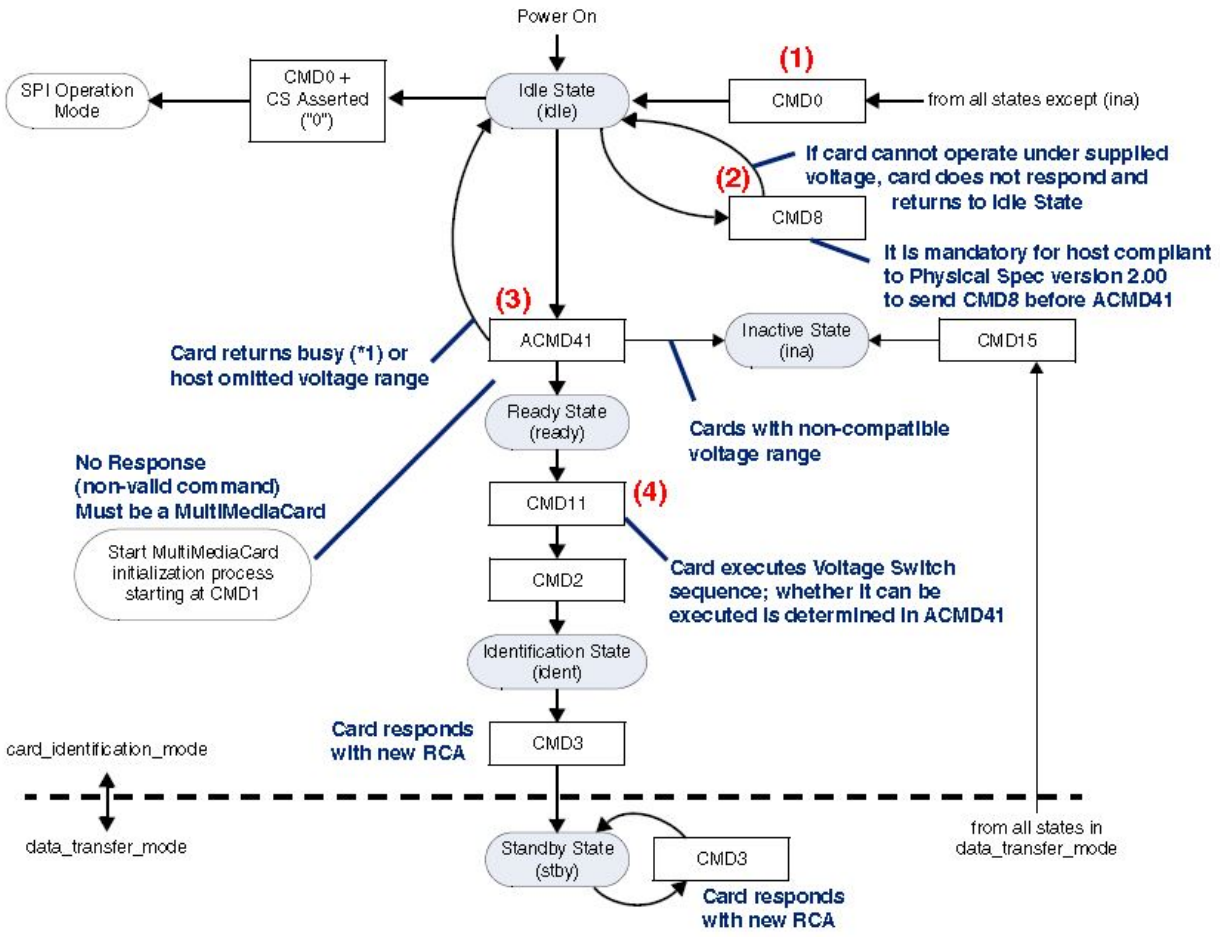
This section describes the general steps to switch voltage level.

The SD/MMC cards support various operating voltages, for example 1.8V and 3.0V. If you have a card which is at 1.8V and you eject it and replace it with another card, which is 3.0V, then voltage switching is required.

Many SD cards have an option to signal at 1.8 or 3.0 V, however the initial power-up voltage requirement is 3.0V. To support these different voltage requirements, external transceivers are needed.

The general steps to switch the voltage level requires you to use a SD/MMC voltage-translation transceiver in between the HPS and the SD/MMC card.

Figure 14-11: Voltage Switching Command Flow Diagram†



(*1) **Note:** Card returns busy when:†

- Card executes internal initializaiton process†
- Card is High or Extended capacity SD Memory Card and host does not support High†

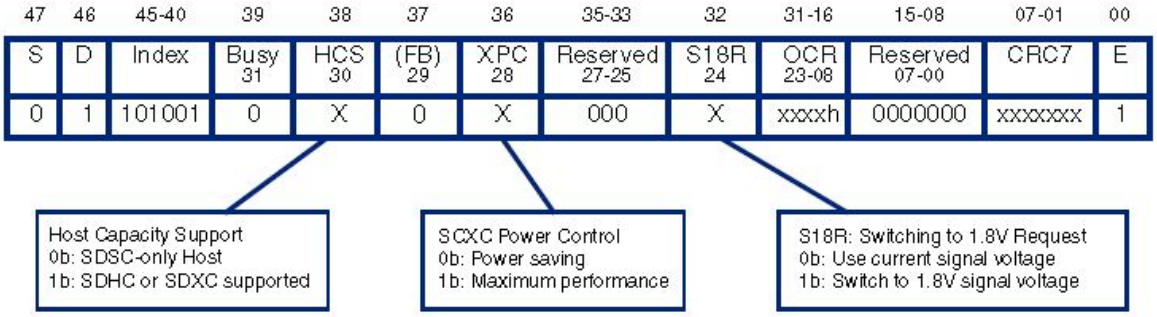
The following outlines the steps for the voltage switch programming sequence.†

1. Software Driver starts CMD0, which selects the bus mode as SD.†
2. After the bus is in SD card mode, CMD8 is started in order to verify if the card is compatible with the SD Memory Card Specification, Version 2.00.†

   CMD8 determines if the card is capable of working within the host supply voltage specified in the VHS (19:16) field of the CMD; the card supports the current host voltage if a response to CMD8 is received.†
3. ACMD 41 is started.†

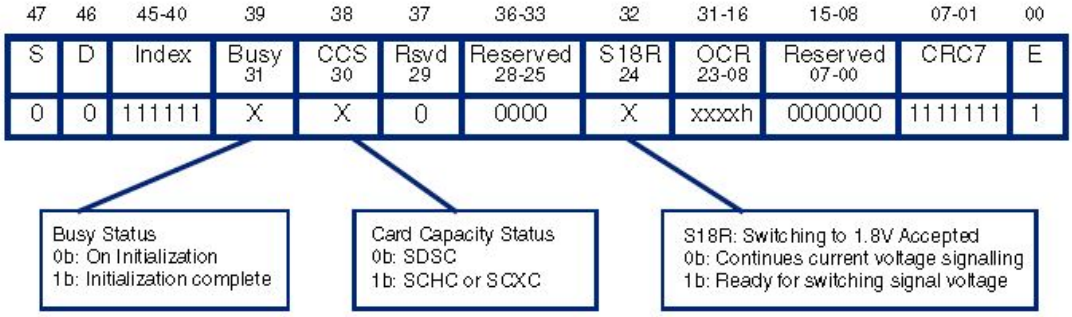
   The response to this command informs the software if the card supports voltage switching; bits 38, 36, and 32 are checked by the card argument of ACMD41.†

Figure 14-12: ACMD41 Argument



a. Bit 30 informs the card if host supports SDHC/SDXC or not; this bit should be set to 1'b1.†
b. Bit 28 can be either 1 or 0.†
c. Bit 24 should be set to 1'b1, indicating that the host is capable of voltage switching.†

Figure 14-13: ACMD41 Response (R3)†



d. Bit 30 – If set to 1'b1, card supports SDHC/SDXC; if set to 1'b0, card supports only SDSC.†
e. Bit 24 – If set to 1'b1, card supports voltage switching and is ready for the switch.†
f. Bit 31 – If set to 1'b1, initialization is over; if set to 1'b0, means initialization in process†

4. If the card supports voltage switching, then the software must perform the steps discussed for either the "Voltage Switch Normal Scenario" or the "Voltage Switch Error Scenario", located in the *Synopsys DesignWare Cores Mobile Storage Host Databook*.

SD/MMC Controller Programming Model

Software and Hardware Restrictions†

Only one data transfer command should be issued at one time. For CE-ATA devices, if CE-ATA device interrupts are enabled (nIEN=0), only one RW_MULTIPLE_BLOCK command (RW_BLK) should be

issued; no other commands (including a new RW_BLK) should be issued before the Data Transfer Over status is set for the outstanding RW_BLK.†

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.†

If the card is enumerated in SDR12 or SDR25 mode, the application must program the `use_hold_reg` bit[29] in the CMD register to 1'b1.†

This programming should be done for all data transfer commands and non-data commands that are sent to the card. When the `use_hold_reg` bit is programmed to 1'b0, the SD/MMC controller bypasses the Hold Registers in the transmit path. The value of this bit should not be changed when a Command or Data Transfer is in progress.†

For more information on using the `use_hold_reg` and the implementation requirements for meeting the card input hold time, refer to the latest version of the Synopsys DesignWare Cores Mobile Storage Host Databook.

Avoiding Glitches in the Card Clock Outputs†

To avoid glitches in the card clock outputs (`sdmmc_cclk_out`), the software should use the following steps when changing the card clock frequency:†

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this, check for 0 in bit 9 of the STATUS register.†
2. Update the Clock Enable register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:†
   - `start_cmd` bit†
   - "update clock registers only" bits†
   - "wait_previous data complete"†

   Note: Wait for the CIU to take the command by polling for 0 on the `start_cmd` bit.†
3. Set the `start_cmd` bit to update the Clock Divider and/or Clock Source registers, and send a command to the CIU in order to update the clock registers; wait for the CIU to take the command.†
4. Set `start_cmd` to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.†

Reading from a Card in Non-DMA Mode†

When a card is read in non-DMA mode, the Data Transfer Over (RINTSTS[3]) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the RX_WMark interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. While using the external DMA interface for reading from a card, the DTO interrupt occurs only after all the data is flushed to memory by the DMA Interface unit.†

Writing to a Card in External DMA Mode†

While writing to a card in external DMA mode, if an undefined-length transfer is selected by setting the Byte Count register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.†

Software Issues a Controller_Reset Command†

If the software issues a controller_reset command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued, then:†

- Any pending DMA transfer on the bus completes correctly†
- DMA data read is ignored†
- Write data is unknown (x)†

Additionally, if dma_reset is also issued, any pending DMA transfer is abruptly terminated. When the DW-DMA/Non-DW-DMA is used, the DMA controller channel should also be reset and reprogrammed.†

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.†

Data-Transfer Requirement Between the FIFO and Host†

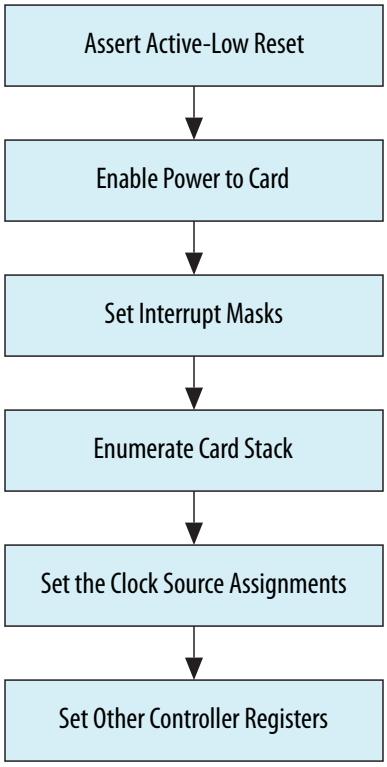
One data-transfer requirement between the FIFO and host is that the number of transfers should be a multiple of the FIFO data width (F_DATA_WIDTH). For example, if F_DATA_WIDTH = 32 and you want to write only 15 bytes to an SD_MMC_CEATA card (BYTCNT), the host should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers, if external DMA mode is enabled. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the host should still read all 16 bytes from the FIFO.†

It is recommended that you not change the FIFO threshold register in the middle of data transfers when DW-DMA/Non-DW-DMA mode is chosen.†

Initialization†

After the power and clock to the controller are stable, the controller active-low reset is asserted. The reset sequence initializes the registers, FIFO buffer pointers, DMA interface controls, and state machines in the controller.†

Figure 14-14: SD/MMC Controller Initialization Sequence†



Power-On Reset Sequence

Software must perform the following steps after the power-on-reset:

1. Before enabling power to the card, confirm that the voltage setting to the voltage regulator is correct. †
2. Enable power to the card by setting the power enable bit (`power_enable`) in the power enable register (`pwren`) to 1. Wait for the power ramp-up time before proceeding to the next step.†
3. Set the interrupt masks by resetting the appropriate bits to 0 in the `intmask` register.†
4. Set the `int_enable` bit of the `ctrl` register to 1.†

   Note: Altera recommends that you write 0xFFFFFFFF to the `rintsts` register to clear any pending interrupts before setting the `int_enable` bit to 1.†
5. Discover the card stack according to the card type. For discovery, you must restrict the clock frequency to 400 kHz in accordance with SD/MMC/CE-ATA standards. For more information, refer to *Enumerated Card Stack*.†
6. Set the clock source assignments. Set the card frequency using the `clkdiv` and `clksrc` registers of the controller. For more information, refer to *Clock Setup*.†
7. The following common registers and fields can be set during initialization process:†

- The response timeout field (`response_timeout`) of the `tmout` register. A typical value is `0x40`.†
- The data timeout field (`data_timeout`) of the `tmout` register, highest of the following:†
  - $10 * N_{AC}$ †

    N_{AC} = card device total access time†

    $= 10 * ((TAAC * F_{OP}) + (100 * NSAC))$†

    where:†

    TAAC = Time-dependent factor of the data access time†

    F_{OP} = The card clock frequency used for the card operation†

    NSAC = Worst-case clock rate-dependent factor of the data access time†
  - Host FIFO buffer latency†

    On read: Time elapsed before host starts reading from a full FIFO buffer†

    On write: Time elapsed before host starts writing to an empty FIFO buffer†
- Debounce counter register (`debnce`). A typical debounce value is 25 ms.†
- TX watermark field (`tx_wmark`) of the FIFO threshold watermark register (`fifoth`). Typically, the threshold value is set to 512, which is half the FIFO buffer depth.†
- RX watermark field (`rx_wmark`) of the `fifoth` register. Typically, the threshold value is set to 511.†

These registers do not need to be changed with every SD/MMC/CE-ATA command. Set them to a typical value according to the SD/MMC/CE-ATA specifications.

Related Information

- **Clock Setup** on page 14-46
  Refer to this section for information on setting the clock source assignments.
- **Enumerated Card Stack** on page 14-43
  Refer to this section for information on discovering the card stack according to the card type.

Enumerated Card Stack

The card stack performs the following tasks:

- Discovers the connected card †
- Sets the relative Card Address Register (RCA) in the connected card†
- Reads the card specific information†
- Stores the card specific information locally†

The card connected to the controller can be an MMC, CE-ATA, SD or SDIO (including IO ONLY, MEM ONLY and COMBO) card.

Identifying the Connected Card Type

To identify the connected card type, the following discovery sequence is needed:

1. Reset the card width 1 or 4 bit (`card_width2`) and card width 8 bit (`card_width1`) fields in the `ctype` register to 0.
2. Identify the card type as SD, MMC, SDIO or SDIO-COMBO:

a. Send an SD/SDIO IO_SEND_OP_COND (CMD5) command with argument 0 to the card.
b. Read resp0 on the controller. The response to the IO_SEND_OP_COND command gives the voltage that the card supports.
c. Send the IO_SEND_OP_COND command, with the desired voltage window in the arguments. This command sets the voltage window and makes the card exit the initialization state.
d. Check bit 27 in resp0:

- If bit 27 is 0, the SDIO card is IO ONLY. In this case, proceed to **step 5**.
- If bit 27 is 1, the card type is SDIO COMBO. Continue with the following steps.

3. Go to **Card Type is Either SDIO COMBO or Still in Initialization** on page 14-44.
4. Go to **Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device** on page 14-45.
5. At this point, the software has determined the card type as SD/SDHC, SDIO or SDIO-COMBO. Now it must enumerate the card stack according to the type that has been discovered.
6. Set the card clock source frequency to the frequency of identification clock rate, 400 KHz. Use one of the following discovery command sequences:

- For an SD card or an SDIO memory section, send the following SD/SDIO command sequence:
  - GO_IDLE_STATE
  - SEND_IF_COND
  - SD_SEND_OP_COND (ACMD41)
  - ALL_SEND_CID (CMD2)
  - SEND_RELATIVE_ADDR (CMD3)
- For an SDIO card, send the following command sequence:
  - IO_SEND_OP_COND
  - If the function count is valid, send the SEND_RELATIVE_ADDR command.
- For an MMC, send the following command sequence:
  - GO_IDLE_STATE
  - SEND_OP_COND (CMD1)
  - ALL_SEND_CID
  - SEND_RELATIVE_ADDR

7. You can change the card clock frequency after discovery by writing a value to the clkdiv register that divides down the sdmmc_clk clock.

   The following list shows typical clock frequencies for various types of cards:

- SD memory card, 25 MHz†
- MMC card device, 12.5 MHz†
- Full speed SDIO, 25 MHz†
- Low speed SDIO, 400 kHz†

Related Information

SD Association

To learn more about how SD technology works, visit the SD Association website (www.sdcard.org).

Card Type is Either SDIO COMBO or Still in Initialization

Only continue with this step if the SDIO card type is COMBO or there is no response received from the previous IO_SEND_OP_COND command. Otherwise, skip to **step 5** of the *Identifying the Connected Card Type* section.

1. Send the SD/SDIO SEND_IF_COND (CMD8) command with the following arguments:

- Bit[31:12] = 0x0 (reserved bits)†
- Bit[11:8] = 0x1 (supply voltage value)†
- Bit[7:0] = 0xAA (preferred check pattern by SD memory cards compliant with SDIO Simplified Specification Version 2.00 and later.)†

Refer to *SDIO Simplified Specification Version 2.00* as described on the SD Association website.

- If a response is received to the previous SEND_IF_COND command, the card supports SD High-Capacity, compliant with *SD Specifications, Part 1, Physical Layer Simplified Specification Version 2.00*.
- If no response is received, proceed to **the next decision statement**.

2. Send the SD_SEND_OP_COND (ACMD41) command with the following arguments:

- Bit[31] = 0x0 (reserved bits)†
- Bit[30] = 0x1 (high capacity status)†
- Bit[29:25] = 0x0 (reserved bits)†
- Bit[24] = 0x1 (S18R --supports voltage switching for 1.8V)†
- Bit[23:0] = supported voltage range†

- If the previous SD_SEND_OP_COND command receives a response, then the card type is SDHC. Otherwise, the card is MMC or CE-ATA. In either case, skip the following steps and proceed to **step 5** of the "Identifying the Connected Card Type" section.
- If the initial SEND_IF_COND command does not receive a response, then the card does not support High Capacity SD2.0. Now, proceed to **step step 3**.

3. Next, issue the GO_IDLE_STATE command followed by the SD_SEND_OP_COND command with the following arguments:

- Bit[31] = 0x0 (reserved bits)†
- Bit[30] = 0x0 (high capacity status)†
- Bit[29:24] = 0x0 (reserved bits)†
- Bit[23:0] = supported voltage range†

If a response is received to the previous SD_SEND_OP_COND command, the card is SD type. Otherwise, the card is MMC or CE-ATA.

Note: You must issue the SEND_IF_COND command prior to the first SD_SEND_OP_COND command, to initialize the High Capacity SD memory card. The card returns busy as a response to the SD_SEND_OP_COND command when any of the following conditions are true:

- The card executes its internal initialization process.
- A SEND_IF_COND command is not issued before the SD_SEND_OP_COND command.
- The ACMD41 command is issued. In the command argument, the Host Capacity Support (HCS) bit is set to 0, for a high capacity SD card.

Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device

Use the following sequence to determine whether the card is a CE-ATA 1.1, CE-ATA 1.0, or MMC device:

Determine whether the card is a CE-ATA v1.1 card device by attempting to select ATA mode.

1. Send the SD/SDIO SEND_IF_COND command, querying byte 504 (S_CMD_SET) of the EXT_CSD register block in the external card.

If bit 4 is set to 1, the card device supports ATA mode.

2. Send the `SWITCH_FUNC (CMD6)` command, setting the ATA bit (bit 4) of the EXT_CSD register slice 191 (CMD_SET) to 1.

   This command selects ATA mode and activates the ATA command set.
3. You can verify the currently selected mode by reading it back from byte 191 of the EXT_CSD register.
4. Skip to **step 5** of the *Identifying the Connected Card Type* section.

   If the card device does not support ATA mode, it might be an MMC card or a CE-ATA v1.0 card. Proceed to the **next section** to determine whether the card is a CE-ATA 1.0 card device or an MMC card device.

Determine whether the card is a CE-ATA 1.0 card device or an MMC card device by sending the RW_REG command.

If a response is received and the response data contains the CE-ATA signature, the card is a CE-ATA 1.0 card device. Otherwise, the card is an MMC card device.

Clock Setup

The following registers of the SD/MMC controller allow software to select the desired clock frequency for the card:

- `clksrc`
- `clkdiv`
- `clkena`

The controller loads these registers when it receives an update clocks command.

Changing the Card Clock Frequency

To change the card clock frequency, perform the following steps:

1. Before disabling the clocks, ensure that the card is not busy with any previous data command. To do so, verify that the `data_busy` bit of the status register (`status`) is 0.
2. Reset the `cclk_enable` bit of the `clkena` register to 0, to disable the card clock generation.
3. Reset the `clksrc` register to 0.
4. Set the following bits in the `cmd` register to 1:
   - `update_clk_regs_only`—Specifies the update clocks command†
   - `wait_prvdata_complete`—Ensures that clock parameters do not change until any ongoing data transfer is complete†
   - `start_cmd`—Initiates the command†
5. Wait until the `start_cmd` and `update_clk_regs_only` bits change to 0. There is no interrupt when the clock modification completes. The controller does not set the `command_done` bit in the `rintsts` register upon command completion. The controller might signal a hardware lock error if it already has another command in the queue. In this case, return to **Step 4**.

   For information about hardware lock errors, refer to the "Interrupt and Error Handling" chapter.
6. Reset the `sdmmc_clk_enable` bit to 0 in the `enable` register of the clock manager peripheral PLL group (`perpllgrp`).
7. In the control register (`ctrl`) of the SDMMC controller group (`sdmmcgrp`) in the system manager, set the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smplsel`) bits to specify the required phase shift value.
8. Set the `sdmmc_clk_enable` bit in the `Enable` register of the clock manager `perpllgrp` group to 1.
9. Set the `clkdiv` register of the controller to the correct divider value for the required clock frequency.
10. Set the `cclk_enable` bit of the `clkena` register to 1, to enable the card clock generation.

You can also use the clkena register to enable low-power mode, which automatically stops the sdmmc_cclk_out clock when the card is idle for more than eight clock cycles.

Interrupt and Error Handling on page 14-72
Refer to this section for information about hardware lock errors.

Timing Tuning

This section is pending further information.

Controller/DMA/FIFO Buffer Reset Usage

The following list shows the effect of reset on various parts in the SD/MMC controller:†

- Controller reset—resets the controller by setting the controller_reset bit in the ctrl register to 1. Controller reset resets the CIU and state machines, and also resets the BIU-to-CIU interface. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†
- FIFO buffer reset—resets the FIFO buffer by setting the FIFO reset bit (fifo_reset) in the ctrl register to 1. FIFO buffer reset resets the FIFO buffer pointers and counters in the FIFO buffer. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†
- DMA reset—resets the internal DMA controller logic by setting the DMA reset bit (dma_reset) in the ctrl register to 1, which immediately terminates any DMA transfer in progress. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†

Note: Ensure that the DMA is idle before performing a DMA reset. Otherwise, the L3 interconnect might be left in an indeterminate state.†

Altera recommends setting the controller_reset, fifo_reset, and dma_reset bits in the ctrl register to 1 first, and then resetting the rintsts register to 0 using another write, to clear any resultant interrupt.

Non-Data Transfer Commands

To send any non-data transfer command, the software needs to write the cmd register and the cmdarg register with appropriate parameters. Using these two registers, the controller forms the command and sends it to the CMD pin. The controller reports errors in the command response through the error bits of the rintsts register.†

When a response is received—either erroneous or valid—the controller sets the command_done bit in the rintsts register to 1. A short response is copied to resp0, while a long response is copied to all four response registers (resp0, resp1, resp2, and resp3).† For long responses, bit 31 of resp3 represents the MSB and bit 0 of resp0 represents the LSB.†

For basic and non-data transfer commands, perform the following steps:

1. Write the cmdarg register with the appropriate command argument parameter.†
2. Write the cmd register with the settings in *Register Settings for Non-Data Transfer Command*.†
3. Wait for the controller to accept the command. The start_cmd bit changes to 0 when the command is accepted.†

   The following actions occur when the command is loaded into the controller:†

- If no previous command is being processed, the controller accepts the command for execution and resets the `start_cmd` bit in the `cmd` register to 0. If a previous command is being processed, the controller loads the new command in the command buffer.†
- If the controller is unable to load the new command—that is, a command is already in progress, a second command is in the buffer, and a third command is attempted—the controller generates a hardware lock error.†

4. Check if there is a hardware lock error.†
5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the controller sets the `command_done` bit in the `rintsts` register to 1. Software can either poll for this bit or respond to a generated interrupt (if enabled).†
6. Check if the response timeout boot acknowledge received (`bar`), `rcrc`, or `re` bit is set to 1. Software can either respond to an interrupt raised by these errors or poll the `re`, `rcrc`, and `bar` bits of the `rintsts` register. If no response error is received, the response is valid. If required, software can copy the response from the response registers.†

Note: Software cannot modify clock parameters while a command is being executed.†

Related Information

cmd Register Settings for Non-Data Transfer Command† on page 14-48
Refer to this table for information about Non-Data Transfer commands.

cmd Register Settings for Non-Data Transfer Command†

Table 14-20: Default

Parameter	Value	Comment
`start_cmd`	1	This bit resets itself to 0 after the command is committed.
`use_hold_reg`	1 or 0	Choose the value based on the speed mode used.
`update_clk_regs_only`	0	Indicates that the command is not a clock update command
`data_expected`	0	Indicates that the command is not a data command
`card_number`	1	For one card
`cmd_index`	Command Index	Set this parameter to the command number. For example, set to 8 for the SD/SDIO SEND_IF_COND (CMD8) command.
`send_initialization`	0 or 1	1 for card reset commands such as the SD/SDIO GO_IDLE_STATE command 0 otherwise

Parameter	Value	Comment
stop_abort_cmd	0 or 1	1 for a command to stop data transfer, such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
response_length	0 or 1	1 for R2 (long) response 0 for short response
response_expect	0 or 1	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR (CMD4), or GO_INACTIVE_STATE (CMD15). 1 otherwise

Table 14-21: User Selectable

Parameter	Value	Comment
wait_prvdata_complete	1	Before sending a command on the command line, the host must wait for completion of any data command already in process. Altera recommends that you set this bit to 1, unless the current command is to query status or stop data transfer when transfer is in progress.
check_response_crc	1 or 0	1 if the response includes a valid CRC, and the software is required to crosscheck the response CRC bits. 0 otherwise

Data Transfer Commands

Data transfer commands transfer data between the memory card and the controller. To issue a data command, the controller requires a command argument, total data size, and block size. Data transferred to or from the memory card is buffered by the controller FIFO buffer.†

Confirming Transfer State

Before issuing a data transfer command, software must confirm that the card is not busy and is in a transfer state, by performing the following steps:†

1. Issue an SD/SDIO SEND_STATUS (CMD13) command. The controller sends the status of the card as the response to the command.†
2. Check the card's busy status.†
3. Wait until the card is not busy.†
4. Check the card's transfer status. If the card is in the stand-by state, issue an SD/SDIO SELECT/DESELECT_CARD (CMD7) command to place it in the transfer state.†

Busy Signal After CE-ATA RW_BLK Write Transfer

During CE-ATA RW_BLK write transfers, the MMC busy signal might be asserted after the last block. If the CE-ATA card device interrupt is disabled (the nIEN bit in the card device's ATA control register is set to 1), the `dto` bit in the `rintsts` register is set to 1 even though the card sends MMC BUSY. The host cannot issue the CMD60 command to check the ATA busy status after a CMD61 command. Instead, the host must perform one of the following actions:†

- Issue the SEND_STATUS command and check the MMC busy status before issuing a new CMD60 command†
- Issue the CMD39 command and check the ATA busy status before issuing a new CMD60 command†

For the data transfer commands, software must set the `ctype` register to the bus width that is programmed in the card.†

Data Transfer Interrupts

The controller generates an interrupt for different conditions during data transfer, which are reflected in the following `rintsts` register bits:†

1. `dto`—Data transfer is over or terminated. If there is a response timeout error, the controller does not attempt any data transfer and the Data Transfer Over bit is never set.†
2. Transmit FIFO data request bit (`txdr`)—The FIFO buffer threshold for transmitting data is reached; software is expected to write data, if available, into the FIFO buffer.†
3. Receive FIFO data request bit (`rxdr`)—The FIFO buffer threshold for receiving data is reached; software is expected to read data from the FIFO buffer.†
4. `hto`—The FIFO buffer is empty during transmission or is full during reception. Unless software corrects this condition by writing data for empty condition, or reading data for full condition, the controller cannot continue with data transfer. The clock to the card is stopped.†
5. `bds`—The card has not sent data within the timeout period.†
6. `dcrc`—A CRC error occurred during data reception.†
7. `sbe`—The start bit is not received during data reception.†
8. `ebe`—The end bit is not received during data reception, or for a write operation. A CRC error is indicated by the card.†

`dcrc`, `sbe`, and `ebe` indicate that the received data might have errors. If there is a response timeout, no data transfer occurs.†

Single-Block or Multiple-Block Read

To implement a single-block or multiple-block read, the software performs the following steps:†

1. Write the data size in bytes to the `bytcnt` register. For a multi-block read, `bytcnt` must be a multiple of the block size.†
2. Write the block size in bytes to the `blksiz` register. The controller expects data to return from the card in blocks of size `blksiz`.†
3. If the read round trip delay, including the card delay, is greater than half of `sdmmc_clk_divided`, write to the card threshold control register (`cardthrctl`) to ensure that the card clock does not stop in the middle of a block of data being transferred from the card to the host. For more information, refer to *Card Read Threshold*.†

   Note: If the card read threshold enable bit (`cardrdthren`) is 0, the host system must ensure that the RX FIFO buffer does not become full during a read data transfer by ensuring that the RX FIFO buffer is read at a rate faster than that at which data is written into the FIFO buffer. Otherwise, an overflow might occur.†
4. Write the `cmdarg` register with the beginning data address for the data read.†

5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Reads*. For SD and MMC cards, use the SD/SDIO READ_SINGLE_BLOCK (CMD17) command for a single-block read and the READ_MULTIPLE_BLOCK (CMD18) command for a multiple-block read. For SDIO cards, use the IO_RW_EXTENDED (CMD53) command for both single-block and multiple-block transfers. The command argument for (CMD53) is shown in the figure, below. After writing to the `cmd` register, the controller starts executing the command. When the command is sent to the bus, the Command Done interrupt is generated.†
6. Software must check for data error interrupts, reported in the `dcrc`, `bds`, `sbe`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer by sending an SD/SDIO STOP command.†
7. Software must check for host timeout conditions in the `rintsts` register:†
   - Receive FIFO buffer data request†
   - Data starvation from host—the host is not reading from the FIFO buffer fast enough to keep up with data from the card. To correct this condition, software must perform the following steps:†
     - Read the `fifo_count` field of the `status` register†
     - Read the corresponding amount of data out of the FIFO buffer†

   In both cases, the software must read data from the FIFO buffer and make space in the FIFO buffer for receiving more data.†
8. When a DTO interrupt is received, the software must read the remaining data from the FIFO buffer.†

cmd Register Settings for Single-Block and Multiple-Block Reads†

Table 14-22: cmd Register Settings for Single-Block and Multiple-Block Reads (Default)

Parameter	Value	Comment
start_cmd	1	This bit resets itself to 0 after the command is committed.
use_hold_reg	1 or 0	Choose the value based on speed mode used.
update_clk_regs_only	0	Does not need to update clock parameters
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer
send_initialization	0	1 for a card reset command such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0	1 for a command to stop data transfer such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
send_auto_stop	0 or 1	Refer to *Auto Stop* for information about how to set this parameter.
read_write	0	Read from card
response_length	0	1 for R2 (long) response 0 for short response
response_expect	1 or 0	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR, and GO_INACTIVE_STATE. 1 otherwise

Table 14-23: cmd Register Settings for Single-Block and Multiple-Block Reads (User Selectable)

Parameter	Value	Comment
wait_prvdata_complete	1 or 0	0 - sends command to CIU immediately 1 - sends command after previous data transfer ends

Parameter	Value	Comment
check_response_crc	1 or 0	0 - Controller must not check response CRC 1 - Controller must check responce CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 17 or 18 for SD/SDIO READ_SINGLE_BLOCK (CMS17) or READ_MULTIPLE_BLOCK (CMD18)

Related Information

Auto-Stop on page 14-29
Refer to this table for information about setting the send_auto_stop parameter.

Single-Block or Multiple-Block Write

The following steps comprise a single-block or multiple-block write:

1. Write the data size in bytes to the bytcnt register. For a multi-block write, bytcnt must be a multiple of the block size.†
2. Write the block size in bytes to the blksiz register. The controller sends data in blocks of size blksiz each.†
3. Write the cmdarg register with the data address to which data must be written.†
4. Write data into the FIFO buffer. For best performance, the host software should write data continuously until the FIFO buffer is full.†
5. Write the cmd register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Write*. For SD and MMC cards, use the SD/SDIO WRITE_BLOCK (CMD24) command for a single-block write and the WRITE_MULTIPLE_BLOCK (CMD25) command for a multiple-block writes. For SDIO cards, use the IO_RW_EXTENDED command for both single-block and multiple-block transfers.†

   After writing to the cmd register, the controller starts executing a command if there is no other command already being processed. When the command is sent to the bus, a Command Done interrupt is generated.†
6. Software must check for data error interrupts; that is, for dcrc, bds, and ebe bits of the rintsts register. If required, software can terminate the data transfer early by sending the SD/SDIO STOP command.†
7. Software must check for host timeout conditions in the rintsts register: †
   - Transmit FIFO buffer data request.†
   - Data starvation by the host—the controller wrote data to the card faster than the host could supply the data.†

   In both cases, the software must write data into the FIFO buffer.†

   There are two types of transfers: open-ended and fixed length.†

- Open-ended transfers—For an open-ended block transfer, the byte count is 0. At the end of the data transfer, software must send the STOP_TRANSMISSION command (CMD12).†
- Fixed-length transfers—The byte count is nonzero. You must already have written the number of bytes to the `bytcnt` register. The controller issues the STOP command for you if you set the `send_auto_stop` bit of the `cmd` register to 1. After completion of a transfer of a given number of bytes, the controller sends the STOP command. Completion of the AUTO_STOP command is reflected by the Auto Command Done interrupt. A response to the AUTO_STOP command is written to the `resp1` register. If software does not set the `send_auto_stop` bit in the `cmd` register to 1, software must issue the STOP command just like in the open-ended case.†

When the `dto` bit of the `rintsts` register is set, the data command is complete.†

cmd Register Settings for Single-Block and Multiple-Block Write

Table 14-24: cmd Register Settings for Single-Block and Multiple-Block Write (Default)†

Parameter	Value	Comment
`start_cmd`	1	This bit resets itself to 0 after the command is committed (accepted by the BIU).
`use_hold_reg`	1 or 0	Choose the value based on speed mode used.
`update_clk_regs_only`	0	Does not need to update clock parameters
`data_expected`	1	Data command
`card_number`	1	For one card
`transfer_mode`	0	Block transfer
`send_initialization`	0	Can be 1, but only for card reset commands such as SD/SDIO GO_IDLE_STATE
`stop_abort_cmd`	0	Can be 1 for commands to stop data transfer such as SD/SDIO STOP_TRANSMISSION
`send_auto_stop`	0 or 1	Refer to *Auto Stop* for information about how to set this parameter.
`read_write`	1	Write to card
`response_length`	0	Can be 1 for R2 (long) responses
`response_expect`	1	Can be 0 for commands with no response. For example, SD/SDIO GO_IDLE_STATE, SET_DSR, GO_INACTIVE_STATE etc.

Table 14-25: cmd Register Settings for Single-Block and Multiple-Block Write (User Selectable)†

Parameter	Value	Comment
wait_prvdata_complete	1	0—Sends command to the CIU immediately 1—Sends command after previous data transfer ends
check_response_crc	1	0—Controller must not check response CRC 1—Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).

Related Information

Auto-Stop on page 14-29
Refer to this table for information about setting the send_auto_stop parameter.

Stream Read and Write

In a stream transfer, if the byte count is equal to 0, the software must also send the SD/SDIO STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the controller sends the STOP command automatically. Completion of this AUTO_STOP command is reflected by the Auto_command_done interrupt. A response to an AUTO_STOP command is written to the resp1 register. A stream transfer is allowed only for card interfaces with a 1-bit data bus.†

A stream read requires the same steps as the block read described in *Single-Block or Multiple-Block Read*, except for the following bits in the cmd register:†

- transfer_mode = 0x1 (for stream transfer)†
- cmd_index = 20 (SD/SDIO CMD20)†

A stream write requires the same steps as the block write mentioned in *Single-Block or Multiple-Block Write*, except for the following bits in the cmd register:†

- transfer_mode = 0x1 (for stream transfer)†
- cmd_index = 11 (SD/SDIO CMD11)†

Related Information

  Refer to this section for more information about a stream read.
- **Single-Block or Multiple-Block Write** on page 14-53
  Refer to this section for more information about a stream write.

Packed Commands

To reduce overhead, read and write commands can be packed in groups of commands—either all read or all write—that transfer the data for all commands in the group in one transfer on the bus. Use the SD/SDIO SET_BLOCK_COUNT (CMD23) command to state ahead of time how many blocks will be transferred. Then issue a single READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command to read or write multiple blocks.†

- SET_BLOCK_COUNT—set block count (number of blocks transferred using the READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command) †
- READ_MULTIPLE_BLOCK—multiple-block read command †
- WRITE_MULTIPLE_BLOCK—multiple-block write command†

Packed commands are organized in packets by the application software and are transparent to the controller.†

Related Information

www.jedec.org
For more information about packed commands, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

Transfer Stop and Abort Commands

This section describes stop and abort commands. The SD/SDIO STOP_TRANSMISSION command can terminate a data transfer between a memory card and the controller. The ABORT command can terminate an I/O data transfer for only an SDIO card. †

STOP_TRANSMISSION (CMD12)

The host can send the STOP_TRANSMISSION (CMD12) command on the CMD pin at any time while a data transfer is in progress. Perform the following steps to send the STOP_TRANSMISSION command to the SD/SDIO card device:†

1. Set the `wait_prvdata_complete` bit of the `cmd` register to 0.†
2. Set the `stop_abort_cmd` in the `cmd` register to 1, which ensures that the CIU stops.†

The STOP_TRANSMISSION command is a non-data transfer command.†

Related Information

Non-Data Transfer Commands on page 14-47
Refer to this section for information on the STOP_TRANSMISSION command.

ABORT

The ABORT command can only be used with SDIO cards. To abort the function that is transferring data, program the ABORT function number in the ASx[2:0] bits at address 0x06 of the card common control register (CCCR) in the card device, using the IO_RW_DIRECT (CMD52) command. The CCCR is located at the base of the card space 0x00 – 0xFF.†

Note: The ABORT command is a non-data transfer command.†

Related Information

Non-Data Transfer Commands on page 14-47
Refer to this section for information on the ABORT command.

Sending the ABORT Command

Perform the following steps to send the ABORT command to the SDIO card device:†

1. Set the `cmdarg` register to include the appropriate command argument parameters listed in *cmdarg Register Settings for SD/SDIO ABORT Command*.†
2. Send the IO_RW_DIRECT command by setting the following fields of the `cmd` register:†

- Set the command index to 0x52 (IO_RW_DIRECT).†
- Set the `stop_abort_cmd` bit of the `cmd` register to 1 to inform the controller that the host aborted the data transfer.†
- Set the `wait_prvdata_complete` bit of the `cmd` register to 0.†

3. Wait for the `cmd` bit in the `rintsts` register to change to 1.†
4. Read the response to the IO_RW_DIRECT command (R5) in the response registers for any errors.†

For more information about response values, refer to the *Physical Layer Simplified Specification*, Version 3.01, available on the SD Association website.

Related Information

SD Association

To learn more about how SD technology works, visit the SD Association website (www.sdcard.org).

cmdarg Register Settings for SD/SDIO ABORT Command†

Table 14-26: cmdarg Register Settings for SD/SDIO ABORT Command

Bits	Contents	Value
31	R/W flag	1
30:28	Function number	0, for access to the CCCR in the card device
27	RAW flag	1, if needed to read after write
26	Don't care	-
25:9	Register address	0x06
8	Don't care	-
7:0	Write data	Function number to abort

Internal DMA Controller Operations

For better performance, you can use the internal DMA controller to transfer data between the host and the controller. This section describes the internal DMA controller's initialization process, and transmission sequence, and reception sequence.

Internal DMA Controller Initialization

To initialize the internal DMA controller, perform the following steps:†

1. Set the required `bmod` register bits: †

- If the internal DMA controller enable bit (de) of the bmod register is set to 0 during the middle of a DMA transfer, the change has no effect. Disabling only takes effect for a new data transfer command.†
- Issuing a software reset immediately terminates the transfer. Prior to issuing a software reset, Altera recommends the host reset the DMA interface by setting the dma_reset bit of the ctrl register to 1.†
- The pbl field of the bmod register is read-only and a direct reflection of the contents of the DMA multiple transaction size field (dw_dma_multiple_transaction_size) in the fifoth register.†
- The fb bit of the bmod register has to be set appropriately for system performance.†

2. Write to the idinten register to mask unnecessary interrupt causes according to the following guidelines:†
   - When a Descriptor Unavailable interrupt is asserted, the software needs to form the descriptor, appropriately set its own bit, and then write to the poll demand register (pldmnd) for the internal DMA controller to re-fetch the descriptor.†
   - It is always appropriate for the software to enable abnormal interrupts because any errors related to the transfer are reported to the software.†
3. Populate either a transmit or receive descriptor list in memory. Then write the base address of the first descriptor in the list to the internal DMA controller's descriptor list base address register (dbaddr). The DMA controller then proceeds to load the descriptor list from memory. *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences* describe this step in detail. †

Related Information

- **Internal DMA Controller Transmission Sequences** on page 14-58
  Refer to this section for information about the Internal DMA Controller Transmission Sequences.
- **Internal DMA Controller Reception Sequences** on page 14-59
  Refer to this section for information about the Internal DMA Controller Reception Sequences.

Internal DMA Controller Transmission Sequences

To use the internal DMA controller to transmit data, perform the following steps:

1. The host sets up the Descriptor fields (DES0—DES3) for transmission and sets the OWN bit (DES0[31]) to 1. The host also loads the data buffer in system memory with the data to be written to the SD card.†
2. The host writes the appropriate write data command (SD/SDIO WRITE_BLOCK or WRITE_MULTIPLE_BLOCK) to the cmd register. The internal DMA controller determines that a write data transfer needs to be performed.†
3. The host sets the required transmit threshold level in the tx_wmark field in the fifoth register.†
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters the suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the pldmnd register.†
5. The host must write the descriptor base address to the dbaddr register.†
6. The internal DMA controller waits for the Command Done (CD) bit in the rintsts register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.†
7. The internal DMA controller engine waits for a DMA interface request from BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the transmit threshold value.†

8. The internal DMA controller fetches the transmit data from the data buffer in the system memory and transfers the data to the FIFO buffer in preparation for transmission to the card.†
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor DES0 field indicates whether the data spans multiple descriptors or not.†
10. When data transmission is complete, status information is updated in the `idsts` register by setting the `ti` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.†

Internal DMA Controller Reception Sequences

To use the internal DMA controller to receive data, perform the following steps:

1. The host sets up the descriptor fields (DES0—DES3) for reception and sets the OWN (DES0 [31]) to 1.†
2. The host writes the read data command to the `cmd` register in BIU. The internal DMA controller determines that a read data transfer needs to be performed.†
3. The host sets the required receive threshold level in the `rx_wmark` field in the `fifoth` register.†
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters suspend state and asserts the Descriptor Unable interrupt. The host then must set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.†
5. The host must write the descriptor base address to the `dbaddr` register.†
6. The internal DMA controller waits for the `CD` bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.†
7. The internal DMA controller engine waits for a DMA interface request from the BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the receive threshold value.†
8. The internal DMA controller fetches the data from the FIFO buffer and transfers the data to system memory.†
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.†
10. When data reception is complete, status information is updated in the `idsts` register by setting the `ri` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.†

Commands for SDIO Card Devices

This section describes the commands to temporarily halt the transfers between the controller and SDIO card device.

Suspend and Resume Sequence

For SDIO cards, a data transfer between an I/O function and the controller can be temporarily halted using the SUSPEND command. This capability might be required to perform a high-priority data transfer with another function. When desired, the suspended data transfer can be resumed using the RESUME command.†

The SUSPEND and RESUME operations are implemented by writing to the appropriate bits in the CCCR (Function 0) of the SDIO card. To read from or write to the CCCR, use the controller's IO_RW_DIRECT command.†

Suspend

To suspend data transfer, perform the following steps:†

1. Check if the SDIO card supports the SUSPEND/RESUME protocol by reading the SBS bit in the CCCR at offset 0x08 of the card.†
2. Check if the data transfer for the required function number is in process. The function number that is currently active is reflected in the function select bits (FSx) of the CCCR, bits 3:0 at offset 0x0D of the card.†

   Note: If the bus status bit (BS), bit 0 at address 0xC, is 1, only the function number given by the FSx bits is valid.†
3. To suspend the transfer, set the bus release bit (BR), bit 2 at address 0xC, to 1.†
4. Poll the BR and BS bits of the CCCR at offset 0x0C of the card until they are set to 0. The BS bit is 1 when the currently-selected function is using the data bus. The BR bit remains 1 until the bus release is complete. When the BR and BS bits are 0, the data transfer from the selected function is suspended.†
5. During a read-data transfer, the controller can be waiting for the data from the card. If the data transfer is a read from a card, the controller must be informed after the successful completion of the SUSPEND command. The controller then resets the data state machine and comes out of the wait state. To accomplish this, set the abort read data bit (`abort_read_data`) in the `ctrl` register to 1.†
6. Wait for data completion, by polling until the `dto` bit is set to 1 in the `rintsts` register. To determine the number of pending bytes to transfer, read the transferred CIU card byte count (`tcbcnt`) register of the controller. Subtract this value from the total transfer size. You use this number to resume the transfer properly.†

Resume

To resume the data transfer, perform the following steps:†

1. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.†
2. If the card is in a disconnect state, select it using the SD/SDIO SELECT/DESELECT_CARD command. The card status can be retrieved in response to an IO_RW_DIRECT or IO_RW_EXTENDED command.†
3. Check that a function to be resumed is ready for data transfer. Determine this state by reading the corresponding RF<*n*> flag in CCCR at offset 0x0F of the card. If RF<*n*> = 1, the function is ready for data transfer.†

   Note: For detailed information about the RF<*n*> flags, refer to SDIO Simplified Specification Version 2.00, available on the SD Association website.†
4. To resume transfer, use the IO_RW_DIRECT command to write the function number at the FSx bits in the CCCR, bits 3:0 at offset 0x0D of the card. Form the command argument for the IO_RW_DIRECT command and write it to the `cmdarg` register. Bit values are listed in the following table.†

Table 14-27: cmdarg Bit Values for RESUME Command†

Bits	Content	Value
31	R/W flag	1
30:28	Function number	0, for CCCR access
27	RAW flag	1, read after write
26	Don't care	-

Bits	Content	Value
25:9	Register address	0x0D
8	Don't care	-
7:0	Write data	Function number that is to be resumed

5. Write the block size value to the `blksiz` register. Data is transferred in units of this block size.†
6. Write the byte count value to the `bytcnt` register. Specify the total size of the data that is the remaining bytes to be transferred. It is the responsibility of the software to handle the data.†

   To determine the number of pending bytes to transfer, read the transferred CIU card byte count register (`tcbcnt`). Subtract this value from the total transfer size to calculate the number of remaining bytes to transfer.†
7. Write to the `cmd` register similar to a block transfer operation. When the `cmd` register is written, the command is sent and the function resumes data transfer. For more information, refer to *Single-Block or Multiple-Block Read* and *Single-Block or Multiple-Block Write*.†
8. Read the resume data flag (DF) of the SDIO card device. Interpret the DF flag as follows:†
   - DF=1—The function has data for the transfer and begins a data transfer as soon as the function or memory is resumed.†
   - DF=0—The function has no data for the transfer. If the data transfer is a read, the controller waits for data. After the data timeout period, it issues a data timeout error.†

Read-Wait Sequence

Read_wait is used with SDIO cards only. It temporarily stalls the data transfer, either from functions or memory, and allows the host to send commands to any function within the SDIO card device. The host can stall this transfer for as long as required. The controller provides the facility to signal this stall transfer to the card.†

Signalling a Stall

To signal the stall, perform the following steps:†

1. Check if the card supports the read_wait facility by reading the SDIO card's SRW bit, bit 2 at offset 0x8 in the CCCR.†
2. If this bit is 1, all functions in the card support the read_wait facility. Use the SD/SDIO IO_RW_DIRECT command to read this bit.†
3. If the card supports the `read_wait` signal, assert it by setting the read wait bit (`read_wait`) in the `ctrl` register to 1.†
4. Reset the `read_wait` bit to 0 in the `ctrl` register.†

CE-ATA Data Transfer Commands

This section describes CE-ATA data transfer commands.

Related Information

Data Transfer Commands on page 14-49
Refer to this section for information about the basic settings and interrupts generated for different conditions.

ATA Task File Transfer Overview

ATA task file registers are mapped to addresses 0x00h through 0x10h in the MMC register space. The RW_REG command is used to issue the ATA command, and the ATA task file is transmitted in a single RW_REG MMC command sequence.†

The host software stack must write the task file image to the FIFO buffer before setting the `cmdarg` and `cmd` registers in the controller. The host processor then writes the address and byte count to the `cmdarg` register before setting the `cmd` register bits.†

For the RW_REG command, there is no CCS from the CE-ATA card device. †

ATA Task File Transfer Using the RW_MULTIPLE_REGISTER (RW_REG) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer.†

Implementing ATA Task File Transfer

To implement an ATA task file transfer (read or write), perform the following steps:†

1. Write the data size in bytes to the `bytcnt` register. `bytcnt` must equal the block size, because the controller expects a single block transfer.†
2. Write the block size in bytes to the `blksiz` register.†
3. Write the `cmdarg` register with the beginning register address.†

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the tables in *Register Settings for ATA Task File Transfer*.†

Related Information

Register Settings for ATA Task File Transfer on page 14-62
Refer to this table for information on how to set these registers.

Register Settings for ATA Task File Transfer

Table 14-28: cmdarg Register Settings for ATA Task File Transfer†

Bit	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:18	0	Starting register address for read or write (DWORD aligned)

Bit	Value	Comment
17:16	0	Register address (DWORD aligned)
15:8	0	Reserved (bits set to 0 by host processor)
7:2	16	Number of bytes to read or write (integral number of DWORD)
1:0	0	Byte count in integral number of DWORD

Table 14-29: cmd Register Settings for ATA Task File Transfer†

Bit	Value	Comment
`start_cmd`	1	
`ccs_expected`	0	CCS is not expected
`read_ceata_device`	0 or 1	Set to 1 if RW_BLK or RW_REG read
`update_clk_regs_only`	0	No clock parameters update command
`card_num`	0	
`send_initialization`	0	No initialization sequence
`stop_abort_cmd`	0	
`send_auto_stop`	0	
`transfer_mode`	0	Block transfer mode. Block size and byte count must match number of bytes to read or write
`read_write`	1 or 0	1 for write and 0 for read
`data_expected`	1	Data is expected
`response_length`	0	
`response_expect`	1	
`cmd_index`	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
`wait_prvdata_complete`	1	• 0 for send command immediately • 1 for send command after previous DTO interrupt

Bit	Value	Comment
check_response_crc	1	• 0 for not checking response CRC • 1 for checking response CRC

Table 14-30: blksiz Register Settings for ATA Task File Transfer†

Bit	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	16	For accessing entire task file (16, 8-bit registers). Block size of 16 bytes

Table 14-31: bytcnt Register Settings for ATA Task File Transfer

Bit	Value	Comment
31:0	16	For accessing entire task file (16, 8-bit registers). Byte count value of 16 is used with the block size set to 16.

Reset and Card Device Discovery Overview

Before starting any CE-ATA operations, the host must perform a MMC reset and initialization procedure. The host and card device must negotiate the MMC transfer (MMC TRAN) state before the card enters the MMC TRAN state.†

The host must follow the existing MMC discovery procedure to negotiate the MMC TRAN state. After completing normal MMC reset and initialization procedures, the host must query the initial ATA task file values using the RW_REG or CMD39 command.†

By default, the MMC block size is 512 bytes—indicated by bits 1:0 of the srcControl register inside the CE-ATA card device. The host can negotiate the use of a 1 KB or 4 KB MMC block sizes. The card indicates MMC block sizes that it can support through the srcCapabilities register in the MMC; the host reads this register to negotiate the MMC block size. Negotiation is complete when the host controller writes the MMC block size into the srcControl register bits 1:0 of the card.†

Related Information

www.jedec.org

For information about the (MMC TRAN) state, MMC reset and initialization, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

ATA Payload Transfer Using the RW_MULTIPLE_BLOCK (RW_BLK) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer. †

Implementing ATA Payload Transfer

To implement an ATA payload transfer (read or write), perform the following steps:†

1. Write the data size in bytes to the `bytcnt` register.†
2. Write the block size in bytes to the `blksiz` register. The controller expects a single/multiple block transfer.†
3. Write to the `cmdarg` register to indicate the data unit count.†

Register Settings for ATA Payload Transfer

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the following tables.†

Table 14-32: cmdarg Register Settings for ATA Payload Transfer†

Bits	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:16	0	Reserved (bits set to 0 by host processor)
15:8	Data count	Data Count Unit [15:8]
7:0	Data count	Data Count Unit [7:0]

Table 14-33: cmd Register Settings for ATA Payload Transfer†

Bits	Value	Comment
`start_cmd`	1	-
`ccs_expected`	1	CCS is expected. Set to 1 for the RW_BLK command if interrupts are enabled in CE-ATA card device (the `nIEN` bit is set to 0 in the ATA control register)
`read_ceata_device`	0 or 1	Set to 1 for a RW_BLK or RW_REG read command
`update_clk_regs_only`	0	No clock parameters update command
`card_num`	0	-
`send_initialization`	0	No initialization sequence
`stop_abort_cmd`	0	-
`send_auto_stop`	0	-
`transfer_mode`	0	Block transfer mode. Byte count must be integer multiple of 4kB. Block size can be 512, 1k or 4k bytes

Bits	Value	Comment
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	-
response_expect	1	-
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	• 0 for send command immediately • 1 for send command after previous DTO interrupt
check_response_crc	1	• 0 for not checking response CRC • 1 for checking response CRC

Table 14-34: blksiz Register Settings for ATA Payload Transfer†

Bits	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	512, 1024 or 4096	MMC block size can be 512, 1024 or 4096 bytes as negotiated by host

Table 14-35: bytcnt Register Settings for ATA Payload Transfer

Bits	Value	Comment
31:0	<n>*block_size	Byte count must be an integer multiple of the block size. For ATA media access commands, byte count must be a multiple of 4 KB. (<*n*>*block_size = <*x*>*4 KB, where <*n*> and <*x*> are integers)

CE-ATA CCS

This section describes disabling the CCS, recovery after CCS timeout, and recovery after I/O read transmission delay (N_{ACIO}) timeout. †

Disabling the CCS

While waiting for the CCS for an outstanding RW_BLK command, the host can disable the CCS by sending a CCSD command:†

- Send a CCSD command—the controller sends the CCSD command to the CE-ATA card device if the `send_ccsd` bit is set to 1 in the `ctrl` register of the controller. This bit can be set only after a response is received for the RW_BLK command.†
- Send an internal stop command—send an internally-generated SD/SDIO STOP_TRANSMISSION (CMD12) command after sending the CCSD pattern. If the `send_auto_stop_ccsd` bit of the `ctrl` register is also set to 1 when the controller is set to send the CCSD pattern, the controller sends the internally-generated STOP command to the `CMD` pin. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1.†

Recovery after CCS Timeout

If a timeout occurs while waiting for the CCS, the host needs to send the CCSD command followed by a STOP command to abort the pending ATA command. The host can set up the controller to send an internally-generated STOP command after sending the CCSD pattern:†

- Send CCSD command—set the `send_ccsd` bit in the `ctrl` register to 1.†
- Send external STOP command—terminate the data transfer between the CE-ATA card device and the controller. For more information about sending the STOP command, refer to *Transfer Stop and Abort Commands*.†
- Send internal STOP command—set the `send_auto_stop_ccsd` bit in the `ctrl` register to 1, which tells the controller to send the internally-generated STOP command. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1. The `send_auto_stop_ccsd` bit must be set to 1 along with setting the `send_ccsd` bit.†

Related Information

Transfer Stop and Abort Commands on page 14-56
Refer to this section for more information about sending the STOP command.

Recovery after I/O Read Transmission Delay (N_{ACIO}) Timeout

If the I/O read transmission delay (N_{ACIO}) timeout occurs for the CE-ATA card device, perform one of the following steps to recover from the timeout:†

- If the CCS is expected from the CE-ATA card device (that is, the `ccs_expected` bit is set to 1 in the `cmd` register), follow the steps in *Recovery after CCS Timeout*.†
- If the CCS is not expected from the CE-ATA card device, perform the following steps: †
  1. Send an external STOP command. †
  2. Terminate the data transfer between the controller and CE-ATA card device. †

Related Information

Recovery after CCS Timeout on page 14-67
For more information about what steps to take if the CCS is expected from the CE-ATA card device.

Reduced ATA Command Set

It is necessary for the CE-ATA card device to support the reduced ATA command subset. This section describes the reduced command set.†

The IDENTIFY DEVICE Command

The IDENTIFY DEVICE command returns a 512-byte data structure to the host that describes device-specific information and capabilities. The host issues the IDENTIFY DEVICE command only if the MMC block size is set to 512 bytes. Any other MMC block size has indeterminate results.†

The host issues a RW_REG command for the ATA command, and the data is retrieved with the RW_BLK command.†

The host controller uses the following settings while sending a RW_REG command for the IDENTIFY DEVICE ATA command. The following list shows the primary bit settings:†

- `cmd` register setting: `data_expected` bit set to 0†
- `cmdarg` register settings: †
  - Bit [31] set to 0†
  - Bits [7:2] set to 128 †
  - All other bits set to 0†
- Task file settings: †
  - Command field of the ATA task file set to 0xEC†
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16†

The host controller uses the following settings for data retrieval (RW_BLK command):†

- `cmd` register settings:†
  - `ccs_expected` set to 1†
  - `data_expected` set to 1†
- `cmdarg` register settings: †
  - Bit [31] set to 0 (read operation) †
  - Bits [15:0] set to 1 (data unit count = 1)†
  - All other bits set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 512†

The READ DMA EXT Command

The READ DMA EXT command reads a number of logical blocks of data from the card device using the Data-In data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.†

The WRITE DMA EXT Command

The WRITE DMA EXT command writes a number of logical blocks of data to the card device using the Data-Out data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.†

The STANDBY IMMEDIATE Command

This ATA command causes the card device to immediately enter the most aggressive power management mode that still retains internal device context. No data transfer (RW_BLK) is expected for this command.†

For card devices that do not provide a power savings mode, the STANDBY IMMEDIATE command returns a successful status indication. The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. Only the status field of the ATA task file contains the success status; there is no error status.†

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command: †

- `cmd` register setting: `data_expected` bit set to 0†
- `cmdarg` register settings: †
  - Bit [31] set to 1 †
  - Bits [7:2] set to 4 †
  - All other bits set to 0 †
- Task file settings: †
  - Command field of the ATA task file set to 0xE0†
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16 †

The FLUSH CACHE EXT Command

For card devices that buffer/cache written data, the FLUSH CACHE EXT command ensures that buffered data is written to the card media. For cards that do not buffer written data, the FLUSH CACHE EXT command returns a success status. No data transfer (RW_BLK) is expected for this ATA command. †

The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. There can be error status for this ATA command, in which case fields other than the status field of the ATA task file are valid.†

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:†

- `cmd` register setting: `data_expected` bit set to 0 †
- `cmdarg` register settings: †
  - Bit [31] set to 1 †
  - Bits [7:2] set to 4†
  - All other bits set to 0†
- Task file settings: †
  - Command field of the ATA task file set to 0xEA †
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16 †

Card Read Threshold

When an application needs to perform a single or multiple block read command, the application must set the `cardthrctl` register with the appropriate card read threshold size in the card read threshold field (`cardrdthreshold`) and set the `cardrdthren` bit to 1. This additional information specified in the controller ensures that the controller sends a read command only if there is space equal to the card read threshold available in the RX FIFO buffer. This in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. Set the card read threshold to the block size of the transfer to guarantee there is a minimum of one block size of space in the RX FIFO buffer before the controller enables the card clock. †

The card read threshold is required when the round trip delay is greater than half of `sdmmc_clk_divided`.†

Table 14-36: Card Read Threshold Guidelines†

Bus Speed Modes	Round Trip Delay (Delay_R) (43)	Is Stopping of Card Clock Allowed?	Card Read Threshold Required?
SDR25	Delay_R > 0.5 * (sdmmc_clk/4)	No	Yes
	Delay_R < 0.5 * (sdmmc_clk/4)	Yes	No
SDR12	Delay_R > 0.5 * (sdmmc_clk/4)	No	Yes
	Delay_R < 0.5 * (sdmmc_clk/4)	Yes	No

Related Information

Arria 10 Device Datasheet

Recommended Usage Guidelines for Card Read Threshold

1. The `cardthrctl` register must be set before setting the `cmd` register for a data read command.†
2. The `cardthrctl` register must not be set while a data transfer command is in progress.†
3. The `cardrdthreshold` field of the `cardthrctl` register must be set to at the least the block size of a single or multiblock transfer. A `cardrdthreshold` field setting greater than or equal to the block size of the read transfer ensures that the card clock does not stop in the middle of a block of data.†
4. If the round trip delay is greater than half of the card clock period, card read threshold must be enabled and the card threshold must be set as per guideline 3 to guarantee that the card clock does not stop in the middle of a block of data.†
5. If the `cardrdthreshold` field is set to less than the block size of the transfer, the host must ensure that the receive FIFO buffer never overflows during the read transfer. Overflow can cause the card clock from the controller to stop. The controller is not able to guarantee that the card clock does not stop during a read transfer.†

Note: If the `cardrdthreshold` field of the `cardthrctl` register, and the `rx_wmark` and `dw_dma_multiple_transaction_size` fields of the `fifoth` register are set incorrectly, the card clock might stop indefinitely, with no interrupts generated by the controller.†

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, support block sizes that are either specified in the card or are fixed to 512 bytes. For SDIO, MMC, and standard capacity SD cards that support partial block read (READ_BL_PARTIAL set to 1 in the CSD register of the card device), the block size is variable and can be chosen by the application.†

(43) Delay_R = Delay_O + tODLY + Delay_I †

Where: †

Delay_O = `sdmmc_clk` to `sdmmc_cclk_out` delay (including I/O pin delay) †

Delay_I = Input I/O pin delay + routing delay to the input register †

tODLY = `sdmmc_cclk_out` to card output delay (varies across card manufactures and speed modes) †

For the delay numbers needed for above calculation, refer to Arria 10 Datasheet. †

To use the card read threshold feature effectively and to guarantee that the card clock does not stop because of a FIFO Full condition in the middle of a block of data being read from the card, follow these steps:†

1. Choose a block size that is a multiple of four bytes.†
2. Enable card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than or equal to the total depth of the FIFO buffer:†

   (block size / 4) ≤ 1024†
3. Choose the card read threshold value: †
   - If (block size / 4) ≥ 512, choose `cardrdthreshold` such that:†
     - `cardrdthreshold` ≤ (block size / 4) in bytes†
   - If (block size / 4) < 512, choose `cardrdthreshold` such that:†
     - `cardrdthreshold` = (block size / 4) in bytes†
4. Set the `dw_dma_multiple_transaction_size` field in the `fifoth` register to the number of transfers that make up a DMA transaction. For example, size = 1 means 4 bytes are moved. The possible values for the size are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Select the size so that the value (block size / 4) is evenly divided by the size.†
5. Set the `rx_wmark` field in the `fifoth` register to the size – 1.†

For example, if your block size is 512 bytes, legal values of `dw_dma_multiple_transaction_size` and `rx_wmark` are listed in the following table.

Table 14-37: Legal Values of dw_dma_multiple_transaction_size and rx_wmark for Block Size = 512†

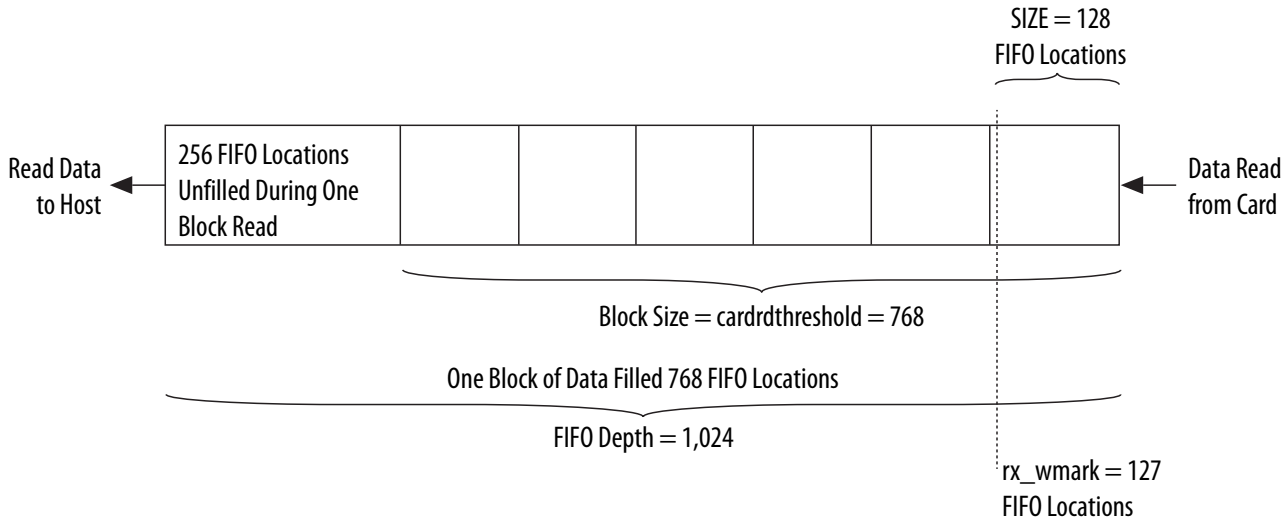
Block Size	dw_dma_multiple_transaction_size	rx_wmark
512	1	0
512	4	3
512	8	7
512	16	15
512	32	31
512	64	63
512	128	127

Card Read Threshold Programming Examples

This section shows examples of how to program the card read threshold.†

- Choose a block size that is a multiple of 4 (the number of bytes per FIFO location), and less than 4096 (1024 FIFO locations). For example, a block size of 3072 bytes is legal, because 3072 / 4 = 768 FIFO locations.†
- For DMA mode, choose the size so that block size is a multiple of the size. For example size = 128, where block size%size = 0.†
- Set the `rx_wmark` field = size – 1. For example, the `rx_wmark` field = 128 – 1 = 127.†
- Because block size > ½ FifoDepth, set the `cardrdthreshold` field to the block size. For example, the `cardrdthreshold` field = 3072 bytes.†

Figure 14-16: FIFO Buffer content when Card Read Threshold is set to 768†



Interrupt and Error Handling

This section describes how to use interrupts to handle errors. On power-on or reset, interrupts are disabled (the `int_enable` bit in the `ctrl` register is set to 0), and all the interrupts are masked (the `intmask` register default is 0). The controller error handling includes the following types of errors:

- Response and data timeout errors—For response time-outs, the host software can retry the command. For data time-outs, the controller has not received the data start bit from the card, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `tcbcnt` register later, the software can decide how many bytes remain to be copied (read). †
- Response errors—Set to 1 when an error is received during response reception. If the response received is invalid, the software can retry the command. †
- Data errors—Set to 1 when a data receive error occurs. Examples of data receive errors: †
  - Data CRC†
  - Start bit not found †
  - End bit not found †

  These errors can be occur on any block. On receipt of an error, the software can issue an SD/SDIO STOP or SEND_IF_COND command, and retry the command for either the whole data or partial data.†
- Hardware locked error—Set to 1 when the controller cannot load a command issued by software. When software sets the `start_cmd` bit in the `cmd` register to 1, the controller tries to load the command. If the command buffer already contains a command, this error is raised, and the new command is discarded, requiring the software to reload the command.†
- FIFO buffer underrun/overrun error—If the FIFO buffer is full and software tries to write data to the FIFO buffer, an overrun error is set. Conversely, if the FIFO buffer is empty and the software tries to read data from the FIFO buffer, an underrun error is set. Before reading or writing data in the FIFO buffer, the software must read the FIFO buffer empty bit (`fifo_empty`) or FIFO buffer full bit (`fifo_full`) in the `status` register.†
- Data starvation by host timeout—This condition occurs when software does not service the FIFO buffer fast enough to keep up with the controller. Under this condition and when a read transfer is in process, the software must read data from the FIFO buffer, which creates space for further data reception. When a transmit operation is in process, the software must write data to fill the FIFO buffer so that the controller can write the data to the card.†
- CE-ATA errors†
- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.
- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.†
- Write operation—Any MMC transport layer error known to the card device causes an outstanding ATA command to be terminated. The ERR bits are set in the ATA status registers and the appropriate error code is sent to the Error Register (Error) on the ATA card device.†

  If the device interrupt bit of the CE-ATA card (the nIEN bit in the ATA control register) is set to 0, the CCS is sent to the host.†

  If the device interrupt bit is set to 1, the card device completes the entire data unit count if the host controller does not abort the ongoing transfer.†

  Note: During a multiple-block data transfer, if a negative CRC status is received from the card device, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register to 1. It then continues further data transmission until all the bytes are transmitted.†
- Read operation—If MMC transport layer errors are detected by the host controller, the host completes the ATA command with an error status. The host controller can issue a CCSD command followed by a STOP_TRANSMISSION (CMD12) command to abort the read transfer. The host can also transfer the entire data unit count bytes without aborting the data transfer.†

Booting Operation for eMMC and MMC

This section describes how to set up the controller for eMMC and MMC boot operation.

Note: The BootROM and initial software do not use the boot partitions that are in the MMC card. This means that there is no boot partition support of the SD/MMC controller.

Boot Operation by Holding Down the CMD Line

The controller can boot from MMC4.3, MMC4.4, and MMC4.41 cards by holding down the CMD line.

For information about this boot method, refer to the following specifications, available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

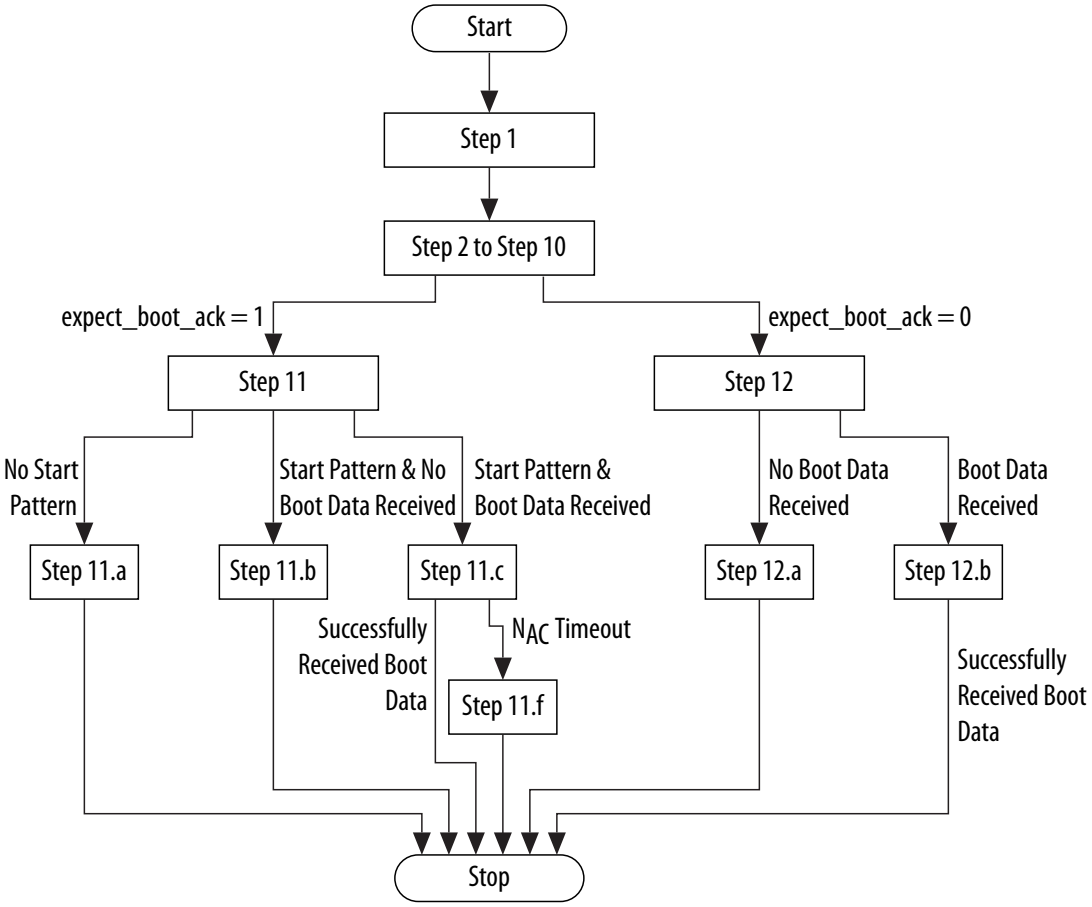
www.jedec.org

For more information about this boot method, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Boot Operation for eMMC Card Device

The following figure illustrates the steps to perform the boot process for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-17: Flow for eMMC Boot Operation†



1. The software driver performs the following checks: †
   - If the eMMC card device supports boot operation (the BOOT_PARTITION_ENABLE bit is set to 1 in the EXT_CSD register of the eMMC card).†
   - The BOOT_SIZE_MULT and BOOT_BUS_WIDTH values in the EXT_CSD register, to be used during the boot process.†
2. The software sets the following bits: †
   - Sets masks for interrupts, by setting the appropriate bits to 0 in the `intmask` register.†
   - Sets the global `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0. †

   Note: Altera recommends that you write 0xFFFFFFFF to the `rintsts` and `idsts` registers to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.†
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following steps: †

- Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*". †
- Set the `use_internal_dmac` bit of the `ctrl` register to 1.†

4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to Clock Setup.†
5. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC}. †
6. Set the `blksiz` register to 0x200 (512 bytes). †
7. Set the `bytcnt` register to a multiple of 128 KB, as indicated by the BOOT_SIZE_MULT value in the card device.†
8. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.†
9. Set the following fields in the `cmd` register:†
   - Initiate the command by setting `start_cmd` = 1†
   - Enable boot (`enable_boot`) = 1†
   - Expect boot acknowledge (`expect_boot_ack`): †
     - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.†
     - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.†
   - Card number (`card_number`) = 0†
   - `data_expected` = 1†
   - Reset the remainder of `cmd` register bits to 0†
10. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) proceed to **step 12**.†
11. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in **step 9**).†
    a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command (**step 9**), the software driver must set the following `cmd` register fields: †
       - `start_cmd` = 1†
       - Disable boot (`disable_boot`)= 1†
       - `card_number` = 0 †
       - All other fields = 0†

       The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.†

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set, indicating the Boot ACK Received timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to the `ces` bit in the `idsts` register.†

       Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must write the following `cmd` register fields:†
       - `start_cmd` = 1†
       - disable_boot = 1†
       - card_number = 0†
       - All other fields = 0†

The controller generates a Command Done interrupt after deasserting the CMD pin of the card interface.†

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†

- The DMA descriptor is closed†
- The ces bit in the idsts register is set, indicating Boot Data Start timeout†
- The ri bit of the idsts register is not set†

c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the rxdr interrupt bit in the rintsts register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level set in the rx_wmark field of the fifoth register is reached.†

At the end of a successful boot data transfer from the card, the following interrupts are generated:†

- The cmd bit and dto bit in the rintsts register†
- The ri bit in the idsts register, in internal DMA controller mode only†

d. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †

- The controller automatically aborts the boot process by pulling the CMD line high†
- The controller generates a Command Done interrupt†
- The controller does not generate a Boot ACK Received interrupt†
- The application aborts the boot transfer†

e. In internal DMA controller mode:†

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. Software cannot reuse the descriptors until they are closed.†
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

f. If N_{AC} is violated between data block transfers, the DRTO interrupt is asserted. In addition, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated.†

The boot operation for eMMC card devices is complete. Do not execute the remaining (**step 12**).†

12. This step handles the case where no start-acknowledge pattern is expected (expect_boot_ack was set to 0 in **step 9**).†

a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 9**), the software driver must write the cmd register with the following fields:†

- start_cmd = 1†
- disable_boot = 1†
- card_number = 0†
- All other fields = 0†

The controller generates a Command Done interrupt after deasserting the CMD line of the card. In internal DMA controller mode, the descriptor is closed and the ces bit in the idsts register is set to 1, indicating a Boot Data Start timeout.†

b. If a Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver

can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.†

At the end of a successful boot data transfer from the card, the following interrupts are generated:†

- The `cmd` bit and `dto` bit in the `rintsts` register†
- The `ri` bit in the `idsts` register, in internal DMA controller mode only†

c. In internal DMA controller mode:†

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.†
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

The boot operation for eMMC card devices is complete.†

Boot Operation for Removable MMC4.3, MMC4.4 and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 Differences

Removable MMC4.3, MMC4.4, and MMC4.41 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation when plugged in. Thus, the controller must: †

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time†
2. Know the card characteristics †
3. Decide whether to perform a boot operation or not†

Booting Removable MMC4.3, MMC4.4 and MMC4.41 Cards

For removable MMC4.3, MMC4.4 and MMC4.41 cards, the software driver must perform the following steps:†

1. Discover the card as described in *Enumerated Card Stack*.†
2. Read the EXT_CSD register of the card and examine the following fields: †
   - BOOT_PARTITION_ENABLE †
   - BOOT_SIZE_MULT†
   - BOOT_INFO †
3. If necessary, the software can manipulate the boot information in the card. †

Note: For more information, refer to "Access to Boot Partition" in the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

4. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH_FUNC command. †
5. After this step, the software driver must power down the card by writing to the `pwren` register. †
6. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*.†

Related Information

- **Enumerated Card Stack** on page 14-43
  Refer to this section for more information on discovering removable MMC cards.
- **www.jedec.org**
  For more information, refer to "Access to Boot Partition" in the following specifications available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.
- **Alternative Boot Operation for eMMC Card Devices** on page 14-79
  Refer to this section for information about alternative boot operation steps.

Alternative Boot Operation

The alternative boot operation differs from the previous boot operation in that software uses the SD/SDIO GO_IDLE_STATE command to boot the card, rather than holding down the CMD line of the card. The alternative boot operation can be performed only if bit 0 in the BOOT_INFO register is set to 1. BOOT_INFO is located at offset 228 in the EXT_CSD registers. †

For detailed information about alternative boot operation, refer to the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

www.jedec.org

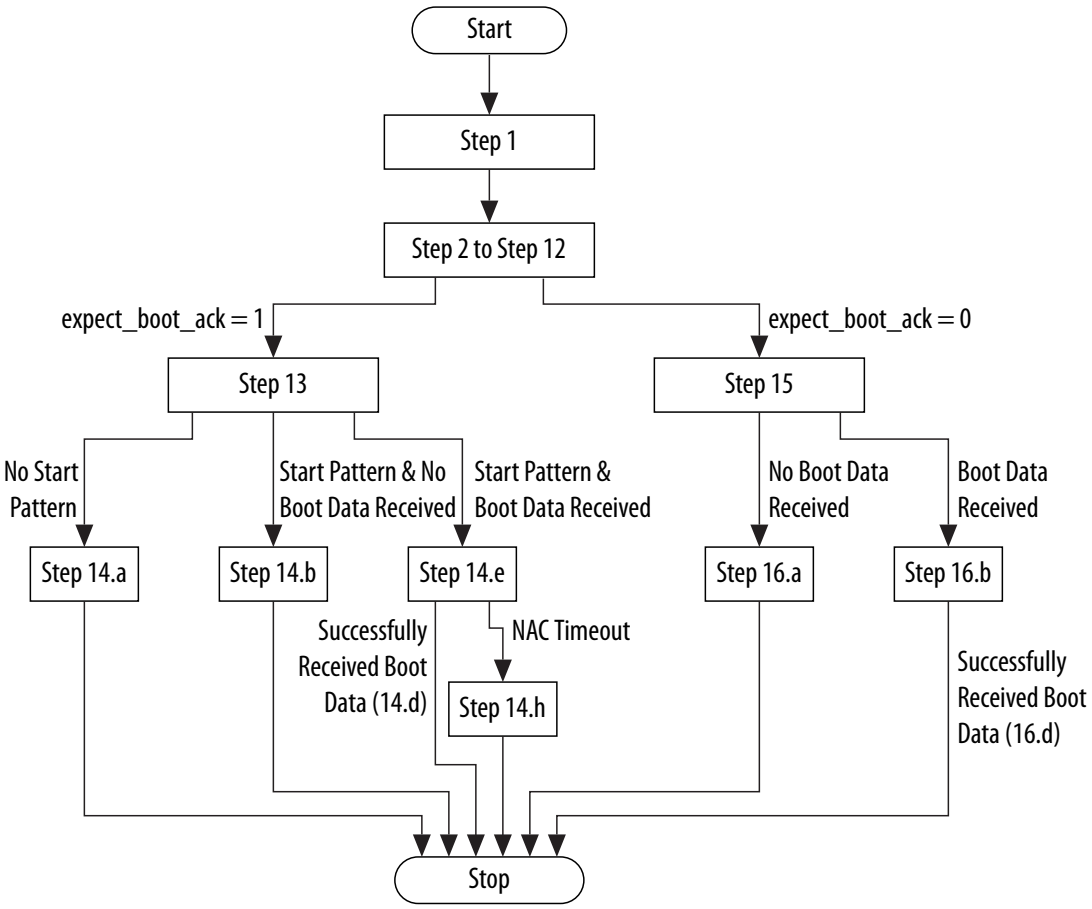
Alternative Boot Operation for eMMC Card Devices

The following figure illustrates the sequence of steps required to perform the alternative boot operation for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-18: Flow for eMMC Alternative Boot Operation†



1. The software driver checks:†
   - If the eMMC card device supports alternative boot operation (the BOOT_INFO bit is set to 1 in the eMMC card).†
   - The BOOT_SIZE_MULT and BOOT_BUS_WIDTH values in the card device to use during the boot process.†
2. The software sets the following bits: †
   - Sets masks for interrupts by resetting the appropriate bits to 0 in the `intmask` register.†
   - Sets the `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0. †

   Note: Altera recommends writing 0xFFFFFFFF to the `rintsts` register and `idsts` register to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.†
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following actions: †
   - Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*. †
   - Set the use internal DMAC bit (`use_internal_dmac`) of the `ctrl` register to 1. †
4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*. Ensure that the card clock is running.†

5. Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.†
6. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC}. †
7. Set the `blksiz` register to 0x200 (512 bytes).†
8. Set the `bytcnt` register to multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card device.†
9. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.†
10. Set the `cmdarg` register to 0xFFFFFFFA. †
11. Initiate the command, by setting the `cmd` register with the following fields: †
    - `start_cmd` = 1†
    - `enable_boot` = 1†
    - `expect_boot_ack`:†
      - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.†
      - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0. †
    - `card_number` = 0 †
    - `data_expected` = 1†
    - `cmd_index` = 0†
    - Set the remainder of `cmd` register bits to 0.†
12. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) jump to **step 15**. †
13. Wait for the Command Done interrupt.†
14. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in **step 11**).†
    a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command (**step 11**), the start pattern was not received. The software driver must discontinue the boot process and start with normal discovery. †

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set to 1, indicating the Boot ACK Received timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to it. †

       Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must discontinue the boot process and start with normal discovery.†

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout: †
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

d. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE command:†

- Reset the `cmdarg` register to 0.†
- Set the `start_cmd` bit of the `cmd` register to 1, and all other bits to 0.†

e. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The `cmd` bit and `dto` bit in the `rintsts` register†
- The `ri` bit in the `idsts` register, in internal DMA controller mode only†

f. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †

- The controller does not generate a Boot ACK Received interrupt. †
- The controller detects Boot Data Start and generates a Boot Data Start interrupt. †
- The controller continues to receive boot data. †
- The application must abort the boot process after receiving a Boot Data Start interrupt.†

g. In internal DMA controller mode: †

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

h. If N_{AC} is violated between data block transfers, a DRTO interrupt is asserted. Apart from this, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated.†

The alternative boot operation for eMMC card devices is complete. Do not execute the remaining steps (**15** and **16**). †

15. Wait for the Command Done interrupt.†

16. This step handles the case where a start-acknowledge pattern is not expected (`expect_boot_ack` was set to 0 in **step 11**). †

a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 11**), the software driver must discontinue the boot process and start with normal discovery. † In internal DMA controller mode:†

- The DMA descriptor is closed.†
- The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.†
- The `ri` bit of the `idsts` register is not set.†

b. If a Boot Data Start interrupt is received, the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.†

c. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE (CMD0) command: †

- Reset the `cmdarg` register to 0.†
- Set the `start_cmd` bit in the `cmd` register to 1, and all other bits to 0.†

d. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The cmd bit and dto bit in the rintsts register†
- The ri bit in the idsts register, in internal DMA controller mode only †

e. In internal DMA controller mode: †

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

The alternative boot operation for eMMC card devices is complete.†

Alternative Boot Operation for MMC4.3 Cards

Removable MMC4.3 Boot Mode Support

Removable MMC4.3 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation. Thus, the controller must: †

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time †
2. Know the card characteristics †
3. Decide whether to perform a boot operation or not†

Discovering Removable MMC4.3 Boot Mode Support

For removable MMC4.3 cards, the software driver must perform the following steps: †

1. Discover the card as described in *Enumerated Card Stack*.†
2. Read the MMC card device's EXT_CSD registers and examine the following fields: †
   - BOOT_PARTITION_ENABLE †
   - BOOT_SIZE_MULT †
   - BOOT_INFO †

   Note: For more information, refer to "Access to Boot Partition" in JEDEC Standard No. JESD84-A43, available on the JEDEC website.†
3. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the contents of the EXT_CSD registers in the MMC card device, by using a SWITCH_FUNC command. †
4. After this step, the software driver must power down the card by writing to the pwren register. †
5. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*. †

   Note: Ignore the EBE if it is generated during an abort scenario.

   If a boot acknowledge error occurs, the boot acknowledge received interrupt times out. †

In internal DMA controller mode, the application needs to depend on the descriptor close interrupt instead of the data done interrupt. †

ctrl

Control register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808000

Offset: 0x0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved						use_internal_dmac RW 0x0	enable_od_pullup RW 0x0	card_voltage_b RW 0x0				card_voltage_a RW 0x0			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				ceata_device_interrupt_status RW 0x0	send_auto_stop_ccsd RW 0x0	send_ccsd RW 0x0	abort_read_data RW 0x0	send_irq_response RW 0x0	read_wait RW 0x0	dma_enable RW 0x0	int_enable RW 0x0	Reserved	dma_reset RW 0x0	fifo_reset RW 0x0	controller_reset RW 0x0

ctrl Fields

Bit	Name	Description	Access	Reset
25	use_internal_dmac	Present only for the Internal DMAC configuration; else, it is reserved. 0-The host performs data transfers through the slave interface 1-Internal DMAC used for data transfer **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
24	enable_od_pullup	External open-drain pullup 0-Disable 1-Enable Inverted value of this bit is output to ccmd_od_pullup_en_n port. When bit is set, command output always driven in open-drive mode; that is, DWC_mobile_storage drives either 0 or high impedance, and does not drive hard 1.	RW	0x0
23:20	card_voltage_b	Card regulator-B voltage setting; output to card_volt_b port. Optional feature; ports can be used as general-purpose outputs	RW	0x0
19:16	card_voltage_a	Card regulator-A voltage setting; output to card_volt_a port. Optional feature; ports can be used as general-purpose outputs	RW	0x0
11	ceata_device_interrupt_status	0-Interrupts not enabled in CE-ATA device 1-Interrupts are enabled in CE-ATA device **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0
10	send_auto_stop_ccsd	0-Clear bit if DWC_mobile_storage does not reset the bit 1-Send internally generated STOP after sending CCSD to CE-ATA device **Value** **Description** 0 DEASSERT 1 ASSERT	RW	0x0

Bit	Name	Description	Access	Reset
9	send_ccsd	0-Clear this bit if DWC_mobile_storage does not reset the bit 1-Send Command Completion Signal Disable (CCSD) to CE-ATA device **Value / Description** 0 DEASSERT 1 ASSERT	RW	0x0
8	abort_read_data	0-No change 1-After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs,software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data statemachine resets to idle. Used in SDIO card suspend sequence. **Value / Description** 0 NOCHANGE 1 ACTIVATE	RW	0x0

Bit	Name	Description	Access	Reset
7	send_irq_response	0-No Change in this 1-Send auto IRQ response Bit automatically clears once response is sent. To wait for MMC card interrupts, host issues CMD40, and DWC_mobile_storage waits for interrupt response from MMC card(s). In meantime, if host wants DWC_mobile_storage to exit waiting for interrupt state, it can set this bit, at which time DWC_mobile_storage command state-machine sends CMD40 response on bus and returns to idle state. **Value** **Description** 0 NOCHANGE 1 ACTIVATE	RW	0x0
6	read_wait	0-Clear read wait 1-Assert read wait For sending read-wait to SDIO cards. **Value** **Description** 0 DEASSERT 1 ASSERT	RW	0x0
5	dma_enable	0-Disable DMA transfer mode 1-Enable DMA transfer mode Valid only if DWC_mobile_storage configured for External DMA interface.	RW	0x0

Bit	Name	Description	Access	Reset
4	int_enable	Global interrupt enable/disable bit: 0-Disable interrupts 1-Enable interrupts The int port is 1 only when this bit is 1 and one or more unmasked interrupts are set. **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0
2	dma_reset	0-No change 1-Reset internal DMA interface control logic To reset DMA interface, firmware should set bit to 1. This bit is auto-cleared after two AHB clocks. **Value** **Description** 0 NOCHANGE 1 ACTIVATE	RW	0x0
1	fifo_reset	0-No change 1-Reset to data FIFO To reset FIFO pointers To reset FIFO, firmware should set bit to 1. This bit is auto-cleared after completion of reset operation. **Value** **Description** 0 NOCHANGE 1 ACTIVATE	RW	0x0

Bit	Name	Description	Access	Reset
0	controller_reset	0-No change 1-Reset DWC_mobile_ storage controller To reset controller, firmware should set bit to 1. This bit is auto-cleared after two AHB and two cclk_in clock cycles. This resets: * BIU/CIU interface * CIU and state machines * abort_read_data, send_irq_response, and read_wait bits of Control register * start_cmd bit of Command register Does not affect any registers or DMA interface, or FIFO or host interrupts **Value** **Description** 0 NOCHANGE 1 ACTIVATE	RW	0x0

pwren

Power Enable Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															power_enable RW 0x0

pwren Fields

Bit	Name	Description	Access	Reset
0	power_enable	Power on/off switch for up to 16 cards; for example, bit[0] controls card 0.Once power is turned on, firmware should wait for regulator/switch ramp-up time before trying to initialize card. 0-power off 1-power on Only NUM_CARDS number of bits are implemented.Bit values output to card_power_en port. Optional feature; ports can be used as general-purpose outputs. **Value** **Description** 0 OFF 1 ON	RW	0x0

clkdiv

Clock Divider Register

Module Instance	Base Address	Register Address

clkdiv Fields

Bit	Name	Description	Access	Reset
31:24	clk_divider3	Clock divider-3 value. Clock division is 2*n. For example, value of 0 means divide by 2*0 = 0 (no division, bypass), a value of 1 means divide by 2*1 = 2, a value of “ff” means divide by 2*255 = 510, and so on. In MMC-Ver3.3-only mode, bits not implemented because only one clock divider is supported.	RO	0x0
23:16	clk_divider2	Clock divider-2 value. Clock division is 2*n. For example, value of 0 means divide by 2*0 = 0 (no division, bypass), value of 1 means divide by 2*1 = 2, value of “ff” means divide by 2*255 = 510, and so on. In MMC-Ver3.3-only mode, bits not implemented because only one clock divider is supported.	RO	0x0
15:8	clk_divider1	Clock divider-1 value. Clock division is 2*n. For example, value of 0 means divide by 2*0 = 0 (no division, bypass), value of 1 means divide by 2*1 = 2, value of “ff” means divide by 2*255 = 510, and so on. In MMC-Ver3.3-only mode, bits not implemented because only one clock divider is supported	RO	0x0
7:0	clk_divider0	Clock divider-0 value. Clock division is 2*n. For example, value of 0 means divide by 2*0 = 0 (no division, bypass), value of 1 means divide by 2*1 = 2, value of “ff” means divide by 2*255 = 510, and so on.	RW	0x0

clksrc

Clock Source Register

Module Instance	Base Address	Register Address

clk_source RO 0x0															

clksrc Fields

Bit	Name	Description	Access	Reset
31:0	clk_source	Clock divider source for up to 16 SD cards supported. Each card has two bits assigned to it. For example, bits[1:0] assigned for card-0, which maps and internally routes clock divider[3:0] outputs to cclk_out[15:0] pins, depending on bit value. 00 Clock divider 0 01 Clock divider 1 10 Clock divider 2 11 Clock divider 3 In MMC-Ver3.3-only controller, only one clock divider supported. The cclk_out is always from clock divider 0, and this register is not implemented. **Value** **Description** 0 CLKDIV0	RO	0x0

clkena

Clock Enable Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															cclk_enable RW 0x0

clkena Fields

Bit	Name	Description	Access	Reset
16	cclk_low_power	Low-power control for up to 16 SD card clocks and one MMC card clock supported. 0-Non-low-power mode 1-Low-power mode; stop clock when card in IDLE (should be normally set to only MMC and SD memory cards; for SDIO cards, if interrupts must be detected, clock should not be stopped). In MMC-Ver3.3-only mode, since there is only one cclk_out, only cclk_low_power[0] is used. **Value** — **Description** 0 — DISABLED 1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
0	cclk_enable	Clock-enable control for up to 16 SD card clocks and one MMC card clock supported. 0-Clock disabled 1-Clock enabled In MMC-Ver3.3-only mode, since there is only one cclk_out, only cclk_enable[0] is used. **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

tmout

Timeout Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808014

Offset: 0x14

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
data_timeout RW 0xFFFFFF															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
data_timeout RW 0xFFFFFF								response_timeout RW 0x40							

tmout Fields

Bit	Name	Description	Access	Reset
31:8	data_timeout	Value for card Data Read Timeout; same value also used for Data Starvation by Host timeout. The timeout counter is started only after the card clock is stopped.Value is in number of card output clocks cclk_out of selected card. Note: The software timer should be used if the timeout value is in the order of 100 ms. In this case, read data timeout interrupt needs to be disabled.	RW	0xFFFFFF
7:0	response_timeout	Response timeout value. Value is in number of card output clocks cclk_out.	RW	0x40

ctype

Card Type Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

cmd Fields

Bit	Name	Description	Access	Reset
31	start_cmd	Start command. Once command is taken by CIU, bit is cleared. When bit is set, host should not attempt to write to any command registers. If write is attempted, hardware lock error is set in raw interrupt register. Once command is sent and response is received from SD_MMC_CEATA cards, Command Done bit is set in raw interrupt register. **Value** — **Description** 0 — NOSTART 1 — START	RW	0x0

Bit	Name	Description	Access	Reset
29	use_hold_reg	Use Hold Register 0 - CMD and DATA sent to card bypassing HOLD Register 1 - CMD and DATA sent to card through the HOLD Register **Value: Description** 0: BYPASS 1: NOBYPASS	RW	0x1
28	volt_switch	Voltage switch bit 0 - No voltage switching 1 - Voltage switching enabled; must be set for CMD11 only **Value: Description** 0: NOVOLTSW 1: VOLTSW	RW	0x0
27	boot_mode	Boot Mode 0 - Mandatory Boot operation 1 - Alternate Boot operation **Value: Description** 0: MANDATORY 1: ALTERNATE	RW	0x0
26	disable_boot	Disable Boot. When software sets this bit along with start_cmd, CIU terminates the boot operation. Do NOT set disable_boot and enable_boot together. **Value: Description** 0: NOTERMBOOT 1: TERMBOOT	RW	0x0

Bit	Name	Description	Access	Reset
25	expect_boot_ack	Expect Boot Acknowledge. When Software sets this bit along with enable_boot, CIU expects a boot acknowledge start pattern of 0-1-0 from the selected card. **Value** **Description** 0 NOBOOTACK 1 BOOTACK	RW	0x0
24	enable_boot	Enable Bootthis bit should be set only for mandatory boot mode. When Software sets this bit along with start_cmd, CIU starts the boot sequence for the corresponding card by asserting the CMD line low. Do NOT set disable_boot and enable_boot together. **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
23	ccs_expected	0-Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device 1-Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device If the command expects Command Completion Signal (CCS) from the CE-ATA device, the software should set this control bit.DWC_mobile_storage sets Data Transfer Over (DTO) bit in RINTSTS register and generates interrupt to host if Data Transfer Over interrupt is not masked. **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
22	read_ceata_device	0-Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device 1-Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers.Maximum value of I/O transmission delay can be no less than 10 seconds. DWC_mobile_storage should not indicate read data timeout while waiting for data from CE-ATA device. **Value** **Description** 0 NORD 1 RD	RW	0x0

Bit	Name	Description	Access	Reset
21	update_clock_ registers_only	0-Normal command sequence 1-Do not send commands, just update clock register value into card clock domain Following register values transferred into card clock domain: CLKDIV, CLRSRC, CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards.During normal command sequence, when update_clock_ registers_only = 0, following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOUT, CTYPE,BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s).When bit is set, there are no Command Done interrupts because no command is sent to SD_MMC_CEATA cards. **Value** **Description** 0 NORMCMD 1 UPDATCLKREG	RW	0x0
20:16	card_number	Card number in use. Represents physical slot number of card being accessed. In MMC-Ver3.3-only mode, up to 30 cards are supported; in SD-only mode, up to 16 cards are supported. Registered version of this is reflected on dw_dma_card_ num and ge_dma_card_num ports, which can be used to create separate DMA requests, if needed. In addition, in SD mode this is used to mux or demux signals from selected card because each card is interfaced to DWC_mobile_storage by separate bus.	RW	0x0

Bit	Name	Description	Access	Reset
15	send_initialization	0-Do not send initialization sequence (80 clocks of 1) before sending this command 1-Send initialization sequence before sending this command After power on, 80 clocks must be sent to card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card. This bit should not be set for either of the boot modes (alternate or mandatory). **Value** **Description** 0 NOINIT 1 INIT	RW	0x0

Bit	Name	Description	Access	Reset
14	stop_abort_cmd	0-Neither stop nor abort command to stop current data transfer in progress. If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0. 1-Stop or abort command intended to stop current data transfer in progress. When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state. This is also applicable for Boot mode transfers. To Abort boot mode, this bit should be set along with CMD[26] = disable_boot. **Value** **Description** 0 NOSTOPABRT 1 STOPABRT	RW	0x0

Bit	Name	Description	Access	Reset
13	wait_prvdata_complete	0-Send command at once, even if previous data transfer has not completed 1-Wait for previous data transfer completion before sending command The wait_prvdata_complete = 0 option typically used to query status of card during data transfer or to stop current data transfer;card_number should be same as in previous command. **Value: Description** 0: NOWAIT 1: WAIT	RW	0x0
12	send_auto_stop	0-No stop command sent at end of data transfer 1-Send stop command at end of data transfer When set, DWC_mobile_storage sends stop command to SD_MMC_CEATA cards at end of data transfer. * when send_auto_stop bit should be set, since some data transfers do not need explicit stop commands * open-ended transfers that software should explicitly send to stop command Additionally, when “resume” is sent to resume suspended memory access of SD-Combo card bit should be set correctly if suspended data transfer needs send_auto_stop.Don't care if no data expected from card. **Value: Description** 0: NOSEND 1: SEND	RW	0x0

Bit	Name	Description	Access	Reset
11	transfer_mode	0-Block data transfer command 1-Stream data transfer command Don't care if no data expected. **Value** **Description** 0 BLK 1 STR	RW	0x0
10	read_write	0-Read from card 1-Write to card Don't care if no data expected from card. **Value** **Description** 0 RD 1 WR	RW	0x0
9	data_expected	0-No data transfer expected (read/write) 1-Data transfer expected (read/write) **Value** **Description** 0 NODATXFEREXP 1 DATAXFEREXP	RW	0x0
8	check_response_crc	0-Do not check response CRC 1-Check response CRC Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller. **Value** **Description** 0 NOCHK 1 CHK	RW	0x0

Bit	Name	Description	Access	Reset
7	response_length	0-Short response expected from card 1-Long response expected from card **Value** **Description** 0 SHORT 1 LONG	RW	0x0
6	response_expect	0-No response expected from card 1-Response expected from card **Value** **Description** 0 RESP 1 NORESP	RW	0x0
5:0	cmd_index	Command index	RW	0x0

FIFO Threshold Watermark Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF80804C

Offset: 0x4C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved	dw_dma_multiple_transaction_size RW 0x0			rx_wmark RW 0x3FF											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				tx_wmark RW 0x0											

fifoth Fields

Bit	Name	Description	Access	Reset
30:28	dw_dma_multiple_transaction_size	Burst size of multiple transaction; should be programmed same as DW-DMA controller multiple-transaction-size SRC/DEST_MSIZE. 000 1 transfers 001 4 010 8 011 16 100 32 101 64 110 128 111 256 The units for transfers is the H_DATA_WIDTH parameter. A single transfer (dw_dma_single assertion in case of Non DW DMA interface) would be signalled based on this value. Value should be sub-multiple of (RX_WMark + 1)* (F_DATA_WIDTH/H_DATA_WIDTH) and (FIFO_DEPTH - TX_WMark)* (F_DATA_WIDTH/H_DATA_WIDTH)	RW	0x0

Bit	Name	Description	Access	Reset
		For example, if FIFO_DEPTH = 16, FDATA_WIDTH == H_DATA_WIDTH Allowed combinations for MSize and TX_WMark are: MSize = 1, TX_WMARK = 1-15 MSize = 4, TX_WMark = 8 MSize = 4, TX_WMark = 4 MSize = 4, TX_WMark = 12 MSize = 8, TX_WMark = 8 MSize = 8, TX_WMark = 4 Allowed combinations for MSize and RX_WMark are: MSize = 1, RX_WMARK = 0-14 MSize = 4, RX_WMark = 3 MSize = 4, RX_WMark = 7 MSize = 4, RX_WMark = 11 MSize = 8, RX_WMark = 7 Recommended: MSize = 8, TX_WMark = 8, RX_WMark = 7 **Value** **Description** 0 TXMSIZE1 1 TXMSIZE4 2 TXMSIZEK8 3 TXMSIZEK16 5 RXMSIZEK1 6 RXMSIZEK4 7 RXMSIZE8		

Bit	Name	Description	Access	Reset
27:16	rx_wmark	FIFO threshold watermark level when receiving data to card. When FIFO data count reaches greater than this number,DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data. In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of host to read remaining bytes on seeing Data Transfer Done interrupt. In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set. 12 bits-1 bit less than FIFO-count of status register, which is 13 bits. Limitation: RX_WMark <= FIFO_DEPTH-2 Recommended: (FIFO_DEPTH/2) - 1; (means greater than (FIFO_DEPTH/2) - 1) NOTE: In DMA mode during CCS time-out, the DMA does not generate the request at the end of packet, even if remaining bytes are less than threshold. In this case, there will be some data left in the FIFO. It is the responsibility of the application to reset the FIFO after the CCS timeout.	RW	0x3FF

Bit	Name	Description	Access	Reset
11:0	tx_wmark	FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number,DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated,regardless of threshold programming. In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, host is responsible for filling FIFO with only required remaining bytes (not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty). In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred. 12 bits-1 bit less than FIFO-count of status register, which is 13 bits. Limitation: TX_WMark >= 1; Recommended: FIFO_DEPTH/2; (means less than or equal to FIFO_DEPTH/2)	RW	0x0

cdetect

Card Detect Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808050

bmod Fields

Bit	Name	Description	Access	Reset
10:8	pbl	Programmable Burst Length. These bits indicate the maximum number of beats to be performed in one IDMAC transaction. The IDMAC will always attempt to burst as specified in PBL each time it starts a Burst transfer on the host bus. The permissible values are 1, 4, 8, 16, 32, 64, 128 and 256. This value is the mirror of MSIZE of FIFOTH register. In order to change this value, write the required value to FIFOTH register. This is an encode value as follows. 000 1 transfers 001 4 transfers 010 8 transfers 011 16 transfers 100 32 transfers 101 64 transfers 110 128 transfers 111 256 transfers Transfer unit is either 16, 32, or 64 bits, based on HDATA_WIDTH. PBL is a read-only value and is applicable only for Data Access; it does not apply to descriptor accesses. **Value — Description** 0 — TRANS1 1 — TRANS4 2 — TRANS8 3 — TRANS16 4 — TRANS32 5 — TRANS64 6 — TRANS128 7 — TRANS256	RO	0x0

Bit	Name	Description	Access	Reset
7	de	IDMAC Enable. When set, the IDMAC is enabled. DE is read/write. **Value** **Description** 0 DISABLED 1 ENABLED	RW	0x0
6:2	dsl	Descriptor Skip Length. Specifies the number of HWord/Word/Dword (depending on 16/32/64-bit bus) to skip between two unchained descriptors. This is applicable only for dual buffer structure. DSL is read/write.	RW	0x0
1	fb	Fixed Burst. Controls whether the AHB Master interface performs fixed burst transfers or not. When set,the AHB will use only SINGLE, INCR4, INCR8 or INCR16 during start of normal burst transfers.When reset,the AHB will use SINGLE and INCR burst transfer operations. FB is read/write. **Value** **Description** 0 NOFIXEDBRST 1 FIXEDBRST	RW	0x0
0	swr	Software Reset.When set,the DMA Controller resets all its internal registers. SWR is read/write. It is automatically cleared after 1 clock cycle. **Value** **Description** 0 NOSFTRESET 1 SFTRESET	RW	0x0

pldmnd

Poll Demand Register

Module Instance	Base Address	Register Address
i_sdmmc_sdmmc	0xFF808000	0xFF808084

Offset: 0x84

Access: WO

Bit Fields

IP_REV_ID

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C00

Offset: 0x0

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIREV RO 0x0															

IP_REV_ID Fields

Bit	Name	Description	Access	Reset
15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C08

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							INITB 0x0	Reserved							INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CNT_RSTB 0x0	CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
24	INITB	Enable for the hardware memory initialization PORTB.	RW	0x0
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
9	CNT_RSTB	Enable to reset internal single-bit error counter B value to zero	RW	0x0

Bit	Name	Description	Access	Reset
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C0C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INITCOMPLETEB 0x0	Reserved							INITCOMPLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
8	INITCOMPLETEB	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C10

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C14

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C18

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C1C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0

Bit	Name	Description	Access	Reset
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C20

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							DERRPENB 0x0	Reserved							SERRPENB 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
24	DERRPENB	Double-bit error pending PORTB.	RW	0x0
16	SERRPENB	Single-bit error pending for PORTB.	RW	0x0
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C24

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved							TDERRB 0x0	Reserved							TSERRB 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
24	TDERRB	Test PORTB Double-bit error.	RW	0x0
16	TSERRB	Test PORTB Single-bit error.	RW	0x0
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C28

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														CMPFLGB 0x0	CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
1	CMPFLGB	Port B compare status flag	RW	0x0
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C2C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C30

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

SERRADDRA Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

DERRADDRB

This register shows the address of PORTB current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C34

Offset: 0x34

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

DERRADDRB Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRB

This register shows the address of PORTB current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C38

Offset: 0x38

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address 0x0									

SERRADDRB Fields

Bit	Name	Description	Access	Reset
9:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C3C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C40

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						ECC_AddrBUS 0x0									

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
9:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C44

Offset: 0x44

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C7C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															ENBUSB 0x0

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0
0	ENBUSB	Start RAM access for PORTB.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C80

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2C90

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						Address RO 0x0									

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

SERRLKUPB0

Single-bit error address in LOOKUP TABLE for PORTB.

Module Instance	Base Address	Register Address
ecc_sdmmc_ecc_registerBlock	0xFF8C2C00	0xFF8C2CD0

Offset: 0xD0

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
9:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

Document Revision History

Table 14-38: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Removed SPI support in tables in the Features section.
May 2016	2016.05.27	Added a link to the *Supported Flash Devices for Arria 10 SoC* webpage.
May 2016	2016.05.03	Maintenance release
November 2015	2015.11.02	• Moved "Interface Signals" section below "SD/MMC Controller Block Diagram and System Integration" section and renamed to "SD/MMC Signal Description." Clarified signals in this section. • Removed the indication that the AV/CV HPS support 8-bit eMMC. • Added information that Card Detect is only supported on interfaces routed via the FPGA fabric.
May 2015	2015.05.04	Added information about clearing out the ECC before the feature is enabled
December 2014	2014.12.15	Maintenance release
August 2014	2014.08.18	Initial release

Quad SPI Flash Controller 15

2016.10.28

a10_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides a quad serial peripheral interface (SPI) flash controller for access to serial NOR flash devices. The quad SPI flash controller supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The quad SPI flash controller is based on Cadence Quad SPI Flash Controller (QSPI_FLASH_CTRL).

Features of the Quad SPI Flash Controller

The quad SPI flash controller supports the following features:

- SPIx1, SPIx2, or SPIx4 (quad SPI) serial NOR flash devices
- Any device clock frequencies up to 108 MHz(44)
- Direct access and indirect access modes
- Single I/O, dual I/O, or quad I/O instructions
- Up to four chip selects
- DMA transfers using the HPS DMA controller
- Configurable clock polarity and phase
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Read data capture tuning
- Local buffering with ECC logic for indirect transfers
- Support eXecute-In-Place(XIP) mode
- Supports the Micron N25Q00AA11GSF40F (1024 Mb, 108 MHz) Quad SPI flash memory that is verified working with the HPS

Related Information

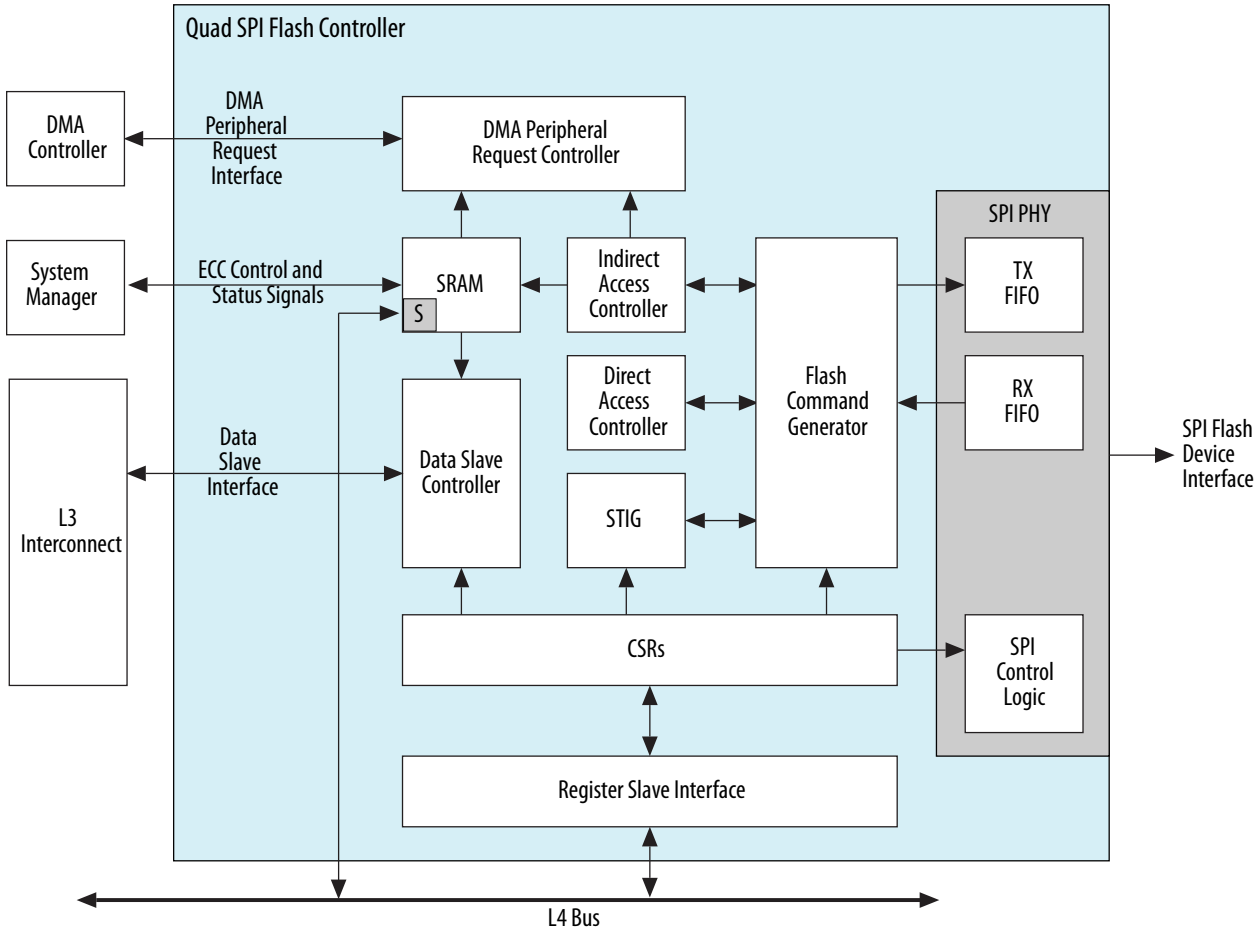
Supported Flash Devices for Arria 10 SoC

For more information, refer to the supported QSPI flash devices section on this page.

(44) The quad SPI controller supports any device frequencies, but this speed is limited by the supported flash devices.

Quad SPI Flash Controller Block Diagram and System Integration

Figure 15-1: Quad SPI Flash Controller Block Diagram and System Integration



The quad SPI controller consists of the following blocks and interfaces:

- Register slave interface - Provides access to the control and status registers (CSRs)
- Data slave controller - Interface and controller that provides the following functionality:
  - Performs data transfers to and from the level 3 (L3) interconnect
  - Validates incoming accesses
  - Performs byte or half-word reordering
  - Performs write protection
  - Forwards transfer requests to direct and indirect controller
- Direct access controller - provides memory-mapped slaves direct access to the flash memory
- Indirect access controller - provides higher-performance access to the flash memory through local buffering and software transfer requests
- Software triggered instruction generator (STIG) - generates flash commands through the flash command register (`flashcmd`) and provides low-level access to flash memory

- Flash command generator - generates flash command and address instructions based on instructions from the direct and indirect access controllers or the STIG
- DMA peripheral request controller - issues requests to the DMA peripheral request interface to communicate with the HPS DMA controller
- SPI PHY - serially transfers data and commands to the external SPI flash devices

The static RAM (SRAM) connected to the indirect access controller, DMA peripheral request controller, and data slave controller has an error correction code (ECC) controller built-in to provide ECC protection. The ECC controller is able to detect single-bit and double-bit errors, and correct the single-bit errors. The ECC operation and functionality is programmable via the ECC register slave interface, as shown in **Figure 15-1**. The ECC register interface provides host access to configure the ECC logic as well as inject bit errors into the memory. It also provides host access to memory initialization hardware used to clear out the memory contents including the ECC bits. The ECC controller generates interrupts upon occurrences of single and double-bit errors, and the interrupt signals are connected to the system manager.

Quad SPI Flash Controller Signal Description

The quad SPI controller provides four chip select outputs to allow control of up to four external quad SPI flash devices. The outputs serve different purposes depending on whether the device is used in single, dual, or quad operation mode. The following table lists the I/O pin use of the quad SPI controller interface signals for each operation mode. For more information on which signals are available to the FPGA and HPS I/O, refer to the *HPS Component Interfaces* chapter.

Table 15-1: Interface Pins

Signal	Pin	Mode	Direction	Function
`qspi_io0_i`	`IO0`	Single	Output	Data output 0
`qspi_io0_o` `qspi_mo_oe[0]`		Dual or quad	Bidirectional	Data I/O 0
`qspi_io1_i`	`IO1`	Single	Input	Data input 0
`qspi_io1_o` `qspi_mo_oe[1]`		Dual or quad	Bidirectional	Data I/O 1
`qspi_io2_i`	`IO2_WPN`	Single or dual	Output	Active low write protect
`qspi_io2_wpn_o` `qspi_mo_oe[2]`		Quad	Bidirectional	Data I/O 2
`qspi_io3_i`	`IO3_HOLD`	Single, dual, or quad	Bidirectional	Data I/O 3
`qspi_io3_hold_o` `qspi_mo_oe[3]`				

Signal	Pin	Mode	Direction	Function
qspi_ss_o[0]	SS0	Single, dual, or quad	Output	Active low slave select 0
qspi_ss_o[1]	SS1			Active low slave select 1
qspi_ss_o[2]	SS2			Active low slave select 2
qspi_ss_o[3]	SS3			Active low slave select 3
qspi_sclk_out	CLK	Single	Output	QSPI serial clock output which connects to the FPGA core fabric
qspi_s2f_clk				QSPI serial clock output which connects to the FPGA clock network **Note:** Use the qspi_s2f_clk as the serial clock output to an external SPI device.

Functional Description of the Quad SPI Flash Controller

Overview

The quad SPI flash controller uses the register slave interface to select the operation modes and configure the data slave interface for data transfers. The quad SPI flash controller uses the data slave interface for direct and indirect accesses, and the register slave interface for software triggered instruction generator (STIG) operation and SPI legacy mode accesses.

Accesses to the data slave are forwarded to the direct or indirect access controller. If the access address is within the configured indirect address range, the access is sent to the indirect access controller.

Data Slave Interface

The quad SPI flash controller uses the data slave interface for direct, indirect, and SPI legacy mode accesses.

The data slave interface is 32 bits wide and permits byte, half-word, and word accesses. For write accesses, incrementing burst lengths of 1, 4, 8 and 16 are supported. For read accesses, all burst types and sizes are supported.

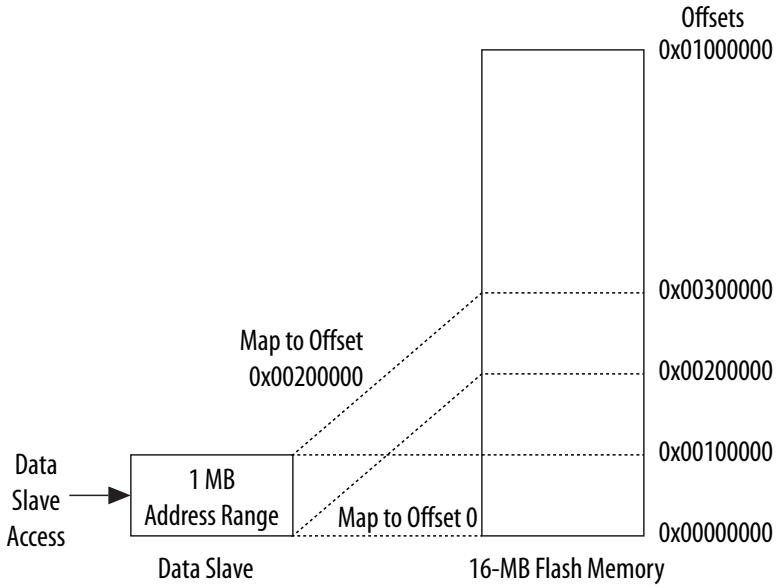
Direct Access Mode

In direct access mode, an access to the data slave triggers a read or write command to the flash memory. To use the direct access mode, enable the direct access controller with the enable direct access controller bit (`endiracc`) of the quad SPI configuration register (`cfg`).

An external master, for example a processor, triggers the direct access controller with a read or write operation to the data slave interface. The data slave exposes a 1 MB window into the flash device. You can remap this window to any 1 MB location within the flash device.

Data Slave Remapping Example

Figure 15-2: Data Slave Remapping Example



To remap the data slave to access other 1 MB regions of the flash device, enable address remapping in the enable ARM® AMBA® advanced high speed bus (AHB) address remapping field (`enahbremap`) of the `cfg` register. All incoming data slave accesses remap to the offset specified in the remap address register (`remapaddr`).

The 20 LSBs of incoming addresses are used for accessing the 1 MB region and the higher bits are ignored.

Note: The quad SPI controller does not issue any error status for accesses that lie outside the connected flash memory space.

AHB

The data slave interface is throttled as the read or write burst is carried out. The latency is designed to be as small as possible and is kept to a minimum when the use of XIP read instructions are enabled.

FLASH erase operations, which may be required before a page write, are triggered by software using the documented programming interface. They are not issued automatically.

Once a page program cycle has been started, the QSPI Flash Controller will automatically poll for the write cycle to complete before allowing any further data slave interface accesses to complete. This is achieved by holding any subsequent AHB direct accesses in wait state.

Indirect Access Mode

In indirect access mode, flash data is temporarily buffered in the quad SPI controller's static RAM (SRAM). Software controls and triggers indirect accesses through the register slave interface. The controller transfers data through the data slave interface.

Indirect Read Operation

An indirect read operation reads data from the flash memory, places the data into the SRAM, and transfers the data to an external master through the data slave interface. The indirect read operations are controlled by the following registers:

- Indirect read transfer register (`indrd`)
- Indirect read transfer watermark register (`indrdwater`)
- Indirect read transfer start address register (`indrdstaddr`)
- Indirect read transfer number bytes register (`indrdcnt`)
- Indirect address trigger register (`indaddrtrig`)

These registers need to be configured prior to issuing indirect read operations. The start address needs to be defined in the `indrdstaddr` register and the total number of bytes to be fetched is specified in the `indircnt` register. Writing 1 to the start indirect read bit (`start`) of the `indrd` register triggers the indirect read operation from the flash memory to populate the SRAM with the returned data.

To read data from the flash device into the SRAM, an external master issues 32-bit read transactions to the data slave interface. The address of the read access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit reads until the last word of an indirect transfer. On the final read, the external master may issue a 32-bit, 16-bit or 8-bit read to complete the transfer. If there are less than four bytes of data to read on the last transfer, the external master can still issue a 32-bit read and the quad SPI controller will pad the upper bits of the response data with zeros.

Assuming the requested data is present in the SRAM at the time the data slave read is received by the quad SPI controller, the data is fetched from SRAM and the response to the read burst is achieved with minimum latency. If the requested data is not immediately present in the SRAM, the data slave interface enters a wait state until the data has been read from flash memory into SRAM. Once the data has been read from SRAM by the external master, the quad SPI controller frees up the associated resource in the SRAM. If the SRAM is full, reads on the SPI interface are backpressured until space is available in the SRAM. The quad SPI controller completes any current read burst, waits for SRAM to free up, and issues a new read burst at the address where the previous burst was terminated.

The processor can also use the SRAM fill level in the SRAM fill register (`sramfill`) to control when data should be fetched from the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indrdwater` register. When the SRAM fill level passes the watermark level, the indirect transfer watermark interrupt is generated. You can disable this watermark feature by writing a value of all zeroes to the `indrdwater` register.

For the final bytes of data read by the quad SPI controller and placed in the SRAM, if the watermark level is greater than zero, the indirect transfer watermark interrupt is generated even when the actual SRAM fill level has not risen above the watermark.

If the address of the read access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the read uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect read bit (`cancel`) of the `indrd` register to 1. For more information, refer to the "Indirect Read Operation with DMA Disabled" section.

Related Information

Indirect Read Operation with DMA Disabled on page 15-17

Indirect Write Operation

An indirect write operation programs data from the SRAM to the flash memory. The indirect write operations are controlled by the following registers:

- Indirect write transfer register (`indwr`)
- Indirect write transfer watermark register (`indwrwater`)
- Indirect write transfer start address register (`indwrstaddr`)
- Indirect write transfer number bytes register (`indwrcnt`)
- `indaddrtrig` register

These registers need to be configured prior to issuing indirect write operations. The start address needs to be defined in the `indwrstaddr` register and the total number of bytes to be written is specified in the `indwrcnt` register. The start indirect write bit (`start`) of the `indwr` register triggers the indirect write operation from the SRAM to the flash memory.

To write data from the SRAM to the flash device, an external master issues 32-bit write transactions to the data slave. The address of the write access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit writes until the last word of an indirect transfer. On the final write, the external master may issue a 32-bit, 16-bit or 8-bit write to complete the transfer. If there are less than four bytes of data to write on the last transfer, the external master can still issue a 32-bit write and the quad SPI controller discards the extra bytes.

The SRAM size can limit the amount of data that the quad SPI controller can accept from the external master. If the SRAM is not full at the point of the write access, the data is pushed to the SRAM with minimum latency. If the external master attempts to push more data to the SRAM than the SRAM can accept, the quad SPI controller backpressures the external master with wait states. When the SRAM resource is freed up by pushing the data from SRAM to the flash memory, the SRAM is ready to receive more data from the external master. When the SRAM holds an equal or greater number of bytes than the size of a flash page, or when the SRAM holds all the remaining bytes of the current indirect transfer, the quad SPI controller initiates a write operation to the flash memory.

The processor can also use the SRAM fill level, in the `sramfill` register, to control when to write more data into the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indwrwater` register. When the SRAM fill level falls below the watermark level, an indirect transfer watermark interrupt is generated to tell the software to write the next page of data to the SRAM. Because the quad SPI controller initiates non-end-of-data writes to the flash memory only when the SRAM contains a full flash page of data, you must set the watermark level to a value greater than one flash page to avoid the system stalling. You can disable this watermark feature by writing a value of all ones to the `indwrwater` register.

If the address of the write access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the write uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect write bit (`cancel`) of the `indwr` register to 1. For more information, refer to the "Indirect Write Operation with DMA Disabled" section.

Related Information

Indirect Write Operation with DMA Disabled on page 15-18

Consecutive Reads and Writes

It is possible to trigger two indirect operations at a time by triggering the `start` bit of the `indrd` or `indwr` register twice in short succession. The second operation can be triggered while the first operation is in progress. For example, software may trigger an indirect read or write operation while an indirect write operation is in progress. The corresponding start and count registers must be configured properly before software triggers each transfer operation.

This approach allows for a short turnaround time between the completion of one indirect operation and the start of a second operation. Any attempt to queue more than two operations causes the indirect read reject interrupt to be generated.

SPI Legacy Mode

SPI legacy mode allows software to access the internal TX FIFO and RX FIFO buffers directly, thus bypassing the direct, indirect and STIG controllers. Software accesses the TX FIFO and RX FIFO buffers by writing any value to any address through the data slave while legacy mode is enabled. You can enable legacy mode with the legacy IP mode enable bit (`enlegacyip`) of the `cfg` register.

Legacy mode allows the user to issue any flash instruction to the flash device, but imposes a heavy software overhead in order to manage the fill levels of the FIFO buffers effectively. The legacy SPI mode is bidirectional in nature, with data continuously being transferred both directions while the chip select is enabled. If the driver only needs to read data from the flash device, dummy data must be written to ensure the chip select stays active, and vice versa for write transactions.

For example, to perform a basic read of four bytes to a flash device that has three address bytes, software must write a total of eight bytes to the TX FIFO buffer. The first byte would be the instruction opcode, the next three bytes are the address, and the final four bytes would be dummy data to ensure the chip select stays active while the read data is returned. Similarly, because eight bytes were written to the TX FIFO buffer, software should expect eight bytes to be returned in the RX FIFO buffer. The first four bytes of this would be discarded, leaving the final four bytes holding the data read from the device.

Because the TX FIFO and RX FIFO buffers are four bytes deep each, software must maintain the FIFO buffer levels to ensure the TX FIFO buffer does not underflow and the RX FIFO buffer does not overflow. Interrupts are provided to indicate when the fill levels pass the watermark levels, which are configurable through the TX threshold register (`txtresh`) and RX threshold register (`rxtresh`).

Register Slave Interface

The quad SPI flash controller uses the register slave interface to configure the quad SPI controller through the quad SPI configuration registers, and to access flash memory under software control, through the `flashcmd` register in the STIG.

STIG Operation

The Software Triggered Instruction Generator (STIG) is used to access the volatile and non-volatile configuration registers, the legacy SPI status register, and other status and protection registers. The STIG also is used to perform ERASE functions. The direct and indirect access controllers are used only to

transfer data. The `flashcmd` register uses the following parameters to define the command to be issued to the flash device:

- Instruction opcode
- Number of address bytes
- Number of dummy bytes
- Number of write data bytes
- Write data
- Number of read data bytes

The address is specified through the flash command address register (`flashcmdaddr`). Once these settings have been specified, software can trigger the command with the execute command field (`execcmd`) of the `flashcmd` register and wait for its completion by polling the command execution status bit (`cmdexecstat`) of the `flashcmd` register. A maximum of eight data bytes may be read from the flash command read data lower (`flashcmdrddatalo`) and flash command read data upper (`flashcmdrddataup`) registers or written to the flash command write data lower (`flashcmdwrdatalo`) and flash command write data upper (`flashcmdwrdataup`) registers per command.

Commands issued through the STIG have a higher priority than all other read accesses and therefore interrupt any read commands being requested by the direct or indirect controllers. However, the STIG does not interrupt a write sequence that may have been issued through the direct or indirect access controller. In these cases, it might take a long time for the `cmdexecstat` bit of the `flashcmd` register indicates the operation is complete.

Note: Altera recommends using the STIG instead of the SPI legacy mode to access the flash device registers and perform erase operations.

Local Memory Buffer

The SRAM local memory buffer is a 128 by 32-bit (512 total bytes) memory and includes support for error correction code (ECC). The ECC controller is able to detect single-bit and double-bit errors, and correct the single-bit errors. The ECC operation and functionality is programmable through the ECC register slave interface, as shown in **Figure 15-1**. The ECC register interface provides host access to configure the ECC logic as well as inject bit errors into the memory. It also provides host access to memory initialization hardware used to clear out the memory contents including the ECC bits.

To prevent spurious ECC errors, software must use the memory initialization block in the ECC controller to initialize the entire memory data and ECC bits. The initialization block clears the memory data. Enabling initialization in the ECC Control Register is independent of enabling the ECC. The ECC controller generates interrupts upon occurrences of single- and double-bit errors. The interrupt requests are sent to the system manager which routes them to the General Interrupt Controller (GIC).

The SRAM has two partitions, with the lower partition reserved for indirect read operations and the upper partition for indirect write operations. The size of the partitions is specified in the SRAM partition register (`srampart`), based on 32-bit word sizes. For example, to specify four bytes of storage, write the value 1. The value written to the indirect read partition size field (`addr`) defines the number of entries reserved for indirect read operations. For example, write the value 32 (0x20) to partition the 128-entry SRAM to 32 entries (25%) for read usage and 96 entries (75%) for write usage.

DMA Peripheral Request Controller

The DMA peripheral request controller is only used for the indirect mode of operation where data is temporarily stored in the SRAM. The quad SPI flash controller uses the DMA peripheral request interface to trigger the external DMA into performing data transfers between memory and the quad SPI controller.

There are two DMA peripheral request interfaces, one for indirect reads and one for indirect writes. The DMA peripheral request controller can issue two types of DMA requests, single or burst, to the external DMA. The number of bytes for each single or burst request is specified in the number of single bytes (`numsglreqbytes`) and number of burst bytes (`numburstreqbytes`) fields of the DMA peripheral register (`dmaper`). The DMA peripheral request controller splits the total amount of data to be transferred into a number of DMA burst and single requests by dividing the total number of bytes by the number of bytes specified in the burst request, and then dividing the remainder by the number of bytes in a single request.

Note: When programming the DMA controller, the burst request size must match the burst request size set in the quad SPI controller to avoid quickly reaching an overflow or underflow condition.

For indirect reads, the DMA peripheral request controller only issues DMA requests after the data has been retrieved from flash memory and written to SRAM. The rate at which DMA requests are issued depends on the watermark level. The `indrdwater` register defines the minimum fill level in bytes at which the DMA peripheral request controller can issue the DMA request. The higher this number is, the more data that must be buffered in SRAM before the external DMA moves the data. When the SRAM fill level passes the watermark level, the transfer watermark reached interrupt is generated.

For example, consider the following conditions:

- The total amount of data to be read using indirect mode is 256 bytes
- The SRAM watermark level is set at 128 bytes
- Software configures the burst type transfer size to 64 bytes

Under these conditions, the DMA peripheral request controller issues the first DMA burst request when the SRAM fill level passes 128 bytes (the watermark level). The DMA peripheral request controller triggers consecutive DMA burst requests as long as there is sufficient data in the SRAM to perform burst type requests. In this example, DMA peripheral request controller can issue at least two consecutive DMA burst requests to transfer a total of 128 bytes. If there is sufficient data in the SRAM, the DMA peripheral request controller requests the third DMA burst immediately. Otherwise the DMA peripheral request controller waits for the SRAM fill level to pass the watermark level again to trigger the next burst request. When the watermark level is triggered, there is sufficient data in the SRAM to perform the third and fourth burst requests to complete the entire transaction.

For the indirect writes, the DMA peripheral request controller issues DMA requests immediately after the transfer is triggered and continues to do so until the entire indirect write transfer has been transferred. The rate at which DMA requests are issued depends on the watermark level. The `indwrwater` register defines the maximum fill level in bytes at which the controller can issue the first DMA burst or single request. When the SRAM fill level falls below the watermark level, the transfer watermark reached interrupt is generated. When there is one flash page of data in the SRAM, the quad SPI controller initiates the write operation from SRAM to the flash memory.

Software can disable the DMA peripheral request interface with the `endma` field of the `cfg` register. If a master other than the DMA performs the data transfer for indirect operations, the DMA peripheral request interface must be disabled. By default, the indirect watermark registers are set to zero, which means the DMA peripheral request controller can issue DMA request as soon as possible.

DMA Controller on page 16-1

Arbitration between Direct/Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

1. The Indirect Access Write
2. The Direct Access Write
3. The STIG
4. The Direct Access Read
5. The Indirect Access Read

Each controller is back pressured while waiting to be serviced.

Configuring the Flash Device

For read and write accesses, software must initialize the device read instruction register (`devrd`) and the device write instruction register (`devwr`). These registers include fields to initialize the instruction opcodes that should be used as well as the instruction type, and whether the instruction uses single, dual or quad pins for address and data transfer. To ensure the quad SPI controller can operate from a reset state, the opcode registers reset to opcodes compatible with single I/O flash devices.

The quad SPI flash controller uses the instruction transfer width field (`instwidth`) of the `devrd` register to set the instruction transfer width for both reads and writes. There is no `instwidth` field in the `devwr` register. If instruction type is set to dual or quad mode, the address transfer width (`addrwidth`) and data transfer width (`datawidth`) fields of both registers are redundant because the address and data type is based on the instruction type. Thus, software can support the less common flash instructions where the opcode, address, and data are sent on two or four lanes. For most instructions, the opcodes are sent serially to the flash device, even for dual and quad instructions. One of the flash devices that supports instructions that can send the opcode over two or four lanes is the Micron N25Q128. For reference, **Table 15-2** and **Table 15-3** show how software should configure the quad SPI controller for each specific read and write instruction, respectively, supported by the Micron N25Q128 device.

Table 15-2: Quad SPI Configuration for Micron N25Q128 Device (Read Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Read	1	1	1	0	0	0
Fast read	1	1	1	0	0	0
Dual output fast read (DOFR)	1	1	2	0	0	1
Dual I/O fast read (DIOFR)	1	2	2	0	1	1

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Quad output fast read (QOFR)	1	1	4	0	0	2
Quad I/O fast read (QIOFR)	1	4	4	0	2	2
Dual command fast read (DCFR)	2	2	2	1	Don't care	Don't care
Quad command fast read (QCFR)	4	4	4	2	Don't care	Don't care

Table 15-3: Quad SPI Configuration for Micron N25Q128 Device (Write Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Page program	1	1	1	0	0	0
Dual input fast program (DIFP)	1	1	2	0	0	1
Dual input extended fast program (DIEFP)	1	2	2	0	1	1

Quad input extended fast program (QIEFP)	1	4	4	0	2	2
Dual command fast program (DCFP)	2	2	2	1	Don't care	Don't care
Quad command fast program (QCFP)	4	4	4	2	Don't care	Don't care

XIP Mode

The quad SPI controller supports XIP mode, if the flash devices support XIP mode. Depending on the flash device, XIP mode puts the flash device in read-only mode, reducing command overhead.

The quad SPI controller must instruct the flash device to enter XIP mode by sending the mode bits. When the enter XIP mode on next read bit (`enterxipnextrd`) of the `cfg` register is set to 1, the quad SPI controller and the flash device are ready to enter XIP mode on the next read instruction. When the enter XIP mode immediately bit (`enterxipimm`) of the `cfg` register is set to 1, the quad SPI controller and flash device enter XIP mode immediately.

When the `enterxipnextrd` or `enterxipimm` bit of the `cfg` register is set to 0, the quad SPI controller and flash device exit XIP mode on the next read instruction. For more information, refer to the *"XIP Mode Operations"* section.

Related Information

XIP Mode Operations on page 15-19

Write Protection

You can program the controller to write protect a specific region of the flash device. The protected region is defined as a set of blocks, specified by a starting and ending block. Writing to an area of protected flash region memory generates an error and triggers an interrupt.

You define the block size by specifying the number of bytes per block through the number of bytes per block field (`bytespersubsector`) of the device size register (`devsz`). The lower write protection register (`lowwrprot`) specifies the first flash block in the protected region. The upper write protection register (`uppwrprot`) specifies the last flash block in the protected region.

The write protection enable bit (`en`) of the write protection register (`wrprot`) enables and disables write protection. The write protection inversion bit (`inv`) of the `wrprot` register flips the definition of protection so that the region specified by `lowwrprt` and `uppwrprt` is unprotected and all flash memory outside that region is protected.

Data Slave Sequential Access Detection

The quad SPI flash controller detects sequential accesses to the data slave interface by comparing the current access with the previous access. An access is sequential when it meets the following conditions:

- The address of the current access sequentially follows the address of the previous access.
- The direction of the current access (read or write) is the same as previous access.
- The size of the current access (byte, half-word, or word) is the same as previous access.

When the access is detected as nonsequential, the sequential access to the flash device is terminated and a new sequential access begins. Altera recommends accessing the data slave sequentially. Sequential access has less command overhead, and therefore, increases data throughput.

Clocks

There are two clock inputs to the quad SPI controller: `l4_mp_clk` and `l4_main_clk`; and one clock output: `qspi_clk`. The quad SPI flash controller uses the `l4_mp_clk` clock to clock the data slave transfers and register slave accesses. The `l4_main_clk` clock is the reference clock for the quad SPI controller and is used to serialize the data and drive the external SPI interface. The `qspi_clk` clock is the generated clock source for the connected flash devices.

The following is true for the following reference clocks:

- l4_main_clk should be greater than l4_mp_clk
- l4_main_clk must be greater than two times qspi_clk

The qspi_clk clock is derived by dividing down the reference clock, l4_main_clk clock by the baud rate divisor field (bauddiv) of the cfg register.

Related Information

Clock Manager on page 2-1

Clock Gating

You can clock gate qspi_ref_clk through software. By programming the qspiclken bit of the en register in the perpllgrp you can enable or disable the qspi_ref_clk to the QSPI Controller.

Related Information

Clock Manager Address Map and Register Definitions on page 2-18

Resets

A single reset signal (qspi_flash_rst_n) is provided as an input to the quad SPI controller. The reset manager drives the reset signal to the ECC controller on a cold or warm reset. This resets the logic inside the ECC controller.

Related Information

Reset Manager on page 3-1

Taking the Quad SPI Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

All interrupt sources are combined to create a single level-sensitive, active-high interrupt (qspi_intr). Software can determine the source of the interrupt by reading the interrupt status register (irqstat). By default, the interrupt source is cleared when software writes a one (1) to the interrupt status register. The interrupts are individually maskable through the interrupt mask register (irqmask). **Table 15-4** lists the interrupt sources in the irqstat register.

Table 15-4: Interrupt Sources in the irqstat Register

Interrupt Source	Description
Underflow detected	When 0, no underflow has been detected. When 1, the data slave write data is being supplied too slowly. This situation can occur when data slave write data is being supplied too slowly to keep up with the requested write operation This bit is reset only by a system reset and cleared only when a 1 is written to it.
Indirect operation complete	The controller has completed a triggered indirect operation.
Indirect read reject	An indirect operation was requested but could not be accepted because two indirect operations are already in the queue.
Protected area write attempt	A write to a protected area was attempted and rejected.
Illegal data slave access detected	An illegal data slave access has been detected. Data slave wrapping bursts and the use of split and retry accesses can cause this interrupt. It is usually an indicator that soft masters in the FPGA fabric are attempting to access the HPS in an unsupported way.
Transfer watermark reached	The indirect transfer watermark level has been reached.
Receive overflow	This condition occurs only in legacy SPI mode. When 0, no overflow has been detected. When 1, an over flow to the RX FIFO buffer has occurred. This bit is reset only by a system reset and cleared to zero only when this register is written to. If a new write to the RX FIFO buffer occurs at the same time as a register is read, this flag remains set to 1.
TX FIFO not full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is full. When 1, the TX FIFO buffer is not full.
TX FIFO full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is not full. When 1, the TX FIFO buffer is full.
RX FIFO not empty	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is empty. When 1, the RX FIFO buffer is not empty.

Interrupt Source	Description
RX FIFO full	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is not full. When 1, the RX FIFO buffer is full.
Indirect read partition overflow	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation

Quad SPI Flash Controller Programming Model

Setting Up the Quad SPI Flash Controller

The following steps describe how to set up the quad SPI controller:

1. Wait until any pending operation has completed.
2. Disable the quad SPI controller with the quad SPI enable field (`en`) of the `cfg` register.
3. Update the `instwidth` field of the `devrd` register with the instruction type you wish to use for indirect and direct writes and reads.
4. If mode bit enable bit (`enmodebits`) of the `devrd` register is enabled, update the mode bit register (`modebit`).
5. Update the `devsz` register as needed.
   Parts or all of this register might have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used.
6. Update the device delay register (`delay`).
   This register allows the user to adjust how the chip select is driven after each flash access. Each device may have different timing requirements. If the serial clock frequency is increased, these timing requirements become more critical. The numbers specified in this register are based on the period of the `qspi_ref_clk` clock. For example, some devices need 50 ns minimum time before the slave select can be reasserted after it has been deasserted. When the device is operating at 100 MHz, the clock period is 10 ns, so 40 ns extra is required. If the `qspi_ref_clk` clock is running at 400 MHz (2.5 ns period), specify a value of at least 16 to the clock delay for chip select deassert field (`nss`) of the `delay` register.
7. Update the `remapaddr` register as needed.
   This register only affects direct access mode.
8. Set up and enable the write protection registers (`wrprot`, `lowwrprot`, and `uppwrprot`) when write protection is required.
9. Enable required interrupts through the `irqmask` register.
10. Set up the `bauddiv` field of the `cfg` register to define the required clock frequency of the target device.
11. Update the read data capture register (`rddatacap`) if you need to change the auto-filled value.

    This register delays when the read data is captured and can help when the read data path from the device to the quad SPI controller is long and the device clock frequency is high.
12. Enable the quad SPI controller with the `en` field of the `cfg` register.

Indirect Read Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA disabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-16 section.
2. Set the flash memory start address in the `indrdstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the `irqmask` register.
6. If the watermark level is used, set the SRAM watermark level through the `indrdwater` register.
7. Start the indirect read operation by setting the `start` field of the `indrd` register to 1.
8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient data in the SRAM.
9. Issue a read transaction to the indirect address to access the SRAM. Repeat **step 8** if more read transactions are needed to complete the indirect read transfer.
10. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the indirect completion status bit (`ind_ops_done_status`) of the `indrd` register.

Indirect Read Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA enabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-16 section.
2. Set the flash memory start address in the `indrdstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indrdwater` register to control the rate DMA requests are issued.
7. Start an indirect read access by setting the `start` field of the `indrd` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the `ind_ops_done_status` field of the `indrd` register.

Indirect Write Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA disabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-16 section.
2. Set the flash memory start address in the `indwrstaddr` register.
3. Set up the number of bytes to be transferred in the `indwrcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the interrupt mask register (`irqmask`).
6. Optionally set the SRAM watermark level in the `indwrwater` register to control the rate DMA requests are issued. The value set must be greater than one flash page. For more information, refer to the **Indirect Write Operation** on page 15-7 section.
7. Start the indirect write operation by setting the `start` field of the `indwr` register to 1.
8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient space in the SRAM.
9. Issue a write transaction to the indirect address to write one flash page of data to the SRAM. Repeat **step 8** if more write transactions are needed to complete the indirect write transfer. The final write may be less than one page of data.

XIP Mode Operations

XIP mode is supported in most SPI flash devices. However, flash device manufacturers do not use a consistent standard approach. Most use signature bits that are sent to the device immediately following the address bytes. Some devices use signature bits and also require a flash device configuration register write to enable XIP mode.

Entering XIP Mode

Micron Quad SPI Flash Devices with Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device with support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x80.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Micron Quad SPI Flash Devices without Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device without support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses will be sent to the flash device.
3. Ensure XIP mode is enabled in the flash device by setting the volatile configuration register (VCR) bit 3 to 1. Use the `flashcmd` register to issue the VCR write command.
4. Set the XIP mode bits in the `modebit` register to 0x00.
5. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
6. Re-enable the direct access controller and, if required, the indirect access controller.

Winbond Quad SPI Flash Devices

To enter XIP mode in a Winbond quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x20.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Spansion Quad SPI Flash Devices

To enter XIP mode a Spansion quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0xA0.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Exiting XIP Mode

To exit XIP mode, perform the following steps:

1. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
2. Restore the mode bits to the values before entering XIP mode, depending on the flash device and manufacturer.
3. Set the `enterxipnextrd` bit of the `cfg` register to 0.

The flash device must receive a read instruction before it can disable its internal XIP mode state. Thus, XIP mode internally stays active until the next read instruction is serviced. Ensure that XIP mode is disabled before the end of any read sequence.

XIP Mode at Power on Reset

Some flash devices can be XIP-enabled as a nonvolatile configuration setting, allowing the flash device to enter XIP mode at power-on reset (POR) without software intervention. Software cannot discover the XIP state at POR through flash status register reads because an XIP-enabled flash device can only be accessed through the XIP read operation. If you known the device will enter XIP mode at POR, have your initial boot software configure the `modebit` register and set the `enterxipimm` bit of the `cfg` register to 1.

If you do not know in advance whether or not the device will enter XIP mode at POR, have your initial boot software issue an XIP mode exit command through the `flashcmd` register, then follow the steps in the *"Entering XIP Mode"* section. Software must be aware of the mode bit requirements of the device, because XIP mode entry and exit varies by device.

cfg Fields

Bit	Name	Description	Access	Reset
31	idle	This is a STATUS read-only bit. Note this is a retimed signal, so there will be some inherent delay on the generation of this status signal. **Value** **Description** 0 NOTSET 1 SET	RO	0x1
30:23	config_resv2_fld		RO	0x0

Bit	Name	Description	Access	Reset
22:19	bauddiv	SPI baud rae = (master reference clock) baud_rate_divisor Value — Description 0 — BAUD2 1 — BAUD4 2 — BAUD6 3 — BAUD8 4 — BAUD10 5 — BAUD12 6 — BAUD14 7 — BAUD16 8 — BAUD18 9 — BAUD20 10 — BAUD22 11 — BAUD24 12 — BAUD26 13 — BAUD28 14 — BAUD30 15 — BAUD32	RW	0xF

Bit	Name	Description	Access	Reset
18	enterxipimm	Value=0 : If XIP is enabled, then setting to 0 will cause the controller to exit XIP mode on the next READ instruction. Value=1 : Operate the device in XIP mode immediately Use this register when the external device wakes up in XIP mode (as per the contents of its non- volatile configuration register). The controller will assume the next READ instruction will be passed to the device as an XIP instruction, and therefore will not require the READ opcode to be transferred. Note: To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only after the next READ instruction is executed. Software therefore should ensure that at least one READ instruction is requested after resetting this bit in order to be sure that XIP mode is exited. **Value** **Description** 0 DISABLE 1 ENABLE	RW	0x0

Bit	Name	Description	Access	Reset
17	enterxipnextrd	Value=0 : If XIP is enabled, then setting to 0 will cause the controller to exit XIP mode on the next READ instruction. Value=1 : If XIP is disabled, then setting to ? 1? will inform the controller that the device is ready to enter XIP on the next READ instruction. The controller will therefore send the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register after the controller has ensured the FLASH device has been configured to be ready to enter XIP mode. Note : To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only AFTER the next READ instruction is executed. Software should therefore ensure that at least one READ instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited. **Value** **Description** 0 DISABLE 1 ENABLE	RW	0x0
16	enahbremap	(Direct Access Mode Only) When set to 1, the incoming AHB address will be adapted and sent to the FLASH device as (address + N), where N is the value stored in the remap address register. **Value** **Description** 0 DISABLE 1 ENABLE	RW	0x0

Bit	Name	Description	Access	Reset
15	endma	Set to 1 to enable the DMA handshaking logic. When enabled the QSPI will trigger DMA transfer requests via the DMA peripheral interface. Set to 0 to disable **Value** / **Description** 0 DISABLE 1 ENABLE	RW	0x0
14	wp	Set to drive the Write Protect pin of the FLASH device. This is resynchronized to the generated memory clock as necessary. **Value** / **Description** 0 WRTPROTOFF 1 WRPROTON	RW	0x0
13:10	percslines	Peripheral chip select lines If pdec = 0, ss[3:0] are output thus: ss[3:0] n_ss_out[3:0] xxx0 1110 xx01 1101 x011 1011 0111 0111 1111 1111 (no peripheral selected) else ss[3:0] directly drives n_ss_out[3:0]	RW	0x0
9	perseldec	0 : only 1 of 4 selects n_ss_out[3:0] is active 1 : allow external 4-to-16 decode (n_ss_out = ss) **Value** / **Description** 0 SEL1OF4 1 SEL4TO16	RW	0x0

Bit	Name	Description	Access	Reset
8	enlegacyip	0 : Use Direct Access Controller/ Indirect Access Controller 1 : legacy Mode is enabled. In this mode, any write to the controller via the AHB interface is serialized and sent to the FLASH device. Any valid AHB read will pop the internal RX-FIFO, retrieving data that was forwarded by the external FLASH device on the SPI lines,4,2 or 1 byte transfers are permitted and controlled via the HSIZE input. **Value** **Description** 0 DIMODE 1 LEGMODE	RW	0x0
7	endiracc	0 : disable the Direct Access Controller once current transfer of the data word (FF_W) is complete. 1 : enable the Direct Access Controller When the Direct Access Controller and Indirect Access Controller are both disabled, all AHB requested are completed with an error response. **Value** **Description** 0 DISABLE 1 ENABLE	RW	0x0
6:3	config_resv1_fld		RO	0x0
2	selclkphase	Selects whether the clock is in an active or inactive phase outside the SPI word. 0 : the SPI clock is active outside the word 1 : the SPI clock is inactive outside the word **Value** **Description** 0 ACTIVE 1 INACTIVE	RW	0x0

Bit	Name	Description	Access	Reset
1	selclkpol	0 : the SPI clock is quiescent low 1 : the SPI clock is quiescent high **Value** **Description** 0 HIGH 1 LOW	RW	0x0
0	en	0 : disable the QSPI once current transfer of the data word (FF_W) is complete. 1 : enable the QSPI When spi_enable = 0, all output enables are inactive and all pins are set to input mode. **Value** **Description** 0 DISABLE 1 ENABLE	RW	0x0

delay

This register is used to introduce relative delays into the generation of the master output signals. All timings are defined in cycles of the SPI REFERENCE CLOCK/ext_clk, defined in this table as SPI master ref clock.

Module Instance	Base Address	Register Address
i_qspi_qspiregs	0xFF809000	0xFF80900C

Offset: 0xC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
nss RW 0x0								btwn RW 0x0

after RW 0x0								init RW 0x0							

delay Fields

Bit	Name	Description	Access	Reset
31:24	nss	Delay in master reference clocks for the length that the master mode chip select outputs are de-asserted between transactions. The minimum delay is always SCLK period to ensure the chip select is never re-asserted within an SCLK period.	RW	0x0
23:16	btwn	Delay in master reference clocks between one chip select being de-activated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.	RW	0x0
15:8	after	Delay in QSPI_CLK clocks between the last bit of the current transaction and deasserting the device chip select (QSPI_SS). By default (when this field is 0x0), QSPI_SS is deasserted on the last falling edge of SCLK_OUT at the completion of the current transaction. When this field is programmed with N, QSPI_SS is deasserted N QSPI_CLK clocks after the last falling edge of SCLK_OUT.	RW	0x0
7:0	init	Delay in master reference clocks between setting n_ss_out low and first bit transfer.	RW	0x0

rxthresh Fields

Bit	Name	Description	Access	Reset
31:4	rx_thresh_resv_fld		RO	0x0

Bit	Name	Description	Access	Reset
3:0	level	Defines the level at which the small RX FIFO not empty interrupt is generated	RW	0x1

irqstat

The status fields in this register are set when the described event occurs and the interrupt is enabled in the mask register. When any of these bit fields are set, the interrupt output is asserted high. The fields are each cleared by writing a 1 to the field. Note that bit fields 6 thru 10 are only valid when legacy SPI mode is active.

Module Instance	Base Address	Register Address

irqstat Fields

Bit	Name	Description	Access	Reset
31:13	irq_stat_resv_fld		RO	0x0

Bit	Name	Description	Access	Reset
12	indsramfull	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation Value: 0 — Description: RDPARTNOTFULL Value: 1 — Description: RDPARTFULL	RW	0x0
11	rxfull	Current FIFO status can be ignored in non-SPI legacy mode 0 : FIFO is not full 1 : FIFO is full Value: 0 — Description: NOTFULL Value: 1 — Description: FULL	RW	0x0
10	rxthreshcmp	Current FIFO status can be ignored in non-SPI legacy mode 0 : FIFO has less than RX THRESHOLD entries, 1 : FIFO has >= THRESHOLD entries Value: 0 — Description: LE Value: 1 — Description: GT	RW	0x0
9	txfull	Current FIFO status can be ignored in non-SPI legacy mode 0 : FIFO is not full, 1 : FIFO is full Value: 0 — Description: NOTFULL Value: 1 — Description: FULL	RW	0x0
8	txthreshcmp	Current FIFO status can be ignored in non-SPI legacy mode 0 : FIFO has >= THRESHOLD entries, 1 : FIFO has less than THRESHOLD entries Value: 0 — Description: GT Value: 1 — Description: LE	RW	0x1

Bit	Name	Description	Access	Reset
7	rxover	This should only occur in Legacy SPI mode. Set if an attempt is made to push the RX FIFO when it is full. This bit is reset only by a system reset and cleared only when this register is read. If a new push to the RX FIFO occurs coincident with a register read this flag will remain set. 0 : no overflow has been detected. 1 : an overflow has occurred. **Value** **Description** 0 NORCVOVER 1 RCVOVER	RW	0x0
6	indxfrlvl	Indirect Transfer Watermark Level Breached **Value** **Description** 0 NOWATERLVL 1 WATERLEVL	RW	0x0
5	illegalacc	Illegal AHB access has been detected. AHB wrapping bursts and the use of SPLIT/RETRY accesses will cause this error interrupt to trigger. **Value** **Description** 0 NOILLEGALAHB 1 ILLEGALAHB	RW	0x0
4	protwrattempt	Write to protected area was attempted and rejected. **Value** **Description** 0 NOWRITEPROT 1 WRITEPROT	RW	0x0

Bit	Name	Description	Access	Reset
3	indrdreject	Indirect operation was requested but could not be accepted. Two indirect operations already in storage. **Value** **Description** 0 NOINDIRECTREQ 1 INDIRECTREQ	RW	0x0
2	indopdone	Controller has completed last triggered indirect operation **Value** **Description** 0 NOINDIRECTOP 1 INDIRECTOP	RW	0x0
1	underflowdet	0 : no underflow has been detected 1 : underflow is detected and an attempt to transfer data is made when the small TX FIFO is empty. This may occur when AHB write data is being supplied too slowly to keep up with the requested write operation This bit is reset only by a system reset and cleared only when the register is read. **Value** **Description** 0 NOUNDERFLOW 1 UNDERFLOW	RW	0x0
0	mode_m_fail_fld	Mode M failure indicates the voltage on pin n_ss_in is inconsis-tent with the SPI mode. Set =1 if n_ss_in is low in master mode (multi-master contention). These conditions will clear the spi_enable bit and disable the SPI. This bit is reset only by a system reset and cleared only when this register is read. 0 : no mode fault has been detected 1 : a mode fault has occurred	RW	0x0

irqmask

0 : the interrupt for the corresponding interrupt status register bit is disabled. 1 : the interrupt for the corresponding interrupt status register bit is enabled.

flashcmdrddataup Fields

Bit	Name	Description	Access	Reset
31:0	data	This is the data that is returned by the FLASH device for any status or configuration read operation carried out by triggering the event in the control register. The register will be valid when the polling bit in the control register is low.	RW	0x0

flashcmdwrdatalo

Module Instance	Base Address	Register Address
i_qspi_qspiregs	0xFF809000	0xFF8090A8

Offset: 0xA8

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
data RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
data RW 0x0															

flashcmdwrdatalo Fields

Bit	Name	Description	Access	Reset
31:0	data	This is the command write data lower byte. This should be setup before triggering the command with execute field (bit 0) of the Flash Command Control register. It is the data that is to be written to the flash for any status or configuration write operation carried out by triggering the event in the Flash Command Control register.	RW	0x0

flashcmdwrdataup

Module Instance	Base Address	Register Address
i_qspi_qspiregs	0xFF809000	0xFF8090AC

Offset: 0xAC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
data RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
data RW 0x0															

flashcmdwrdataup Fields

Bit	Name	Description	Access	Reset
31:0	data	This is the command write data upper byte. This should be setup before triggering the command with execute field (bit 0) of the Flash Command Control register. It is the data that is to be written to the flash for any status or configuration write operation carried out by triggering the event in the Flash Command Control register.	RW	0x0

moduleid

qspi_ecc Address Map

Module Instance	Base Address	End Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C87FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
IP_REV_ID on page 11-315	0x0	32	RO	0x0	
CTRL on page 11-316	0x8	32	RW	0x0	ECC Control Register
INITSTAT on page 11-316	0xC	32	RW	0x0	This bit is used to set the initialize the memory and ecc to a known value
ERRINTEN on page 11-317	0x10	32	RW	0x0	Error Interrupt enable
ERRINTENS on page 11-318	0x14	32	RW	0x0	Error Interrupt set
ERRINTENR on page 11-319	0x18	32	RW	0x0	Error Interrupt reset.
INTMODE on page 11-320	0x1C	32	RW	0x0	Reads reflect SERRINTEN.
INTSTAT on page 11-320	0x20	32	RW	0x0	This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.
INTTEST on page 11-321	0x24	32	RW	0x0	This bits is used to test interrupt from ECC RAM to GIC
MODSTAT on page 11-322	0x28	32	RW	0x0	Counter feature status flag

Register	Offset	Width	Access	Reset Value	Description
DERRADDRA on page 11-323	0x2C	32	RO	0x0	This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.
SERRADDRA on page 11-323	0x30	32	RO	0x0	This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.
SERRCNTREG on page 11-324	0x3C	32	RW	0x0	Maximum counter value for single-bit error interrupt
ECC_Addrbus on page 11-325	0x40	32	RW	0x0	MSB bit of address is determined by ADR.
ECC_RData0bus on page 11-326	0x44	32	RO	0x0	Data will be read to this register field.
ECC_RData1bus on page 11-326	0x48	32	RO	0x0	Data will be read to this register field.
ECC_RData2bus on page 11-327	0x4C	32	RO	0x0	Data will be read to this register field.
ECC_RData3bus on page 11-328	0x50	32	RO	0x0	Data will be read to this register field.
ECC_WData0bus on page 11-328	0x54	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData1bus on page 11-329	0x58	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData2bus on page 11-330	0x5C	32	WO	0x0	Data from the register will be written to the RAM.
ECC_WData3bus on page 11-330	0x60	32	WO	0x0	Data from the register will be written to the RAM.

Register	Offset	Width	Access	Reset Value	Description
ECC_RDataecc0bus on page 11-331	0x64	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_RDataecc1bus on page 11-332	0x68	32	RO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc0bus on page 11-333	0x6C	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_WDataecc1bus on page 11-334	0x70	32	WO	0x0	The msb bit for the register is configured based on DAT parameter (RAM word size). Unimplemented bytes of this register will be reserved.
ECC_dbytectrl on page 11-335	0x74	32	RW	0x0	Max number of implemented byte enabled is DAT/8
ECC_accctrl on page 11-336	0x78	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_startacc on page 11-336	0x7C	32	RW	0x0	These bits determine which byte of data/ecc to write to RAM.
ECC_wdctrl on page 11-337	0x80	32	RW	0x0	Bits to Enable/Disable Watch Dog Timer
SERRLKUPA0 on page 11-338	0x90	32	RW	0x0	Single-bit error address in LOOKUP TABLE for PORTA.

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C841C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8420

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8424

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8428

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C842C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

DERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8430

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address 0x0						

SERRADDRA Fields

Bit	Name	Description	Access	Reset
6:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C843C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8440

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									ECC_AddrBUS 0x0						

ECC_Addrbus Fields

Bit	Name	Description	Access	Reset
6:0	ECC_AddrBUS	Address will be driven to RAM to either read or write the data. Address will be latched by the RAM when the Enbus is asserted.	RW	0x0

ECC_RData0bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8444

Offset: 0x44

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData0bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[31:0].	RO	0x0

ECC_RData1bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8448

Offset: 0x48

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECC_RDataBUS 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECC_RDataBUS 0x0															

ECC_RData1bus Fields

Bit	Name	Description	Access	Reset
31:0	ECC_RDataBUS	ECC_RDataBUS[63:32].	RO	0x0

ECC_RData2bus

Data will be read to this register field.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C844C

Offset: 0x4C

Access: RO

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved															DBEN 0x0

ECC_dbytectrl Fields

Bit	Name	Description	Access	Reset
0	DBEN	Byte or word enable for access.	RW	0x0

ECC_accctrl

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8478

Offset: 0x78

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							RDWR 0x0	Reserved						ECCOVR 0x0	DATAOVR 0x0

ECC_accctrl Fields

Bit	Name	Description	Access	Reset
8	RDWR	Control for read/write.	RW	0x0
1	ECCOVR	ECC Data Override.	RW	0x0
0	DATAOVR	RAM Data Override. Override the ECC_dataBUS register with RAM data in read mode set by ECC_RW. 1'b0: Data override disabled. 1'b1: Data override enabled.	RW	0x0

ECC_startacc

These bits determine which byte of data/ecc to write to RAM.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C847C

Offset: 0x7C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															ENBUSA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															

ECC_startacc Fields

Bit	Name	Description	Access	Reset
16	ENBUSA	Start RAM access for PORTA.	RW	0x0

ECC_wdctrl

Bits to Enable/Disable Watch Dog Timer

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8480

Offset: 0x80

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															WDEN_RAM 0x0

ECC_wdctrl Fields

Bit	Name	Description	Access	Reset
0	WDEN_RAM	Enable watchdog timeout for OCP register access to IP RAM.	RW	0x0

SERRLKUPA0

Single-bit error address in LOOKUP TABLE for PORTA.

Module Instance	Base Address	Register Address
ecc_qspi_ecc_registerBlock	0xFF8C8400	0xFF8C8490

Offset: 0x90

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALID RW 0x0	Reserved														
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									Address RO 0x0						

SERRLKUPA0 Fields

Bit	Name	Description	Access	Reset
31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
6:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

Document Revision History

Table 15-5: Document Revision History

Date	Version	Changes
October 2016	2016.10.28	Maintenance release
May 2016	2016.05.27	• Changed the name of the internal QSPI reference clock from qspi_clk to qspi_ref_clk; and the external QSPI output clock, from sclk_out to qspi_clk. • Added a link to the *Supported Flash Devices for Arria 10 SoC* webpage. • Re-worded information about disabling the watermark feature in the "Indirect Read Operation" and "Indirect Write Operation" sections.
May 2016	2016.05.03	Maintenance release
November 2015	2015.11.02	• Renamed "Interface Pins" section to "Quad SPI Flash Controller Signal Description" and moved it below the "Quad SPI Flash Controller Block Diagram and System Integration" section • Corrected the link to the HPS Address Map. • Added the Arria 10 register map. • Better defined l4_main_clk clock. • Added Clock Gating information.
May 2015	2015.05.04	Added information about clearing out the ECC before the feature is enabled
December 2014	2014.12.15	Maintenance release
August 2014	2014.08.18	Initial release

DMA Controller 16

2016.10.28

a10_5v4 Subscribe Send Feedback

This chapter describes the direct memory access controller (DMAC) contained in the hard processor system (HPS). The DMAC transfers data between memory and peripherals and other memory locations in the system. The DMA controller is an instance of the ARM Corelink DMA Controller (DMA-330).

- Microcoded to support flexible transfer types
- Supports up to eight channels
- Provides 8-, 16-, 32-, and 64-bit transfer support
- Supports flow control with 32 peripheral request interfaces

Features of the DMA Controller

The HPS provides one DMAC to handle the data transfer between memory-mapped peripherals and memories, off-loading this work from the MPU subsystem.

- The DMAC supports multiple transfer types:
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Scatter-gather
- Supports up to eight DMA channels
- Supports up to eight outstanding AXI read and eight outstanding AXI write transactions
- Supports scheduling up to 16 outstanding read and 16 outstanding write instructions
- Supports nine interrupt lines into the MPU subsystem:
  - One for DMA thread abort
  - Eight for events
- Supports 32 peripheral request interfaces:
  - Eight for FPGA
    - FPGA 5 is multiplexed with Security Manager TX
    - FPGA 6 is multiplexed with I^2C_EMAC2_TX
    - FPGA 7 is multiplexed with I^2C_EMAC2_RX
  - Five for I^2C
  - Three for I^2C (EMAC)
  - Eight for SPI
  - Two for quad SPI
  - One for System Trace Macrocell
  - Four for UART
  - One for FPGA manager

The DMA controller provides:

- An instruction processing block that enables it to process program code that controls a DMA transfer
- An ARM Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) master interface unit to fetch the program code from system memory into its instruction cache

  Note: The AXI master interface is used to perform DMA data transfer as well. The DMA instruction execution engine executes the program code from its instruction cache and schedules read or write AXI instructions through the respective instruction queues.
- A multi-FIFO (MFIFO) data buffer that it uses to store data that it reads, or writes, during a DMA transfer
- Nine interrupt outputs to enable efficient communication of events to the MPU interrupt controller

  Note: The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory transfers to occur, without intervention from the processor. Since the HPS supports some peripherals that do not comply with ARM DMA peripheral interface protocol, adapters are added to allow these peripherals to work with the DMAC.

The following peripheral interface protocols are supported:

- Synopsys protocol
  - FPGA manager
  - Serial peripheral interface (SPI)
  - Universal asynchronous receiver transmitter (UART)
  - Inter-integrated circuit (I^2C)
  - FPGA
- ARM protocol
  - Quad SPI flash controller
  - System trace macrocell (STM)

Dual slave interfaces enable the operation of the DMA controller to be partitioned into a secure and non-secure state. The network interconnect must be configured to ensure that only secure transactions can access the secure interface. The slave interfaces can access status registers and also be used to directly issue and execute instructions in the DMA controller.

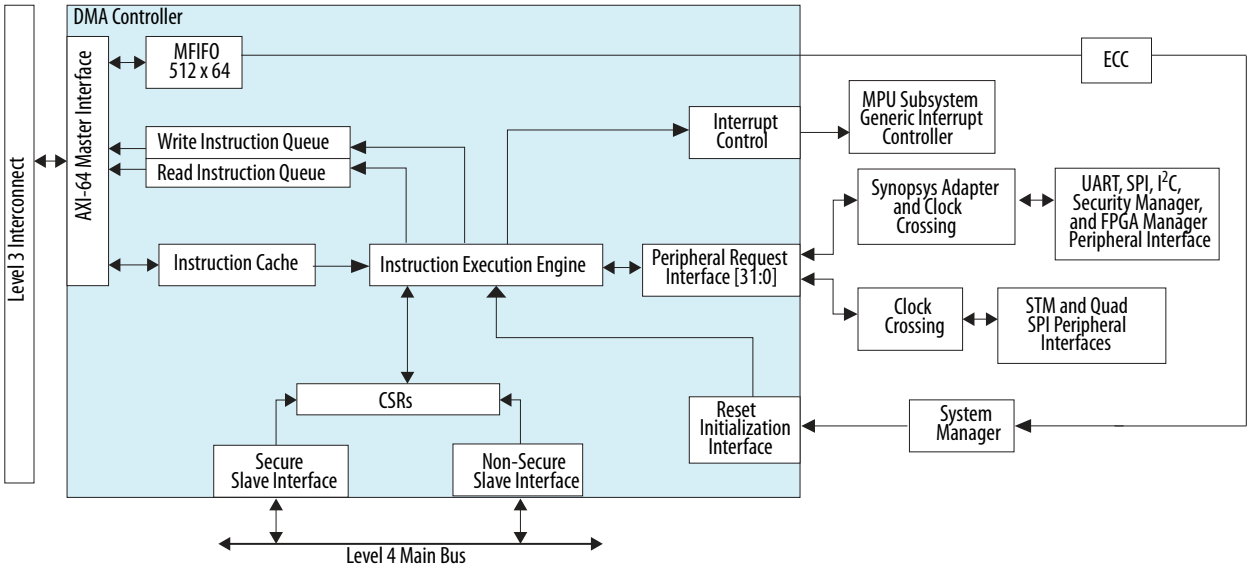
The DMAC has the following features:

- A small instruction set that provides a flexible method of specifying the DMA operations. This architecture provides greater flexibility than the fixed capabilities of a Linked-List Item (LLI) based DMA controller

DMA Controller Block Diagram and System Integration

The following figure shows a block diagram of the DMAC and how it integrates into the rest of the HPS system.

Figure 16-1: DMA Controller Connectivity



The l4_main_clk clock drives the DMA controller, controller logic, and all the interfaces. The DMA controller accesses the level 3 (L3) main switch with its 64-bit AXI master interface.

The DMA controller provides the following slave interfaces that connect to the L4 bus:

- Non-secure slave interface
- Secure slave interface
- ECC register slave interface

Both non-secure and secure slave interfaces may access registers that control the functionality of the DMA controller. The DMA controller implements TrustZone secure technology with one interface operating in the secure state and the other operating in the non-secure state.

The MFIFO has an ECC controller built-in to provide ECC protection. The ECC controller is able to detect single-bit and double-bit errors, and correct the single-bit errors. The ECC operation and functionality is programmable via the ECC register slave interface, as shown in **Figure 16-1**. The ECC register interface provides host access to configure the ECC logic as well as inject bit errors into the memory. It also provides host access to memory initialization hardware used to clear out the memory contents including the ECC bits. The ECC controller generates interrupts upon occurrences of single and double-bit errors, and the interrupt signals are connected to the system manager.

Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Functional Description of the DMA Controller

This section describes the major interfaces and components of the DMAC and its operation.

The DMAC contains an instruction processing block that processes program code to control a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI master interface. The DMAC stores instructions temporarily in an internal cache.

The DMAC has eight DMA channels. Each channel supports a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads.

The DMAC executes one instruction per clock cycle. To ensure that it regularly executes each active thread, the DMAC alternates by processing the DMA manager thread and then a DMA channel thread. It performs a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate program counter (PC) register for each DMA channel.

The DMAC includes a 16-line instruction cache to improve the instruction fetch performance. Each instruction cache line contains eight, four-byte words for a total cache line size of 32 bytes. The DMAC instruction cache size is therefore 16 lines times 32 bytes per line which equals 512 bytes. When a thread requests an instruction from an address, the cache performs a lookup. If a cache hit occurs, then the cache immediately provides the instruction. Otherwise, the thread is stalled while the DMAC performs a cache line fill through the AXI master interface. If an instruction spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the instruction.

Note: When a cache line fill is in progress, the DMAC enables other threads to access the cache. But if another cache miss occurs, the pipeline stalls until the first line fill is complete.

When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI. The DMAC also contains an MFIFO data buffer in which it stores data that it reads or writes during a DMA transfer.

The DMAC provides multiple interrupt outputs to enable efficient communication of events to the system CPUs. The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory DMA transfers to occur without intervention from the microprocessor.

Dual slave interfaces enable the operation of the DMAC to be partitioned into the secure state and non-secure states. You can access status registers and also directly execute instructions in the DMAC with the slave interfaces.

AXI Characteristics for a DMA Transfer

This table is a reference table to find out more information about how the DMAC AXI controls the AXI control signals.

Table 16-1: AXI Characteristics for a DMA Transfer

<table>
<tr><th>Access Type</th><th>Protection</th><th>Length</th><th>Burst</th><th>Size</th><th>Cache</th></tr>
<tr><td>DMA channel load</td><td colspan="5" rowspan="2">For more information, refer to the "Channel Control Registers" chapter in the CoreLink DMA Controller DMA-330 Revision: r1p2 Technical Reference Manual.</td></tr>
<tr><td>DMA channel store</td></tr>
<tr><td>DMA manager instruction fetch</td><td>Privileged. Secure state from DNS(45) bit.</td><td rowspan="2">See ARLEN and ARSIZE for instruction fetches.</td><td rowspan="2">INCR</td><td rowspan="2">See ARLEN and ARSIZE for instruction fetches.</td><td rowspan="2">• Cacheable write-through
• Allocate on reads only</td></tr>
<tr><td>DMA channel instruction fetch</td><td>Privileged. Secure state from CNS(46) bit.</td></tr>
</table>

Note: Any cacheable access made by the DMA master is routed to the ACP.

(45) The DSR Register contains the DNS bit. For more information, refer to the "DMA Manager Status Register" chapter in the *CoreLink DMA Controller DMA-330 Revision: r1p2* Technical Reference Manual.

(46) The CSR_n Register contains the CNS bit for DMA channel <*n*>. For more information, refer to the "Channel Status Registers" chapter in the *CoreLink DMA Controller DMA-330 Revision: r1p2* Technical Reference Manual.

ARLEN and ARSIZE for Instruction Fetches

When performing an instruction fetch, the DMAC sets **ARLEN** and **ARSIZE** as follows:

- Instruction cache length ≤ AXI data bus width
  - **ARLEN** = 1
  - **ARSIZE** = length of instruction cache in bytes
- Instruction cache length > AXI data bus width
  - **ARLEN** = ratio of the length of an instruction cache line in bytes to the width of the AXI data bus in bytes
  - **ARSIZE** = width of AXI data bus in bytes

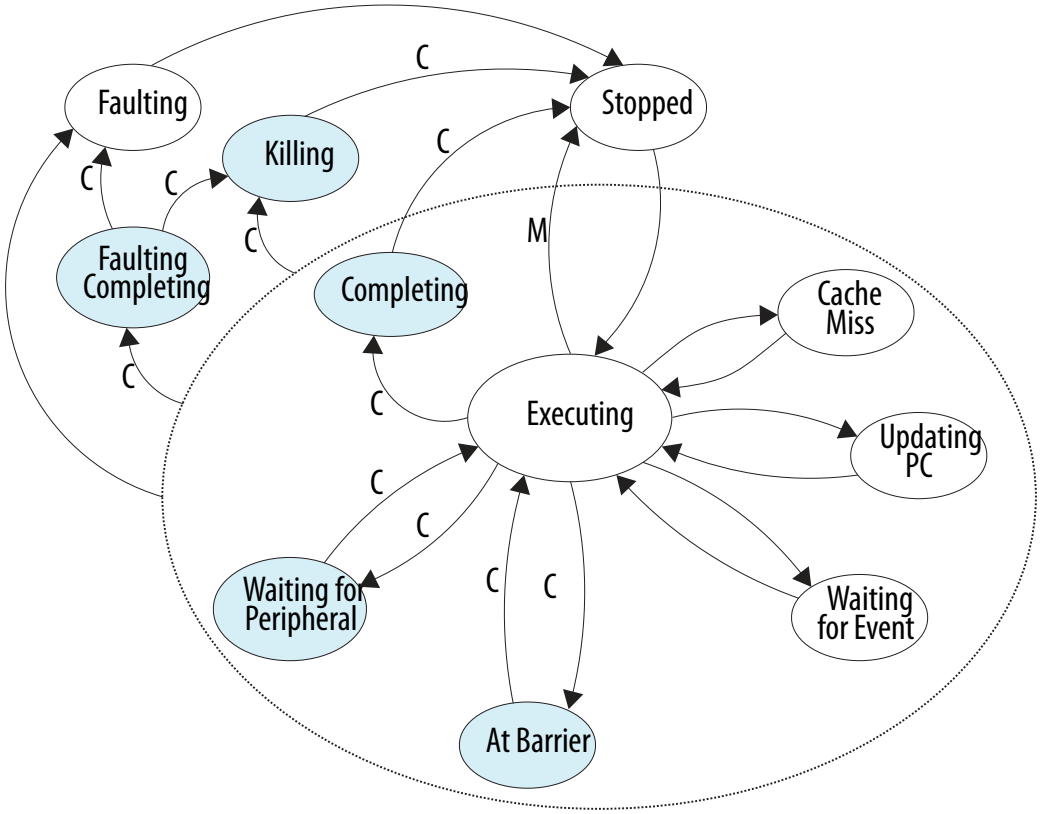
Operating States

The following figure shows the transitions among operating states for the DMA manager thread and DMA channel threads. The DMAC provides a separate state machine for each thread.

Figure 16-2: Thread Operating States



In the above figure, the DMAC permits all of the following:

- Only DMA channel threads can use states shown in blue
- Arcs with no letter designator indicate state transitions for the DMA manager and DMA channel threads, otherwise use is restricted as follows:
  - **C**—DMA channel threads only
  - **M**—DMA manager thread only
- States within the dotted line can transition to the Faulting completing, Faulting, or Killing

After the DMAC exits from reset, it sets all DMA channel threads to the Stopped state, and the status of `boot_from_pc` controls the DMA manager thread state.

- When `boot_from_pc` is LOW, then the DMA manager thread moves to the Stopped state.
- When `boot_from_pc` is HIGH, then the DMA manager thread moves to the Executing state.

The following list describes the Thread Operating states:

Stopped

The thread has an invalid PC (Program Counter) and it is not fetching instructions. Depending on the thread type, you can cause the thread to move to the Executing state by all of the following:

- DMA manager thread—Issuing the DMAGO instruction through the slave interface
- DMA channel thread—Programming the DMA manager thread to execute `DMAGO` for a DMA channel thread in the Stopped state

Executing

The thread has a valid PC and therefore the DMAC includes the thread when it arbitrates. The thread can then change to one of the following states under the following conditions:

- **Stopped**—When the DMA manager thread executes `DMAEND`
- **Cache Miss**—When the instruction cache does not contain the next instruction for either the DMA manager thread or the DMA channel thread
- **Updating PC**—When the DMAC calculates the address of the next access in the cache
- **Waiting for Event**—When a thread executes `DMAWFE`
- **At Barrier**—When a DMA channel thread either:
  - Executes `DMARMB`, `DMAWMB`, or `DMAFLUSHP`
  - Updates control registers that affect alignment during a DMA Cycle
- **Waiting for Peripheral**—When a DMA channel thread executes `DMAWFP`
- **Killing**—When a DMA channel thread executes `DMAKILL`
- **Faulting Completing**—For a DMA channel thread when either:
  - The thread executes an undefined or invalid instruction
  - An AXI error occurs during an instruction fetch or data transfer
- **Faulting**—For the DMA manager thread when either:
  - The thread executes an undefined or invalid instruction
  - An AXI error occurs during an instruction fetch

  For a DMA channel thread when a watchdog timeout abort occurs.
- **Completing**—When a DMA channel thread executes `DMAEND`

Cache Miss

The thread is stalled and the DMAC is performing a cache line fill. After it completes the cache fill, the thread returns to the Executing state.

Updating PC

The DMAC is calculating the address of the next access in the cache. After it calculates the PC, the thread returns to the Executing state.

Waiting For Event

The thread is stalled and is waiting for the DMAC to execute `DMASEV` using the corresponding event number. After the corresponding event occurs, the thread returns to the Executing state.

At Barrier

A DMA channel thread is stalled and the DMAC is waiting for transactions on the AXI to complete. After the AXI transactions complete, the thread returns to the Executing state.

Waiting For Peripheral

A DMA channel thread is stalled and the DMAC is waiting for the peripheral to provide the requested data. After the peripheral provides the data, the thread returns to the Executing state.

Faulting Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Faulting state.

Faulting

The thread is stalled indefinitely. The thread moves to the Stopped state when you use the `DBGCMD` register to instruct the DMAC to execute `DMAKILL` for that thread.

Killing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Error Checking and Correction

The SRAM local memory buffer is 64 by 512 bits, providing 4096 bytes of memory. The buffer provides ECC capability. The ECC block is integrated around the SRAM local memory buffer and provides the following features:

- Output to notify the system manager when single-bit correctable errors are detected and corrected
- Output to notify the system manager when double-bit uncorrectable errors are detected
- Provision for the injection of single-bit and double-bit errors for test purposes

The ECC is disabled by default. For information on using the ECC feature, refer to the ECC chapter in the Arria 10 Device handbook.

The system manager provides registers to set or mask single-bit or double-bit ECC error interrupts.

Related Information

Error Checking and Correction Controller on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Initializing and Clearing of Memory before Enabling ECC

Due to the DMA controller FIFO implementation, you must initialize and clear the FIFO before you enable the ECC to avoid a single event upset (SEU).

The following describes the initialization requirements:

- You must write a known pattern for data and ECC syndrome bits in memory, which involves the initialization of data to zero and corresponding nonzero ECC in hardware.
- Software must wait for the initialization process to complete before memory access is allowed. The initialization process cannot be interrupted nor stopped.

Related Information

Error Checking and Correction Controller on page 11-1
For more information about ECC, refer to the *Error Checking and Correction Controller* chapter of the Arria 10 Device Handbook.

Initializing the DMAC

The DMAC provides several memory-mapped control signals that initialize its operating state when it exits from reset. The DMAC does not automatically begin executing code when it exits from reset. The system manager controls these memory-mapped control signals.

How to Set the Security State of the DMA Manager

The security state of the DMAC manager thread is controlled by a bit in the DMA register in the System Manager. The `mgr_ns` bit controls the security state and when released from reset the DMA is in the secure state.

Related Information

- **DMA Manager Thread in Secure State** on page 16-28
  Describes how the security state of the DMA manager affects how the DMAC operates.
- **DMA Manager Thread in Non-Secure State** on page 16-28

How to Set the Security State for the Interrupt Outputs

You can set the security of an event-interrupt resource through the `irq_ns` bitfield in the DMA register found in the System Manager register map.

Related Information

Security Usage on page 16-27
Describes how the security state of the irq[x] signals affects how the DMAC executes the DMAWFE and DMASEV instructions.

How to Set the Security State for a Peripheral Request Interface

You can control the security state of each peripheral request interface by programming bits in the `dma_periph` register found in the System Manager. Each bit corresponds to a peripheral request interface. So if bit 0 is 0, then the peripheral interface 0 operates in the secure state.

Related Information

Security Usage on page 16-27
Describes the effect of the security state of the peripheral request interfaces on the execution of the DMAWFP, DMALDP, DMASTP, or DMAFLUSHP instructions by a DMA channel thread.

Using the Slave Interfaces

The slave interfaces connect the DMAC to the level 4 (L4) main bus and enable the MPU to access the registers. Using these registers, the MPU can perform the following functions:

- Access the status of the DMA manager thread
- Access the status of the DMA channel threads
- Enable or clear interrupts
- Enable events
- Execute an instruction for the DMAC by programming the following debug registers:
  - `DBGCMD` register
  - `DBGINST0` register
  - `DBGINST1` register

Issuing Instructions to the DMAC using a Slave Interface

When the DMAC is operating, you can only issue the following instructions:

- `DMAGO`—Starts a DMA transaction using a DMA channel that you specify
- `DMASEV`—Signals the occurrence of an event, or interrupt, using an event number that you specify
- `DMAKILL`—Terminates a thread

You must ensure that you use the appropriate slave interface, depending on the security state in which the `boot_manager_ns` signal initializes the DMAC. For example, if the DMAC is in the secure state, you must

issue the instruction using the secure slave interface, otherwise the DMAC ignores the instruction. You can use the secure or non-secure slave interface to start or restart a DMA channel when the DMAC is in the non-secure state.

Note: Before you can issue instructions using the debug instruction registers or the DBGCMD register, you must read the DBGSTATUS register to ensure that debug is idle, otherwise the DMAC ignores the instructions.

The DMAC immediately processes any instructions received from a slave interface, unless the pipeline is busy processing another instruction.

Note: Prior to issuing DMAGO, you must ensure that the system memory contains a suitable program for the DMAC to execute, starting at the address that the DMAGO specifies.

Using DMAGO with the Debug Instruction Registers

The following example shows the necessary steps to start a DMA channel thread using the debug instruction registers:

1. Create a program for the DMA channel.
2. Store the program in a region of system memory.
3. Program one of the slave interfaces on the DMAC to a DMAGO instruction as follows:
   a. Poll the DBGSTATUS register to ensure that debug is idle, and the dbgstatus bit is 0.
   b. Write to the DBGINST0 register and enter all of the following:
      - Instruction byte 0 encoding for DMAGO
      - Instruction byte 1 encoding for DMAGO
      - Debug thread bit to 0 to select the DMA manager thread
   c. Write to the DBGINST1 register with the DMAGO instruction byte [5:2] data. You must set these four bytes to the address of the first instruction in the program that is written to system memory in **step 2** above.
4. Instruct the DMAC to execute the instruction that the debug instruction registers contain by writing zero to the DBGCMD register. The DMAC starts the DMA channel thread and sets the dbgstatus bit to 1. After the DMAC completes execution of the instruction, it clears the dbgstatus bit to 0.

Peripheral Request Interface

You can enable each direct memory access (DMA) controller peripheral request interface, individually. Setting each of the eight peripheral request IDs enables or disables a peripheral request interface. When set to enable, it allows for FPGA soft logic to request a DMA transfer. For DMA transfers to or from the FPGA, this feature is only necessary if your design requires transfer flow control.

The DMA peripheral request interface communicates with peripherals by either the ARM protocol or the Synopsys protocol.

- ARM Protocol -

  For peripherals using the ARM protocol, clock-crossing logic is the only logic between the DMA and the peripheral.
- Synopsys Protocol Overview -

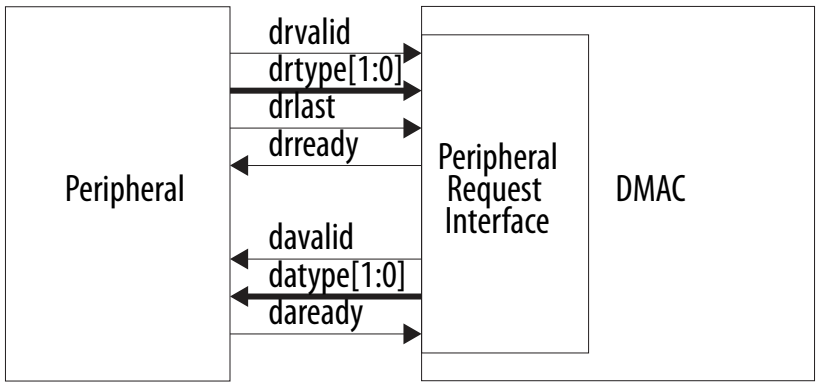
  The Synopsys protocol is used for the hardware flow control that is not the same as the protocol used by the DMA-330 core.

  For peripherals using the Synopsys protocol, clock-crossing logic and protocol adaptation logic exist between the DMA and the peripheral.

The following figure shows that the peripheral request interface consists of a peripheral request bus and a DMAC acknowledge bus that use the prefixes:

- `dr`—The peripheral request bus
- `da`—The DMAC acknowledge bus

Figure 16-3: Request and Acknowledge Buses on the Peripheral Request Interface



Both buses use the valid and ready handshake that the AXI protocol describes.

The peripheral uses `drtype[1:0]` to either:

- Request a single transfer
- Request a burst transfer
- Acknowledge a flush request

The peripheral uses `drlast` to notify the DMAC that the request on `drtype[1:0]` is the last request of the DMA transfer sequence. `drlast` is transferred at the same time as `drtype[1:0]`.

The DMAC can indicate the following using `datype[1:0]`:

- When it completes the requested single transfer
- When it completes the requested burst transfer
- When it issues a flush request

Note: If you configure the DMAC to provide more than one peripheral request interface, each interface is assigned a unique identifier, _<x> where <x> represents the number of the interface.

For the Synopsys protocol, the following signals are used in the handshaking protocol:

- dma_tx_req_n
- dma_rx_req_n
- dma_tx_ack_n
- dma_rx_ack_n
- dma_tx_single_n
- dma_rx_single_n

Handshake Rules

The DMAC uses the DMA handshake rules that are listed, below, when a DMA channel thread is active, that is, not in the **Stopped** state.

- drvalid can change from LOW to HIGH on any aclk cycle, but it must only change from HIGH to LOW when drready is HIGH.
- drtype can only change when either drready is HIGH, or drvalid is LOW.
- drlast can only change when either drready is HIGH, or drvalid is LOW.
- davalid can change from LOW to HIGH on any aclk cycle, but it must only change from HIGH to LOW when daready is HIGH.
- datype can only change when either daready is HIGH, OR davalid is LOW.

Table 16-2: DMA Peripheral Interface Signal Definition

Signal	Description
drready	Indicates whether the DMAC can accept the information that the peripheral provides on drtype_<x>[1:0]: • 0 = DMAC not ready • 1 = DMAC ready **Note:** If drvalid is HIGH then the DMAC sets drready to HIGH when it accepts the peripheral request.
drvalid	Indicates when the peripheral provides valid control information: • 0 = No control information is available • 1 = drtype_<x>[1:0] and drlast_<x> contain valid information for the DMAC **Note:** The peripheral sets drvalid HIGH when it starts to provide valid control information on drlast and drtype. The state of drvalid, drlast and drtype must remain constant until the DMAC sets drready HIGH.
drtype[1:0]	Indicates the type of acknowledgment, or request, that the peripheral signals: • b00 = single level request • b01 = burst level request • b10 = acknowledging a flush request that the DMAC requested • b11 = reserved

Signal	Description
drlast	Indicates that the peripheral is sending the last data transfer for the current DMA transfer: • 0 = last data request is not in progress • 1 = last data request is in progress **Note:** The DMAC only uses this signal when drtype_<x>[1:0] is b00 or b01.
daready	Indicates whether the peripheral can accept the information that the DMAC provides on datype_<x>[1:0]: • 0 = peripheral not ready • 1 = peripheral ready **Note:** If davalid is HIGH, the peripheral sets daready HIGH when either it: • Accepts a flush request from the DMAC • Acknowledges the completion of a DMA transfer
davalid	Indicates when the DMAC provides valid control information: • 0 = no control information is available • 1 = datype_<x>[1:0] contains valid information for the peripheral **Note:** The DMAC sets davalid HIGH when it starts to provide valid control information on datype. The state of davalid and datype remain constant until the peripheral sets daready HIGH.
datype[1:0]	Indicates the type of acknowledgment, or request, that the DMAC signals: • b00 = The DMAC has completed the single DMA transfer • b01 = The DMAC has completed the burst DMA transfer • b10 = DMAC requesting the peripheral to perform a flush request • b11 = reserved

For more information, refer to the "Peripheral Request Interface Timing Diagrams" chapter.

Peripheral Request Interface Mapping

You can assign a peripheral request interface to any of the DMA channels. When a DMA channel thread executes DMAWFP, the value programmed in the peripheral [4:0] field specifies the peripheral associated with that DMA channel.

The DMAC supports 32 peripheral request handshakes. Each request handshake can receive up to four outstanding requests, and is assigned a specific peripheral device ID. The following table lists the peripheral device ID assignments.

Table 16-3: Peripheral Request Interface Mapping

Peripheral	Request Interface ID	Protocol
FPGA 0	0	Synopsys
FPGA 1	1	Synopsys
FPGA 2	2	Synopsys

Mapping to a DMA Channel

The DMAC enables you to assign a peripheral request interface to any of the DMA channels. When a DMA channel thread executes `DMAWFP`, the value programmed in the peripheral [4:0] field specifies the peripheral associated with that DMA channel.

Related Information

DMAWFP on page 16-51

Request Acceptance Capability

During configuration of the DMAC, you can set the number of simultaneous active requests that a DMAC is able to accept, for each peripheral request interface. An active request is where the DMAC has not started the requested AXI data transfers.

The DMAC has a request FIFO, for each peripheral interface, which it uses to capture the requests from a peripheral. The depth of a FIFO depends on the number of simultaneous active requests that the corresponding peripheral request interface is configured to support. To store the state of an active request from the peripheral, the request FIFO uses two bits to store the state of:

- `drtype_<x>[0]` - Indicates the request type, burst or single
- `drlast_<x>` - Indicates if the peripheral is requesting the last data transfer of the DMA transfer

When a request FIFO is full, then the DMAC sets the corresponding `drready_<x>` to LOW to signal that the DMAC cannot accept any requests sent from the peripheral.

Peripheral Length Management

A peripheral can control the quantity of data that a DMA cycle contains, without the DMAC being aware of how many data transfers it contains. The peripheral controls the DMA cycle in one of the following ways:

- Selects a single transfer
- Selects a burst transfer
- Notifies the DMAC when it commences the final request in the current series

When the DMAC executes a `DMAWFP` peripheral instruction, it halts execution of the thread and waits for the peripheral to send a request. When the peripheral sends the request, the DMAC sets the request flags depending on the state of the following signals:

- `drtype_<x>[1:0]` —The DMAC sets the state of the `request_type` flag:
  - `drtype_<x>[1:0]`=b00—`request_type` <x> = Single
  - `drtype_<x>[1:0]`=b01—`request_type` <x> = Burst
- `drlast_<x>`—The DMAC sets the state of the `request_last` flag:
  - `drlast_<x>`=0—`request_last` <x> = 0
  - `drlast_<x>`=1—`request_last` <x> = 1

Note: If the DMAC executes a `DMAWFP` single or `DMAWFP` burst instruction then the DMAC sets:

- The request_type<x> flag to Single or Burst, respectively
- The request_last<x> flag to 0

`DMALPFE` is an assembler directive that forces the associated `DMALPEND` instruction to have its `nf` bit cleared, creating a program loop that does not use a loop counter to terminate the loop.

The DMAC exits the loop when the `request_last` flag is set.

The DMAC conditionally executes the following instructions, depending on the state of the `request_type` and `request_last` flags:

- **`DMALD`** , **`DMAST`** , **`DMALPEND`** - When these instructions use the optional B|S suffix then the DMAC executes a `DMANOP` if the `request_type` flag does not match.
- **`DMALDP<B|S>`** , **`DMASTP<B|S>`** - The DMAC executes a `DMANOP` if the `request_type` <x> flag does not match the B|S.
- **`DMALPEND`** - When the `nf` bit is 0, the DMAC executes a `DMANOP` if the `request_last` flag is set.

Use the `DMALDB`, `DMALDPB`, `DMASTB` and `DMASTPB` instructions if you require the DMAC to issue a burst transfer when the DMAC receives a burst request. The values in the `CCR`*n* register control the amount of data that the DMAC transfers.

Use the `DMALDS`, `DMALDPS`, `DMASTS` and `DMASTPS` instructions if you require the DMAC to issue a single transfer when the DMAC receives a single request. The DMAC ignores the value of the `src_burst_len` and `dst_burst_len` fields in the `CCR`*n* register and sets the `arlen[3:0]` or `awlen[3:0]` buses to 0x0.

Example Program for Peripheral Length Management

This example shows a DMAC program that transfers 64 words from memory to peripheral zero, when the peripheral sends a burst request, that is, `drtype_<x>[1:0] = b01`. When the peripheral sends a single request, that is, `drtype_<x>[1:0] = b00`, then the DMAC program transfers one word from memory to peripheral zero.

To transfer the 64 words, the program instructs the DMAC to perform 16 AXI transfers. Each AXI transfer consists of a 4-beat burst (SB=4, DB=4), each beat of which moves a word of data (SS=32, DS=32).

The following program shows the use of the:

- `DMAWFP periph` instruction - The DMAC waits for either a burst or single request from the peripheral.
- `DMASTPB and DMASTPS` instructions - The DMAC informs the peripheral when a transfer is complete.

Example 16-1: Peripheral Length Management Program

```
# Set up for burst transfers (4-beat burst, so SB4 and DB4), (word data
width, so SS32 and DS32)
DMAMOV CCR SB4 SS32 DB4 DS32
DMAMOV SAR ...
DMAMOV DAR ...
# Initialize peripheral '0'
DMAFLUSHP P0
# Perform peripheral transfers
# Outer loop - DMAC responds to peripheral requests until peripheral sets
drlast_0 = 1
DMALPFE
# Wait for request, DMAC sets request_type0 flag depending on the request
type it receives
DMAWFP 0, periph
# Set up loop for burst request: first 15 of 16 sets of transactions
# Note: B suffix - conditionally executed only if request_type0 flag = Burst
DMALP 15
DMALDB
DMASTB
# Only loop back if servicing a burst, otherwise treat as a NOP
DMALPENDB
# Perform final transaction (16 of 16). Send the peripheral acknowledgement
of burst request completion
DMALDB
DMASTPB P0
# Perform transaction if the peripheral signals a single request
# Note: S suffix - conditionally executed only if request_type0 flag = Single
DMALDS
DMASTPS P0
# Exit loop if DMAC receives the last request, that is, drlast_0 = 1
DMALPEND
DMAEND
```

DMAC Length Management

The DMAC controls the total amount of data. The peripheral uses the peripheral request interface to notify the DMAC when it requires the DMAC to transfer data to or from the peripheral. The DMA channel thread controls how the DMAC responds to the peripheral requests.

The following constraints apply to DMAC length management:

- The total quantity of data for all the single requests from a peripheral must be less than the quantity of data for a burst request for that peripheral.

  Note: The `CCRn` register controls how much data is transferred for a burst request and a single request. Altera recommends that you do not update a `CCRn` register when a transfer is in progress for channel `n`.

- After the peripheral sends a burst request, the peripheral must not send a single request until the DMAC acknowledges that the burst request is complete.

Program the DMAWFP single instruction when you require the program thread to halt execution until the peripheral request interface receives any request type.

- Single— If the head entry in the request FIFO buffer is a single request type, the DMAC pops the entry from the FIFO buffer and continues program execution.
- Burst—If the head entry in the request FIFO buffer is a burst request type, the DMAC leaves the entry in the FIFO buffer and continues program execution.

Note: The burst request entry remains in the request FIFO buffer until the DMAC executes a DMAWFP burst instruction or a DMAFLUSHP instruction.

Program the DMAWFP burst instruction when you require the program thread to halt execution until the peripheral request interface receives a burst request.

- Single—If the head entry in the request FIFO buffer is a single request type, the DMAC removes the entry from the FIFO buffer and continues program execution.
- Burst—If the head entry in the request FIFO buffer is a burst request type, the DMAC pops the entry from the FIFO buffer and continues program execution.

Program the DMALDP instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI read transfers. Similarly, use the DMASTP instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI write transfers. The DMAC uses the acknowledge bus to signal a transfer acknowledgment to the peripheral.

Note: The DMAC sends an acknowledgment for a read transaction when the rvalid and rlast signals are high and for a write transaction when bvalid signal is high. The DMAC might send an acknowledgment to the peripheral while the transfer of write data to the end destination is still in progress.

Use the DMAFLUSHP instruction to reset the request FIFO buffer for the peripheral request interface. After the DMAC executes DMAFLUSHP, it ignores peripheral requests until the peripheral acknowledges the flush request. This protocol enables the DMAC and peripheral to synchronize with each other.

Example Program for DMAC Length Management

This example shows a DMAC program that can transfer 1027 words when a peripheral signals 16 consecutive burst requests and three consecutive single requests.

Example 16-2: DMAC Length Management Program

```
# Set up for AXI burst transfer (4-beat burst, so SB4 and DB4), (word data
width, so SS32 and DS32)
DMAMOV CCR SB4 SS32 DB4 DS32
DMAMOV SAR ...
DMAMOV DAR ...
# Initialize peripheral '0'
DMAFLUSHP P0
# Perform peripheral transfers
# Burst request loop to transfer 1024 words
DMALP 16
# Wait for the peripheral to signal a burst request. DMAC transfers 64 words
for each burst request
DMAWFP 0, burst
# Set up loop for burst request: first 15 of 16 sets of transactions
DMALP 15
DMALD
DMAST
```

```
DMALPEND
# Perform final transaction (16 of 16). Send the peripheral acknowledgement
of burst request completion
DMALD
DMASTPB 0
# Finish burst loop
DMALPEND
# Set up for AXI single transfer (word data width, so SS32 and DS32)
DMAMOV CCR SB1 SS32 DB1 DS32
# Single request loop to transfer 3 words
DMALP 3
# Wait for the peripheral to signal a single request. DMAC to transfer one
word
DMAWFP 0, single
# Perform transaction for single request and send completion acknowledgement
to the peripheral
DMALDS
DMASTPS P0
# Finish single loop
DMALPEND
# Flush the peripheral, in case the single transfers were in response to a
burst request
DMAFLUSHP 0
DMAEND
```

Peripheral Request Interface Timing Diagrams

The following are examples of the functional operation of the peripheral request interface using the rules that the "Handshake Rules" chapter describes.

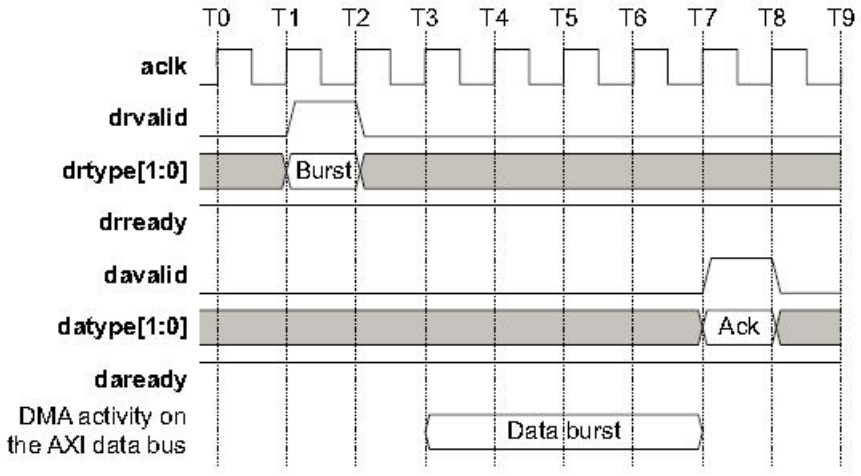
Related Information

Handshake Rules on page 16-13

Burst Request

DMA request timing when a peripheral requests a burst transfer.

Figure 16-4: Burst Request Signaling

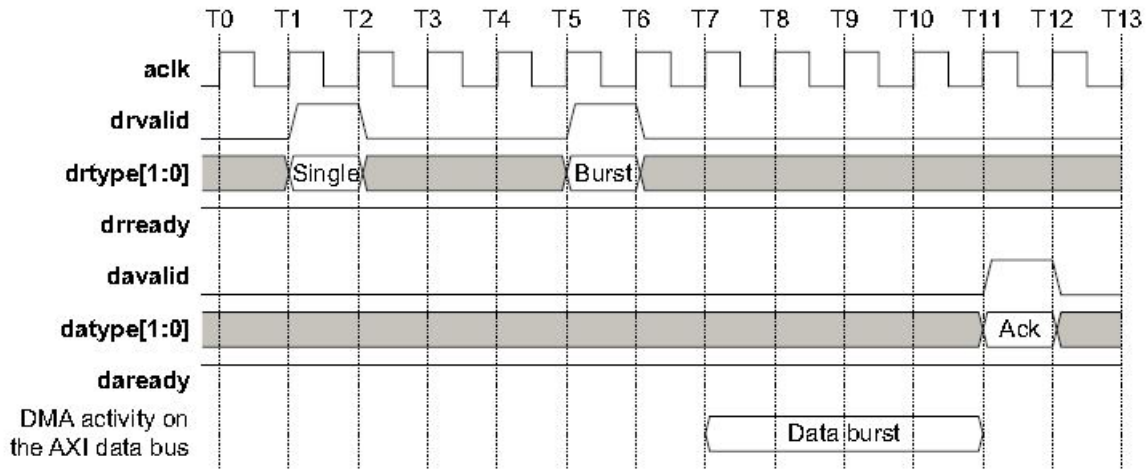


Timing	Description
T1	The DMAC detects a request for a burst transfer.
T3 - T6	The DMAC performs a burst transfer.
T7	The DMAC sets `davalid` HIGH and sets `datype[1:0]` to indicate that the burst transfer is complete.

Single and Burst Request

DMA request timing when a peripheral requests a single and a burst transfer.

Figure 16-5: Single and Burst Request Signaling



Timing	Description
T1	The DMAC detects a request for a single transfer.
T3	The DMAC ignores the single transfer request because the DMA channel thread had executed a DMAWFP burst instruction.
T5	The DMAC detects a request for a burst transfer.
T7 - T10	The DMAC performs a burst transfer.
T11	The DMAC sets `davalid` HIGH and sets `datype[1:0]` to indicate that the burst transfer is complete.

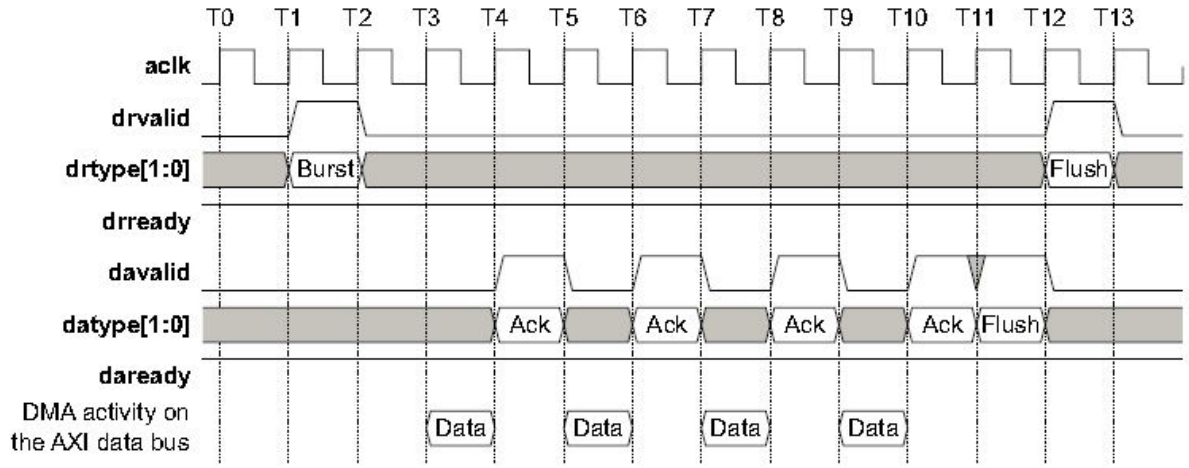
Related Information

DMAWFP on page 16-51

DMAC Performs Single Transfers for a Burst Request

DMA request timing when a peripheral requests a burst transfer, but the DMAC has insufficient data remaining in the MFIFO to generate a burst and therefore completes the request using single transfers.

Figure 16-6: Single Transfers for a Burst Request



Timing	Description
T1	The DMAC detects a request for a burst transfer.
T3	The MFIFO contains insufficient data for the DMAC to generate a burst transfer and therefore, the DMAC performs a single transfer.
T4	The DMAC signals `davalid` and `datype[1:0]` to indicate completion of a single transfer.
T5 - T10	The DMAC performs the remaining three single transfers.
T11	The DMAC signals `davalid` and `datype[1:0]` to request the peripheral to flush the contents of any control registers that are associated with the current DMA cycle.
T12	The peripheral signals `drvalid` and `drtype[1:0]` to acknowledge the flush request.

Using Events and Interrupts

The DMAC can support up to eight events and interrupts. The `INTEN` register determines whether each event-interrupt resource is an event or an interrupt.

When the DMAC executes a `DMASEV` instruction, it modifies the event-interrupt resource that you specify. The `INTEN` register sets the event-interrupt resource to function as an:

- **Event**—The DMAC generates an event for the specified event-interrupt resource. When the DMAC executes a `DMAWFE` instruction for the same event-interrupt resource then it clears the event.
- **Interrupt**—The DMAC sets the `irq` <event_num> signal high, where <event_num> is the number of the specified event resource. To clear the interrupt you must write to the `INTCLR` register.

Using an Event to Restart DMA Channels

When you program the `INTEN` register to generate an event, you can use the `DMASEV` and `DMAWFE` instructions to restart one or more DMA channels.

DMAC executes DMAWFE before DMASEV

To restart a single DMA channel:

1. The first DMA channel executes `DMAWFE` and then stalls while it waits for the event to occur.
2. The other DMA channel executes `DMASEV` using the same event number generating an event and restarting the first DMA channel. The DMAC clears the event, one clock cycle after it executes `DMASEV`.

You can program multiple channels to wait for the same event. For example, if four DMA channels have all executed `DMAWFE` for event 2, and another DMA channel executes `DMASEV` for event 2, the four DMA channels all restart at the same time. The DMAC clears the event, one clock cycle after it executes `DMASEV`.

DMAC executes DMASEV before DMAWFE

If the DMAC executes `DMASEV` before another channel executes `DMAWFE`, the event remains pending until the DMAC executes `DMAWFE`. When the DMAC executes `DMAWFE`, it halts execution for one `aclk` clock cycle, clears the event and then continues execution of the channel thread.

For example, if the DMAC executes `DMASEV 6` and none of the other threads have executed `DMAWFE 6`, then the event remains pending. If the DMAC executes the `DMAWFE 6` instruction for channel 4 and then executes the `DMAWFE 6` instruction for channel 3, the following actions occur:

1. The DMAC halts execution of the channel 4 thread for one clock cycle.
2. The DMAC clears event 6.
3. The DMAC resumes execution of the channel 4 thread.
4. The DMAC halts execution of the channel 3 thread and the thread stalls while it waits for the next occurrence of event 6.

Interrupting the MPU Subsystem

The DMAC provides the `irq[x]` signals for use as active-high level-sensitive interrupts to the MPU subsystem. When you program the `INTEN` register to generate an interrupt, after the DMAC executes `DMASEV`, it sets the corresponding `irq[x]` signal high.

The MPU subsystem can clear the interrupt by writing to the `INTCLR` register.

Note: Executing `DMAWFE` does not clear an interrupt.

If you use the `DMASEV` instruction to notify a microprocessor when the DMAC completes a `DMALD` or `DMAST` instruction then you should insert a memory barrier instruction before the `DMASEV`. Otherwise the DMAC might signal an interrupt before the AXI transfers complete.

The following program shows the example of Memory Barrier Instruction.

```
DMALD
DMAST
# Issue a write memory barrier
# Wait for the AXI write transfer to complete before the DMAC
# can send an interrupt
DMAWMB
# The DMAC sends the interrupt
DMASEV
```

Aborts

Abort Types

An abort can be classified as either precise or imprecise, depending on whether the DMAC provides an abort handler with the precise state of the DMAC when the abort occurs.

- Precise Abort - The DMAC updates the `PC` register with the address of the instruction that created the abort.
- Imprecise Abort - The `PC` register might contain the address of an instruction that did not cause the abort to occur.

Abort Sources

The DMAC indicates a precise abort under any of the following conditions:

- A DMA channel thread in the Non-secure state attempts to program its `CCRn` register and generate a secure AXI transaction.
- A DMA channel thread in the Non-secure state executes `DMAWFE` or `DMASEV` for an event that is set as secure. The `boot_irq_ns` memory-mapped control signals initialize the security state for an event.

Note: For each event, the `INTEN` register controls if the DMAC generates an event or signals an interrupt.

- A DMA channel thread attempts to execute `DMAST` but the DMAC calculates that when it eventually performs the store, the MFIFO buffer contains insufficient data to enable it to complete the store.
- A DMA channel thread in the Non-secure state executes `DMAWFP`, `DMALDP`, `DMASTP`, or `DMAFLUSHP` for a peripheral request interface that is set as secure. The `boot_periph_ns` memory-mapped control signals initialize the security state for a peripheral request interface.
- A DMA manager thread in the Non-secure state executes `DMAGO` to attempt to start a secure DMA channel thread.
- The DMAC receives an ERROR response on the AXI master interface when it performs an instruction fetch.
- A thread executes an undefined instruction.
- A thread executes an instruction with an operand that is invalid for the configuration of the DMAC.

Note: When the DMAC signals a precise abort, the instruction that triggers the abort is not executed. Instead, the DMAC executes a `DMANOP`.

The DMAC signals an imprecise abort under the following conditions:

- The DMAC receives an ERROR response on the AXI master interface when it performs a data load.
- The DMAC receives an ERROR response on the AXI master interface when it performs a data store.
- A DMA channel thread executes `DMALD` or `DMAST`, and the MFIFO buffer is too small to hold the required amount of data.
- A DMA channel thread executes `DMAST` but the thread has not executed sufficient `DMALD` instructions.
- A DMA channel thread locks up because of resource starvation, and this causes the internal watchdog timer to time out.

Watchdog Abort

The DMAC can lock up if one or more DMA channel programs are running and the MFIFO buffer is too small to satisfy the storage requirements of the DMA programs.

The DMAC contains logic to prevent it from remaining in a state where it is unable to complete a DMA transfer.

The DMAC detects a lock up when all of the following conditions occur:

- Load queue is empty.
- Store queue is empty.
- All of the running channels are prevented from executing a `DMALD` instruction either because the MFIFO buffer does not have sufficient free space or another channel owns the load-lock.

When the DMAC detects a lockup, it signals an interrupt and can also abort the contributing channels. The DMAC behavior depends on the state of the `wd_irq_only` bit in the `WD` register, if:

- `wd_irq_only=0`—The DMAC aborts all of the contributing DMA channels and sets the `irq_abort` signal high.
- `wd_irq_only=1`—The DMAC sets the `irq_abort` signal high.

Related Information

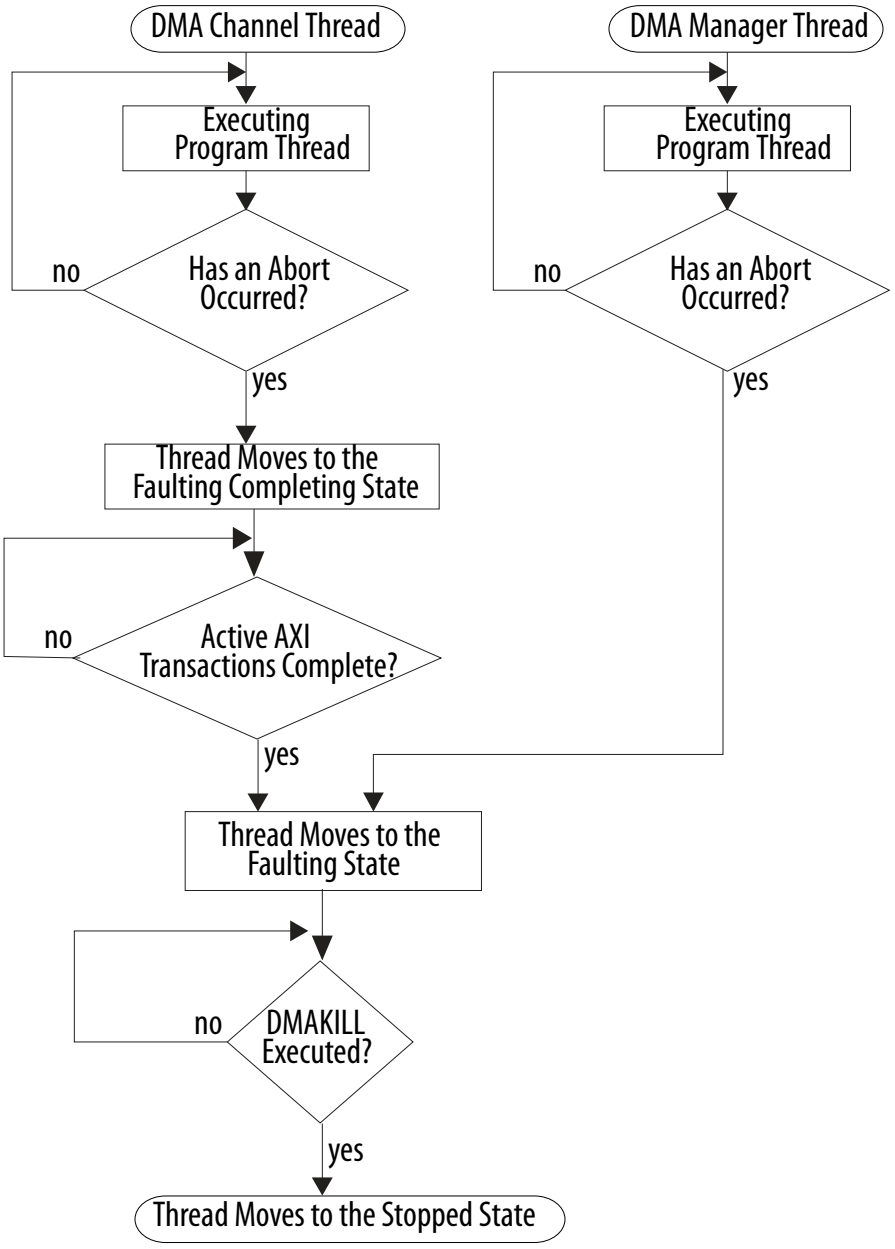
Resource Sharing Between DMA Channels on page 16-32

Abort Handling

The architecture of the DMAC is not designed to recover from an abort. You must use an external agent, such as the MPU, to terminate a thread when an abort occurs.

The following figure shows the operating states for the DMA channel and DMA manager threads after an abort occurs.

Figure 16-7: Abort Process



After an abort occurs, the action of the DMAC depends on the thread type:

- DMA channel thread—The thread immediately moves to the Faulting completing state. In this state, the DMAC performs the following operations:
  - Sets the `irq_abort` signal high.
  - Stops executing instructions for the DMA channel.
  - Invalidates all cache entries for the DMA channel updates the `CPC`*n* register to contain the address of the aborted instruction provided that the abort is precise.
  - Does not generate AXI accesses for any instructions remaining in the read queue and write queue.
  - Permits currently active AXI transactions to complete.

  Note: After the transactions for the DMA channel finish, the thread moves to the Faulting state.
- DMA manager thread—The thread immediately moves to the Faulting state and the DMAC sets the `irq_abort` signal high.

  The external agent can respond to the assertion of the `irq_abort` signal by all of the following:

  - Reading the status of the `FSRD` register to determine if the DMA manager is Faulting. In the Faulting state, the `FSRD` register provides the cause of the abort.
  - Reading the status of the `FSRC` register to determine if a DMA channel is Faulting. In the Faulting state, the `FSRC` register provides the cause of the abort.

  To enable a thread in the Faulting state to move to the Stopped state, the external agent must:

  - Program the `DBGINST0` register with the encoding for the `DMAKILL` instruction.
  - Write to the `DBGCMD` register.

  Note: If the aborted thread is secure, you must use the secure slave interface to update these registers.

  After a thread in the Faulting state executes `DMAKILL`, it moves to the Stopped state.

Security Usage

When the DMAC exits from reset, the status of the configuration signals configures the security for:

- DMA manager thread—The `DNS` bit in the DSR register returns the security state of the DMA manager thread.
- Events and interrupts—The `INS` bit in the `CR3` register returns the security state of the event-interrupt resources.
- Peripheral request interfaces—The `PNS` bit in the `CR4` register returns the security state of these interfaces.

Additionally, each DMA channel thread contains a dynamic non-secure bit, `CNS`, that is valid when the channel is not in the Stopped state.

DMA Manager Thread in Secure State

If the DNS bit is 0, the DMA manager thread operates in the secure state and performs only secure instruction fetches. When a DMA manager thread in the secure state processes:

- DMAGO—The DMAC uses the status of the ns bit, to set the security state of the DMA channel thread by writing to the CNS bit for that channel.
- DMAWFE—The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit.
- DMASEV—The DMAC sets the corresponding bit in the INT_EVENT_RIS register, irrespective of the security state of the corresponding INS bit.

DMA Manager Thread in Non-Secure State

If the DNS bit is 1, the DMA manager thread operates in the non-secure state, and it only performs non-secure instruction fetches. When a DMA manager thread in the non-secure state processes:

DMAGO - The DMAC uses the status of the ns bit to control if it starts a DMA channel thread.

- If ns = 0, then the DMAC does not start a DMA channel thread and instead it:
  - Executes an NOP
  - Sets the FSRD register
  - Sets the dmago_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If ns = 1, then the DMAC starts a DMA channel thread in the non-secure state and programs the CNS bit to be non-secure.

DMAWFE - The DMAC uses the status of the corresponding INS bit in the CR3 register to control whether it waits for the event.

- If INS = 0, then the event is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the FSRD register
  - Sets the mgr_evnt_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If INS = 1, then the event is in the non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

DMASEV - The DMAC uses the status of the corresponding INS bit in the CR3 register to control if it creates the event interrupt.

- If INS = 0, then the event-interrupt resource is in the secure state. The DMAC:
  - Executes a NOP
  - Sets the FSRD register
  - Sets the mgr_evnt_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If INS = 1, then the event-interrupt resource is in the non-secure state. The DMAC creates the event interrupt.

DMA Channel Thread in Secure State

When the CNS bit is 0, the DMA channel thread is programmed to operate in the secure state and to only perform secure instruction fetches.

When a DMA channel thread in the secure state processes the following instructions:

- DMAWFE - The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, regardless of the security state of the corresponding INS bit in the CR3 register.
- DMASEV - The DMAC creates the event interrupt, regardless of the security state of the corresponding INS bit in the CR3 register.
- DMAWFP - The DMAC halts execution of the thread until the peripheral signals a DMA request at which point the DMAC continues execution of the thread, regardless of the security state of the corresponding PNS bit in the CR4 register.
- DMALDP and DMASTP - The DMAC sends a message to the peripheral to communicate that data transfer is complete, regardless of the security state of the corresponding PNS bit in the CR4 register.
- DMAFLUSHP - The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status, regardless of the security state of the corresponding PNS bit in the CR4 register.

When a DMA channel thread is in the secure state, it enables the DMAC to perform secure and non-secure AXI accesses.

DMA Channel Thread in Non-Secure State

When the CNS bit is 1, the DMA channel thread is programmed to operate in the non-secure state and to only perform non-secure instruction fetches.

When a DMA channel thread in the non-secure state processes the following instructions:

DMAWFE - The DMAC uses the status of the corresponding INS bit in the CR3 register, to control if it waits for the event.

- If INS =0, then the event is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
  - Sets the ch_evnt_err bit in the FTRn register
  - Moves the DMA channel to the Faulting completing state
- If INS =1, then the event is in the non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

DMASEV - The DMAC uses the status of the corresponding INS bit in the CR3 register, to control if it creates the event.

- If INS =0, then the event-interrupt resource is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
  - Sets the ch_evnt_err bit in the FTRn register
  - Moves the DMA channel to the Faulting completing state
- If INS =1, then the event-interrupt resource is in the non-secure state. The DMAC creates the event interrupt.

DMAWFP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it waits for the peripheral to signal a request.

- If PNS =0, then the peripheral is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
  - Sets the ch_periph_err bit in the FTRn register
  - Moves the DMA channel to the Faulting completing state
- If PNS =1, then the peripheral is in the non-secure state. The DMAC halts execution of the thread and waits for the peripheral to signal a request.

DMALDP and DMASTP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it sends an acknowledgement to the peripheral.

- If PNS =0, then the peripheral is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
  - Sets the ch_periph_err bit in the FTRn register
  - Moves the DMA channel to the Faulting completing state
- If PNS =1, then the peripheral is in the non-secure state. The DMAC sends a message to the peripheral to communicate when the data transfer is complete.

DMAFLUSHP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it sends a flush request to the peripheral.

- If PNS =0, then the peripheral is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
  - Sets the ch_periph_err bit in the FTRn register
  - Moves the DMA channel to the Faulting completing state
- If PNS =1, then the peripheral is in the non-secure state. The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status.

When a DMA channel thread is in the non-secure state, and a DMAMOV CCR instruction attempts to program the channel to perform a secure AXI transaction, the DMAC:

1. Executes a DMANOP
2. Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
3. Sets the ch_rdwr_err bit in the FTR*n* register
4. Moves the DMA channel thread to the Faulting completing state

Programming Restrictions

Certain restrictions apply when programming the DMAC.

Fixed Unaligned Bursts

The DMAC does not support fixed unaligned bursts. The DMAC treats the following conditions as programming errors:

- **Unaligned read**
  - src_inc field is 0 in the CCRn register.
  - The SARn register contains an address that is not aligned to the size of data that the src_burst_size field contains.
- **Unaligned write**
  - dst_inc field is 0 in the CCRn register.
  - The DARn register contains an address that is not aligned to the size of data that the dst_burst_size field contains.

Endian Swap Size Restrictions

If you program the endian_swap_size field in the CCRn register, to enable a DMA channel to perform an endian swap, then you must set the corresponding SAR register and the corresponding DARn register to contain an address that is aligned to the size that the endian_swap_size field specifies before executing any DMALD or DMAST instructions.

Note: If you update any of endian_swap_size, SARn, or DARn, for example, using a DMAADDH SAR instruction, then you must ensure that the SARn and DARn registers contain an address aligned to the size that the endian_swap_size field specifies before executing any additional DMALD or DMAST instructions.

If you program the src_inc field in the CCR register to use a fixed address, you must program the src_burst_size field to select a burst size that is greater than or equal to the value that the endian_swap_size field specifies. Similarly, if you program the dst_inc field to select a fixed destination address, you must program the dst_burst_size field to select a burst size that is greater than or equal to the value that the endian_swap_size field specifies.

If you program the dst_inc field in the CCRn register to use an incrementing address, you must program the CCRn register so that dst_burst_len times dst_burst_size is a multiple of endian_swap_size. For example, if endian_swap_size = 2, 32-bit, and dst_burst_size = 1, 2 bytes per beat, then you can program dst_burst_len = 1, 3, 5, ..., 15, that is 2, 4, 6, ..., 16 transfers.

Updating DMA Channel Control Registers During a DMA Cycle

Prior to the DMAC executing a sequence of DMALD and DMAST instructions, the values you program in to the CCRn register, SARn register, and DARn register control the data byte lane manipulation that the DMAC performs when it transfers the data from the source address to the destination address.

You can update these registers during a DMA cycle, but if you change certain register fields, then the DMAC may discard data. The following sections describe the register fields that could have a detrimental impact on a data transfer.

Updates that affect the destination address

If you use a DMAMOV instruction to update the DARn register or CCRn register part way through a DMA cycle, then there may be a discontinuity in the destination data stream.

A discontinuity occurs if you change any of the following:

- `endian_swap_size` field.
- `dst_inc` bit.
- `dst_burst_size` field when `dst_inc` = 0, that is, fixed-address burst.
- `DARn` register so that it modifies the destination byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the `DARn` register.

When a discontinuity in the destination data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read and write operations for the channel. That is, as if the DMAC were executing `DMARMB` and `DMAWMB`.
3. Discards any residual MFIFO buffer data for the channel.
4. Resumes execution of the DMA channel thread.

Updates that affect the source address

If you use a `DMAMOV` instruction to update the `SARn` register or `CCRn` register part way through a DMA cycle, then this might cause a discontinuity in the source data stream.

A discontinuity occurs if you change any of the following:

- `src_inc` bit.
- `src_burst_size` field.
- `SAR` register so that it modifies the source byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the `SAR` register.

When a discontinuity in the source data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read operations for the channel. That is, as if the DMAC were executing `DMARMB`
3. Resumes execution of the DMA channel thread. No data is discarded from the MFIFO buffer.

Resource Sharing Between DMA Channels

DMA channel programs share the MFIFO buffer data storage resource. You must not start a set of concurrently running DMA channel programs with a resource requirement that exceeds 512, the size of the MFIFO buffer. If you exceed this limit, then the DMAC might lock up and generate a Watchdog abort.

Refer to the "Watchdog Abort" section for more information regarding the abort mechanism.

The DMAC includes a mechanism called the *load-lock* to ensure that the shared MFIFO buffer resource is used correctly. The load-lock is either owned by one channel or it is free. The channel that owns the load-lock can execute `DMALD` instructions successfully. A channel that does not own the load-lock pauses at a `DMALD` instruction until it takes ownership of the load-lock.

A channel claims ownership of the load-lock when:

- It executes a `DMALD` or `DMALDP` instruction
- No other channel currently owns the load-lock

A channel releases ownership of the load-lock when any of the following occur:

- It executes a `DMAST`, `DMASTP`, or `DMASTZ`
- It reaches a barrier by executing `DMARMB` or `DMAWMB`
- It waits by executing `DMAWFP` or `DMAWFE`
- It terminates normally, that is, it executes `DMAEND`
- It aborts for any reason, including `DMAKILL`

The MFIFO buffer resource usage of a DMA channel program is measured in MFIFO buffer entries, and rises and falls as the program proceeds. The MFIFO buffer resource requirement of a DMA channel program is described using a *static requirement* and a *dynamic requirement* which are affected by the load-lock mechanism.

The static requirement is defined to be the maximum number of MFIFO buffer entries that a channel is currently using before that channel does one of the following:

- Executes a WFP or WFE instruction
- Claims ownership of the load-lock.

The dynamic requirement is defined to be the difference between the static requirement and the maximum number of MFIFO buffer entries that a channel program uses at any time during its

To calculate the total MFIFO buffer requirement, add the largest dynamic requirement to the sum of all the static requirements.

To avoid DMAC lockup, the total MFIFO buffer requirement of the set of channel programs must be equal to or less than 512, the MFIFO buffer depth.

Clocks and Resets

Clock

The DMA controller operates on the `l4_main_clk` input.

The DMA controller interfaces with the HPS peripherals through the peripheral request interface (PRI). The peripherals are in different clock domains, so clock crossing adapters are required between the DMA Controller and the peripherals.

Clock Manager on page 2-1

Resets

The DMA controller has nine reset signals. The reset manager drives the `aresetn` signal to the DMA controller on a cold or warm reset. The reset manager drives the `dma_fpga_if_rst_n[7:0]` signals to reset the eight FPGA PRIs.

Table 16-4: Reset inputs to the DMA controller

Reset Signal	Description
`aresetn`	Resets DMA controller
`dma_fpga_if_rst_n[7:0]`	Resets the eight FPGA peripheral request interfaces

Related Information

Reset Manager on page 3-1

Taking the DMA Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the Cortex-A9 MPCore CPU boots, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

- **Reset Manager** on page 3-1
- **Error Checking and Correction Controller** on page 11-1

Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

Constraints and Limitations of Use

DMA Channel Arbitration

The DMAC uses a round-robin scheme to serve the active DMA channels. To ensure that the DMAC continues to serve the DMA manager, it always serves the DMA manager prior to serving the next DMA channel.

Note: You cannot alter the arbitration process of the DMAC.

DMA Channel Prioritization

The DMAC responds to all active DMA channels with equal priority. You cannot increase the priority of a DMA channel over any other DMA channels.

Instruction Cache Latency

When a cache miss occurs, most of the delay is introduced by the memory containing the DMA code; the DMAC adds minimal delay.

AXI Data Transfer Size

The DMAC can only perform data accesses up to 64 bits in width. If you program the `src_burst_size` or `dst_burst_size` fields to be larger, the DMAC indicates a precise abort.

Related Information

Abort Sources on page 16-24

AXI Bursts Crossing 4 KB Boundaries

The AXI specification does not permit AXI bursts to cross 4 KB address boundaries. If you program the DMAC with a combination of burst start address, size, and length that would cause a single burst to cross a 4 KB address boundary, then the DMAC generates a pair of bursts with a combined length equal to that specified. This operation is transparent to the DMAC channel thread program so that, for example, the DMAC responds to a single `DMALD` instruction by generating the appropriate pair of AXI read bursts.

AXI Burst Types

You can program the DMAC to generate only fixed-address or incrementing-address burst types for data accesses. It does not generate wrapping-address bursts for data accesses or for instruction fetches.

AXI Write Addresses

The DMAC can issue up to eight outstanding write addresses. The DMAC does not issue a write address until it has read in all of the data bytes required to fulfill that write transaction.

AXI Write Data Interleaving

The DMAC does not generate interleaved write data. All write data beats for one write transaction are output before any write data beat for the next write transaction.

DMA Controller Programming Model

Instruction Syntax Conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

- `< >` - Any item bracketed by < and > is mandatory. A description of the item and of how it is encoded in the instruction is supplied by subsequent text.
- `[ ]` - Any item bracketed by [and] is optional. A description of the item and of how its presence or absence is encoded in the instruction is supplied by subsequent text.
- `" "` (spaces) - To separate items, single spaces are used for clarity. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

Instruction Set Summary

The DMAC instructions:

- Indicate a DMA prefix, to provide a unique name-space
- Have 8-bit opcodes that might use a variable data payload of 0, 8, 16, or 32 bits
- Indicate suffixes that are consistent.

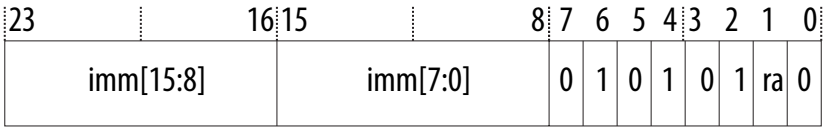
Instructions

DMAADDH

Add Halfword adds an immediate 16-bit value to the SARn register or DARn register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations.

Note: The immediate unsigned 16-bit value is zero-extended before the DMAC adds it to the address, using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000.

Figure 16-8: DMAADDH Instruction Encoding



Assembler syntax

```
DMAADDH <address_register>, <16-bit bit immediate>
```

where:

`<address_register>` Selects the address register to use. It must be either:

- SAR SAR*n* register and sets `ra` to 0
- DAR DAR*n* register and sets `ra` to 1

`<16-bit immediate>` The immediate value to be added to the `<address_register>`.

Operation

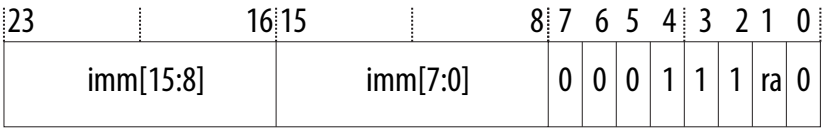
You can only use this instruction in a DMA channel thread.

DMAADNH

Add Negative Halfword adds an immediate negative 16-bit value to the SARn register or DARn register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations, or reading or writing an area of memory in a different order to naturally incrementing addresses.

Note: The immediate unsigned 16-bit value is one-extended to 32 bits, to create a value that is the two's complement representation of a negative number between -65536 and -1, before the DMAC adds it to the address using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000. The net effect is to subtract between 65536 and 1 from the current value in the source or destination address register.

Figure 16-9: DMAADNH Encoding



Assembler syntax

`DMAADNH <address_register>, <16 -bit immediate>`

where:

`<address_register>` Selects the address register to use. It must be either:

`SAR SAR`*n* register and sets `ra` to 0

`DAR DAR`*n* register and sets `ra` to 1

`<16- bit immediate>` The immediate value to be added to the `<address_register>`.

Note: You should specify the 16-bit immediate as the number that is to be represented in the instruction encoding. For example, `DMAADNH DAR`, 0xFFF0 causes the value 0xFFFFFFF0 to be added to the current value of the Destination Address register, effectively subtracting 16 from the `DAR`.

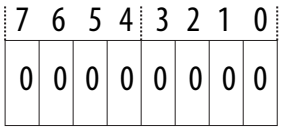
Operation

You can only use this instruction in a DMA channel thread.

DMAEND

End signals to the DMAC that the DMA sequence is complete. After all DMA transfers are complete for the DMA channel, the DMAC moves the channel to the Stopped state. It also flushes data from the MFIFO buffer and invalidates all cache entries for the thread.

Figure 16-10: DMAEND Instruction Encoding



Assembler syntax

`DMAEND`

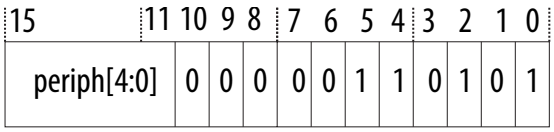
Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

DMAFLUSHP

Flush Peripheral clears the state in the DMAC that describes the contents of the peripheral and sends a message to the peripheral to resend its level status.

Figure 16-11: DMAFLUSHP Instruction Encoding



Assembler syntax

`DMAFLUSHP <peripheral>`

where:

`<peripheral>` 5-bit immediate, value 0-31

Operation

You can only use this instruction in a DMA channel thread.

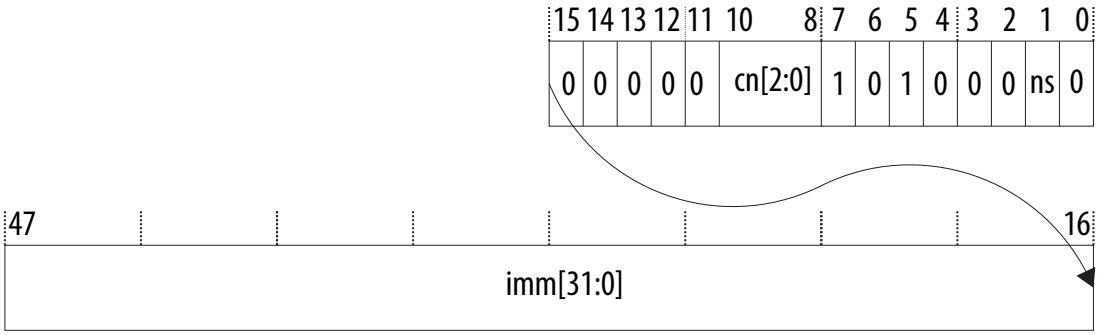
DMAGO

When the DMA manager executes Go for a DMA channel that is in the Stopped state, it performs the following steps on the DMA channel:

1. Moves a 32-bit immediate into the program counter
2. Sets its security state
3. Updates it to the Executing state.

Note: If a DMA channel is not in the Stopped state when the DMA manager executes `DMAGO` then the DMAC does not execute `DMAGO` but instead it executes `DMANOP`.

Figure 16-12: DMAGO Instruction Encoding



Assembler syntax

`DMAGO <channel_number>, <32- bit_immediate> [, ns]`

where:

`<channel_number>` Selects a DMA channel. It must be one of:

`C0` DMA channel 0

`C1` DMA channel 1

C2 DMA channel 2

C3 DMA channel 3

C4 DMA channel 4

C5 DMA channel 5

C6 DMA channel 6

C7 DMA channel 7

Note: If you provide a channel number that is not available for your configuration of the DMAC, the DMA manager thread aborts.

<32- bit_immediate> The immediate value that is written to the CPC*n* register for the selected <channel_number>.

[ns]

- If ns is present, the DMA channel operates in the Non-secure state.
- Otherwise, the execution of the instruction depends on the security state of the DMA manager:

DMA manager is in the Secure state—DMA channel operates in the Secure state.

DMA manager is in the Non-secure state—The DMAC aborts.

Operation

You can only use this instruction with the DMA manager thread.

DMAKILL

Kill instructs the DMAC to immediately terminate execution of a thread. Depending on the thread type, the DMAC performs the following steps:

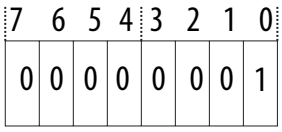
DMA Manager Thread

1. Invalidates all cache entries for the DMA manager.
2. Moves the DMA manager to the Stopped state.

DMA Channel Thread

1. Moves the DMA channel to the Killing state.
2. Waits for AXI transactions, with an ID equal to the DMA channel number, to complete.
3. Invalidates all cache entries for the DMA channel.
4. Remove all entries in the MFIFO buffer for the DMA channel.
5. Remove all entries in the read buffer queue and write buffer queue for the DMA channel.
6. Moves the DMA channel to the Stopped state.

Figure 16-13: DMAKILL Instruction Encoding



Assembler syntax

DMAKILL

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

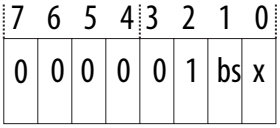
Note: You must not use the DMAKILL instruction in DMA channel programs. To issue a DMAKILL instruction, use the DBGINST0 register.

DMALD[S | B]

Load instructs the DMAC to perform a DMA load, using AXI transactions that the source address registers and channel control registers specify. It places the read data into the MFIFO buffer and tags it with the corresponding channel number. DMALD is an unconditional instruction but DMALDS and DMALDB are conditional on the state of the request_type flag. If the src_inc bit in the channel control registers is set to incrementing, the DMAC updates the source address registers after it executes DMALD[S|B].

Note: The DMAC sets the value of request_type when it executes a DMAWFP instruction.

Figure 16-14: DMALD[S|B] Instruction Encoding



Assembler syntax

DMALD[S|B]

where:

[S] If S is present, the assembler sets bs to 0 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single

The DMAC performs a DMALD instruction and it sets arlen[3:0]=0x0 so that the AXI read transaction length is one. The DMAC ignores the value of the src_burst_len field in the channel control registers.

- request_type = Burst

The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

[B] If B is present, the assembler sets bs to 1 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single

The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

- request_type = Burst

The DMAC performs a DMALD.

If you do not specify the S or B operand, the assembler sets bs to 0 and x to 0, and the DMAC always executes a DMA load.

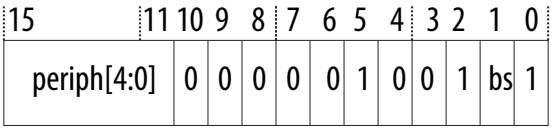
Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of `request_type` matching that of the instruction.

DMALDP<S | B>

Load and notify Peripheral instructs the DMAC to perform a DMA load, using AXI transactions that source address registers and channel control registers specify. It places the read data into a FIFO buffer that is tagged with the corresponding channel number and after it receives the last data item, it sends an acknowledgement to the peripheral that the data transfer is complete. If the `src_inc` bit in the channel control registers is set to incrementing, the DMAC updates source address registers after it executes `DMALDP<S|B>`.

Figure 16-15: DMALDP<S|B> Instruction Encoding



Assembler syntax

```
DMALDP<S|B> <peripheral>
```

where:

`<S>` When S is present, the assembler sets `bs` to 0. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMALDP` instruction and it sets `arlen[3:0]`=0x0 so that the AXI read transaction length is one. The DMAC ignores the value of the src_burst_len field in the channel control registers.

- `request_type` = Burst

The DMAC performs a `DMANOP`.

`<B>` When B is present, the assembler sets `bs` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMANOP`.

- `request_type` = Burst

The DMAC performs a load using a burst DMA transfer.

`<peripheral>` 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread. Execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

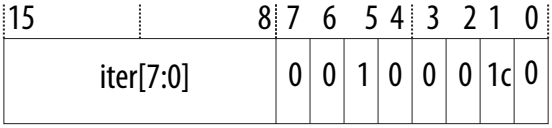
DMALP

Loop instructs the DMAC to load an 8-bit value into the loop counter register you specify.

This instruction indicates the start of a section of instructions, and you set the end of the section using the `DMALPEND` instruction. The DMAC repeats the set of instructions that you insert between `DMALP` and `DMALPEND` until the value in the loop counter register reaches zero.

Note: The DMAC saves the value of the PC for the instruction that follows `DMALP`. After the DMAC executes `DMALPEND`, and the loop counter register is not zero, this enables it to execute the first instruction in the loop.

Figure 16-16: DMALP Instruction Encoding



Assembler syntax

`DMALP <loop_iterations>`

where:

`<loop_iterations>`

Specifies the number of loops to perform, range 1-256.

- The assembler determines the loop counter register to use and either:
- Sets `lc` to 0, and the DMAC writes the value loop_iterations minus 1 to the loop counter 0 registers
- Sets `lc` to 1, and the DMAC writes the value loop_iterations minus 1 to the loop counter 1 registers.

Operation

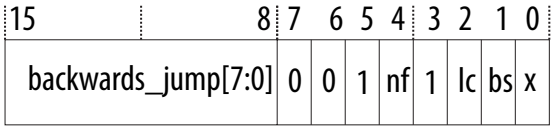
You can only use this instruction in a DMA channel thread.

DMALPEND[S | B]

Loop End indicates the last instruction in the program loop but the behavior of the DMAC depends on whether `DMALP` or `DMALPFE` starts the loop. If a loop starts with:

- `DMALP` The loop has a defined loop count and `DMALPEND[S|B]` instructs the DMAC to read the value of the loop counter register. If a loop counter register returns:
  - Zero—The DMAC executes a `DMANOP` and therefore exits the loop.
  - Nonzero—The DMAC decrements the value in the loop counter register and updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the `DMALP`.
- `DMALPFE` The loop has an undefined loop count and the DMAC uses the state of the `request_last` flag to control when it exits the loop. If the `request_last` flag is:
  - 0—The DMAC updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the `DMALP`.
  - 1—The DMAC executes a `DMANOP` and therefore exits the loop.

Figure 16-17: DMALPEND[S|B] Instruction Encoding



Assembler syntax

`DMALPEND[S|B]`

where:

`[S]` If S is present and the loop starts with `DMALP`, then the assembler sets `bs` to 0 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
  - The DMAC executes the `DMALPEND`
- `request_type` = Burst
  - The DMAC performs a `DMANOP` and therefore exits the loop.

`[B]` If B is present and the loop starts with `DMALP`, then the assembler sets `bs` to 1 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
  - The DMAC performs a `DMANOP` and therefore exits the loop.
- `request_type` = Burst
  - The DMAC executes the `DMALPEND`

If you do not specify the S or B operand, the assembler sets `bs` to 0 and `x` to 0, and the DMAC always executes the `DMALPEND`.

Note: You must not specify the S or B operand when a loop starts with `DMALPFE`. If you do, the assembler issues a warning message and sets `bs` to 0, `x` to 0, and `nf` to 1. In the same way as for `DMALPFE`, the DMAC uses the state of the `request_last` flag to control when it exits the loop.

Note: The DMAC sets the value of the:

- `request_type` flag when it executes a `DMAWFP` instruction.
- `request_last` flag to 1 when the corresponding peripheral issues the last request command through the peripheral request interface.

To correctly assign the additional bits in the `DMALPEND` instruction, the assembler determines the values for:

`backwards_jump[7:0]` Sets the relative location of the first instruction in the program loop. The assembler calculates the value for `backwards_jump[7:0]` by subtracting the address of the first instruction in the loop from the address of the `DMALPEND`.

- `nf` sets it to:
  - 0 if `DMALPFE` started the program loop
  - 1 if `DMALP` started the program loop.
- `lc` sets it to:
  - 0 if the loop counter 0 registers contains the loop counter value
  - 1 if the loop counter 1 registers contains the loop counter value
  - 1 if `DMALPFE` started the program loop.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

Related Information

- **Peripheral Length Management** on page 16-17
- **DMAWFP** on page 16-51

DMALPFE

The assembler uses Loop Forever to configure certain bits in `DMALPEND`.

Note: When the assembler encounters `DMALPFE`, it does not create an instruction for the DMAC, but instead, it modifies the behavior of `DMALPEND`. The insertion of `DMALPFE` in program code identifies the start of the loop.

Assembler syntax

```
DMALPFE
```

Related Information

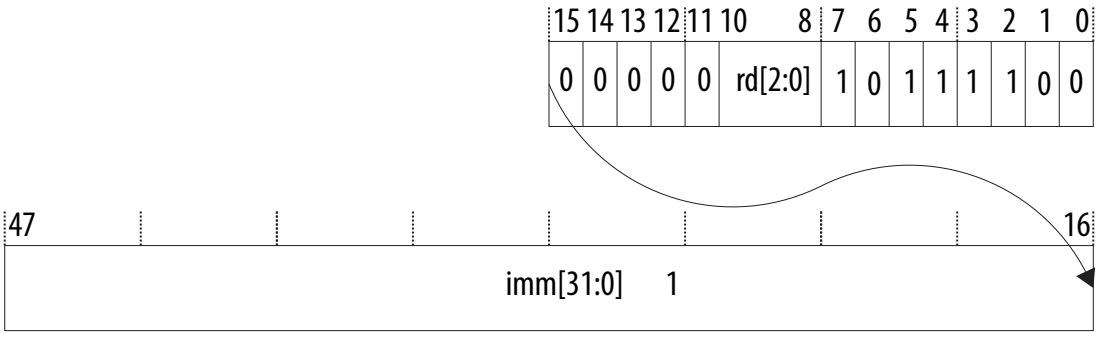
DMALPEND[S | B] on page 16-43

DMAMOV

Move instructs the DMAC to move a 32-bit immediate into the following registers:

- source address registers
- destination address registers
- channel control registers

Figure 16-18: DMAMOV Instruction Encoding



Assembler syntax

```
DMAMOV <destination_register>, <32- bit_immediate>
```

where:

`<destination_register>`

The valid registers are:

- `SAR`—selects the source address registers and sets `rd` to b000
- `CCR`—selects the channel control registers and sets `rd` to b001
- `DAR`—selects the destination address registers and sets `rd` to b010

`<32 -bit_immediate>`

A 32-bit value that is written to the specified destination register.

Note: For information about using the assembler to program the various fields that the channel control registers, refer to DMAMOV CCR section

Operation

You can only use this instruction in a DMA channel thread.

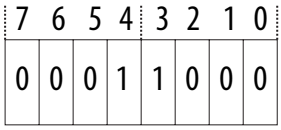
Related Information

DMAMOV CCR on page 16-53
Information about using the assembler to program the various fields that the channel control registers

DMANOP

No Operation does nothing. You can use this instruction for code alignment purposes.

Figure 16-19: DMANOP Instruction Encoding



Assembler syntax

```
DMANOP
```

Operation

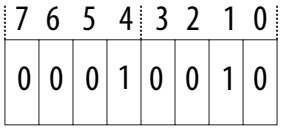
You can use the instruction with the DMA manager thread and the DMA channel thread.

DMARMB

Read Memory Barrier forces the DMA channel to wait until all of the executed `DMALD` instructions for that channel have been issued on the AXI master interface and have completed.

This enables write-after-read sequences to the same address location with no hazards.

Figure 16-20: DMARMB Instruction Encoding



Assembler syntax

```
DMARMB
```

Operation

You can only use this instruction in a DMA channel thread.

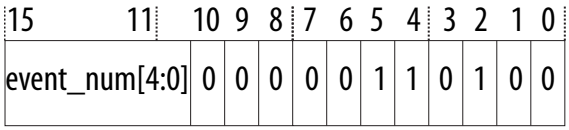
DMASEV

Send Event instructs the DMAC to modify an event-interrupt resource. Depending on how you program the interrupt enable register, this either:

- Generates event <event_num>

  Note: Typically, you use `DMAWFE` to stall a thread and then another thread executes `DMASEV`, using the appropriate event number, to unstall the waiting thread.
- Signals an interrupt using `irq <event_num>`.

Figure 16-21: DMASEV Instruction Encoding



Assembler syntax

```
DMASEV <event_num>
```

where:

`<event_num>` 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select an event number that is not available.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

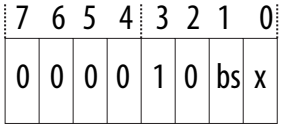
Related Information

- **Using Events and Interrupts** on page 16-22
- **Using an Event to Restart DMA Channels** on page 16-22

DMAST[S | B]

Store instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers specify. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMAST[S|B]`.

Figure 16-22: DMAST[S|B] Instruction Encoding



Assembler syntax

`DMAST[S|B]`

where:

`[S]` If S is present, the assembler sets `bs` to 0 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
- The DMAC performs a `DMAST` instruction and it sets `awlen[3:0]`=0x0 so that the AXI write transaction length is one. The DMAC ignores the v value of the dst_burst_len field in the channel control registers.
- `request_type` = Burst
- The DMAC performs a `DMANOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

`[B]` If B is present, the assembler sets `bs` to 1 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
- The DMAC performs a `DMANOP` instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.
- `request_type` = Burst
- The DMAC performs a `DMAST`.
- If you do not specify the S or B operand, the assembler sets `bs` to 0 and `x` to 0, and the DMAC always executes a DMA store.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

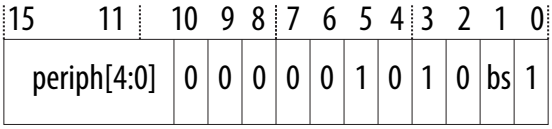
Related Information

DMAWFP on page 16-51

DMASTP<S | B>

Store and notify Peripheral instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers specify. It uses the DMA channel number to access the appropriate location in the FIFO buffer. After the DMA store is complete, and the DMAC has received a buffered write response, it issues an acknowledgement to the peripheral that the data transfer is complete. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMASTP<S|B>`.

Figure 16-23: DMASTP<S|B> Instruction Encoding



Assembler syntax

`DMASTP<S|B> <peripheral>`

where:

`<S>` Sets `bs` to 0. This instructs the DMAC to perform:

- A single DMA store operation if `request_type` is programmed to Single
- The DMAC ignores the state of the dst_burst_len field in the channel control registers and always performs an AXI transfer with a burst length of one.
- A `DMANOP` if `request_type` is programmed to Burst.

`<B>` Sets `bs` to 1. This instructs the DMAC to perform:

- The DMA store if `request_type` is programmed to Burst
- A `DMANOP` if `request_type` is programmed to Single.

`<peripheral>` 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

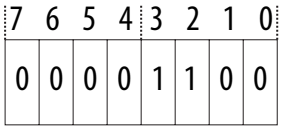
Related Information

DMAWFP on page 16-51

DMASTZ

Store Zero instructs the DMAC to store zeros, using AXI transactions that the destination address registers and channel control registers specify. If the `dst_inc` bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes `DMASTZ`.

Figure 16-24: DMASTZ Instruction Encoding



Assembler syntax

```
DMASTZ
```

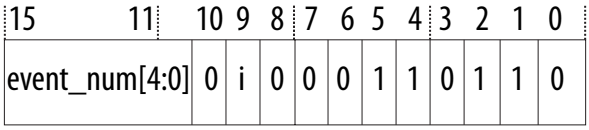
Operation

You can only use this instruction in a DMA channel thread.

DMAWFE

Wait For Event instructs the DMAC to halt execution of the thread until the event, that <event_num> specifies, occurs. When the event occurs, the thread moves to the Executing state and the DMAC clears the event.

Figure 16-25: DMAWFE Instruction Encoding



Assembler syntax

`DMAWFE <event_num>[, invalid]`

where:

`<event_num>` 5-bit immediate, value 0-31

`[invalid]` Sets `i` to 1. If `invalid` is present, the DMAC invalidates the instruction cache for the current DMA thread. If `invalid` is not present, then the assembler sets `i` to 0 and the DMAC does not invalidate the instruction cache for the current DMA.

- The DMAC aborts the thread if you select an event number that is not available for your configuration of the DMAC. To ensure cache coherency, you must use `invalid` when a processor writes the instruction stream for a DMA channel.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

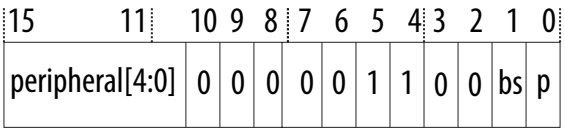
Related Information

Using Events and Interrupts on page 16-22

DMAWFP

Wait For Peripheral instructs the DMAC to halt execution of the thread until the specified peripheral signals a DMA request for that DMA channel.

Figure 16-26: DMAWFP Instruction Encoding



Assembler syntax

`DMAWFP <peripheral>, <single|burst|periph>`

where:

`<peripheral>` 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select a peripheral number that is not available.

`<single>` Sets `bs` to 0 and `p` to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the `request_type` to Single, for that DMA channel.

`<burst>` Sets `bs` to 1 and `p` to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a burst DMA request. The DMAC sets the `request_type` to Burst.

Note: The DMAC ignores single burst DMA requests.

`<periph>` Sets `bs` to 0 and `p` to 1. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the `request_type` to:

- **Single:** When it receives a single DMA request.
- **Burst:** When it receives a burst DMA request.

Operation

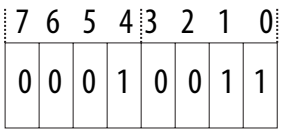
You can only use this instruction in a DMA channel thread.

DMAWMB

Write Memory Barrier forces the DMA channel to wait until all of the executed `DMAST` instructions for that channel have been issued on the AXI master interface and have completed.

This permits read-after-write sequences to the same address location with no hazards.

Figure 16-27: DMAWMB Instruction Encoding



Assembler syntax

```
DMAWMB
```

Operation

You can only use this instruction in a DMA channel thread.

Assembler Directives

The assembler provides several additional commands.

DCD

Assembler directive to place a 32-bit immediate in the instruction stream.

Syntax

DCD imm32

DCB

Assembler directive to place an 8-bit immediate in the instruction stream.

Syntax

DCB imm8

DMALP

Assembler directive to insert an iterative loop.

Syntax

DMALP [<LC0>|<LC1>] `<loop_iterations>`

where:

`<loop_iterations>`

An 8-bit value that specifies the number of loops to perform.

Note: For clarity in writing assembler instructions, the 8-bit value is the actual number of iterations of the loop to be executed. The assembler decrements this by one to create the actual value, 0-255, that the DMAC uses.

`[LC0]` If `LC0` is present, the DMAC stores `<loop_iterations>` in the loop counter 0 registers.

`[LC1]` If `LC1` is present, the DMAC stores `<loop_iterations>` in the loop counter 1 registers.

Note: If `LC0` or `LC1` is not present, the assembler determines the loop counter register to use.

DMALPFE

Assembler directive to insert a repetitive loop.

Syntax

DMALPFE

Enables the assembler to clear the `nf` bit that is present in `DMALPEND[S | B]`.

DMAMOV CCR

Assembler directive that enables you to program the channel control registers using the specified format.

Syntax

```
DMAMOV CCR,
[SB<1-16>] [SS<8|16|32|64|128>] [SA<I|F>]
[SP<imm3>] [SC<imm4>]
[DB<1-16>] [DS<8|16|32|64|128>] [DA<I|F>]
[DP<imm3>] [DC<imm4>]
[ES<8|16|32|64|128>]
```

Table 16-6: DMAMOV CCR Argument Description and Default Values

Syntax	Description	Options	Default
SA	Source address increment. Sets the value of `arburst[0]`	I = Increment F = Fixed	I
SS	Source burst size in bits. Sets the value of `arsize[2:0]`	8, 16, 32, or 64	8
SB	Source burst length. Sets the value of `arlen[3:0]`	1 to 16	1
SP	Source protection	0 to 7 (47)	0
SC	Source cache	0 to 15 (47)(48)	0
DA	Destination address increment. Sets the value of `awburst[0]`	I = Increment F = Fixed	I
DS	Destination burst size in bits. Sets the value of `awsize[2:0]`	8, 16, 32, or 64	8
DB	Destination burst length. Sets the value of `awlen[3:0]`	1 to 16	1
DP	Destination protection	0 to 7(47)	0
DC	Destination cache	0 to 15(47)(49)	0

(47) You must use decimal values when programming this immediate value.
(48) Because the DMAC ties ARCACHE[3] low, the assembler always sets bit 3 to 0 and uses bits [2:0] of your chosen value for SC.
(49) Because the DMAC ties AWCACHE[2] low, the assembler always sets bit 2 to 0 and uses bit [3] and bits [1:0] of your chosen value for DC.

Syntax	Description	Options	Default
ES	Endian swap size, in bits	8, 16, 32, or 64	8

MFIFO Buffer Usage Overview

About MFIFO Buffer Usage Overview

The MFIFO buffer is a shared resource that is utilized on a first-come, first-served basis by all currently active channels. To a program, it appears as a set of variable-depth parallel FIFO buffers, one per channel, with the restriction that the total depth of all the FIFOs cannot exceed the size of the MFIFO, which is 512 entries. The width of the AXI master interface is the same as the MFIFO buffer width.

The DMAC is capable of realigning data from the source to the destination. For example, the DMAC shifts the data by two byte lanes when it reads a word from address 0x103 and writes to address 0x205. All byte manipulations occur when data enters the MFIFO buffer, as a result of an AXI read due to a `DMALD` instruction, so that the DMAC does not need to manipulate the data when it removes it from the MFIFO buffer, as a result of an AXI write due to a `DMAST` instruction. Therefore the storage and packing of the data in the MFIFO buffer is determined by the destination address and transfer characteristics.

When a program specifies that incrementing transactions are to be performed to the destination, the DMAC packs data into the MFIFO buffer to minimize the usage of the MFIFO buffer entries. For example, the DMAC packs two 32-bit words into a single entry in the MFIFO buffer when the program uses a source address of 0x100, and destination address of 0x200.

The number of entries required to store the data loaded from a source is not a simple calculation of amount of source data divided by MFIFO buffer width in the following situations:

- The source address is not aligned to the AXI bus width.
- The destination address is not aligned to the AXI bus width.
- The transactions are to a fixed destination, that is, a non-incrementing address.

The `DMALD` and `DMAST` instructions each specify that an AXI transaction is to be performed. The amount of data transferred by an AXI transaction depends on the values programmed in to the `CCR` *n* register and the address of the transaction.

The following sections provide several example DMAC programs together with illustrations of the MFIFO buffer usage.

Note: These sections show MFIFO buffer usage in the following ways:

- A graph of the number of MFIFO buffer entries versus time
- A diagram of the byte-lane manipulation that the DMAC performs when data enters the MFIFO buffer.

Note: The numbers 0 and 7 in the MFIFO buffer diagrams indicate the byte lanes in the MFIFO buffer.

Aligned Transfers

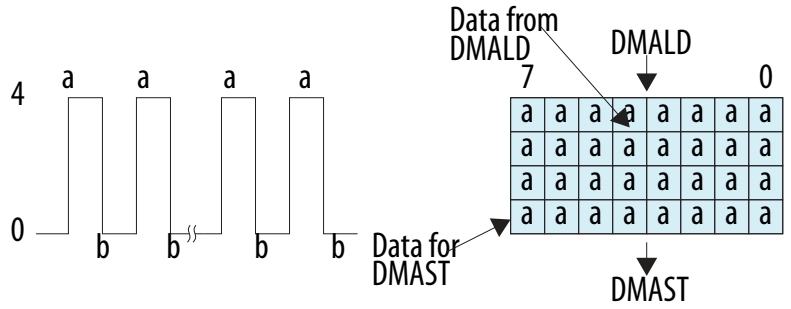
Simple Aligned Program

The following program shows the MFIFO buffer usage. In this program, the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in figure below
               DMAST    ; shown as b in figure below
DMALPEND
DMAEND
```

Figure 16-28: Simple Aligned Program

Each `DMALD` requires four entries and each `DMAST` removes four entries.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

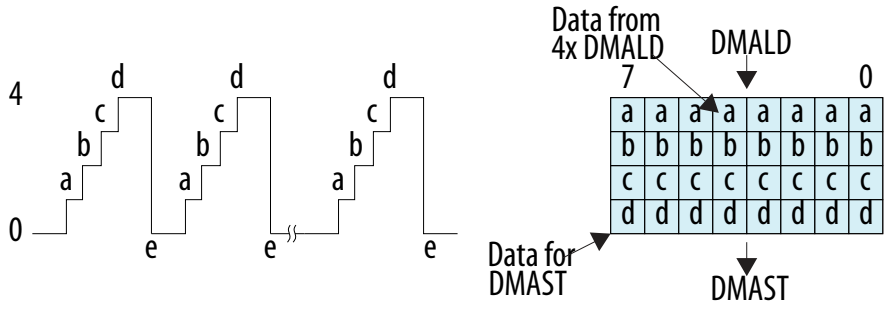
Aligned Asymmetric Program with Multiple Loads

The following program performs four loads for each store and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB1 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in the figure below
    DMALD ; shown as b in the figure below
    DMALD ; shown as c in the figure below
    DMALD ; shown as d in the figure below
    DMAST ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-29: Aligned Asymmetric Program with Multiple Loads

Each DMALD requires one entry and each DMAST removes four entries.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

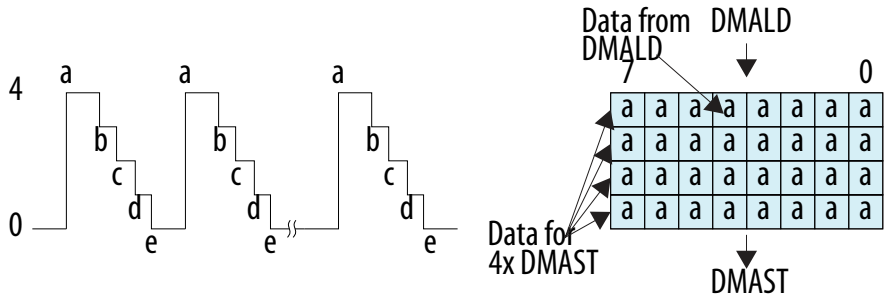
Aligned Asymmetric Program with Multiple Stores

The following program performs four stores for each load and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB1 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
    DMAST ; shown as c in the figure below
    DMAST ; shown as d in the figure below
    DMAST ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-30: Aligned Asymmetric Program with Multiple Stores

Each DMALD requires four entries and each DMAST removes one entry.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Transfers

Aligned Source Address to Unaligned Destination Address

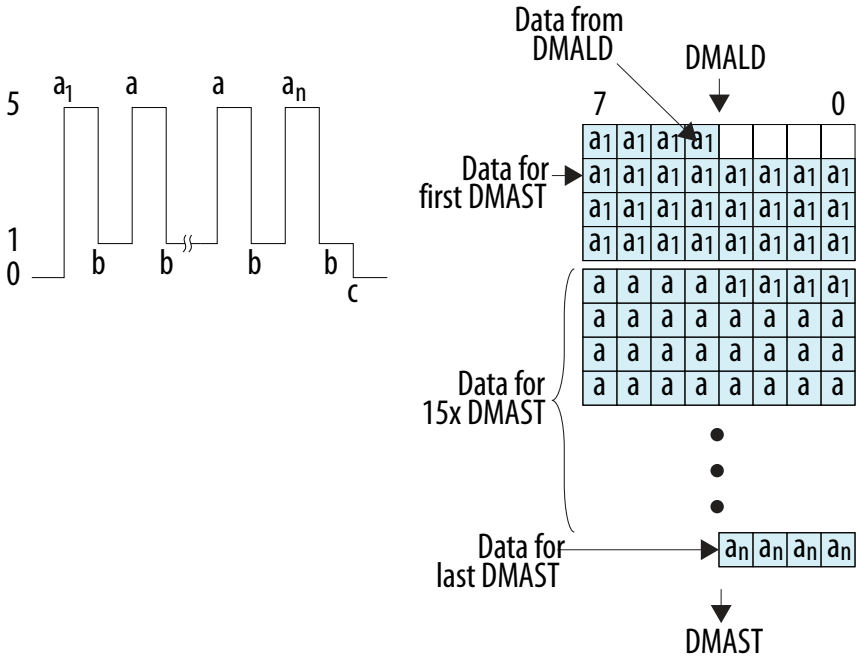
In the following program, the source address is aligned with the AXI data bus width but the destination address is unaligned. The destination address is not aligned to the destination burst size so the first DMAST instruction removes less data than the first DMALD instruction reads. Therefore, a final DMAST of a single word is required to clear the data from the MFIFO buffer.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
    DMALD ; shown as a1, ... a, an in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAMOV CCR, SB4 SS64 DB1 DS32
DMAST ; shown as c in the figure below
DMAEND
```

Figure 16-31: Aligned to Unaligned Program

The first DMALD instruction loads four doublewords but because the destination address is unaligned, the DMAC shifts them by four bytes and therefore uses five entries in the MFIFO buffer.

Each DMAST requires only four entries of data, and therefore the extra entry remains in use for the duration of the program, until it is emptied by the last DMAST.



This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address

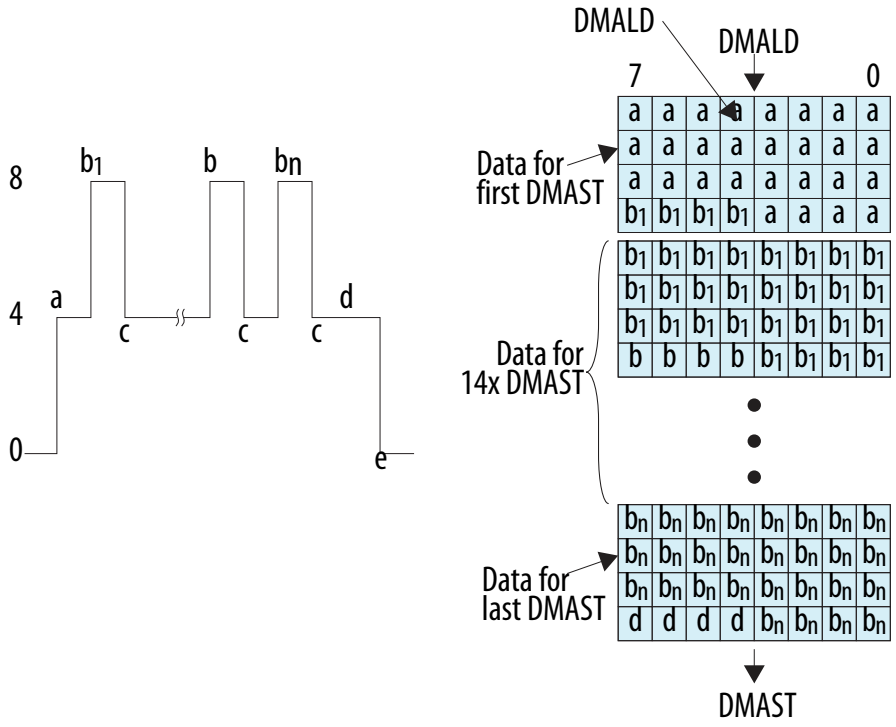
In this program, the source address is unaligned with the AXI data bus width but the destination address is aligned. The source address is not aligned to the source burst size so the first DMALD instruction reads in less data than the DMAST. Therefore, an extra DMALD is required to satisfy the first DMAST.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMALP 15
    DMALD ; shown as b1, ... b, bn in the figure below
    DMAST ; shown as c in the figure below
DMALPEND
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as d in the figure below
DMAST ; shown as e in the figure below
DMAEND
```

Figure 16-32: Unaligned to Aligned Program

The first DMALD instruction does not load sufficient data to enable the DMAC to execute a DMAST and therefore the program includes an additional DMALD, prior to the start of the loop.

After the first DMALD, the subsequent DMALDs align with the source burst size. This optimizes the **b** performance but it requires a larger number of MFIFO buffer entries.



Note: The DMALD shown as **d** does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of four MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address with Excess Initial Load

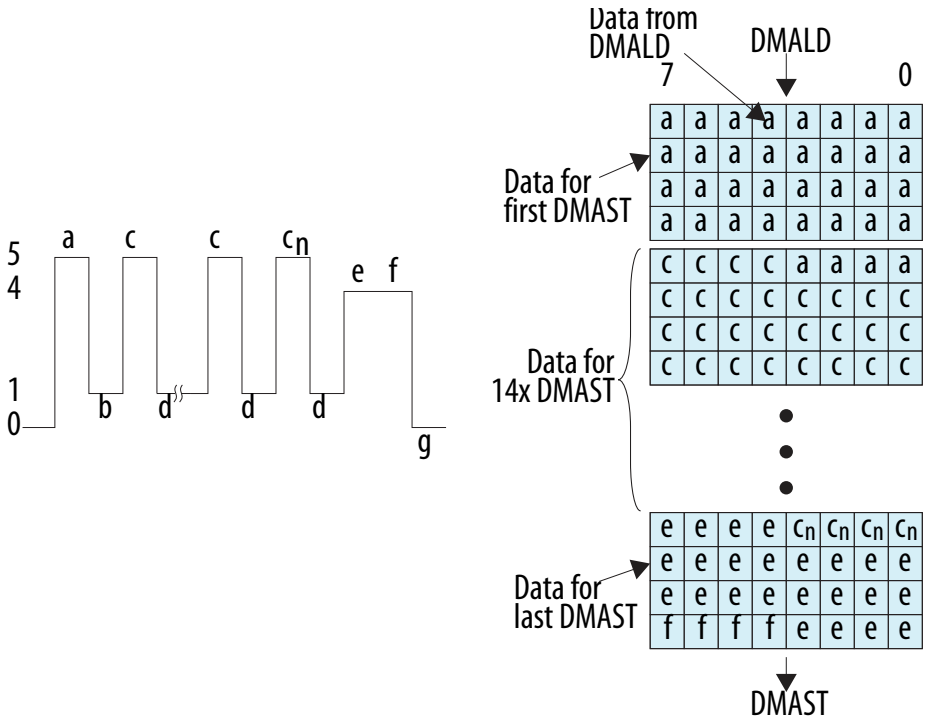
This program is an alternative to that described in *Unaligned Source Address to Aligned Destination Address*. The program executes a different sequence of source bursts that might be less efficient, but requires fewer MFIFO buffer entries.

```
DMAMOV CCR, SB5 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMAST ; shown as b in the figure below
DMAMOV CCR, SB4 SS64 DB4 DS64
DMALP 14
    DMALD ; shown as c and cn in the figure below
                DMAST ; shown as d in the figure below
DMALPEND
DMAMOV CCR, SB3 SS64 DB4 DS64
DMALD ; shown as e in the figure below
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as f in the figure below
DMAST ; shown as g in the figure below
DMAEND
```

Figure 16-33: Unaligned to Aligned with Excess Initial Load

The first DMALD instruction loads five bursts of data to enable the DMAC to execute the first DMAST.

After the first DMALD, the subsequent DMALDs are not aligned to the source burst size, for example the second DMALD reads from address 0x1028. After the loop, the final two DMALDs read the data required to satisfy the final DMAST.



Note: The DMALD shown as **f** does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Related Information

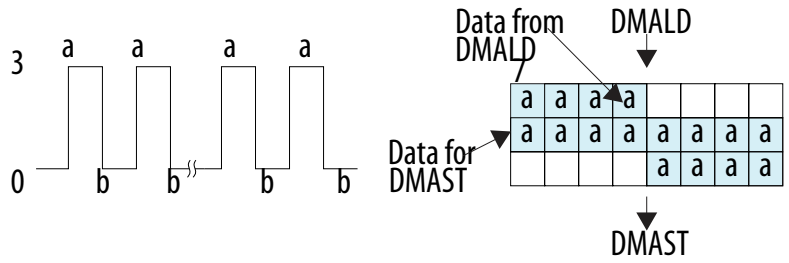
Unaligned Source Address to Aligned Destination Address on page 16-58

Aligned Burst Size Unaligned MFIFO Buffer

In this program, the destination address, which is narrower than the MFIFO buffer width, aligns with the burst size, but does not align with the MFIFO buffer width.

```
DMAMOV CCR, SB4 SS32 DB4 DS32
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
 DMALD ; shown as a in the figure below
 DMAST ; shown as b in the figure below
DMALPEND
DMAEND
```

Figure 16-34: Aligned Burst with Unaligned MFIFO Buffer Width



In this example, the destination address is not 64-bit aligned, it requires three rather than the expected two MFIFO buffer entries.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of three MFIFO buffer entries.

Fixed Transfers

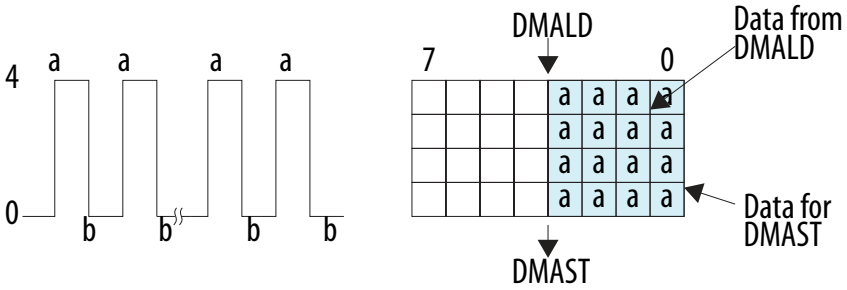
Fixed Destination with Aligned Address

In this program, the source address and destination address are aligned with the AXI data bus width, and the destination address is fixed.

```
DMAMOV CCR, SB2 SS64 DB4 DS32 DAF
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAEND
```

Figure 16-35: Fixed Destination with Aligned Address

Each `DMALD` in the program loads two 64-bit data transfers into the MFIFO buffer. Because the destination address is a 32-bit fixed address, then the DMAC splits each 64-bit data item across two entries in the MFIFO buffer.

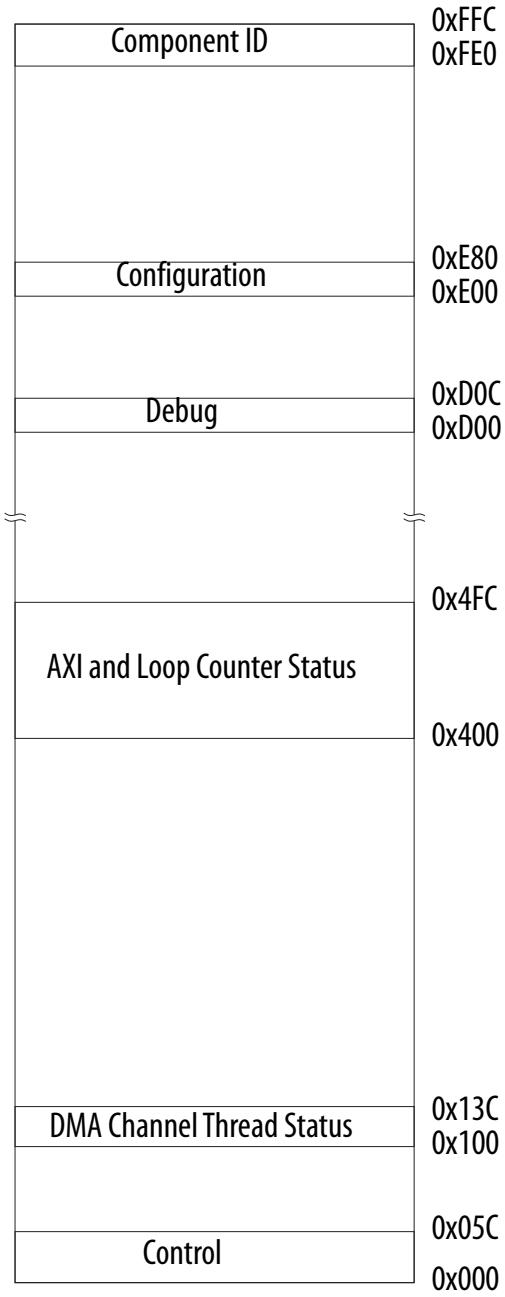


This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

DMA Controller Address Map and Register Definitions

The following DMAC register map spans a 4 KB region, consists of the following sections.

Figure 16-36: DMAC Summary Register Map



- **Control registers—** allow you to control the DMAC.
- **DMA channel thread status registers—**provide the status of the DMA channel threads.
- **AXI and loop counter status registers—**provide the AXI transfer status and the loop counter status for each DMA channel thread.
- **Debug registers—**enable the following functionality:
  - Allow you to send instructions to a thread when debugging the program code.
  - Allow system firmware to send instructions to the DMA manager thread.
- **Configuration registers—**enable system firmware to identify the configuration of the DMAC and control the behavior of the watchdog.
- **Component ID registers—** enable system firmware to identify peripherals. Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in an unpredictable behavior.

15:0	SIREV	IP Rev # These bits indicate the silicon revision number.	RO	0x0

CTRL

ECC Control Register

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8008

Offset: 0x8

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INITA 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CNT_RSTA 0x0	Reserved							ECC_EN 0x0

CTRL Fields

Bit	Name	Description	Access	Reset
16	INITA	Enable for the hardware memory initialization PORTA.	RW	0x0
8	CNT_RSTA	Enable to reset internal single-bit error counter A value to zero	RW	0x0
0	ECC_EN	Enable for the ECC detection and correction logic.	RW	0x0

INITSTAT

This bit is used to set the initialize the memory and ecc to a known value

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C800C

Offset: 0xC

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															INITCOMPLETEA 0x0

INITSTAT Fields

Bit	Name	Description	Access	Reset
0	INITCOMPLETEA	This bit is used to verify if the hardware memory initialization has completed PORTB.	RW	0x0

ERRINTEN

Error Interrupt enable

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTEN 0x0

ERRINTEN Fields

Bit	Name	Description	Access	Reset
0	SERRINTEN	This bit is used to enable the single bit error interrupt of ECC RAM system	RW	0x0

ERRINTENS

Error Interrupt set

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8014

Offset: 0x14

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTS 0x0

ERRINTENS Fields

Bit	Name	Description	Access	Reset
0	SERRINTS	This bit is used to set the single-bit error interrupt bit.	RW	0x0

ERRINTENR

Error Interrupt reset.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															SERRINTR 0x0

ERRINTENR Fields

Bit	Name	Description	Access	Reset
0	SERRINTR	This bit is used to reset the single-bit error interrupt bit. Reads reflect SERRINTEN. 1'b0: Writing of zero has no effect. 1'b1: By writing one, this bit will reset SERRINTEN bit to 0. This is performing a bitwise writing of this feature.	RW	0x0

INTMODE

Reads reflect SERRINTEN.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C801C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															INTONCMP 0x0
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							INTONOVF 0x0	Reserved							INTMODE 0x0

INTMODE Fields

Bit	Name	Description	Access	Reset
16	INTONCMP	Enable interrupt on compare.	RW	0x0
8	INTONOVF	Enable interrupt on overflow.	RW	0x0
0	INTMODE	Interrupt mode for single-bit errors.	RW	0x0

INTSTAT

This bit is used to enable interrupt generation on SERR lookup table overflow. When all the entries in the table are valid=1 and this is bit is enabled, serr_req signal will be asserted.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8020

Offset: 0x20

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							DERRPENA 0x0	Reserved							SERRPENA 0x0

INTSTAT Fields

Bit	Name	Description	Access	Reset
8	DERRPENA	Double-bit error pending for PORTA.	RW	0x0
0	SERRPENA	Single-bit error pending for PORTA.	RW	0x0

INTTEST

This bits is used to test interrupt from ECC RAM to GIC

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8024

Offset: 0x24

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							TDERRA 0x0	Reserved							TSERRA 0x0

INTTEST Fields

Bit	Name	Description	Access	Reset
8	TDERRA	Test PORTA Double-bit error.	RW	0x0
0	TSERRA	Test PORTA Single-bit error.	RW	0x0

MODSTAT

Counter feature status flag

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8028

Offset: 0x28

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CMPFLGA 0x0

MODSTAT Fields

Bit	Name	Description	Access	Reset
0	CMPFLGA	Port A compare status flag	RW	0x0

DERRADDRA

This register shows the address of PORTA current double-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C802C

Offset: 0x2C

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

DERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent double-bit error address.	RO	0x0

SERRADDRA

This register shows the address of PORTA current single-bit error. RAM size will determine the maximum number of address bits.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8030

Offset: 0x30

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							Address 0x0								

SERRADDRA Fields

Bit	Name	Description	Access	Reset
8:0	Address	Recent single-bit error address.	RO	0x0

SERRCNTREG

Maximum counter value for single-bit error interrupt

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C803C

Offset: 0x3C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SERRCNT 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SERRCNT 0x0															

SERRCNTREG Fields

Bit	Name	Description	Access	Reset
31:0	SERRCNT	Counter value	RW	0x0

ECC_Addrbus

MSB bit of address is determined by ADR.

Module Instance	Base Address	Register Address
ecc_dmac_ecc_registerBlock	0xFF8C8000	0xFF8C8040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31	VALID	Valid flag bit. Valid bit indicates if the address in this register is current or stale.	RW	0x0
8:0	Address	Recent Single-bit error address. This register shows the address of the each single-bit error. RAM size will determine the maximum number of address bits. If ram size is 32 Kbytes, bit 30-16 will be reserved and read as zero.	RO	0x0

dma_NSCONTROL Address Map

This address space is allocated for DMA control registers.

Module Instance	Base Address	End Address
i_dma_NSCONTROL	0xFFDA0000	0xFFDA00FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_NSCHANNELSTATUS Address Map

This address space is allocated for the registers that provide the status of the DMA channel threads.

Module Instance	Base Address	End Address
i_dma_NSCHANNELSTATUS	0xFFDA0100	0xFFDA03FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_NSAXISTATUS Address Map

This address space is allocated for the registers that provide the AXI transfer status and loop counter status for each DMA channel thread.

Module Instance	Base Address	End Address
i_dma_NSAXISTATUS	0xFFDA0400	0xFFDA0CFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_NSDEBUG Address Map

This address space is allocated for the debug registers.

Module Instance	Base Address	End Address
i_dma_NSDEBUG	0xFFDA0D00	0xFFDA0DFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_NSCONFIG Address Map

This address space holds registers that can be read for configuration data and control watchdog behavior.

Module Instance	Base Address	End Address
i_dma_NSCONFIG	0xFFDA0E00	0xFFDA0FDF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_NSCOMPID Address Map

This address space holds peripheral ID information.

Module Instance	Base Address	End Address
i_dma_NSCOMPID	0xFFDA0FE0	0xFFDA0FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SCONTROL Address Map

This address space is allocated for DMA control registers.

Module Instance	Base Address	End Address
i_dma_SCONTROL	0xFFDA1000	0xFFDA10FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SCHANNELSTATUS Address Map

This address space is allocated for the registers that provide the status of the DMA channel threads.

Module Instance	Base Address	End Address
i_dma_SCHANNELSTATUS	0xFFDA1100	0xFFDA13FF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SAXISTATUS Address Map

This address space is allocated for the registers that provide the AXI transfer status and loop counter status for each DMA channel thread.

Module Instance	Base Address	End Address
i_dma_SAXISTATUS	0xFFDA1400	0xFFDA1CFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SDEBUG Address Map

This address space is allocated for the debug registers.

Module Instance	Base Address	End Address
i_dma_SDEBUG	0xFFDA1D00	0xFFDA1DFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SCONFIG Address Map

This address space holds registers that can be read for configuration data and control watchdog behavior.

Module Instance	Base Address	End Address
i_dma_SCONFIG	0xFFDA1E00	0xFFDA1FDF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

dma_SCOMPID Address Map

This address space holds peripheral ID information.

Module Instance	Base Address	End Address
i_dma_SCOMPID	0xFFDA1FE0	0xFFDA1FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Ethernet Media Access Controller 17

2016.10.28

a10_5v4

The hard processor system (HPS) provides three Ethernet media access controller (EMAC) peripherals. Each EMAC can be used to transmit and receive data at 10/100/1000 Mbps over Ethernet connections in compliance with the IEEE 802.3 specification. The EMACs are instances of the Synopsys DesignWare Universal 10/100/1000 Ethernet MAC (version 3.72a).

The EMAC has an extensive memory-mapped control and status register (CSR) set, which can be accessed by the ARM Cortex-A9® MPCore.

For an understanding of this chapter, you should be familiar with the basics of IEEE 802.3 media access control (MAC). (50)

Related Information

IEEE Standards Association

For complete information about IEEE 802.3 MAC, refer to the *IEEE 802.3 2008 Part 3: Carrier sense multiple access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications*, available on the IEEE Standards Association website.

Features of the Ethernet MAC

MAC

- IEEE 802.3-2008 compliant
- Data rates of 10/100/1000 Mbps
- Full duplex and half duplex modes
  - IEEE 802.3x flow control automatic transmission of zero-quanta pause frame on flow control input deassertion
  - Optional forwarding of received pause control frames to the user
  - Packet bursting and frame extension in 1000 Mbps half-duplex
  - IEEE 802.3x flow control in full-duplex
  - Back-pressure support for half-duplex
- 4 KB TX FIFO RAM and 16 KB RX FIFO RAM with ECC support
- IEEE 1588-2002 and IEEE 1588-2008 precision networked clock synchronization
- IEEE 802.3-az, version D2.0 for Energy Efficient Ethernet (EEE)
- IEEE 802.1Q Virtual Local Area Network (VLAN) tag detection for reception frames
- Preamble and start-of-frame data (SFD) insertion in transmit and deletion in receive paths
- Automatic cyclic redundancy check (CRC) and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length supporting standard and jumbo Ethernet frames (with sizes up to 3800 bytes)
- Programmable inter-frame gap (IFG), from 40- to 96-bit times in steps of eight bits
- Preamble lengths of one, three, five and seven bytes supported
- Supports internal loopback asynchronous FIFO on the GMII/MII for debugging
- Supports a variety of flexible address filtering modes
  - Up to 31 additional 48-bit perfect destination address (DA) filters with masks for each byte
  - Up to 31 48-bit source address (SA) comparison check with masks for each byte
  - 256-bit hash filter (optional) for multicast and unicast DAs
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report

DMA

- 32-bit interface
- Programmable burst size for optimal bus utilization
- Single-channel mode transmit and receive engines
- Byte-aligned addressing mode for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptors can each transfer up to 8 KB of data
- Independent DMA arbitration for transmit and receive with fixed priority or round robin

Management Interface

- 32-bit host interface to CSR set
- Comprehensive status reporting for normal operation and transfers with errors
- Configurable interrupt options for different operational conditions
- Per-frame transmit/receive complete interrupt control
- Separate status returned for transmission and reception packets

Acceleration

- Transmit and receive checksum offload for transmission control protocol (TCP), user datagram protocol (UDP), or Internet control message protocol (ICMP) over Internet protocol (IP)

PHY Interface

Different external PHY interfaces are provided depending on whether the Ethernet Controller signals are routed through the HPS I/O pins or the FPGA I/O pins.

The PHY interfaces supported using the HPS I/O pins are:

- Reduced Media Independent Interface (RMII)
- Reduced Gigabit Media Independent Interface (RGMII)

The PHY interfaces supported using the FPGA I/O pins are:

- Media Independent Interface (MII)
- Gigabit Media Independent Interface (GMII)
- Reduced Media Independent Interface (RMII) with additional required adaptor logic

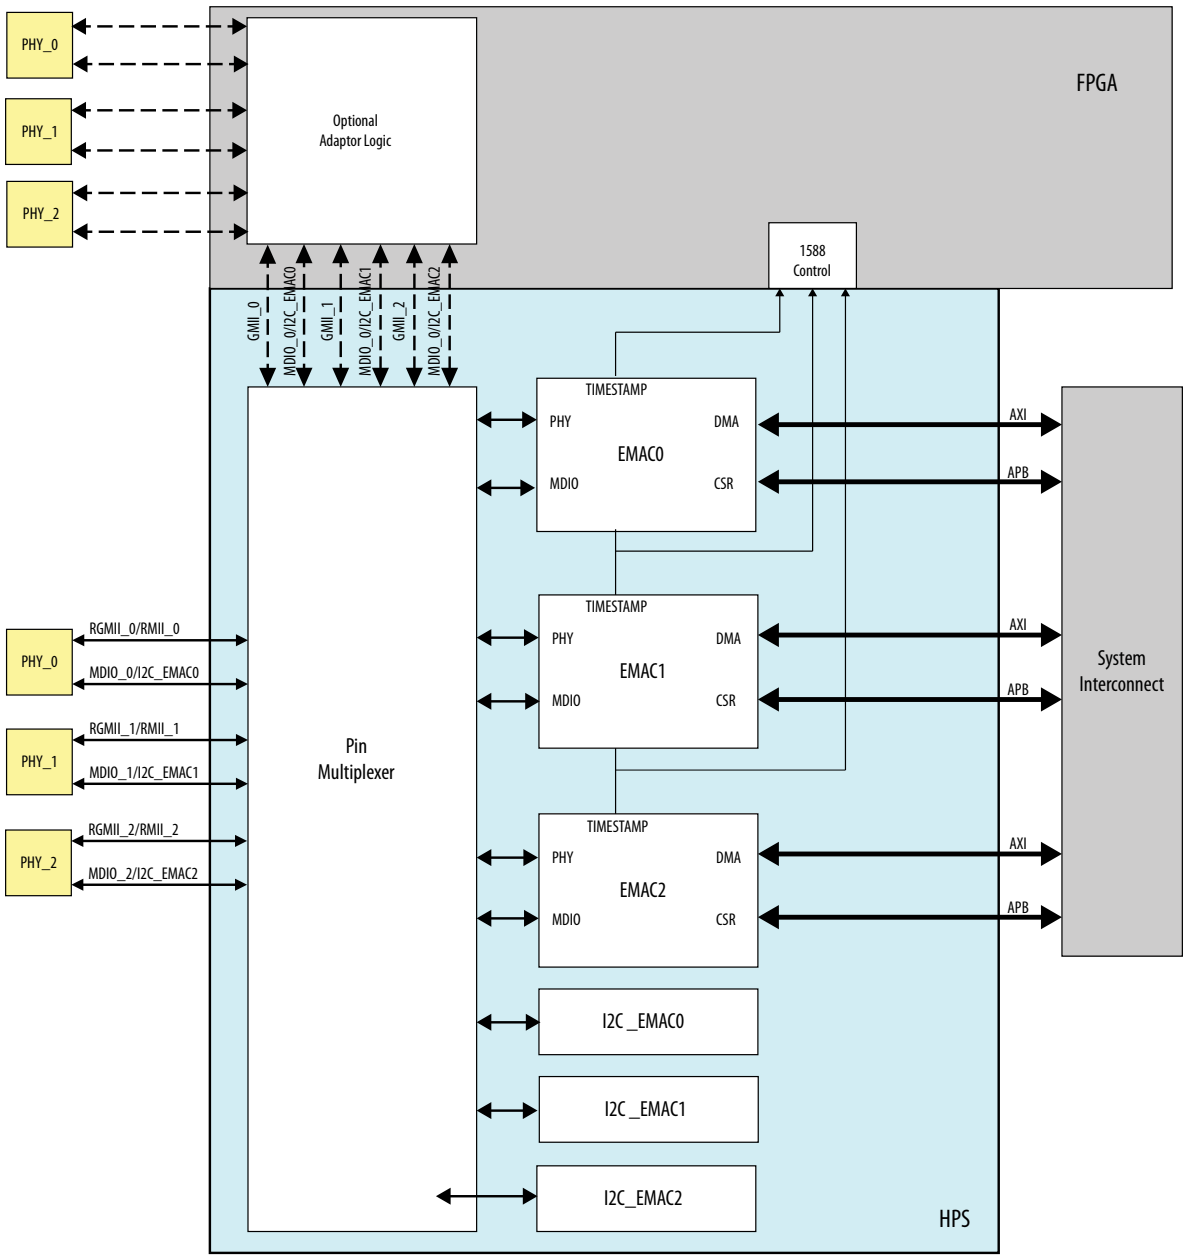
  Note: Additional adaptor logic for RMII not provided.
- Reduced Gigabit Media Independent Interface (RGMII) with additional required adaptor logic
- Serial Gigabit Media Independent Interface (SGMII) supported through transceiver I/O or high-speed low-voltage differential signaling (LVDS) with soft clock data recover (CDR) I/O with additional required adaptor logic

The Ethernet Controller has two choices for the management control interface used for configuration and status monitoring of the PHY:

- Management Data Input/Output (MDIO)
- I^2C PHY management through a separate I^2C module within the HPS

EMAC Block Diagram and System Integration

Figure 17-1: EMAC System Integration



EMAC Overview

Each EMAC is an internal bus master that sends Ethernet packets to and from the System Interconnect. The EMAC uses a descriptor ring protocol, where the descriptor contains an address to a buffer to fetch or store the packet data.

Each EMAC has an MDIO Management port to send commands to the external PHY. Alternatively, you can use an I^2C module in the HPS for the management interface.

Each EMAC has an IEEE 1588 Timestamp interface with 10 ns resolution. The ARM Cortex-A9 microprocessor unit (MPU) subsystem can use it to maintain synchronization between the time counters that are internal to the three MACs. The clock reference for the timestamp can be provided by the Clock Manager (`emac_ptp_clk`) or the FPGA fabric (`f2s_emac_ptp_ref_clk`). The clock reference is selected by the `ptp_clk_sel` bit in the `emac_global` register in the system manager.

Note: All three EMACs must use the same clock reference. In addition, EMAC0 can be configured to provide the timestamp for EMAC1, EMAC2, or both by setting the `ptp_ref_sel` bit in the `emac*` register in the System Manager.

EMAC Signal Description

The EMAC provides a variety of PHY interfaces and control options through the HPS and the FPGA I/Os.

For designs in which the HPS is pin-limited, the EMAC signals can be routed through the FPGA as any one of the following interfaces by using soft adaptor logic in the FPGA:

- RMII/RGMII
- MII/GMII
- SGMII

The figure below depicts a design which routes the EMAC0 and EMAC1 signals through the FPGA to provide an RMII and SGMII interface. EMAC2 is routed through the HPS.

Refer to the "EMAC FPGA Interface Initialization" section to find out more information about configuring EMAC interfaces through FPGA.

HPS EMAC I/O Signals

There are three EMACs available in the HPS. The following table lists the EMAC signals that can be routed from the EMACs to the HPS I/O pins. These signals provide the RMII/RGMII interface. For more

information on routing EMAC signals to the FPGA and the HPS I/O, refer to the *HPS Component Interfaces* chapter.

Note: The "n" in EMACn stands for the EMAC peripheral number.

Table 17-1: HPS EMAC I/O Signals

EMAC HPS I/O		In/Out	Width	Description
EMAC0_TX_CLK EMAC1_TX_CLK EMAC2_TX_CLK	Transmit Clock routed from one of three Qsys port signals emac[2:0]_phy_txclk_o	Out	1	This signal provides the transmit clock for RGMII (125/25/2.5 MHz in 1G/100M/10Mbps). This signal is one option for the common transmit and receive clock in RMII mode (50 MHz in 100M or 10 Mbps mode). The other possible source for the common transmit and receive clock is an external clock source, in which case EMACn_TX_CLK is left unconnected. In RMII mode, if this signal is the clock source for the receiver, then connect EMACn_TX_CLK to EMACn_RX_CLK. All PHY transmit signals generated by the EMAC are synchronous to this clock.
EMAC0_TXD[3:0] EMAC1_TXD[3:0] EMAC2_TXD[3:0]	PHY Transmit Data, routed from one of three groups of Qsys port signals emac[2:0]_phy_txd_o[3:0]	Out	4	This group of transmit data signals is driven by the MAC. Bits [3:0] provide the RGMII transmit data, and bits [1:0] provide the RMII transmit data. In RGMII mode, the data bus carries transmit data at double rate and are sampled on both the rising and falling edges of the transmit clock. The validity of the data is qualified with EMACn_TX_CTL.
EMAC0_TX_CTL EMAC1_TX_CTL EMAC2_TX_CTL	PHY Transmit Data Enable, routed from one of three Qsys port signals emac[2:0]_phy_txen	Out	1	This signal is driven by the EMAC component. In RGMII mode, this signal acts as the control signal for the transmit data, and is driven on both edges of the transmit clock, EMACn_TX_CLK. In RMII mode, this signal is high to indicate valid data.

EMAC HPS I/O		In/Out	Width	Description
EMAC0_RX_CLK EMAC1_RX_CLK EMAC2_RX_CLK	Receive Clock, routed to one of three Qsys port signals emac[2:0]_clk_rx_i	In	1	In RGMII mode, this clock frequency is 125/25/2.5 MHz in 1 G/100 M/10 Mbps modes. It is provided by the external PHY. All PHY signals received by the EMAC are synchronous to this clock. In RMII mode, this clock frequency is 50 MHz. The source of this clock can be: • An external source: In this case EMACn_TX_CLK should be left unconnected. • EMACn_TX_CLK: In this case, EMACn_TX_CLK must be connected to EMACn_RX_CLK.
EMAC0_RXD[3:0] EMAC1_RXD[3:0] EMAC2_RXD[3:0]	PHY Receive Data, routed to one of three groups of Qsys port signals emac[2:0]_phy_rxd[3:0]	In	4	These data signals are received from the PHY. In RGMII mode, data is received at double data rate with bits[3:0] valid on the rising and falling edges of EMACn_RX_CLK. In RMII mode, data is received at single data rate with bits [1:0] valid on the rising edge of EMACn_RX_CLK. The validity of the data is qualified with EMACn_RX_CTL.
EMAC0_RX_CTL EMAC1_RX_CTL EMAC2_RX_CTL	PHY Receive Data Valid, routed to one of three groups of Qsys port signals emac[2:0]_phy_rxdv.	In	1	This signal is driven by the PHY and functions as the receive control signal used to qualify the data received on EMACn_RXD[3:0]. This signal is sampled on both edges of the clock in RGMII mode. See row above for clock to data relationships across the modes.

FPGA EMAC I/O Signals

Three Ethernet Media Access Controllers are provided in the HPS. The table below describes the signals that are available from each Ethernet Media Access Controller to the FPGA I/O. For more information on routing EMAC signals to the FPGA and HPS I/O, refer to the *HPS Component Interfaces* chapter. See the HPS I/O table for general clock to data relationships across the modes.

Table 17-2: FPGA EMAC I/O Signals

Signal Name		In/Out	Width	Description
emac_clk_tx_i	Transmit Clock	In	1	This is the transmit clock (2.5 MHz/25 MHz) provided by the MII PHYs only. This clock comes from the FPGA Interface and is used for TX data capture. This clock is not used in GMII mode. **Note:** This clock must be able to perform glitch free switching between 2.5 and 25 MHz.
emac_phy_txclk_o	Transmit Clock Output	Out	1	In GMII mode, this signal is the transmit clock output to the PHY to sample data. For MII, this clock is unused.
emac_phy_txd_o[7:0]	PHY Transmit Data	Out	8	These are a group of eight transmit data signals driven by the EMAC. All eight bits provide the GMII transmit data byte. For the lower speed MII operation, only bits[3:0] are used. The validity of the data is qualified with phy_txen_o and phy_txer_o. Synchronous to phy_txclk_o.
emac_phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC and is used in GMII mode. When driven high, this signal indicates that valid data is being transmitted on the clk_tx_o bus.
emac_phy_txer_o	PHY Transmit Error	Out	1	This signal is driven by the EMAC and when high, indicates a transmit error or carrier extension on the phy_txd bus. It is also used to signal low power states in Energy Efficient Ethernet operation.

Signal Name		In/Out	Width	Description
emac_rst_clk_tx_n_o	Transmit Clock Reset output	Out	1	Transmit clock reset output to the FPGA fabric, which is the internal synchronized reset to clk_tx_int output from the EMAC. May be used by logic implemented in the FPGA fabric as desired. The reset pulse width of the rst_clk_tx_n_o signal is three transmit clock cycles.
emac_clk_rx_i	Receive Clock	In	1	Receive clock from external PHY. For GMII, the clock frequency is 125 MHz. For MII, the receive clock is 25 MHz for 100 Mbps and 2.5 MHz for 10 Mbps.
emac_phy_rxd_i[7:0]	PHY Receive Data	In	8	This is an eight-bit receive data bus from the PHY. In GMII mode, all eight bits are sampled. The validity of the data is qualified with phy_rxdv_i and phy_rxer_i. For lower speed MII operation, only bits [3:0] are sampled. These signals are synchronous to phy_clk_rx_i.
emac_phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY. In GMII mode, when driven high, it indicates that the data on the phy_rxd bus is valid. It remains asserted continuously from the first recovered byte of the frame through the final recovered byte.
emac_phy_rxer_i	PHY Receive Error	In	1	This signal indicates an error or carrier extension (GMII) in the received frame. This signal is synchronous to phy_clk_rx_i.
emac_rst_clk_rx_n_o	Receive clock reset output.	Out	1	Receive clock reset output. The reset pulse width of the rst_clk_rx_n_o signal is three transmit clock cycles.

Signal Name		In/Out	Width	Description
emac_phy_mac_speed_o[1:0]	EMAC Speed	Out	2	This signal indicates the 10-Mbps, 100-Mbps or 1000-Mbps operating speed and reflects the Port Select and FES bit of the MAC Configuration register. The signal value encodings are: • 0x0: 1000 Mbps (GMII) • 0x1: 1000 Mbps (GMII) • 0x2: 10 Mbps (MII) • 0x3: 100 Mbps (MII)
emac_phy_crs_i	PHY Carrier Sense	In	1	This signal is asserted by the PHY when either the transmit or receive medium is not idle. The PHY de-asserts this signal when both transmit and receive interfaces are idle. This signal is not synchronous to any clock.
emac_phy_col_i	PHY Collision Detect	In	1	This signal, valid only when operating in half duplex, is asserted by the PHY when a collision is detected on the medium. This signal is not synchronous to any clock.

PHY Management Interface

The HPS can provide support for either MDIO or I^2C PHY management interfaces.

MDIO Interface

The MDIO interface signals are synchronous to l4_mp_clk in all supported modes.

Note: The MDIO interface signals can be routed to both the FPGA and HPS I/O.

Table 17-3: PHY MDIO Management Interface

Signal	HPS I/O Pin Name	In/Out	Width	Description
emac_gmii_mdi_i	EMACn_MDIO	In	1	Management Data In. The PHY generates this signal to transfer register data during a read operation. This signal is driven synchronously with the gmii_mdc_o clock.
emac_gmii_mdo_o		Out	1	Management Data Out. The EMAC uses this signal to transfer control and data information to the PHY.
emac_gmii_mdo_o_e		Out	1	Management Data Output Enable. This enable signal drives the gmii_mdo_o signal from an external three-state I/O buffer. This signal is asserted whenever valid data is driven on the gmii_mdo_o signal. The active state of this signal is high.
emac_gmii_mdc_o	EMACn_MDC	Out	1	Management Data Clock. The EMAC provides timing reference for the gmii_mdi_i and gmii_mdo_o signals on MII through this aperiodic clock. The maximum frequency of this clock is 2.5 MHz. This clock is generated from the application clock through a clock divider.

I²C External PHY Management Interface

Some PHY devices use the I²C instead of MDIO for their control interface. Small form factor pluggable (SFP) optical or pluggable modules are often among those with this interface.

The HPS or FPGA can use three of the five general purpose I²C peripherals for controlling the PHY devices:

- i2c_emac_0 at base address 0xFFC02400
- i2c_emac_1 at base address 0xFFC02500
- i2c_emac_2 at base address 0xFFC02600

EMAC Internal Interfaces

DMA Master Interface

The DMA interface acts as a bus master on the system interconnect. Two types of data are transferred on the interface: data descriptors and actual data packets. The interface is very efficient in transferring full duplex Ethernet packet traffic. Read and write data transfers from different DMA channels can be

performed simultaneously on this port, except for transmit descriptor reads and write-backs, which cannot happen simultaneously.

DMA transfers are split into a software configurable number of burst transactions on the interface. The `AXI_Bus_Mode` register in the `dmagrp` group is used to configure bursting behavior.

The interface assigns a unique ID for each DMA channel and also for each read DMA or write DMA request in a channel. Data transfers with distinct IDs can be reordered and interleaved.

The DMA interface can be configured to perform cacheable accesses. This configuration can be done in the System Manager when the DMA interface is inactive.

Write data transfers are generally performed as posted writes with OK responses returned as soon as the system interconnect has accepted the last beat of a data burst. Descriptors (status or timestamp), however, are always transferred as non-posted writes in order to prevent race conditions with the transfer complete interrupt logic.

The slave may issue an error response. When that happens, the EMAC disables the DMA channel that generated the original request and asserts an interrupt signal. The host must reset the EMAC with a hard or soft reset to restart the DMA to recover from this condition.

The EMAC supports up to 16 outstanding transactions on the interface. Buffering outstanding transactions smooths out back pressure behavior improving throughput when resource contention bottlenecks arise under high system load conditions.

Timestamp Interface

The timestamp clock reference can come from either the Clock Manager or the FPGA fabric. If the FPGA has implemented the serial capturing of the timestamp interface, then the FPGA must provide the PTP clock reference.

Each EMAC provides its internal timestamp as an output. In some applications, it is advantageous to allow the FPGA fabric access to the Ethernet timestamp. In that case, the timestamp output from each EMAC is sampled in the `clk_ptp_ref_i` clock domain and serially shifted out to the FPGA fabric. The PTP timestamp clock must be selected to come from the FPGA fabric if the serial timestamp is used in the FPGA.

In addition to providing a timestamp clock reference, the FPGA can monitor the pulse-per-second output from each EMAC module and trigger a snapshot from each auxiliary time stamp timer.

The following table lists the EMAC to FPGA IEEE1588 Timestamp Interface signals to and from each EMAC module.

Table 17-4: EMAC to FPGA IEEE 1588 Timestamp Interface Signals

Signal Name		In/Out	Width	Description
f2s_emac_ptp_ref_clk	Timestamp PTP Clock reference from the FPGA	In	1	Used as PTP Clock reference for each EMAC when the FPGA has implemented Timestamp capture interface. The timestamp clock is common to all three EMACs. The frequency of this clock can be up to 100 MHz.
ptp_tstmp_en	Timestamp Serial Interface Enable	Out	1	When the local timestamp of each EMAC is sampled, the enable signal is pulsed with the first of 64 bits of serially shifted data. Synchronous to f2s_emac_ptp_ref_clk.
ptp_tstmp_data	Timestamp Serial Interface Data	Out	1	The 64-bit sampled timestamp is shifted serially to the FPGA fabric from the EMAC. The enable is asserted only on the first bit. The first bit transferred is the least significant bit of the sampled ptp_timestamp[63:0], or ptp_timestamp[0].
ptp_pps_o	Pulse Per Second Output	Out	1	This signal is asserted based on the PPS mode selected in the Register 459 (PPS Control Register). Otherwise, this pulse signal is asserted every time the seconds counter is incremented. This signal is synchronous to f2s_emac_ptp_ref_clk and may only be sampled if the FPGA clock is used as timestamp reference.

Signal Name		In/Out	Width	Description
ptp_aux_ts_trig_i	Auxiliary Timestamp Trigger	In	1	This signal is asserted to take an auxiliary snapshot of the time. The rising edge of this internal signal is used to trigger the auxiliary snapshot. The signal is synchronized internally with clk_ptp_ref_i which results in an additional delay of 3 cycles. This input is asynchronous input and its assertion period must be greater than 2 PTP active clocks to be sampled.

Each EMAC supports either internal or external timestamp reference. In addition, EMAC0 has the option to be the master that provides the timestamp to EMAC1 and EMAC2. In this configuration, EMAC0 must be programmed to select internal timestamp generation in the System Manager and EMAC1 and EMAC2 must be programmed to select external timestamp generation.

System Manager Configuration Interface

The System Manager configures several static EMAC functions as shown in the following table. Software must configure these functions appropriately prior to using the EMAC module. Refer to the *Ethernet Programming Model* section for more details regarding pertinent System Manager registers.

Table 17-5: System Manager Control Settings

Function	Description
PHY Select	Select RESET, RGMII, RMII or GMII/MII as the PHY interface. The RESET mode is the default out of reset and configures the EMAC to use an internal clock rather than depending on a PHY to provide and active clock. The RESET mode cannot be used with any PHY, and another setting must be programmed before attempting to communicate with a PHY.
PTP Timestamp Reference Select	This field selects if the Timestamp reference is internally or externally generated. EMAC0 must be set to Internal Timestamp. EMAC0 may be the master to generate the timestamp for EMAC1 and EMAC2. EMAC1 and EMAC2 may be set to either Internal or External.

Function	Description
PTP Timestamp Clock Select	Selects the source of the PTP reference clock between `emac_ptp_clk` from the Clock Manager or `f2s_emac_ptp_ref_clk` from the FPGA Fabric. All three EMAC modules must use the same reference clock.
AXI Cache and Protection Settings	Static settings are provided to drive the ARCACHE, AWCACHE, ARPROT, and AWPROT signals for the AXI DMA bus.
FPGA Interface Enable	This field enables logic from the FPGA. This signal is only for safety to prevent spurious inputs from the FPGA before the FPGA is configured.

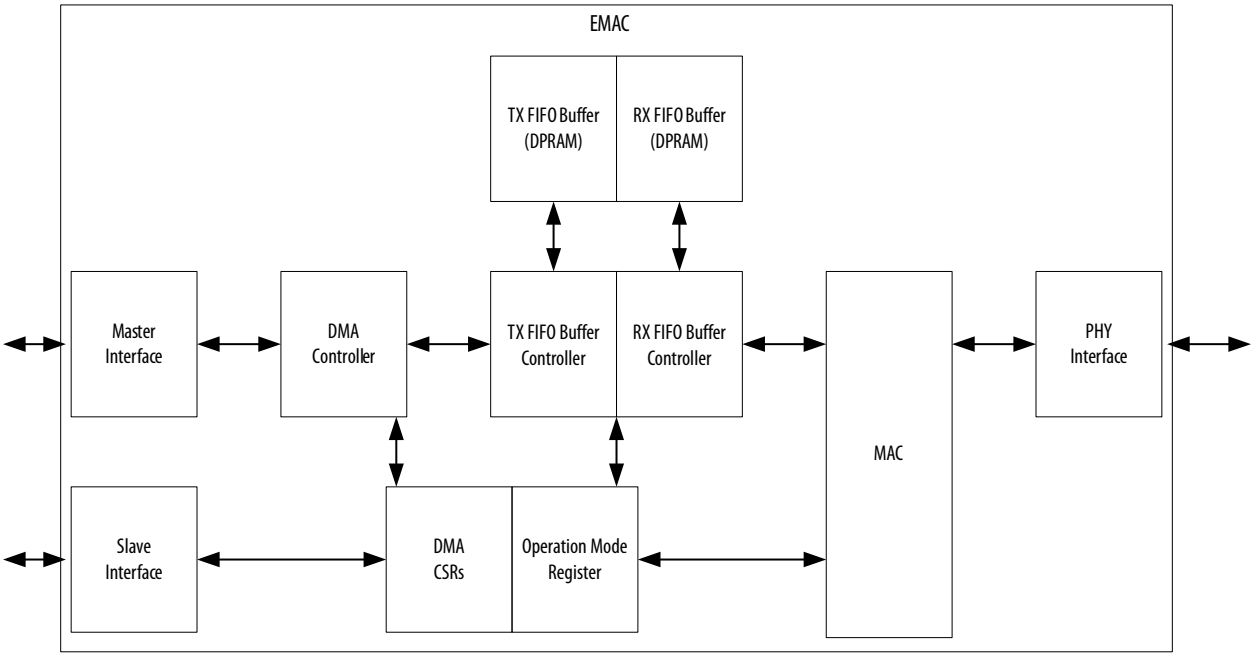
Functional Description of the EMAC

Figure 17-3: EMAC High-Level Block Diagram with Interfaces



There are two host interfaces to the Ethernet MAC. The management host interface, a 32-bit slave interface, provides access to the CSR set regardless of whether or not the EMACs are used directly through the FPGA fabric. The data interface is a 32-bit master interface, and it controls data transfer between the direct memory access (DMA) controller channels and the rest of the HPS system through the L3 interconnect.

The built-in DMA controller is optimized for data transfer between the MAC controller and system memory. The DMA controller has independent transmit and receive engines and a CSR set. The transmit engine transfers data from system memory to the device port, while the receive engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal host intervention.

The EMAC also contains FIFO buffer memory to buffer and regulate the Ethernet frames between the application system memory and the EMAC module. Each EMAC module has one 4 KB TX FIFO and one 16 KB RX FIFO. On transmit, the Ethernet frames write into the transmit FIFO buffer, and eventually trigger the EMAC to perform the transfer. Received Ethernet frames are stored in the receive FIFO buffer and the FIFO buffer fill level is communicated to the DMA controller. The DMA controller then initiates the configured burst transfers. Receive and transmit transfer statuses are read by the EMAC and transferred to the DMA.

Transmit and Receive Data FIFO Buffers

Each EMAC component has associated transmit and receive data FIFO buffers to regulate the frames between the application system memory and the EMAC. The RX FIFO buffer is a 16 KB dual-ported memory and the TX FIFO buffer is a 4 KB dual-ported memory. Both buffers are designed to support jumbo frames. A FIFO buffer word consists of:

- Data: 32 bits
- Sideband:
  - Byte enables: 2 bits
  - End of frame (EOF): 1 bit
  - Error correction code (ECC): 7 bits

The FIFO RAMs are each supported by an ECC controller that performs single-bit error detection and correction and double-bit error detection. The ECC Controllers have a dedicated hardware block for memory data initialization and can log error events and generate interrupts on single and double-error events. See the *Error Checking and Correction (ECC) Controller* for more information regarding the function of the ECC RAMs.

TX FIFO

The time at which data is sent from the TX FIFO to the EMAC is dependent on the transfer mode selected:

- Cut-through mode: Data is popped from the TX FIFO when the number of bytes in the TX FIFO crosses the configured threshold level (or when the end of the frame is written before the threshold is crossed). The threshold level is configured using the TTC bit of Register 0 (Bus Mode Register).

  Note: After more than 96 bytes (or 548 bytes in 1000 Mbps mode) are popped to the EMAC, the TX FIFO controller frees that space and makes it available to the DMA and a retry is not possible.
- Store-and-Forward mode: Data is popped from the TX FIFO when one or more of the following conditions are true:
  - A complete frame is stored in the FIFO
  - The TX FIFO becomes almost full

The application can flush the TX FIFO of all contents by setting bit 20 (FTF) of Register 6 (Operation Mode Register). This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer to the EMAC, further transfers are stopped because the FIFO is considered empty. This cessation causes an underflow event and a runt frame to be transmitted and the corresponding status word is forwarded to the DMA.

If a collision occurs in half-duplex mode operation before an end of the frame, a retry attempt is sent before the end of the frame is transferred. When notified of the retransmission, the MAC pops the frame from the FIFO again.

Note: Only packets of 3800 bytes or less can be supported when the checksum offload feature is enabled by software.

RX FIFO

Frames received by the EMAC are pushed into the RX FIFO. The fill level of the RX FIFO is indicated to the DMA when it crosses the configured receive threshold which is programmed by the RTC field of Register 6 (Operation Mode Register). The time at which data is sent from the RX FIFO to the DMA is dependent on the configuration of the RX FIFO:

- Cut-through (default) mode: When 64 bytes or a full packet of data is received into the FIFO, data is popped out of the FIFO and sent to the DMA until a complete packet has been transferred. Upon completion of the end-of-frame transfer, the status word is popped and sent to the DMA.
- Store and forward mode: A frame is read out only after being written completely in the RX FIFO. This mode is configured by setting the RSF bit of Register 6 (Operation Mode Register).

If the RX FIFO is full before it receives the EOF data from the EMAC, an overflow is declared and the whole frame (including the status word) is dropped and the overflow counter in the DMA, (Register 8) Missed Frame and Buffer Overflow Counter Register, is incremented. This outcome is true even if the Forward Error Frame (FEF) bit of Register 6 (Operation Mode Register) is set. If the start address of such a frame has already been transferred, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status indicates a partial frame because of overflow. In such frames, the Frame Length field is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped.

Note: In store-and-forward mode, only received frames with length 3800 bytes or less prevent overflow errors and frames from being dropped.

Error Checking and Correction Controller on page 11-1
Error Checking and Correction (ECC) controllers provide single- and double-bit error memory protection for integrated on-chip RAM and peripheral RAMs within the hard processor system (HPS).

DMA Controller

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory to the device port or MAC transaction layer (MTL), while the receive engine transfers data from the device port to the system memory. Descriptors are used to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as frame transmit and receive transfer completion as well as error conditions.

The DMA and the Host driver communicate through two data structures:†

- Control and Status registers (CSR)†
- Descriptor lists and data buffers †

Descriptor Lists and Data Buffers†

The DMA transfers data frames received by the MAC to the receive Buffer in the Host memory, and transmit data frames from the transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.†

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register), respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors (RDES1[14] and TDES0[20]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.†

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.†

Figure 17-4: Descriptor Ring Structure

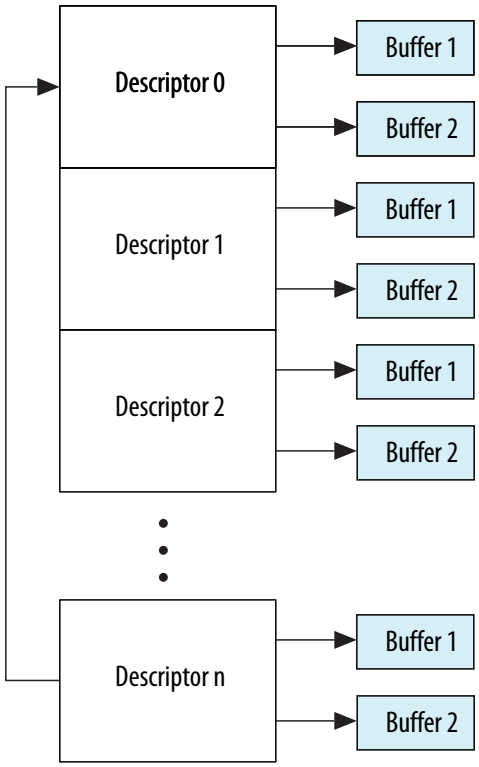

Figure 17-5: Descriptor Chain Structure

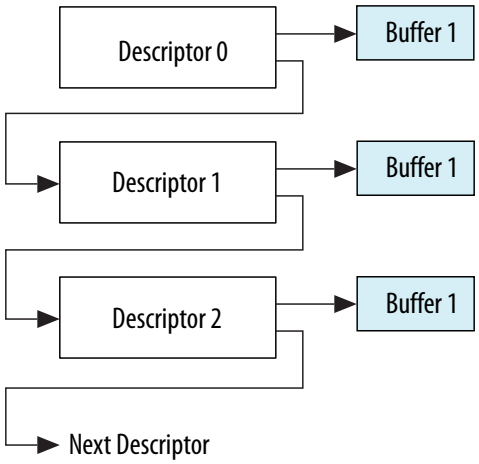

Note: You can select a descriptor structure during RTL configuration. The control bits in the descriptor structure are assigned so that the application can use an 8 KB buffer. All descriptions refer to the default descriptor structure.

Host Bus Burst Access

The DMA attempts to execute fixed-length burst transfers on the master interface if configured to do so through the FB bit of Register 0 (Bus Mode Register). The maximum burst length is indicated and limited by the PBL field (Bits [13:8]) Register 0 (Bus Mode Register). The receive and transmit descriptors are always accessed in the maximum possible (limited by packet burst length (PBL) or 16 * 8/bus width) burst size for the 16- bytes to be read.

The transmit DMA initiates a data transfer only when the MTL transmit FIFO has sufficient space to accommodate the configured burst or the number of bytes remaining in the frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of INCR4, 8, or 16 and SINGLE transactions. When not configured for fixed-length burst, it transfers data using INCR (undefined length) and SINGLE transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL receive FIFO buffer or when the end of frame (when it is less than the configured burst length) is detected in the receive FIFO buffer. The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of INCR4, 8, or 16 and SINGLE transactions. If the end-of-frame is reached before the fixed burst ends on the interface, then dummy transfers are performed in order to complete the fixed burst. If the FB bit of Register 0 (Bus Mode Register) is clear, it transfers data using INCR (undefined length) and SINGLE transactions.

When the interface is configured for address aligned words, both DMA engines ensure that the first burst transfer initiated is less than or equal to the size of the configured packet burst length. Thus, all subsequent

beats start at an address that is aligned to the configured packet burst length. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the interface does not support more than INCR16.

Host Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.†

Example: Buffer Read

If the transmit buffer address is 0x00000FF2, and 15 bytes must be transferred, then the DMA reads five full words from address 0x00000FF0, but when transferring data to the MTL transmit FIFO buffer, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last three bytes of the last transfer are also ignored. The DMA always ensures it transfers data in 32-bit increments to the MTL transmit FIFO buffer, unless it is the end-of-frame.

Example: Buffer Write

If the receive buffer address is 0x00000FF2 and 16 bytes of a received frame must be transferred, then the DMA writes 3 full words from address 0x00000FF0. But the first two bytes of first transfer and the last two bytes of the fourth transfer have dummy data.

Buffer Size Calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver must perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by the buffer size field of TDES1) to the MAC. If a descriptor is marked as th first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as the last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of-frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of-frame is received from the MTL. If a descriptor is not marked as the last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as the last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

Transmission

The DMA can transmit with or without an optional second frame (OSF).

Related Information

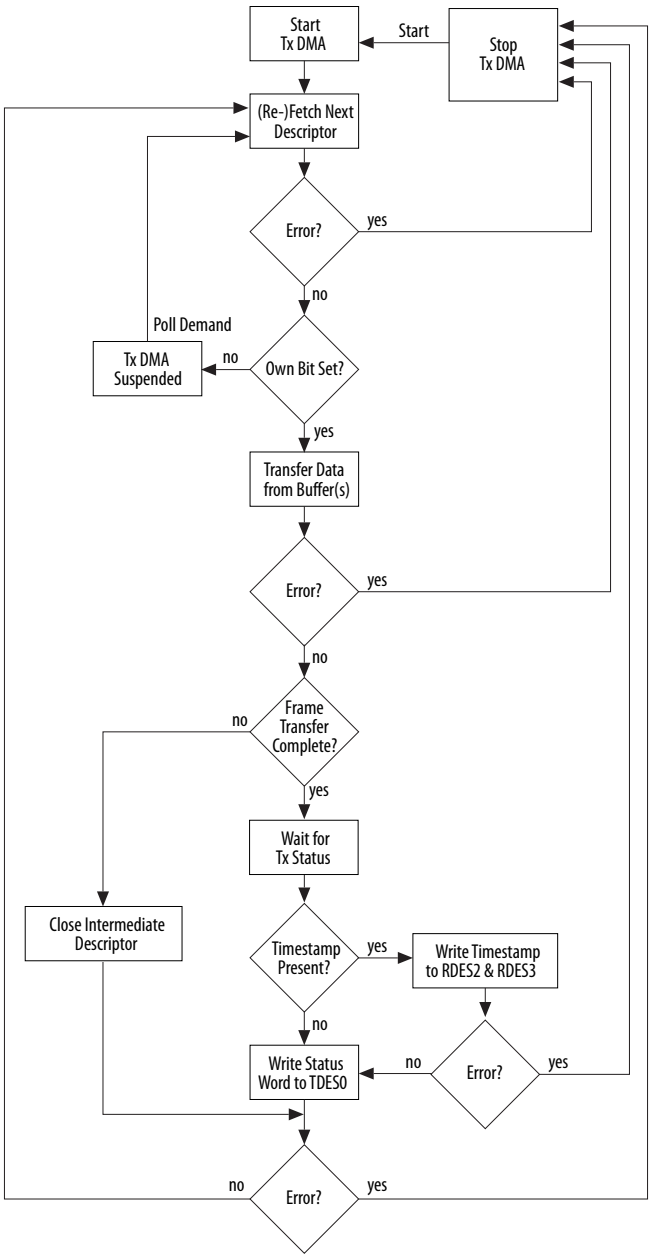
Transmit Descriptor on page 17-31

TX DMA Operation: Default (Non-OSF) Mode

The transmit DMA engine in default mode proceeds as follows: †

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data. †
2. When Bit 13 (ST) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. †
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host (TDES0[31] = 0), or if an error condition occurs, transmission is suspended and both the Bit 2 (Transmit Buffer Unavailable) and Bit 16 (Normal Interrupt Summary) of the Register 5 (Status Register) are set. The transmit Engine proceeds to **step 9**.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the Host memory and transfers the data to the MTL for transmission. †
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Repeat **step 3**, **step 4**, and **step 5** until the end-of-Ethernet-frame data is transferred to the MTL. †
7. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3. †
8. Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last descriptor. The DMA engine then returns to **step 3**. †
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to **step 3**) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. †

Figure 17-6: TX DMA Operation in Default Mode



TX DMA Operation: OSF Mode

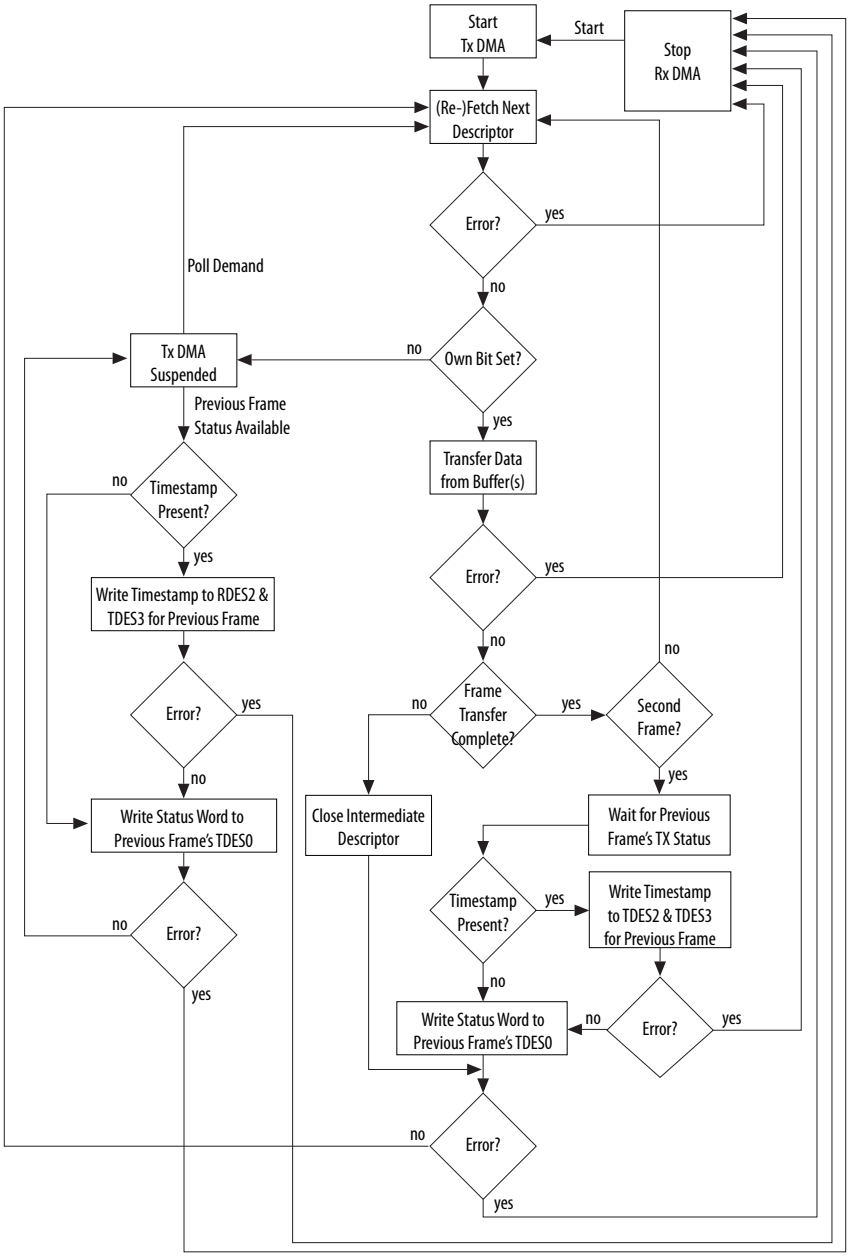
While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first [if Bit 2 (OSF) in Register 6 (Operation Mode Register) is set]. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. †

In OSF mode, the Run state transmit DMA operates in the following sequence: †

1. The DMA operates as described in steps 1 - 6 of the **TX DMA Operation: Default (Non-OSF) Mode** on page 17-22 section.
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor. †
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to **step 7**.†
4. The DMA fetches the transmit frame from the Host memory and transfers the frame to the MTL until the End-of-frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors. †
5. The DMA waits for the previous frame's frame transmission status and timestamp. Once the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3. †
6. If enabled, the transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to **step 3** (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (**step 7**). †
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode. †
8. The DMA can exit Suspend mode and enter the Run state (go to **step 1** or **step 2** depending on pending status) only after receiving a Transmit Poll demand (Register 1 (Transmit Poll Demand Register). †

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than two different descriptors for correct and proper operation. †

Figure 17-7: TX DMA Operation in OSF Mode



Transmit Frame Processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields and that the DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. †

Frames can be datachained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively. †

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL transmit FIFO buffer. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the transmit Process attempts to acquire the Next descriptor. The transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame. †

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) is set, the Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set, the Next descriptor is fetched, and the process repeats. †

The actual frame transmission begins after the MTL transmit FIFO buffer has reached either a programmable transmit threshold (Bits [16:14] of Register 6 (Operation Mode Register)), or a full frame is contained in the FIFO buffer. There is also an option for Store and Forward Mode (Bit 21 of Register 6 (Operation Mode Register)). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame. †

Note: To ensure proper transmission of a frame and the next frame, you must specify a non-zero buffer size for the transmit descriptor that has the Last Descriptor (TDES1[30]) set. †

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions: †

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command. †
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. †

If the DMA goes into SUSPEND state because of the first condition, then both Bit 16 (Normal Interrupt Summary) and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) are set. If the second condition occur, both Bit 15 (Abnormal Interrupt Summary) and Bit 5 (Transmit Underflow) of Register 5 (Status Register) are set, and the information is written to Transmit Descriptor 0, causing the suspension. †

In both cases, the position in the transmit List is retained. The retained position is that of the descriptor following the Last descriptor closed by the DMA. †

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause. †

Reception

Receive functions use receive descriptors.

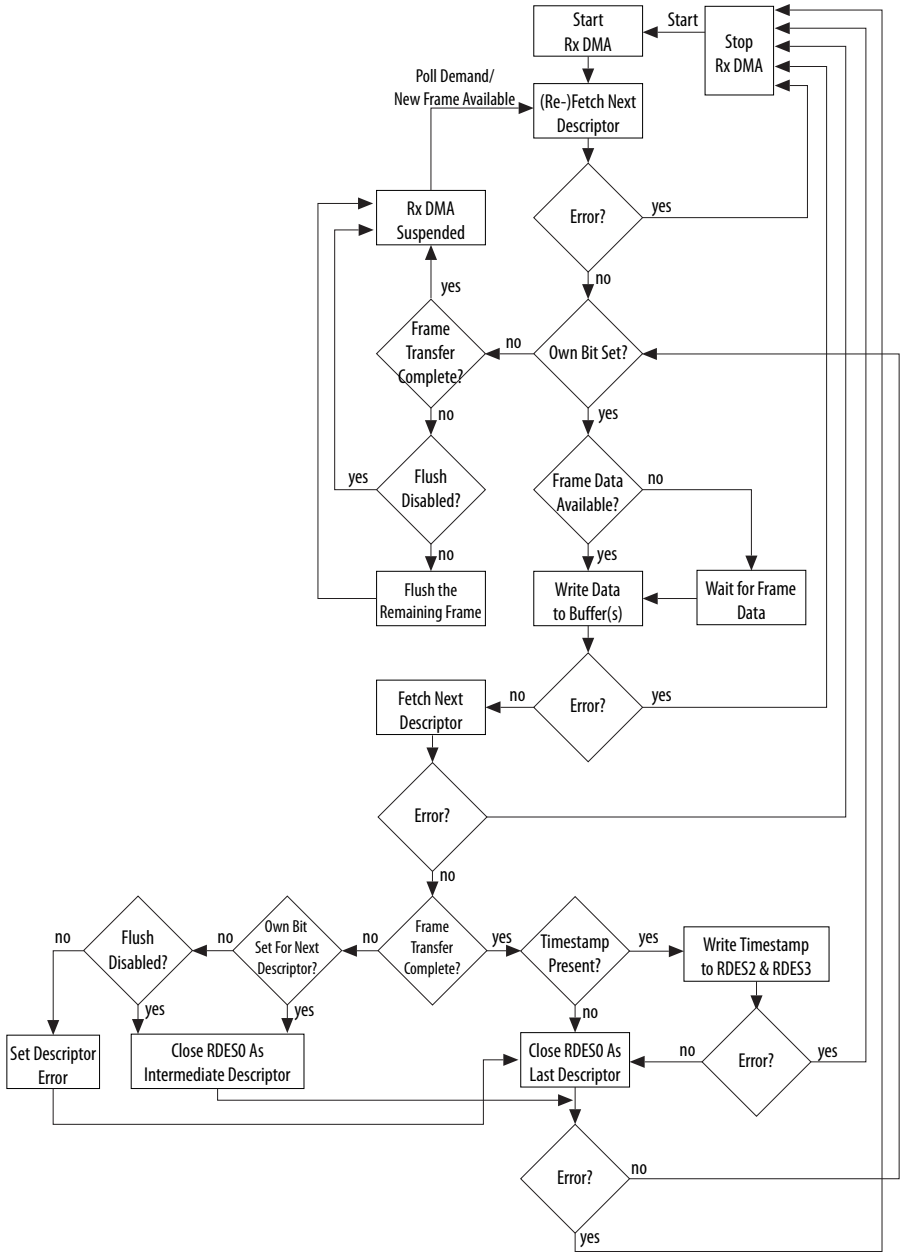
The receive DMA engine's reception sequence is proceeds as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).†
2. When Bit 1 (SR) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to **step 9**.†
3. The DMA decodes the receive data buffer address from the acquired descriptors.†
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.†
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.†
6. If the current frame transfer is complete, the DMA proceeds to **step 7**. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled in Bit 24 of Register 6 (Operation

Mode Register)). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to **step 8**. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to **step 4**.†

7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.†
8. The receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 0), the Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the DMA receive engine enters the Suspended state (Step 9). If the DMA owns the descriptor, the engine returns to **step 4** and awaits the next frame.
9. Before the receive engine enters the Suspend state, partial frames are flushed from the receive FIFO buffer. You can control flushing using Bit 24 of Register 6 (Operation Mode Register). †
10. The receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's receive FIFO buffer. The engine proceeds to **step 2** and refetches the next descriptor. †

Figure 17-8: Receive DMA Operation



When software has enabled timestamping through the `tsena` bit of register 448 (Timestamp Control Register) and a valid timestamp value is not available for the frame (for example, because the receive FIFO buffer was full before the timestamp could be written to it), the DMA writes all ones to RDES2 and RDES3 descriptors . Otherwise (that is, if timestamping is not enabled), the RDES2 and RDES3 descriptors remain unchanged.

Receive Descriptor Acquisition

The receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied: †

- Bit 1 (Start or Stop Receive) of Register 6 (Operation Mode Register) has been set immediately after being placed in the Run state. †
- The data buffer of the current descriptor is full before the frame ends for the current transfer. †
- The controller has completed frame reception, but the current receive descriptor is not yet closed. †
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received. †
- A Receive poll demand has been issued. †

Receive Frame Processing

The MAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to the configurable threshold bytes set for the receive FIFO buffer of MTL, or when the complete frame is written to the FIFO buffer in store-and-forward mode. †

If the frame fails the address filtering, it is dropped in the MAC block itself (unless Bit 31 (Receive All) of Register 1 (MAC Frame Filter) is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the MTL receive FIFO buffer. †

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (RDES0[9]) after the DMA Host interface becomes ready to receive a data transfer (if the DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is clear, either as the Data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES0[8]) and First Descriptor (RDES0[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets bit 6 (Receive Interrupt) of Register 5 (Status Register). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs,Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the receive process enters the Suspend state. The position in the receive list is retained. †

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the receive process re-enters the run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL RX FIFO buffer and increments the missed frame counter. If more than one frame is stored in the MTL EX FIFO buffer, the process repeats. †

The discarding or flushing of the frame at the top of the MTL EX FIFO buffer can be avoided by disabling Flushing (Bit 24 of Register 6 (Operation Mode Register)). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state. †

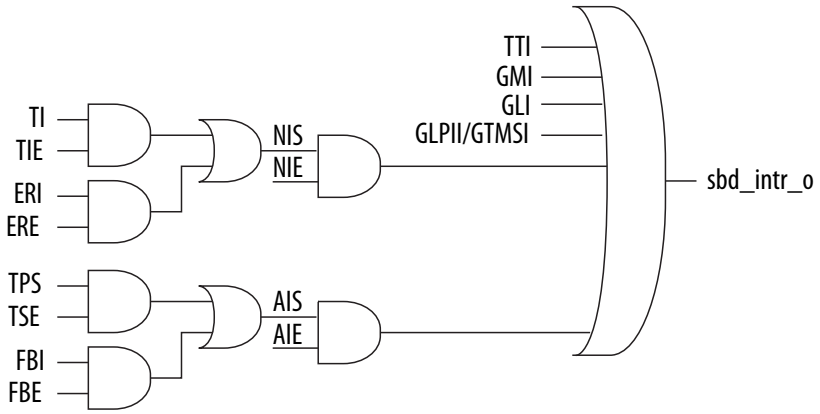
Interrupts

Interrupts can be generated as a result of various events. The DMA Register 5 (Status Register) contains a status bit for each of the events that can cause an interrupt. Register 7 (Interrupt Enable Register) contains an enable bit for each of the possible interrupt sources.

There are two groups of interrupts, Normal and Abnormal, as described in Register 5 (Status Register). Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts

within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the sbd_intr_o interrupt signal is deasserted. If the MAC is the cause for assertion of the interrupt, then any of the GLI, GMI, TTI, or GLPII bits of Register 5 (Status Register) are set to 1.

Figure 17-9: Summary Interrupt (sbd_intr_o) Generation(51)



Note: Register 5 (Status Register) is the interrupt status register. The interrupt pin (sbd_intr_o) is asserted because of any event in this status register only if the corresponding interrupt enable bit is set in Register 7 (Interrupt Enable Register). †

Interrupts are not queued, and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Bit 6 (Receive Interrupt) of Register 5 (Status Register) indicates that one or more frames were transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for multiple, simultaneous events. The driver must scan Register 5 (Status Register) for the cause of the interrupt. After the driver has cleared the appropriate bit in Register 5 (Status Register), the interrupt is not generated again until a new interrupting event occurs. For example, the controller sets Bit 6 (Receive Interrupt) of Register 5 (Status Register) and the driver begins reading Register 5 (Status Register). Next, the interrupt indicated by Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) occurs. The driver clears the receive interrupt (bit 6). However, the sbd_intr_o signal is not deasserted, because of the active or pending Receive Buffer Unavailable interrupt.

Bits 7:0 (riwt field) of Register 9 (Receive Interrupt Watchdog Timer Register) provide for flexible control of the receive interrupt. When this Interrupt timer is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31]). When this timer runs out as per the programmed value, the AIS bit is set and the interrupt is asserted if the corresponding AIE is enabled in Register 7 (Interrupt Enable Register). This timer is disabled before it runs out, when a frame is transferred to memory, and the receive interrupt is triggered if it is enabled.

Receive Descriptor on page 17-38

Error Response to DMA

If the slave replies with an error response to any data transfer initiated by a DMA channel, that DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Register 5 (Status Register). The

(51) Signals NIS and AIS are registered.

DMA controller can resume operation only after soft resetting or hard resetting the EMAC and reinitializing the DMA.

Descriptor Overview

The DMA in the Ethernet subsystem transfers data based on a single enhanced descriptor, as explained in the DMA Controller section. The enhanced descriptor is created in the system memory. The descriptor addresses must be word-aligned.

The enhanced or alternate descriptor format can have 8 DWORDS (32 bytes) instead of 4 DWORDS as in the case of the normal descriptor format.

The features of the enhanced or alternate descriptor structure are:

- The alternative descriptor structure is implemented to support buffers of up to 8 KB (useful for Jumbo frames).†
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (advanced timestamp or IPC full offload configuration), and RDES1. †
- The transmit descriptor stores the timestamp in TDES6 and TDES7 when you select the advanced timestamp. †
- The receive descriptor structure is also used for storing the extended status (RDES4) and timestamp (RDES6 and RDES7) when advanced timestamp, IPC Full Checksum Offload Engine, or Layer 3 and Layer 4 filter feature is selected. †
- You can select one of the following options for descriptor structure:
  - If timestamping is enabled in Register 448 (Timestamp Control Register) or Checksum Offload is enabled in Register 0 (MAC Configuration Register), the software must to allocate 32 bytes (8 DWORDS) of memory for every descriptor by setting Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register).
  - If timestamping or Checksum Offload is not enabled, the extended descriptors (DES4 to DES7) are not required. Therefore, software can use descriptors with the default size of 16 bytes (4 DWORDS) by clearing Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register) to 0.

Related Information

DMA Controller on page 17-18

Transmit Descriptor

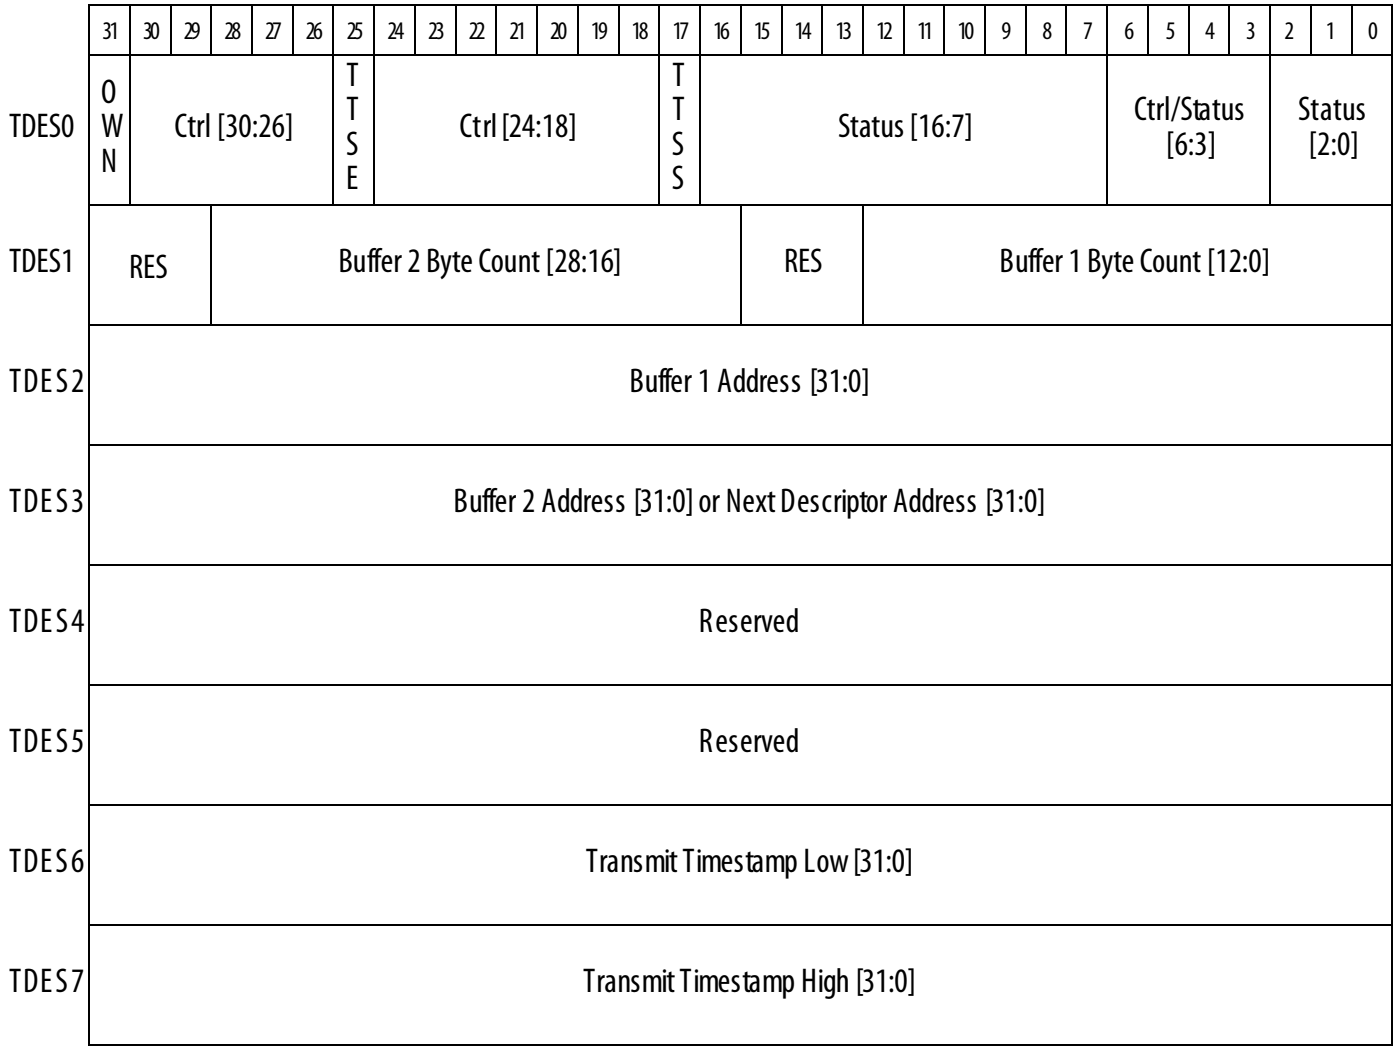
The application software must program the control bits TDES0[31:18] during the transmit descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits[7:0].

With the advance timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7 as indicated by the status Bit 17 (TTSS) of TDES0.

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Note: When the advanced timestamp feature is enabled, software should set Bit 7 of Register 0 (Bus Mode Register), so that the DMA operates with extended descriptor size. When this control bit is clear, the TDES4-TDES7 descriptor space is not valid. †

Figure 17-10: Transmit Enhanced Descriptor Fields - Format



The DMA always reads or fetches four DWORDS of the descriptor from system memory to obtain the buffer and control information. †

Figure 17-11: Transmit Descriptor Fetch (Read) Format

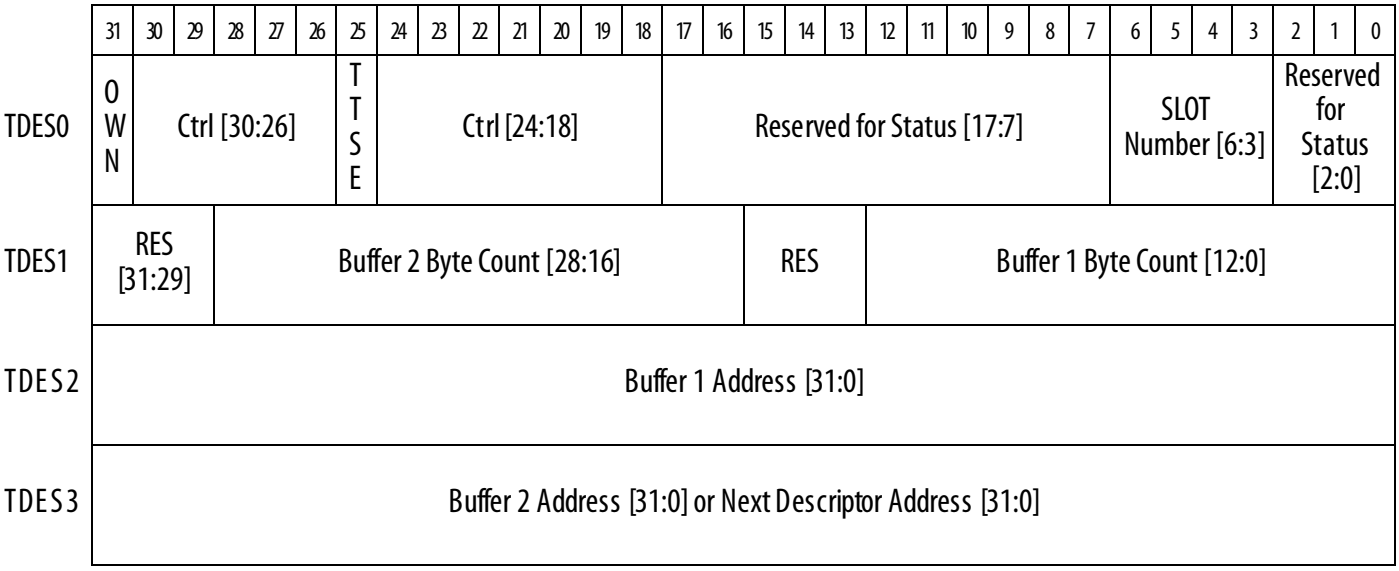


Table 17-6: Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is cleared, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set to avoid a possible race condition between fetching a descriptor and the driver setting an ownership bit. †
30	IC: Interrupt on Completion When set, this bit enables the Transmit Interrupt (Register 5[0]) to be set after the present frame has been transmitted. †
29	LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value. †
28	FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame. †
27	DC: Disable CRC When this bit is set, the MAC does not append a CRC to the end of the transmitted frame. This bit is valid only when the first segment (TDES0[28]) is set. †

Bit	Description
26	DP: Disable Pad When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is cleared, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This bit is valid only when the first segment (TDES0[28]) is set. †
25	TTSE: Transmit Timestamp Enable When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.
24	Reserved
23:22	CIC: Checksum Insertion Control. These bits control the checksum calculation and insertion. The following list describes the bit encoding: ▪ 0x0: Checksum insertion disabled. ▪ 0x1: Only IP header checksum calculation and insertion are enabled. ▪ 0x2: IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware. ▪ 0x3: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware. This field is valid when the First Segment control bit (TDES0[28]) is set.
21	TER: Transmit End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †
20	TCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20]. †
19:18	Reserved
17	TTSS: Transmit Timestamp Status This field is used as a status bit to indicate that a timestamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a timestamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set. †

Bit	Description
16	IHE: IP Header Error When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IPheader version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5. † This bit is valid only when the Tx Checksum Offload is enabled. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.†
15	ES: Error Summary Indicates the logical OR of the following bits: ▪ TDES0[14]: Jabber Timeout ▪ TDES0[13]: Frame Flush ▪ TDES0[11]: Loss of Carrier ▪ TDES0[10]: No Carrier ▪ TDES0[9]: Late Collision ▪ TDES0[8]: Excessive Collision ▪ TDES0[2]: Excessive Deferral ▪ TDES0[1]: Underflow Error ▪ TDES0[16]: IP Header Error ▪ TDES0[12]: IP Payload Error †
14	JT: Jabber Timeout When set, this bit indicates the MAC transmitter has experienced a jabber time-out. This bit is only set when Bit 22 (Jabber Disable) of Register 0 (MAC Configuration Register) is not set. †
13	FF: Frame Flushed When set, this bit indicates that the DMA or MTL flushed the frame because of a software Flush command given by the CPU. †
12	IPE: IP Payload Error When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch. †

Bit	Description
11	LC: Loss of Carrier When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This bit is valid only for the frames transmitted without collision when the MAC operates in the half-duplex mode. †
10	NC: No Carrier When set, this bit indicates that the Carrier Sense signal form the PHY was not asserted during transmission. †
9	LC: Late Collision When set, this bit indicates that frame transmission is aborted because of a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set.
8	EC: Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If Bit 9 (Disable Retry) in Register 0 (MAC Configuration Register) is set, this bit is set after the first collision, and the transmission of the frame is aborted. †
7	VF: VLAN Frame When set, this bit indicates that the transmitted frame is a VLAN-type frame. †
6:3	CC: Collision Count (Status field) These status bits indicate the number of collisions that occurred before the frame was transmitted. This count is not valid when the Excessive Collisions bit (TDES0[8]) is set. The EMAC updates this status field only in the half-duplex mode.
2	ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbps mode or if Jumbo frame is enabled) if Bit 4 (Deferral Check) bit in Register 0 (MAC Configuration Register) is set. †
1	UF: Underflow Error When set, this bit indicates that the MAC aborted the frame because the data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). †
0	DB: Deferred Bit When set, this bit indicates that the MAC defers before transmission because of the presence of carrier. This bit is valid only in the half-duplex mode. †

Table 17-7: Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set. †
15:13	Reserved †
12:0	TBS1: Transmit Buffer 1 Size This field indicates the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). †

Table 17-8: Transmit Descriptor 2 (TDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. †

Table 17-9: Transmit Descriptor 3 (TDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES0[20]) bit is set, this address contains the pointer to the physical memory where the Next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES0[20] is set. (LSBs are ignored internally.) †

Table 17-10: Transmit Descriptor 6 (TDES6)

Bit	Description
31:0	TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Table 17-11: Transmit Descriptor 7 (TDES7)

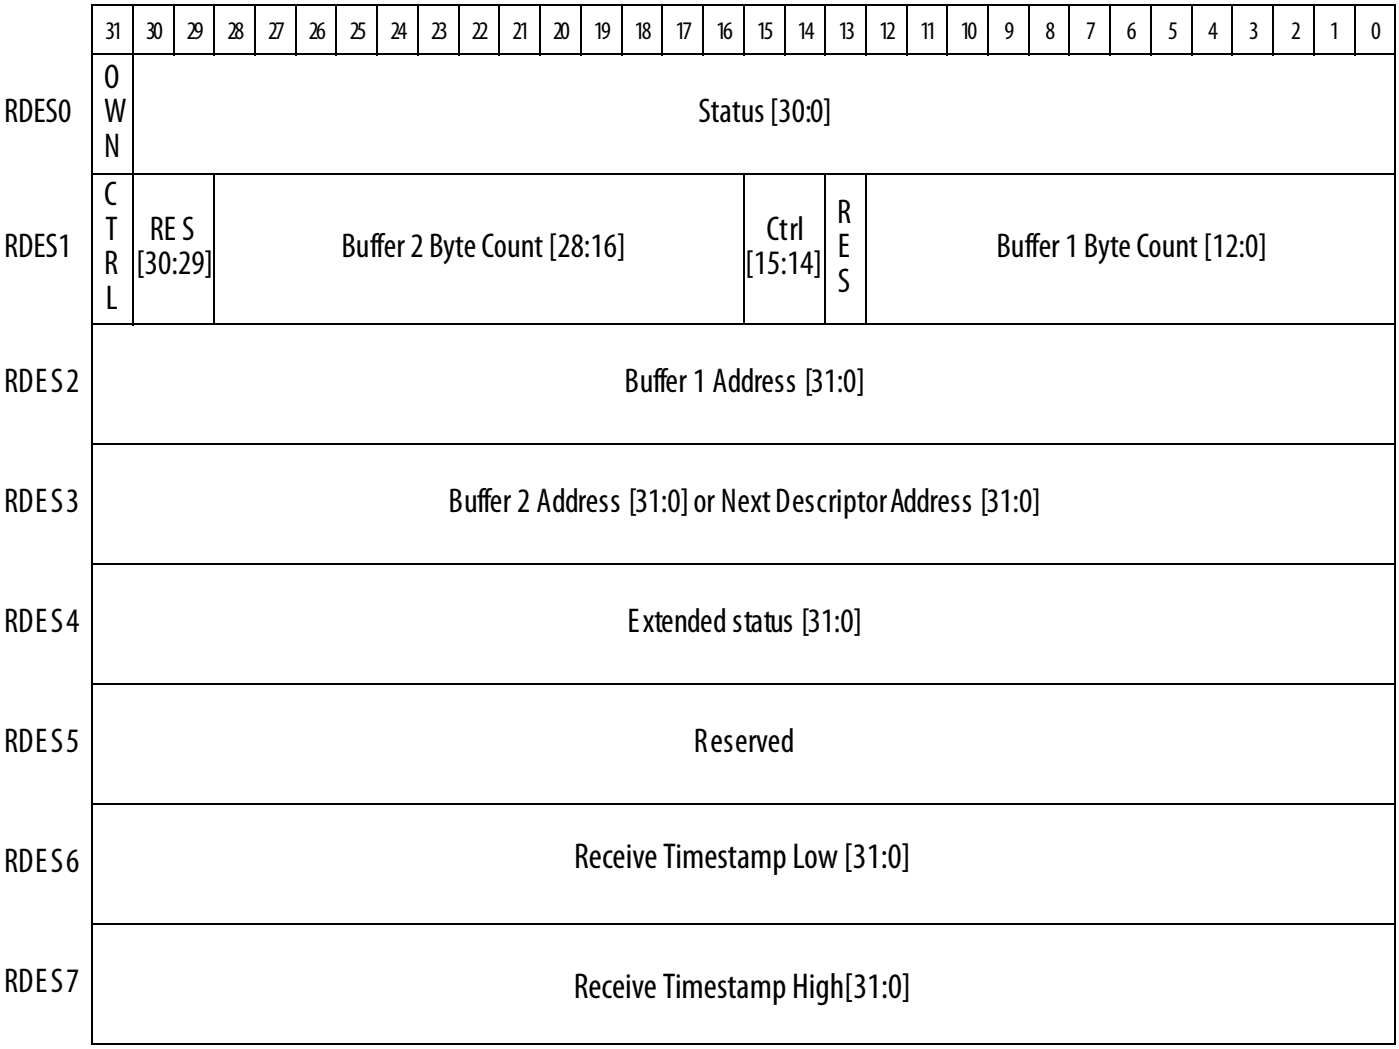
Bit	Description
31:0	TTSH: Transmit Frame Timestamp High This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Receive Descriptor

The receive descriptor can have 32 bytes of descriptor data (8 DWORDs) when advanced timestamp or IPC Full Offload feature is selected. When either of these features is enabled, software should set bit 7 of Register 0 (Bus Mode Register) so that the DMA operates with extended descriptor size. When this control bit is clear, the RDES0[0] is always cleared and the RDES4-RDES7 descriptor space is not valid. †

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Figure 17-12: Receive Enhanced Descriptor Fields Format



Receive Descriptor Field 0 (RDES0)

Table 17-12: Receive Descriptor Field 0 (RDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA of the EMAC. When this bit is cleared, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM: Destination Address Filter Fail When set, this bit indicates a frame that failed in the DA Filter in the MAC. †
29:16	FL: Frame Length These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are cleared. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. †
15	ES: Error Summary Indicates the logical OR of the following bits: • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header or Payload Error (Receive Descriptor Field 4 (RDES4)) • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set. †

Bit	Description
14	DE: Descriptor Error When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next descriptor. The frame is truncated. This bit is valid only when the Last Descriptor (RDES0[8]) bit is set. †
13	SAF: Source Address Filter Fail When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC. †
12	LE: Length Error When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is clear. †
11	OE: Overflow Error When set, this bit indicates that the received frame was damaged because of buffer overflow in MTL. Note: This bit is set only when the DMA transfers a partial frame to the application, which happens only when the RX FIFO buffer is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in the RX FIFO buffer. †
10	VLAN: VLAN Tag When set, this bit indicates that the frame to which this descriptor is pointing is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking the VLAN fields of the received frame based on the Register 7 (VLAN Tag Register) setting. †
9	FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame. †
8	LD: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame. †

Bit	Description
7	Timestamp Available When set, bit[7] indicates that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set.
6	LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in the half-duplex mode. †
5	FT: Frame Type When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600). When this bit is cleared, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. †
3	RE: Receive Error When set, this bit indicates that the `gmii_rxer_i` signal is asserted while `gmii_rxdv_i` is asserted during frame reception.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. †
1	CE: CRC Error When set, this bit indicates that a CRC error occurred on the received frame. This bit is valid only when the Last Descriptor (RDES0[8]) is set. †

Bit	Description
0	Extended Status Available/RX MAC Address When either advanced timestamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set. When the Advance Timestamp Feature or IPC Full Offload is not selected, this bit indicates RX MAC Address status. When set, this bit indicates that the RX MAC Address registers value (1 to 15) matched the frame's DA field. When clear, this bit indicates that the RX MAC Address Register 0 value matched the DA field. †

Receive Descriptor Field 1 (RDES1)

Table 17-13: Receive Descriptor Field 1 (RDES1)

Bit	Description
31	DIC: Disable Interrupt on Completion When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. As a result, the RI interrupt for the frame is disabled and is not asserted to the Host.†
30:29	Reserved †
28:16	RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer2 address pointer) in the Receive Descriptor Field 3 (RDES3) is not aligned to the bus width. If the buffer size is not an appropriate multiple of 4, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.
15	RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †

Bit	Description
14	RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14]. †
13	Reserved †
12:0	RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, even if the value of RDES2 (buffer1 address pointer), in the Receive Descriptor Field 2 (RDES2), is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14). For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.

Receive Descriptor Fields (RDES2) and (RDES3)

Receive Descriptor Field 2 (RDES2)

Table 17-14: Receive Descriptor Field 2 (RDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the value programmed in RDES2[1:0] for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of the frame but the frame is shifted as per the actual buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. For more information about buffer address alignment, refer to the *Host Data Buffer Alignment* section.

Related Information

Host Data Buffer Alignment on page 17-21

Receive Descriptor Field 3 (RDES3)

Table 17-15: Receive Descriptor Field 3 (RDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[14]) bit in Receive Descriptor Field 1 (RDES1) is set, this address contains the pointer to the physical memory where the Next descriptor is present. If RDES1[14], in the Receive Descriptor Field 1 (RDES1) is set, the buffer (Next descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0. LSBs are ignored internally.) However, when RDES1[14] in the Receive Descriptor Field 1 (RDES1) is cleared, there are no limitations on the RDES3 value, except for the following condition: the DMA uses the value programmed in RDES3 [1:0] for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.

Receive Descriptor Field 4 (RDES4)

The extended status is written only when there is status related to IPC or timestamp available. The availability of extended status is indicated by Bit 0 in RDES0. This status is available only when the Advance Timestamp or IPC Full Offload feature is selected.

Table 17-16: Receive Descriptor Field 4 (RDES4)

Bit	Description
31:28	Reserved †
27:26	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received frame. • 00: Filter 0 • 01: Filter 1 • 10: Filter 2 • 11: Filter 3 This field is valid only when Bit 24 or Bit 25 is set. When more than one filter matches, these bits give only the lowest filter number. †

Bit	Description
25	Layer 4 Filter Match When set, this bit indicates that the received frame matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match. • All enabled Layer 3 and Layer 4 filter fields match. When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits [27:26]. †
24	Layer 3 Filter Match When set, this bit indicates that the received frame matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. • All enabled filter fields match. When more than one filter matches, this bit gives the layer 3 filter status of the filter indicated by Bits [27:26]. †
23:15	Reserved
14	Timestamp Dropped When set, this bit indicates that the timestamp was captured for this frame but got dropped in the MTL RX FIFO buffer because of overflow.
13	PTP Version When set, this bit indicates that the received PTP message has the IEEE 1588 version 2 format. When clear, it has the version 1 format.
12	PTP Frame Type When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7.

Bit	Description
11:8	Message Type These bits are encoded to give the type of the message received. • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1110: Reserved • 1111: PTP packet with Reserved message type
7	IPv6 Packet Received When set, this bit indicates that the received packet is an IPv6 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.
6	IPv4 Packet Received When set, this bit indicates that the received packet is an IPv4 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.
5	IP Checksum Bypassed When set, this bit indicates that the checksum offload engine is bypassed.
4	IP Payload Error When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the EMAC calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. This bit is valid when either Bit 7 or Bit 6 is set.
3	IP Header Error When set, this bit indicates that either the 16-bit IPv4 header checksum calculated by the EMAC does not match the received checksum bytes, or the IP datagram version is not consistent with the Ethernet Type value. This bit is valid when either Bit 7 or Bit 6 is set.

Bit	Description
2:0	IP Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the receive Checksum Offload Engine (COE). The COE also sets these bits to 0 if it does not process the IP datagram's payload due to an IP header error or fragmented IP. • 0x0: Unknown or did not process IP payload • 0x1: UDP • 0x2: TCP • 0x3: ICMP • 0x4–0x7: Reserved This bit is valid when either Bit 7 or Bit 6 is set.

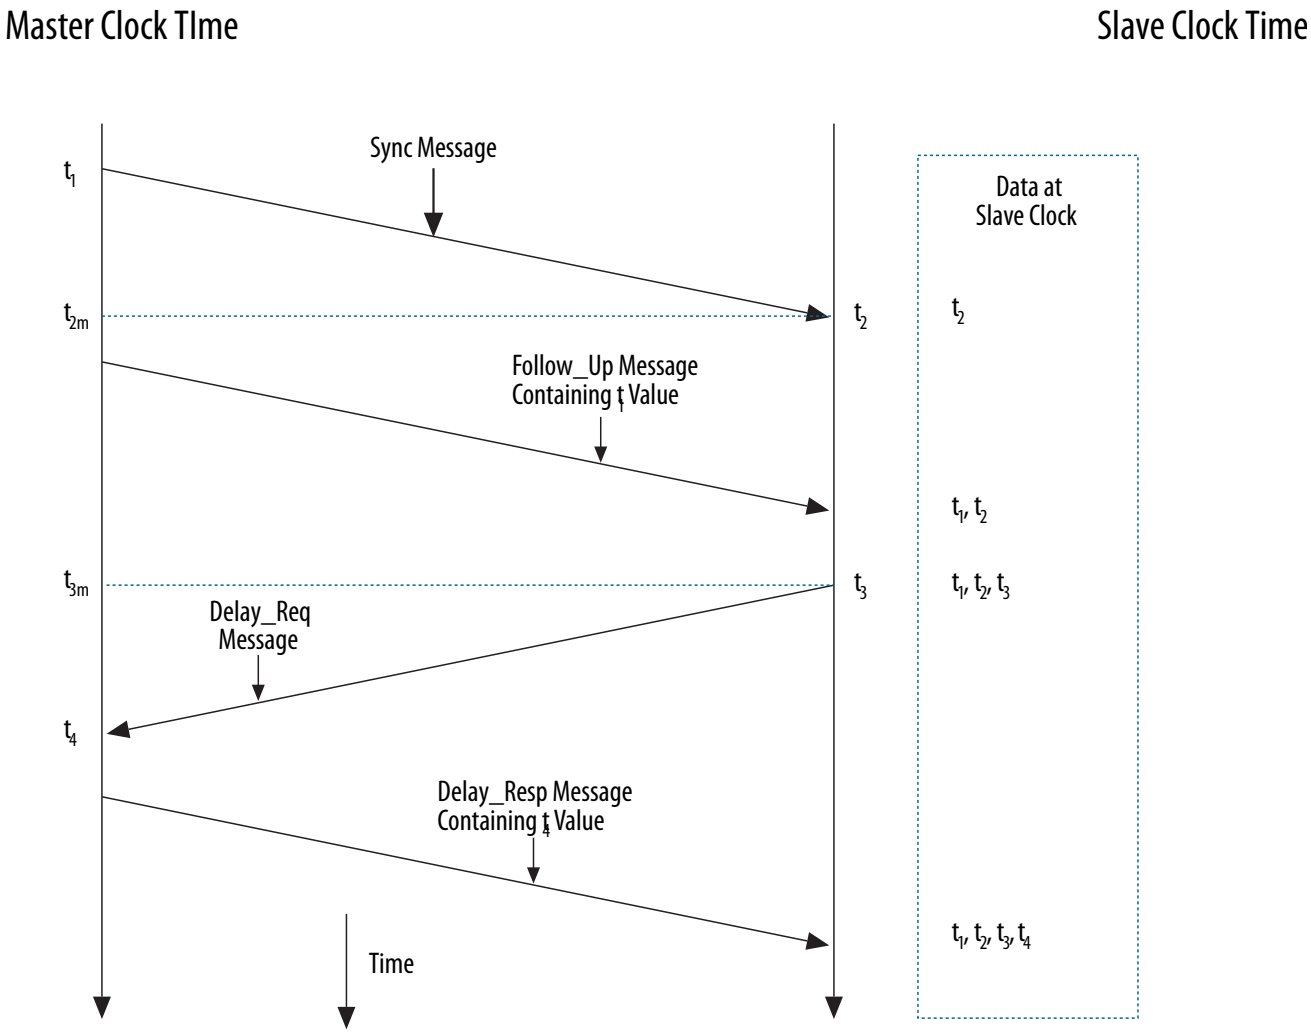
IEEE 1588-2002 Timestamps

The IEEE 1588-2002 standard defines the Precision Time Protocol (PTP) that enables precise synchronization of clocks in a distributed network of devices. The PTP applies to systems communicating by local area networks supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. It is frequently used in automation systems where a collection of communicating machines such as robots must be synchronized and hence operate over a common time base.(†)

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing and clock information.†

The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 17-13: Networked Time Synchronization



The PTP uses the following process for synchronizing a slave node to a master node by exchanging the PTP messages:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1. This time must be captured, for Ethernet ports, at the PHY interface.†
2. The slave receives the sync message and also captures the exact time, t2, using its timing reference.†
3. The master sends a follow_up message to the slave, which contains t1 information for later use.†
4. The slave sends a delay_req message to the master, noting the exact time, t3, at which this frame leaves the PHY interface.†
5. The master receives the message, capturing the exact time, t4, at which it enters its system.†
6. The master sends the t4 information to the slave in the delay_resp message.†
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.†

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the PHY interface. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.†

The EMAC is intended to support IEEE 1588 operation in all modes with a resolution of 10 ns. When the three EMACs are operating in an IEEE 1588 environment, the MPU subsystem is responsible for maintaining synchronization between the time counters internal to the three MACs.

The IEEE 1588 interface to the FPGA allows the FPGA to provide a source for the `emac_ptp_ref_clk` input as well to allow it to monitor the pulse per second output from each EMAC controller.

The EMAC component provides a hardware assisted implementation of the IEEE 1588 protocol. Hardware support is for timestamp maintenance. Timestamps are updated when receiving any frame on the PHY interface, and the receive descriptor is updated with this value. Timestamps are also updated when the SFD of a frame is transmitted and the transmit descriptor is updated accordingly.†

Reference Timing Source

To get a snapshot of the time, the EMAC takes the reference clock input and uses it to generate the reference time (64-bit) internally and capture timestamps.†

System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock, `clk_ptp_ref`, which can be the `emac_ptp_clk` from the HPS or the `f2s_ptp_ref_clk` from the FPGA. The `emac_ptp_clk` in the HPS is a derivative of the `osc1_clk` and is configured in the clock manager. This input reference clock is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the PHY interface.

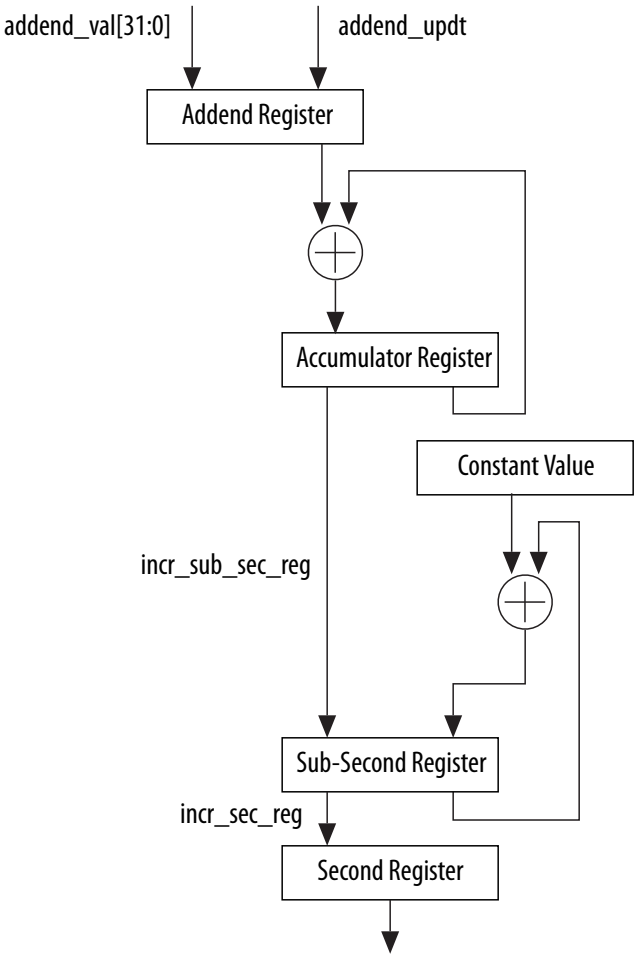
The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, each EMAC's system time counter is written with the value in the Timestamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

With the fine correction method, a slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This protocol helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.†

With this method, an accumulator sums up the contents of the Timestamp_Addend register, as shown in the figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.†

Figure 17-14: Algorithm for System Time Update Using Fine Method



The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division ratio (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to program in the register is 232 / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 232 / 1.30, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (232 / 1.32) must be programmed.†

In the above figure, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.†

Initially, the slave clock is set with `FreqCompensationValue0` in the Addend register. This value is as follows:†

$$FreqCompensationValue_0 = 232 / FreqDivisionRatio^{\dagger}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.†

The algorithm is as follows:†

- At time $MasterSyncTime_n$ the master sends the slave clock a sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as:†

  $$MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n^{\dagger}$$

- The master clock count for current sync cycle, $MasterClockCount_n$ is given by:†

  $$MasterClockCount_n = MasterClockTime_n - MasterClockTime_{n-1}$$

  (assuming that MasterToSlaveDelay is the same for sync cycles n and n – 1)†

- The slave clock count for current sync cycle, $SlaveClockCount_n$ is given by:†

  $$SlaveClockCount_n = SlaveClockTime_n - SlaveClockTime_{n-1}^{\dagger}$$

- The difference between master and slave clock counts for current sync cycle, $ClockDiffCount_n$ is given by:†

  $$ClockDiffCount_n = MasterClockCount_n - SlaveClockCount_n^{\dagger}$$

- The frequency-scaling factor for the slave clock, $FreqScaleFactor_n$ is given by:†

  $$FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n^{\dagger}$$

- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is given by: †

  $$FreqCompensationValue_n = FreqScaleFactor_n \times FreqCompensationValue_{n-1} - 1^{\dagger}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.†

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.†

Transmit Path Functions

The MAC captures a timestamp when the start-of-frame data (SFD) is sent on the PHY interface. You can control the frames for which timestamps are captured on a per frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame. †

You can use the conrol bits in the transmit descriptor to indicate whether a timestamp should be capture for a frame. The MAC returns the timestamp to the software inside the corrsponding transmit descriptor,

thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields. T†

Receive Path Functions

The MAC captures the timestamp of all frames received on the PHY interface. The DMA returns the timestamp to the software in the corresponding receive descriptor. The timestamp is written only to the last receive descriptor.†

Timestamp Error Margin

According to the IEEE1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the PHY interface. Because the PHY interface receive and transmit clocks are not synchronous to the reference timestamp clock (`clk_ptp_ref`) a small amount of drift is introduced when a timestamp is moved between asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of two PTP clocks, meaning that the captured timestamp has a reference timing source value that is occurred within two clocks after the SFD is transmitted on the PHY interface.

Similarly, in the receive path, the error margin is three PHY interface clocks, plus up to two PTP clocks. You can ignore the error margin due to the PHY interface clock by assuming that this constant delay is present in the system (or link) before the SFD data reaches the PHY interface of the MAC.†

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the EMAC clock domain to the FPGA clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four PHY interface clock cycles and three PTP clock cycles. If the delay between two timestamp captures is less than this amount, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (20 ns resulting in 50 MHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.†

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the PHY interface clock frequency is fixed by the IEEE 1588 specification, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC.†

Table 17-19: Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
100-Mbps full-duplex operation	168 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 16 clocks of preamble)	(3 * PTP) + (4 * MII) <= 168 * MII, that is, ~0.5 MHz (168 – 4) * 40 ns ÷ 3 = 2180 ns period)

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
1000-Mbps half duplex operation	24 GMII clocks (4 for a jam pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	(3 * PTP) + 4 * GMII <= 24 * GMII, that is, 18.75 MHz

IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.†

- Supports the IEEE 1588-2008 (version 2) timestamp format. †
- Provides an option to take a timestamp of all frames or only PTP-type frames. †
- Provides an option to take a timestamp of event messages only. †
- Provides an option to take the timestamp based on the clock type: ordinary, boundary, end-to-end, or peer-to-peer. †
- Provides an option to configure the EMAC to be a master or slave for ordinary and boundary clock. †
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status. †
- Provides an option to measure sub-second time in digital or binary format. †

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) messages in addition to SYNC, Delay Request, Follow-up, and Delay Response messages.†

Clock Types

The EMAC supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock†
- Boundary clock†
- End-to-End transparent clock†
- Peer-to-Peer transparent clock†

Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device. †

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:†

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in the `Timestamp Control (gmacgrp_timestamp_control)` register.†
- Maintains the data sets such as timestamp values.†

The table below shows the messages for which you can take the timestamp snapshot on the receive side for Master and slave nodes. For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the control bit (`tsver2ena`) and selecting the snapshot mode in the `Timestamp Control (gmacgrp_timestamp_control)` register.†

Table 17-20: Ordinary Clock: PTP Messages for Snapshot†

Master	Slave
Delay_Req	SYNC

Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action. The boundary clock is similar to the ordinary clock except for the following features:†

- The clock data sets are common to all ports of the boundary clock .†
- The local clock is common to all ports of the boundary clock. Therefore, the features of the ordinary clock are also applicable to the boundary clock.†

End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the ingess port to the egress port.†

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet inside the end-to-end transparent clock is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both ingress and egress ports only for PTP messages SYNC or Delay_req. You can take the snapshot by setting the snapshot select bits (`SNAPTYPSEL`) to b'10 in the `Timestamp Control (gmacgrp_timestamp_control)` register.†

The `snaptypsel` bits, along with bits 15 and 14 in the `Timestamp Control` register, decide the set of PTP packet types for which a snapshot needs to be taken. The encoding is shown in the table below:†

Table 17-21: Timestamp Snapshot Dependency on Register Bits†

X is defined as a "don't care" in the table.

snaptypsel (bits[17:16])	tsmstrena (bit 15)	tsevntena (bit 14)	PTP Messages
0x0	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
0x0	0	1	SYNC
0x0	1	1	Delay_Req
0x1	X	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_ Follow_Up
0x1	0	1	SYNC, Pdelay_Req, Pdelay_Resp
0x1	1	1	Delay_Req, Pdelay_Req, Pdelay_ Resp
0x2	X	X	SYNC, Delay_Req
0x3	X	X	Pdelay_Req, Pdelay_Resp

Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.†

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet.†

Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in the table below.†

Table 17-22: Peer-to-Peer Transparent Clock: PTP Messages for Snapshot†

PTP Messages
SYNC
Pdelay_Req
Pdelay_Resp

You can take the snapshot by setting the snapshot select bits (`snaptypsel`) to b'11 in the `Timestamp Control` register.†

Reference Timing Source

The EMAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 48-bit seconds field†
- Fixed pulse-per-second output†
- Flexible pulse-per-second output†
- Auxiliary snapshots (timestamps) with external events

Transmit Path Functions

The advanced timestamp feature is supported through the descriptors format.

Receive Path Functions

The MAC processes the received frames to identify valid PTP frames. You can control the snapshot of the time to be sent to the application, by using the following options:†

- Enable timestamp for all frames.†
- Enable timestamp for IEEE 1588 version 2 or version 1 timestamp.†
- Enable timestamp for PTP frames transmitted directly over Ethernet or UDP/IP Ethernet.†
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.†
- Enable timestamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP) only.†
- Enable the node to be a master or slave and select the timestamp type to control the type of messages for which timestamps are taken.†

The DMA returns the timestamp to the software inside the corresponding transmit or receive descriptor.

Auxiliary Snapshot

The auxiliary snapshot feature allows you to store a snapshot (timestamp) of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i` from the FPGA. One auxiliary snapshot input is available. The depth of the auxiliary snapshot FIFO buffer is 16.

The timestamps taken for any input are stored in a common FIFO buffer. The host can read Register 458 (Timestamp Status Register) to know which input's timestamp is available for reading at the top of this FIFO buffer.

Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from Register 457 (System Time - Higher Word Seconds Register) when it is present. When a snapshot is stored, the MAC indicates this to the host with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (`ATSSTM`) is set in Register 458 (Timestamp Status Register). This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full. When a host reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting Bit 19 (`ATSFC`) in Register 448 (Timestamp Control Register). When multiple snapshots are present in the FIFO, the count is indicated in Bits [27:25], `ATSNS`, of Register 458 (Timestamp Status Register). †

IEEE 802.3az Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) standardized by IEEE 802.3-az, version D2.0 is supported by the EMAC. It is supported by the MAC operating in 10/100/1000 Mbps rates. EEE is only supported when the EMAC

is configured to operate with the RGMII PHY interface operating in full-duplex mode. It cannot be used in half-duplex mode.

EEE enables the MAC to operate in Low-Power Idle (LPI) mode. Either end point of an Ethernet link can disable functionality to save power during periods of low link utilization. The MAC controls whether the system should enter or exit LPI mode and communicates this information to the PHY.†

Related Information

IEEE 802.3 Ethernet Working Group

For details about the *IEEE 802.3az Energy Efficient Ethernet standard*, refer to the IEEE 802.3 Ethernet Working Group website.†

LPI Timers

Two timers internal to the EMAC are associated with LPI mode:

- LPI Link Status (LS) Timer†
- LPI Time Wait (TW) Timer†

The LPI LS timer counts, in ms, the time expired since the link status has come up. This timer is cleared every time the link goes down and is incremented when the link is up again and the terminal count as programmed by the software is reached. The PHY interface does not assert the LPI pattern unless the terminal count is reached. This protocol ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as one second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10 bits wide, so the software can program up to 1023 ms.†

The LPI TW timer counts, in µs, the time expired since the deassertion of LPI. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. The LPI TW timer is 16 bits wide, so the software can program up to 65535 µs.†

The EMAC generates the LPI interrupt when the transmit or receive channel enters or exits the LPI state.†

Checksum Offload

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. Supported offloading types:

- Transmit IP header checksum†
- Transmit TCP/UDP/ICMP checksum†
- Receive IP header checksum†
- Receive full checksum†

Frame Filtering

The EMAC implements the following types of filtering for receive frames.

Source Address or Destination Address Filtering

The Address Filtering Module checks the destination and source address field of each incoming packet.†

Unicast Destination Address Filter

Up to 128 MAC addresses for unicast perfect filtering are supported. The filter compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr127 are selected with an individual enable bit. For MacAddr1–MacAddr31 addresses, you can mask each byte during comparison with the corresponding received DA byte. This enables group address filtering for the DA. The MacAddr32-MacAddr127 addresses do not have mask control and all six bytes of the MAC address are compared with the received six bytes of DA.†

In hash filtering mode, the filter performs imperfect filtering for unicast addresses using a 256-bit hash table. It uses the upper ten bits of the CRC of the received destination address to index the content of the hash table. A value of 0 selects Bit 0 of the selected register, and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, the unicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.†

Multicast Destination Address Filter

The MAC can be programmed to pass all multicast frames. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported. In hash filtering mode, the filter performs imperfect filtering using a 256-bit hash table. For hash filtering, it uses the upper ten bits of the CRC of the received multicast address to index the contents of the hash table. A value of 0 selects Bit 0 of the selected register and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, then the multicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.†

Hash or Perfect Address Filter

The filter can be configured to pass a frame when its DA matches either the hash filter or the Perfect filter. This configuration applies to both unicast and multicast frames.†

Broadcast Address Filter

The filter does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames, the filter drops any broadcast frame.†

Unicast Source Address Filter

The MAC can also perform a perfect filtering based on the source address field of the received frames. Group filtering with SA is also supported. You can filter a group of addresses by masking one or more bytes of the address.†

Inverse Filtering Operation (Invert the Filter Match Result at Final Output)

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. The result of the unicast or multicast destination address filter is inverted in this mode.†

Destination and Source Address Filtering Summary

The tables below summarize the destination and source address filtering based on the type of frames received and the configuration of bits within the Mac_Frame_Filter register.†

Table 17-23: Destination Address Filtering†

Note: The "X" in the table represents a "don't care" term.

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	Destination Address Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfrect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause frames if PCF= 0X
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause frames if PCF = 0X
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause frames if PCF = 0X
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause frames if PCF=0X
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Paus frames if PCF = 0X
	0	1	X	1	1	0	X	Fail Hash on Perfect/Group filter match and drop Pause frames if PCF = 0X

Table 17-24: Source Address Filtering†

Frame Type	PR	DAIF	DBF	Source Address Filter Operation
Unicast	1	X	X	Pass all frames
	0	0	0	Pass status on Perfect or Group filter match but do not drop frames that fail.
	0	1	0	Fail on Perfect or Group filter match but do not drop frame
	0	0	1	Pass on Perfect or Group filter match and drop frames that fail
	0	1	1	Fail on Perfect or Group filter match and drop frames that fail

VLAN Filtering

The EMAC supports the two kinds of VLAN filtering:

- VLAN tag-based filtering†
- VLAN hash filtering†

VLAN Tag-Based Filtering

In the VLAN tag-based frame filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. You can also enable the inverse matching for VLAN frames. In addition, you can enable matching of SVLAN tagged frames along with the default Customer Virtual Local Area Network (C-VLAN) tagged frames.†

VLAN Hash Filtering with a 16-Bit Hash Table

The MAC provides VLAN hash filtering with a 16-bit hash table. The MAC also supports the inverse matching of the VLAN frames. In inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.†

Layer 3 and Layer 4 Filters

Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering. The frames are filtered in the following ways:†

- Matched frames†
- Unmatched frames†
- Non-TCP or UDP IP frames†

Matched Frames

The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if one of the following conditions is true:†

- All enabled Layer 3 and Layer 4 fields match.†
- At least one of the enabled field matches and other fields are bypassed or disabled.†

Using the CSR set, you can define up to four filters, identified as filter 0 through filter 3. When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides status of the lowest filter with filter 0 being the lowest and filter 3 being the highest. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.†

Unmatched Frames

The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. You can configure the EMAC so that when a frame is dropped, it receives a partial frame with appropriate abort status or drops it completely.†

NonTCP or UDP IP Frames

By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.†

Layer 3 and Layer 4 Filters Register Set

The MAC implements a set of registers for Layer 3 and Layer 4 based frame filtering. In this register set, there is a control register for frame filtering and five address registers.†

You can configure the MAC to have up to four such independent set of registers.†

The registers available for programming are as follows:

- `gmacgrp_l3_l4_control0` through `gmacgrp_l3_l4_control3` registers: Layer and Layer 4 Control registers
- `gmacgrp_layer4_address0` through `gmacgrp_layer4_address3` registers: Layer 4 Address registers
- `gmacgrp_layer3_addr0_reg0` through `gmacgrp_layer3_addr0_reg3` registers: Layer 3 Address 0 registers
- `gmacgrp_layer3_addr1_reg0` through `gmacgrp_layer3_addr1_reg3` registers: Layer 3 Address 1 registers
- `gmacgrp_layer3_addr2_reg0` through `gmacgrp_layer3_addr2_reg3` registers: Layer 3 Address 2 registers
- `gmacgrp_layer3_addr3_reg0` through `gmacgrp_layer3_addr3_reg3` registers: Layer 3 Address 3 registers

Ethernet MAC Address Map and Register Definitions on page 17-78

Layer 3 Filtering

The EMAC supports perfect matching or inverse matching for the IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits. †

For IPv6 frames filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source or Destination Address should be programmed in the order defined in the IPv6 specification. The specification requires that you program

the first byte of the received frame IP Source or Destination Address in the higher byte of the register. Subsequent registers should follow the same order.†

For IPv4 frames filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source and Destination Address should be programmed in the order defined in the IPv4 specification. The specification requires that you program the first byte of received frame IP Source and Destination Address in the higher byte of the respective register.†

Layer 4 Filtering

The EMAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number. †

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received frame is in the higher byte of the register.†

Clocks and Resets

Clock Structure

The Ethernet Controller has four main clock domains.

- l4_mp_clk clock
- EMAC RX clock
- EMAC TX clock
- clk_ptp_ref

Figure 17-15: EMAC Clock Diagram

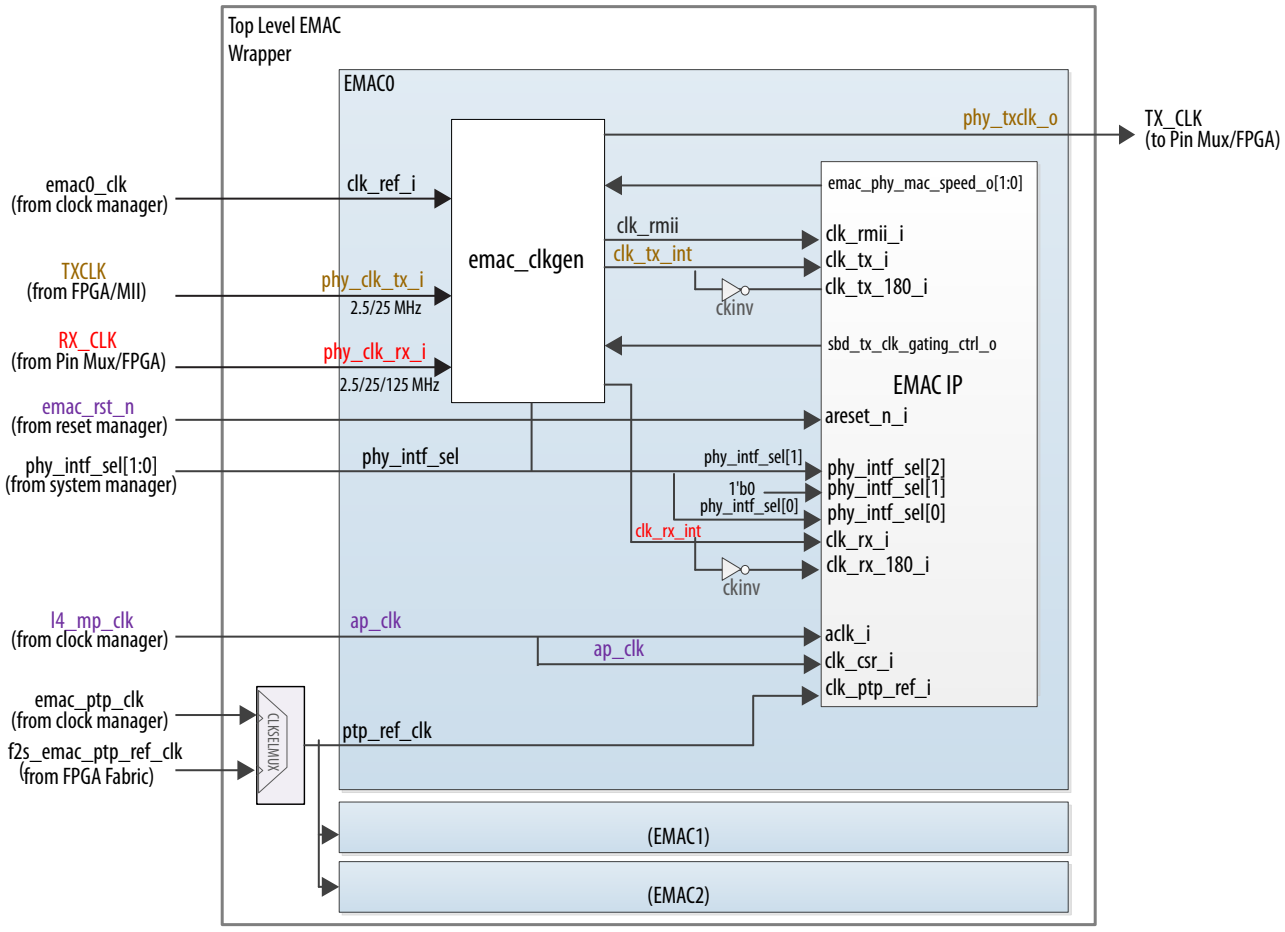

Figure 17-16: emac_clkgen Module

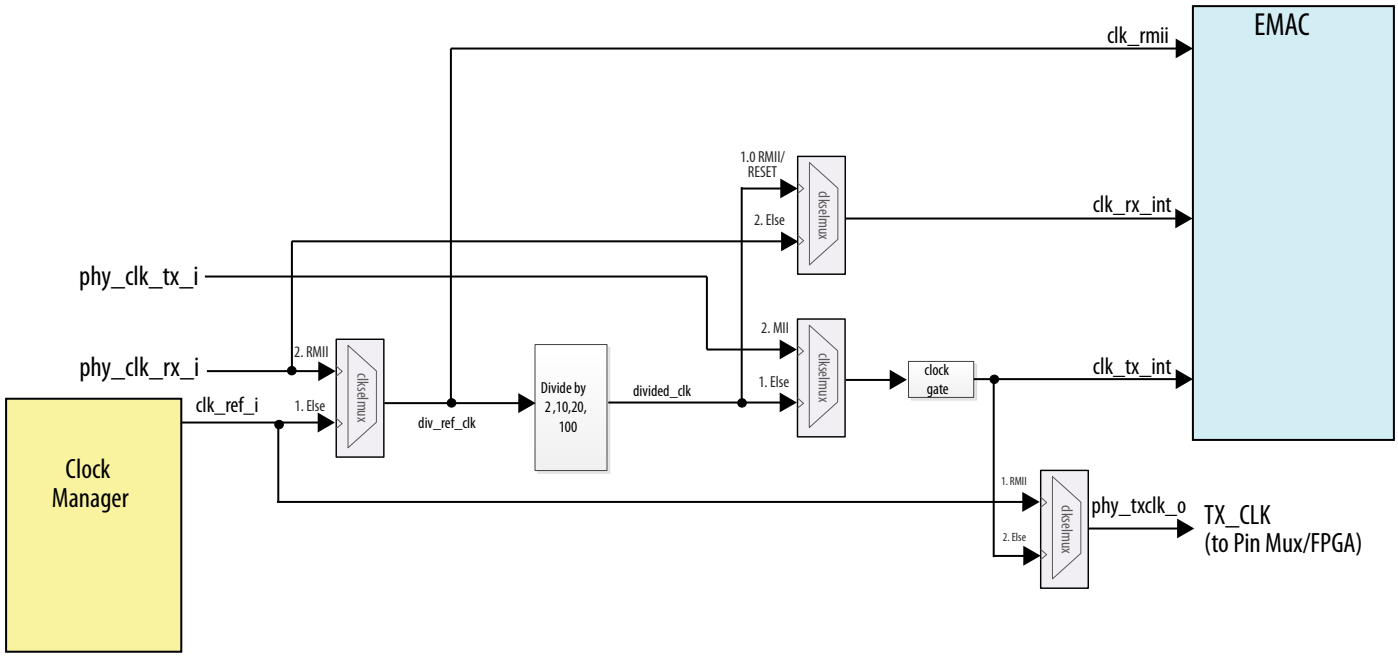


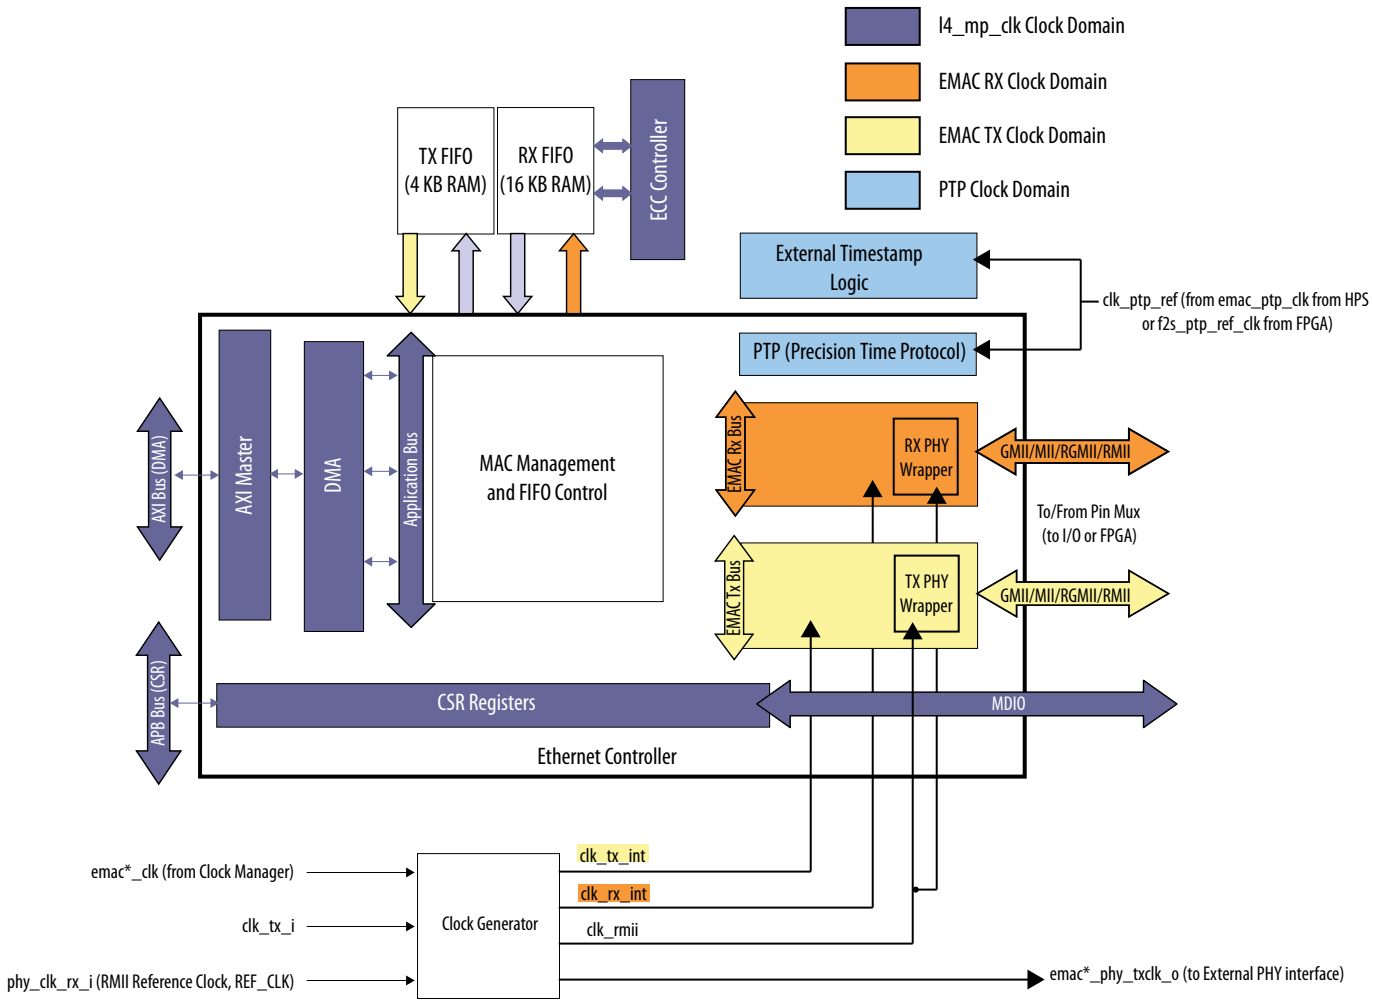
Depending on the interface, different clock domains are used:

- When the DMA master interface is used for EMAC packet transfers, the `l4_mp_clk` is used as a clock source for both the AXI bus and the CSR register interface. This clock domain is a fully synchronous.
- The RX and TX FIFO RAMs are driven by the `l4_mp_clk`.
- The MDIO interface's clock domain is a derivative of the CSR clock, which comes from l4_mp_clk. Typically MDC clock has a frequency between 1 to 2.5 MHz, however, faster MDC frequencies are supported in this design.
- The EMAC contains an RX datapath, TX datapath and timestamp interface that all run on separate clock domains.
  - The RX datapath is in the EMAC RX clock domain.
  - The TX datapath is in the EMAC TX clock domain.
  - The timestamp interface is in the clk_ptp_ref clock domain.

The timestamp clock domain provides the capability for EMAC0 to be a timestamp master with internal timestamp enabled and the other two EMACs to be timestamp slaves using the timestamp generated from EMAC0.

The diagram below summarizes the clock domains of the EMAC module:

Figure 17-17: EMAC Clock Domains



The following table summarizes the clock inputs and outputs to the EMAC.

Table 17-25: EMAC Module Clock Inputs and Outputs

Clock	Input/Output	Frequency	Source	Description
`l4_mp_clk`	Input	200 MHz	Clock Manager	Application clock for DMA bus interface, CSR interface and ECC FIFO RAMs.

Clock	Input/Output	Frequency	Source	Description
clk_ptp_ref	Input	up to 100 MHz	Clock Manager or FPGA fabric	This signal is sourced by either the PTP reference clock from the Clock Manager or the FPGA fabric. The source can be selected through the ptp_clk_sel bit of the emac_global register in the System Manager module. When the bit is clear, the emac_ptp_clk is selected and when it is set, the f2s_ptp_ref_clk is selected.
emac*_clk	Input	Variable depending on divider value of programmed in Clock Manager.	Input from Clock Manager	This signal is configured in the Clock Manager module and can be enabled to drive the clk_tx_in and clk_rx int signals to the TX and RX clock domains.
clk_tx_i	Input	Used only in MII mode as a 25 or 2.5 MHz clock source at 100 Mbps and 10 Mbps, respectively.	Input from FPGA fabric I/O	This signal is used only in MII mode as a TX reference clock. **Note:** This clock must be able to perform glitch free switching between 2.5 and 25 MHz.
phy_clk_rx_i	Input	• GMII mode: 125 MHz • RGMII mode: 125, 25, or 2.5 MHz • MII mode: 25 or 2.5 MHz • RMII mode: 50 MHz	This clock input is driven to FPGA or by an HPS I/O input from an external PHY	For all modes except, RMII, this clock signal is the RX PHY input clock. For RMII mode, this input is a 50 MHz reference clock (REF_CLK) from the board or from phy_txclk_o that is divided down automatically to generate the datapath clocks, emac*_clk_rx_i and emac*_clk_tx_i signals. These datapath clocks are 2.5 MHz when operating in 10 Mbps mode and 25 MHz when operating in 100 Mbps mode.
phy_txclk_o	Output	125, 50, 25, or 2.5 MHz	From internal HPS clk_tx_int to HPS I/O or from FPGA fabric.	This signal is an TX output clock to the PHY. In RMII mode, this signal can provide the reference clock (50 MHz in 100M /10 Mbps).

Clock Gating for EEE

For the RGMII PHY interface, you can gate the transmit clock for Energy Efficient Ethernet (EEE) applications.

Programming Guidelines for Energy Efficient Ethernet on page 17-75

Reset

The EMAC module accepts a single reset input, `emac_rst_n`, which is active low.

Note: In all modes, the EMAC core depends on the PHY clocks to be active for the internal EMAC clock sources to be valid.

Taking the Ethernet MAC Out of Reset

When a cold or warm reset is issued in the HPS, the Reset Manager resets the EMAC module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the Reset Manager's corresponding reset register. Before deasserting the reset signal, you must make sure the PHY interface type and all other corresponding EMAC settings in the System Manager have been configured. For details about reset registers, refer to the "Module Reset Signals" section in the *Reset Manager* chapter. For more information about EMAC configuration in the System Manager, refer to the "System Level EMAC Configuration Registers" section.

EMAC ECC RAM Reset

An EMAC ECC RAM reset asserts a reset to both the memory and the multiplexed EMAC bus interface clock, `ap_clk`. You should ensure that both the EMAC ECC RAM and the EMAC Module resets are deasserted before beginning transactions. Program the `emac*ocp` bits and the `emac*` bits in the `per0modrst` register of the Reset Manager to deassert reset in the EMAC's ECC RAM and the EMAC module, respectively.

  For more information about reset registers refer to this section in the *Reset Manager* chapter.

Interrupts

Interrupts are generated as a result of specific events in the EMAC and external PHY device. The interrupt status register indicates all conditions which may trigger an interrupt and the interrupt enable register determines which interrupts can propagate.

Ethernet MAC Programming Model

The initialization and configuration of the EMAC and its interface is a multi-step process that includes system register programming in the System Manager and Clock Manager and configuration of clocks in multiple domains.

Note: When the EMAC interfaces to HPS I/O and register content is being transferred to a different clock domain after a write operation, no further writes should occur to the same location until the first

write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Thus, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).† If the CSR is accessed multiple times quickly, you must ensure that a minimum number of destination clock cycles have occurred between accesses.

Note: If the EMAC signals are routed through the FPGA fabric and it is assumed that the transmit clock supplied by the FPGA fabric switches within 6 transmit clock cycles, then the minimum time required between two write accesses to the same register is 10 transmit clock cycles.

System Level EMAC Configuration Registers

In addition to the registers in the Ethernet Controller, there are other system level registers in the Clock Manager, System Manager and Reset Manager that must be programmed in order to configure the EMAC and its interfaces.

The following table gives a summary of the important System Manager clock register bits that control operation of the EMAC. These register bits are static signals that must be set while the corresponding EMAC is in reset.

Table 17-26: System Manager Clock and Interface Settings

Register.Field	Description
`emac_global.ptp_clk_sel`	1588 PTP reference clock. This bit selects the source of the 1588 PTP reference clock. • 0x0= `emac_ptp_clk` (default from Clock Manager) • 0x1=`f2s_emac_ptp_ref_clk` (from FPGA fabric; in this case, the FPGA must be in usermode with an active reference clock)

`emac0.phy_intf_sel`
`emac1.phy_intf_sel`
`emac2.phy_intf_sel`
	PHY Interface Select. These two bits set the PHY mode.
	• 0x0= GMII or MII
	• 0x1= RGMII
	• 0x2= RMII
	• 0x3= RESET (default)

The following table summarizes the important System Manager configuration register bits. All of the fields, except the AXI cache settings, are assumed to be static and must be set before the EMAC is brought out of reset. If the FPGA interface is used, the FPGA must be in user mode and enabled with the appropriate clock signals active before the EMAC can be brought out of reset.

Table 17-27: System Manager Static Control Settings

Register.Field	Description
fpgaintf_en_3.emac0 fpgaintf_en_3.emac1 fpgaintf_en_3.emac2	FPGA interface to EMAC disable. This field is used to disable signals from the FPGA to the EMAC modules that could potentially interfere with the EMAC's or FPGA's operation. • 0x0= Disable (default) • 0x1=Enable
emac0.axi_disable emac1.axi_disable emac2.axi_disable	AXI Disable. Disables the AXI bus to EMAC. • 0x0= Enable (default) • 0x1= Disable
emac0.awcache emac1.awcache emac2.awcache emac0.arcache emac1.arcache emac2.arcache	EMAC AXI Master AxCACHE settings. It is recommended that these bits are set while the EMAC is idle or in reset.
emac0.awprot emac1.awprot emac2.awprot emac0.arprot emac1.arprot emac2.arprot	EMAC Master AxPROT settings. It is recommended that these bits are set while the EMAC is idle or in reset.
emac0.ptp_ref_sel emac1.ptp_ref_sel emac2.ptp_ref_sel	Internal/External Timestamp reference. This field selects if the timestamp reference is internally or externally generated. EMAC0 may be the master to generate the timestamp for EMAC1 and EMAC2. EMAC0 must be set to internal timestamp; EMAC1 and EMAC2 may be set either to internal or external. • 0x0= Internal (default) • 0x1= External

Various registers within the Clock Manager must also be configured in order for the EMAC controller to perform properly.

Table 17-28: Clock Manager Settings

Register.Field	Description
en.emacptpen	emac_ptp_clk output enable.
en.emac0en en.emac1en en.emac2en	Enables clock emac0_clk, emac1_clk and emac2_clk output. **Note:** There are corresponding ens and enr registers that allow the same fields to be set or cleared on a bit-by-bit basis.
bypass.emacptp	EMAC PTP clock bypass. This bit indicates if the emac_ptp_clk is bypassed to the input clock reference of the peripheral PLL. • 0x0= No bypass occurs • 0x1= emac_ptp_clk is bypassed to the input clock reference of the main PLL. **Note:** There are corresponding bypasss and bypassr registers that allow the same bits to be set or cleared on a bit-by-bit basis.
bypass.emaca bypass.emacb	Clock Bypass. This bit indicates whether emaca_free_clk or emacb_free_clk is bypassed to the input clock reference of the main PLL. • 0x0= No bypass occurs • 0x1= emac*_free_clk is bypassed to the input clock reference of the main PLL. **Note:** There are corresponding bypasss and bypassr registers that allow the same bits to be set or cleared on a bit-by-bit basis.
emacctl.emac0sel emacctl.emac1sel emacctl.emac2sel	EMAC clock source select. This bit selects the source for the emac*clk as either emaca_free_clk or emacb_free clk • 0x0= emaca_free_clk • 0x1=emacb_free_clk

EMAC FPGA Interface Initialization

To initialize the Ethernet controller to use the FPGA GMII/MII interface, specific software steps must be followed.

In general, the FPGA interface must be active in user mode with valid PHY clocks, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac*` bit in the `per0modrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate registers in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. If the PTP clock source is from the FPGA, ensure that the FPGA `f2s_ptp_ref_clk` is active.
5. The soft GMII/MII adaptor must be loaded with active clocks propagating. The FPGA must be configured to user mode and a reset to the user soft FPGA IP may be required to propagate the PHY clocks to the HPS.
6. Once all clock sources are valid, apply the following clock settings:
   a. Program the `phy_intf_sel` field of the `emac*` register in the System Manager to 0x0 to select GMII/MII PHY interface.
   b. If the PTP clock source is from the FPGA, set the `ptp_clk_sel` bit to 0x1 in the `emac_global` register of the System Manager.
   c. Enable the Ethernet Controller FPGA interface by setting the `emac_*` bit in the `fpgaintf_en_3` register of the System Manager.
7. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include the AxPROT[1:0] and AxCACHE signal values which are programmed in the `emac*` register of the System Manager.
8. Execute a register read back to confirm the clock and static configuration settings are valid.
9. After confirming the settings are valid, software can clear the `emac*` bit in the `per0modrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

Note: These same steps can be applied to convert the HPS GMII to an RGMII, RMII or SGMII interface through the FPGA, except that in step 5 during FPGA configuration, you would load the appropriate soft adaptor for the interface and apply reset to it as well. The PHY interface select encoding would remain as 0x0. For the SGMII interface additional external transceiver logic would be required. Routing the Ethernet signals through the FPGA is useful for designs that are pin-limited in the HPS.

EMAC HPS Interface Initialization

To initialize the Ethernet controller to use the HPS interface, specific software steps must be followed including selecting the correct PHY interface through the System Manager.

In general, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac*` bit in the `per0modrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate registers in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. When all the clocks are valid, program the following clock settings:

   a. Program the `phy_intf_sel` field of the `emac*` register in the System Manager to 0x1 or 0x2 to select RGMII or RMII PHY interface.
   b. Disable the Ethernet Controller FPGA interface by clearing the `emac_*` bit in the `fpgaintf_en_3` register of the System Manager.
5. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include the AxPROT[1:0] and AxCACHE signal values, which are programmed in the `emac*` register of the System Manager.
6. Execute a register read back to confirm the clock and static configuration settings are valid.
7. After confirming the settings are valid, software can clear the `emac*` bit in the `per0modrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

DMA Initialization

This section provides the instructions for initializing the DMA registers in the proper sequence. This initialization sequence can be done after the EMAC interface initialization has been completed. Perform the following steps to initialize the DMA:

1. Provide a software reset to reset all of the EMAC internal registers and logic. (DMA Register 0 (Bus Mode Register) – bit 0). †
2. Wait for the completion of the reset process (poll bit 0 of the DMA Register 0 (Bus Mode Register), which is only cleared after the reset operation is completed). †
3. Poll the bits of Register 11 (AXI Status) to confirm that all previously initiated (before software reset) or ongoing transactions are complete.

   Note: If the application cannot poll the register after soft reset (because of performance reasons), then it is recommended that you continue with the next steps and check this register again (as mentioned in step **12** on page 1-74) before triggering the DMA operations.†
4. Program the following fields to initialize the Bus Mode Register by setting values in DMA Register 0 (Bus Mode Register):†
   - Mixed Burst and AAL
   - Fixed burst or undefined burst†
   - Burst length values and burst mode values†
   - Descriptor Length (only valid if Ring Mode is used)†
5. Program the interface options in Register 10 (AXI Bus Mode Register). If fixed burst-length is enabled, then select the maximum burst-length possible on the bus (bits[7:1]).†
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (bit 31 of descriptor should be set). When OSF mode is used, at least two descriptors are required.
7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.†
8. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register) respectively).†
9. Program the following fields to initialize the mode of operation in Register 6 (Operation Mode Register):

- Receive and Transmit Store And Forward†
- Receive and Transmit Threshold Control (RTC and TTC)†
- Hardware Flow Control enable†
- Flow Control Activation and De-activation thresholds for MTL Receive and Transmit FIFO buffers (RFA and RFD)†
- Error frame and undersized good frame forwarding enable†
- OSF Mode†

10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit (DMA Register 5 (Status Register)).†
11. Enable the interrupts by programming Register 7 (Interrupt Enable Register).†

    Note: Perform step 12 on page 1-74 only if you did not perform step 3 on page 1-73.†
12. Read Register 11 (AHB or AXI Status) to confirm that all previous transactions are complete.†

    Note: If any previous transaction is still in progress when you read the Register 11 (AXI Status), then it is strongly recommended to check the slave components addressed by the master interface.†
13. Start the receive and transmit DMA by setting SR (bit 1) and ST (bit 13) of the control register (DMA Register 6 (Operation Mode Register). †

EMAC Initialization and Configuration

The following EMAC configuration operations can be performed after DMA initialization. If the EMAC initialization and configuration is done before the DMA is set up, then enable the MAC receiver (last step below) only after the DMA is active. Otherwise, the received frame could fill the RX FIFO buffer and overflow.

1. Program the `GMII Address Register` (offset 0x10) for controlling the management cycles for the external PHY. Bits[15:11] of the `GMII Address Register` are written with the Physical Layer Address of the PHY before reading or writing. Bit 0 indicates if the PHY is busy and is set before reading or writing to the PHY management interface. †
2. Read the 16-bit data of the `GMII Data Register` from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits[15:11] of the `GMII Address Register`. †
3. Provide the MAC address registers (`MAC Address0 High Register` through `MAC Address15 High Register` and `MAC Address0 Low Register` through `MAC Address15 Low Register`).
4. Program the `Hash Table Registers` 0 through 7 (offset 0x500 to 0x51C).
5. Program the following fields to set the appropriate filters for the incoming frames in the `MAC Frame Filter Register`: †

    - Receive All †
    - Promiscuous mode †
    - Hash or Perfect Filter †
    - Unicast, multicast, broadcast, and control frames filter settings †
6. Program the following fields for proper flow control in the `Flow Control Register`: †

- Pause time and other pause frame control bits †
- Receive and Transmit Flow control bits †
- Flow Control Busy/Backpressure Activate †

7. Program the `Interrupt Mask Register` bits, as required and if applicable for your configuration. †
8. Program the appropriate fields in `MAC Configuration Register` to configure receive and transmit operation modes. After basic configuration is written, set bit 3 (`TE`) and bit 2 (`RE`) in this register to enable the receive and transmit state machines. †

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the EMAC DMA is actively transmitting or receiving. Software should change these parameters only when the EMAC DMA transmitter and receiver are not active.

Performing Normal Receive and Transmit Operation

For normal operation, perform the following steps: †

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive). †
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data. †
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the TX/RX poll demand registers, (Register 1 (Transmit Poll Demand Register) and Register 2 (Receive Poll Demand Register)). †
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (Register 18 (Current Host Transmit Descriptor Register) and Register 19 (Current Host Receive Descriptor Register)). †
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register 20 (Current Host Transmit Buffer Address Register) and Register 21 (Current Host Receive Buffer Address Register)). †

Stopping and Starting Transmission

Perform the following steps to pause the transmission for some time: †

1. Disable the transmit DMA (if applicable), by clearing bit 13 (Start or Stop Transmission Command) of Register 6 (Operation Mode Register). †
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Register 9 (Debug Register). †
3. Disable the EMAC transmitter and EMAC receiver by clearing Bit 3 (TE) and Bit 2 (RE) in Register 0 (MAC Configuration Register). †
4. Disable the receive DMA (if applicable), after making sure that the data in the RX FIFO buffer is transferred to the system memory (by reading Register 9 (Debug Register). †
5. Make sure that both the TX FIFO buffer and RX FIFO buffer are empty. †
6. To re-start the operation, first start the DMA and then enable the EMAC transmitter and receiver. †

Programming Guidelines for Energy Efficient Ethernet

Entering and Exiting the TX LPI Mode

The Energy Efficient Ethernet (EEE) feature is available in the EMAC. To use it, perform the following steps during EMAC initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values. †
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop the RX clock in LPI mode.) †
3. Program Bits[16:5], LST, and Bits[15:0], TWT, in Register 13 (LPI Timers Control Register). †
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 (PLS) of Register 12 (LPI Control and Status Register) accordingly. This update should be done whenever the link status in the PHY changes. †
5. Set Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to make the MAC enter the LPI state. The MAC enters the LPI mode after completing the transmission in progress and sets Bit 0 (TLPIEN). †

   Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the TX FIFO buffer, you should set Bit 19 (LPITXA) in Register 12 (LPI Control and Status Register). †

   Note: To switch off the transmit clock during the LPI state, use the `sbd_tx_clk_gating_ctrl_o` signal for gating the clock input. †

   Note: To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of Register 12 (LPI Control and Status Register) to be generated. Restore the clocks before performing step 6 on page 1-76 when you want to come out of the LPI state. †
6. Clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI state. †

The MAC waits for the time programmed in Bits [15:0], TWT, before setting the TLPIEX interrupt status bit and resuming the transmission. †

Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.†

Gating Off the CSR Clock in the RX LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY. †

1. The MAC RX enters the LPI mode and the RX LPI entry interrupt status [RLPIEN interrupt of Register 12 (`LPI_Control_Status`)] is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12 (LPI_Control_Status). †

After the `sbd_intr_o` interrupt is asserted and the MAC TX is also in the LPI mode, you can gate off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR. †

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on `lpi_intr_o` (synchronous to `clk_rx_i`). The `lpi_intr_o` interrupt is cleared when Register 12 is read. †

Gating Off the CSR Clock in the TX LPI Mode

The following operations are performed when Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) is set: †

1. The Transmit LPI Entry interrupt (TLPIEN bit of Register 12) is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12. †

After the `sbd_intr_o` interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR. †

To restore the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. †

After the CSR clock is resumed, clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI mode. †

Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

Generating a Single Pulse on PPS

To generate single Pulse on PPS: †

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to 0001 to instruct the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers (register 455 and 456). †

Once the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse: †

1. Program the start time for the next pulse in the Target Time registers (register 455 and 456). This time should be more than the time at which the falling edge occurs for the previous pulse. †
2. Program the width of the next PPS signal output in Register 473 (PPS0 Width Register). †
3. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to generate a single pulse on the PPS signal output after the time at which the previous pulse is de-asserted. And at the time programmed in Target Time registers. If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the EMAC may generate only 1 extended pulse.

Generating a Pulse Train on PPS

To generate a pulse train on PPS: †

1. Program 11 or 10 (for an interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of the PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the interval value between the train of pulses on the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
5. Program Bits[3:0], PPSCMD, of Register 459 (PPS Control Register) to 0010 to instruct the MAC to generate a train of pulses on the PPS signal output with the start time programmed in the Target Time registers (register 455 and 456). By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. †
6. Program the stop value in the Target Time registers (register 455 and 456). Ensure that Bit 31 (TSTRBUSY) of Register 456 (Target Time Nanoseconds Register) is clear before programming the Target Time registers (register 455 and 456) again. †
7. Program the PPSCMD field (bit 3:0) of Register 459 (PPS Control Register) to 0100 to stop the train of pulses on the PPS signal output after the programmed stop time specified in step 6 on page 1-78 elapses. †

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in step 7 on page 1-78) by programming 0110 in the PPSCMD field before the time (programmed in step 6 on page 1-78) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in step 2 on page 1-78) elapses. †

Generating an Interrupt without Affecting the PPS

Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) enable you to program the Target Time registers (register 455 and 456) to do any one of the following: †

- Generate only interrupts. †
- Generate interrupts and the PPS start and stop time. †
- Generate only PPS start and stop time. †

To program the Target Time registers (register 455 and 456) to generate only interrupt events: †

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the target time interrupt. †
2. Program a target time value in the Target Time registers (register 455 and 456) to instruct the MAC to generate an interrupt when the target time elapses. If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Ethernet MAC Address Map and Register Definitions

The address map and register definitions pertain to the following modules:

- EMAC Module 0
- EMAC Module 1
- EMAC Module 2

In addition to the EMAC modules, the address map and register definitions for the ECC controllers of the 4-KB Tx FIFO RAM and the 16-KB Rx FIFO RAM are listed in this section.

Related Information

Error Checking and Correction Controller on page 11-1
For more information on the functionality and programming of the ECC Controller.

emac Address Map

Module Instance	Base Address	End Address
i_emac_emac0	0xFF800000	0xFF801FFF
i_emac_emac1	0xFF802000	0xFF803FFF
i_emac_emac2	0xFF804000	0xFF807FFF

Important: To prevent indeterminate system behavior, reserved areas of memory must not be accessed by software or hardware. Any area of the memory map that is not explicitly defined as a register space or accessible memory is considered reserved.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_configuration on page 17-494	0x0	32	RW	0x0	Register 0 (MAC Configuration Register) The MAC Configuration register establishes receive and transmit operating modes.
gmacgrp_mac_frame_filter on page 17-508	0x4	32	RW	0x0	Register 1 (MAC Frame Filter) The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_gmii_address on page 17-516	0x10	32	RW	0x0	Register 4 (GMII Address Register) The GMII Address register controls the management cycles to the external PHY through the management interface. Note: This register is present for all PHY interface when you select the Station Management (MDIO) feature in coreConsul-tant.
gmacgrp_gmii_data on page 17-520	0x14	32	RW	0x0	Register 5 (GMII Data Register) The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_flow_control on page 17-521	0x18	32	RW	0x0	Register 6 (Flow Control Register) The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control module. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_vlan_tag on page 17-527	0x1C	32	RW	0x0	Register 7 (VLAN Tag Register) The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. If the VLAN Tag register is configured to be double-synchron-ized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.
gmacgrp_version on page 17-531	0x20	32	RO	0x1037	Register 8 (Version Register) The Version registers identifies the version of the DWC_gmac.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_debug on page 17-531	0x24	32	RO	0x0	Register 9 (Debug Register) The Debug register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths. Note: The reset values, given for the Debug register, are valid only if the following clocks are present during the reset operation: * clk_csr_i, clk_app_i, hclk_i, or aclk_i * clk_tx_i * clk_rx_i
gmacgrp_lpi_control_status on page 17-537	0x30	32	RW	0x0	Register 12 (LPI Control and Status Register) The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_lpi_timers_control on page 17-543	0x34	32	RW	0x3E80000	Register 13 (LPI Timers Control Register) The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.
gmacgrp_interrupt_status on page 17-544	0x38	32	RO	0x0	Register 14 (Interrupt Register) The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding feature is enabled during operation. Therefore, these bits are reserved when the corresponding features are not present in the core.
gmacgrp_interrupt_mask on page 17-550	0x3C	32	RW	0x0	Register 15 (Interrupt Mask Register) The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address0_high on page 17-552	0x40	32	RW	0x8000FFFF	Register 16 (MAC Address0 High Register) The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address0 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destina-tion clock domain.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address0_low on page 17-553	0x44	32	RW	0xFFFFFFFF	Register 17 (MAC Address0 Low Register) The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.
gmacgrp_mac_address1_high on page 17-554	0x48	32	RW	0xFFFF	Register 18 (MAC Address1 High Register) The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address1 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address1_low on page 17-559	0x4C	32	RW	0xFFFFFFFF	Register 19 (MAC Address1 Low Register) The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address2_high on page 17-560	0x50	32	RW	0xFFFF	Register 20 (MAC Address2 High Register) The MAC Address2 High register holds the upper 16 bits of the third 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address2 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address2 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address2_low on page 17-565	0x54	32	RW	0xFFFFFFFF	Register 21 (MAC Address2 Low Register) The MAC Address2 Low register holds the lower 32 bits of the third 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address3_high on page 17-565	0x58	32	RW	0xFFFF	Register 22 (MAC Address3 High Register) The MAC Address3 High register holds the upper 16 bits of the fourth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address3 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address3 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address3_low on page 17-571	0x5C	32	RW	0xFFFFFFFF	Register 23 (MAC Address3 Low Register) The MAC Address3 Low register holds the lower 32 bits of the fourth 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address4_high on page 17-571	0x60	32	RW	0xFFFF	Register 24 (MAC Address4 High Register) The MAC Address4 High register holds the upper 16 bits of the fifth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address4 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address4 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address4_low on page 17-577	0x64	32	RW	0xFFFFFFFF	Register 25 (MAC Address4 Low Register) The MAC Address4 Low register holds the lower 32 bits of the fifth 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address5_high on page 17-577	0x68	32	RW	0xFFFF	Register 26 (MAC Address5 High Register) The MAC Address5 High register holds the upper 16 bits of the sixth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address5 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address5 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address5_low on page 17-583	0x6C	32	RW	0xFFFFFFFF	Register 27 (MAC Address5 Low Register) The MAC Address5 Low register holds the lower 32 bits of the sixth 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address6_high on page 17-583	0x70	32	RW	0xFFFF	Register 28 (MAC Address6 High Register) The MAC Address6 High register holds the upper 16 bits of the seventh 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address6 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this MAC Address6 Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address6_low on page 17-588	0x74	32	RW	0xFFFFFFFF	Register 29 (MAC Address6 Low Register) The MAC Address6 Low register holds the lower 32 bits of the seventh 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address7_high on page 17-589	0x78	32	RW	0xFFFF	Register 30 (MAC Address7 High Register) The MAC Address7 High register holds the upper 16 bits of the eighth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address7 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this MAC Address7 Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address7_low on page 17-594	0x7C	32	RW	0xFFFFFFFF	Register 31 (MAC Address7 Low Register) The MAC Address7 Low register holds the lower 32 bits of the eighth 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address8_high on page 17-594	0x80	32	RW	0xFFFF	Register 32 (MAC Address8 High Register) The MAC Address8 High register holds the upper 16 bits of the nineth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address8 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this MAC Address8 Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address8_low on page 17-599	0x84	32	RW	0xFFFFFFFF	Register 33 (MAC Address8 Low Register) The MAC Address8 Low register holds the lower 32 bits of the nineth 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address14_high on page 17-627	0xB0	32	RW	0xFFFF	Register 44 (MAC Address14 High Register) The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address15 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this MAC Address14 Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address14_low on page 17-632	0xB4	32	RW	0xFFFFFFFF	Register 45 (MAC Address14 Low Register) The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address15_high on page 17-633	0xB8	32	RW	0xFFFF	Register 46 (MAC Address15 High Register) The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address15 Low Register are written. For proper synchroniza-tion updates, the consecutive writes to this MAC Address15 Low Register should be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address15_low on page 17-637	0xBC	32	RW	0xFFFFFFFF	Register 47 (MAC Address15 Low Register) The MAC Address15 Low register holds the lower 32 bits of the 16th 6-byte MAC address of the station.
gmacgrp_sgmii_rgmii_smii_control_status on page 17-638	0xD8	32	RO	0x0	Register 54 (SGMII/ RGMII/SMII Status Register)
gmacgrp_wdog_timeout on page 17-640	0xDC	32	RW	0x0	Register 55 (Watchdog Timeout Register) This register controls the watchdog timeout for received frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_genpio on page 17-641	0xE0	32	RW	0x0	Register 56 (General Purpose IO Register) This register provides the control to drive up to 4 bits of output ports (GPO) and the status of up to 4 input ports (GPIS). It also provides the control to generate interrupts on events occurring on the gpi_i pin.
gmacgrp_mmc_control on page 17-644	0x100	32	RW	0x0	Register 64 (MMC Control Register) The MMC Control register establishes the operating mode of the management counters. Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mmc_receive_interrupt on page 17-648	0x104	32	RO	0x0	Register 65 (MMC Receive Interrupt Register) The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mmc_transmit_interrupt on page 17-656	0x108	32	RO	0x0	Register 66 (MMC Transmit Interrupt Register) The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mmc_receive_interrupt_mask on page 17-664	0x10C	32	RW	0x0	Regsiter 67 (MMC Receive Interrupt Mask Register) The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when the receive statistic counters reach half of their maximum value, or maximum value. This register is 32-bits wide.
gmacgrp_mmc_transmit_interrupt_mask on page 17-674	0x110	32	RW	0x0	Register 68 (MMC Transmit Interrupt Mask Register) The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or maximum value. This register is 32-bits wide.
gmacgrp_txoctet-count_gb on page 17-683	0x114	32	RO	0x0	Register 69 (Transmit Octet Count for Good and Bad Frames) This register maintains the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_txframe-count_gb on page 17-684	0x118	32	RO	0x0	Register 70 (Transmit Frame Count for Good and Bad Frames) This register maintains the number of good and bad frames transmitted, exclusive of retried frames.
gmacgrp_txbroadcast-frames_g on page 17-685	0x11C	32	RO	0x0	Register 71 (Transmit Frame Count for Good Broadcast Frames) This register maintains the number of transmitted good broadcast frames.
gmacgrp_txmulticast-frames_g on page 17-686	0x120	32	RO	0x0	Register 72 (Transmit Frame Count for Good Multicast Frames) This register maintains the number of transmitted good multicast frames.
gmacgrp_tx64octets_gb on page 17-687	0x124	32	RO	0x0	Register 73 (Transmit Octet Count for Good and Bad 64 Byte Frames) This register maintains the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_tx65to127octets_gb on page 17-687	0x128	32	RO	0x0	Register 74 (Transmit Octet Count for Good and Bad 65 to 127 Bytes Frames) This register maintains the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.
gmacgrp_tx128to255octets_gb on page 17-688	0x12C	32	RO	0x0	Register 75 (Transmit Octet Count for Good and Bad 128 to 255 Bytes Frames) This register maintains the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.
gmacgrp_tx256to511octets_gb on page 17-689	0x130	32	RO	0x0	Register 76 (Transmit Octet Count for Good and Bad 256 to 511 Bytes Frames) This register maintains the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_tx512to1023octets_gb on page 17-690	0x134	32	RO	0x0	Register 77 (Transmit Octet Count for Good and Bad 512 to 1023 Bytes Frames) This register maintains the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.
gmacgrp_tx1024tomaxoctets_gb on page 17-691	0x138	32	RO	0x0	Register 78 (Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Frames) This register maintains the number of transmitted good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.
gmacgrp_txunicast-frames_gb on page 17-692	0x13C	32	RO	0x0	Register 79 (Transmit Frame Count for Good and Bad Unicast Frames) This register maintains the number of transmitted good and bad unicast frames.
gmacgrp_txmulticast-frames_gb on page 17-693	0x140	32	RO	0x0	Register 80 (Transmit Frame Count for Good and Bad Multicast Frames) This register maintains the number of transmitted good and bad multicast frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_txbroadcast-frames_gb on page 17-694	0x144	32	RO	0x0	Register 81 (Transmit Frame Count for Good and Bad Broadcast Frames) This register maintains the number of transmitted good and bad broadcast frames.
gmacgrp_txunderflo-werror on page 17-695	0x148	32	RO	0x0	Register 82 (Transmit Frame Count for Underflow Error Frames) This register maintains the number of frames aborted because of frame underflow error.
gmacgrp_txsinglecol_g on page 17-695	0x14C	32	RO	0x0	Register 83 (Transmit Frame Count for Frames Transmitted after Single Collision) This register maintains the number of successfully transmitted frames after a single collision in the half-duplex mode.
gmacgrp_txmulticol_g on page 17-696	0x150	32	RO	0x0	Register 84 (Transmit Frame Count for Frames Transmitted after Multiple Collision) This register maintains the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_txdeferred on page 17-697	0x154	32	RO	0x0	Register 85 (Transmit Frame Count for Deferred Frames) This register maintains the number of successfully transmitted frames after a deferral in the half-duplex mode.
gmacgrp_txlatecol on page 17-698	0x158	32	RO	0x0	Register 86 (Transmit Frame Count for Late Collision Error Frames) This register maintains the number of frames aborted because of late collision error.
gmacgrp_txexesscol on page 17-699	0x15C	32	RO	0x0	Register 87 (Transmit Frame Count for Excessive Collision Error Frames) This register maintains the number of frames aborted because of excessive (16) collision error.
gmacgrp_txcarriererr on page 17-699	0x160	32	RO	0x0	Register 88 (Transmit Frame Count for Carrier Sense Error Frames) This register maintains the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_txoctetcnt on page 17-700	0x164	32	RO	0x0	Register 89 (Transmit Octet Count for Good Frames) This register maintains the number of bytes transmitted, exclusive of preamble, in good frames.
gmacgrp_txframe-count_g on page 17-701	0x168	32	RO	0x0	Register 90 (Transmit Frame Count for Good Frames) This register maintains the number of transmitted good frames, exclusive of preamble.
gmacgrp_txexcessdef on page 17-702	0x16C	32	RO	0x0	Register 91 (Transmit Frame Count for Excessive Deferral Error Frames) This register maintains the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.
gmacgrp_txpauseframes on page 17-703	0x170	32	RO	0x0	Register 92 (Transmit Frame Count for Good PAUSE Frames) This register maintains the number of transmitted good PAUSE frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_txvlanframes_g on page 17-703	0x174	32	RO	0x0	Register 93 (Transmit Frame Count for Good VLAN Frames) This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.
gmacgrp_txoversize_g on page 17-704	0x178	32	RO	0x0	Register 94 (Transmit Frame Count for Good Oversize Frames) This register maintains the number of transmitted good Oversize frames, exclusive of retried frames.
gmacgrp_rxframe-count_gb on page 17-705	0x180	32	RO	0x0	Register 96 (Receive Frame Count for Good and Bad Frames) This register maintains the number of received good and bad frames.
gmacgrp_rxoctet-count_gb on page 17-706	0x184	32	RO	0x0	Register 97 (Receive Octet Count for Good and Bad Frames) This register maintains the number of bytes received, exclusive of preamble, in good and bad frames.
gmacgrp_rxoctet-count_g on page 17-707	0x188	32	RO	0x0	Register 98 (Receive Octet Count for Good Frames) This register maintains the number of bytes received, exclusive of preamble, only in good frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rxbroadcast-frames_g on page 17-708	0x18C	32	RO	0x0	Register 99 (Receive Frame Count for Good Broadcast Frames) This register maintains the number of received good broadcast frames.
gmacgrp_rxmulticast-frames_g on page 17-708	0x190	32	RO	0x0	Register 100 (Receive Frame Count for Good Multicast Frames) This register maintains the number of received good multicast frames.
gmacgrp_rxcrcerror on page 17-709	0x194	32	RO	0x0	Register 101 (Receive Frame Count for CRC Error Frames) This register maintains the number of frames received with CRC error.
gmacgrp_rxalignmen-terror on page 17-710	0x198	32	RO	0x0	Register 102 (Receive Frame Count for Alignment Error Frames) This register maintains the number of frames received with alignment (dribble) error. This field is valid only in the 10 or 100 Mbps mode.
gmacgrp_rxrunterror on page 17-711	0x19C	32	RO	0x0	Register 103 (Receive Frame Count for Runt Error Frames) This register maintains the number of frames received with runt error(<64 bytes and CRC error).

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rxjabbererror on page 17-712	0x1A0	32	RO	0x0	Register 104 (Receive Frame Count for Jabber Error Frames) This register maintains the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.
gmacgrp_rxundersize_g on page 17-713	0x1A4	32	RO	0x0	Register 105 (Receive Frame Count for Undersize Frames) This register maintains the number of frames received with length less than 64 bytes and without errors.
gmacgrp_rxoversize_g on page 17-713	0x1A8	32	RO	0x0	Register 106 (Receive Frame Count for Oversize Frames) This register maintains the number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames) and without errors.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rx64octets_gb on page 17-714	0x1AC	32	RO	0x0	Register 107 (Receive Frame Count for Good and Bad 64 Byte Frames) This register maintains the number of received good and bad frames with length 64 bytes, exclusive of preamble.
gmacgrp_rx65to127octets_gb on page 17-715	0x1B0	32	RO	0x0	Register 108 (Receive Frame Count for Good and Bad 65 to 127 Bytes Frames) This register maintains the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.
gmacgrp_rx128to255octets_gb on page 17-716	0x1B4	32	RO	0x0	Register 109 (Receive Frame Count for Good and Bad 128 to 255 Bytes Frames) This register maintains the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.
gmacgrp_rx256to511octets_gb on page 17-717	0x1B8	32	RO	0x0	Register 110 (Receive Frame Count for Good and Bad 256 to 511 Bytes Frames) This register maintains the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rx512to1023octets_gb on page 17-718	0x1BC	32	RO	0x0	Register 111 (Receive Frame Count for Good and Bad 512 to 1,023 Bytes Frames) This register maintains the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.
gmacgrp_rx1024tomaxoctets_gb on page 17-719	0x1C0	32	RO	0x0	Register 112 (Receive Frame Count for Good and Bad 1,024 to Maxsize Bytes Frames) This register maintains the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble.
gmacgrp_rxunicast-frames_g on page 17-720	0x1C4	32	RO	0x0	Register 113 (Receive Frame Count for Good Unicast Frames) This register maintains the number of received good unicast frames.
gmacgrp_rxlengtherror on page 17-721	0x1C8	32	RO	0x0	Register 114 (Receive Frame Count for Length Error Frames) This register maintains the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rxoutofrange-type on page 17-722	0x1CC	32	RO	0x0	Register 115 (Receive Frame Count for Out of Range Frames) This register maintains the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).
gmacgrp_rxpauseframes on page 17-722	0x1D0	32	RO	0x0	Register 116 (Receive Frame Count for PAUSE Frames) This register maintains the number of received good and valid PAUSE frames.
gmacgrp_rxfifoover-flow on page 17-723	0x1D4	32	RO	0x0	Register 117 (Receive Frame Count for FIFO Overflow Frames) This register maintains the number of received frames missed because of FIFO overflow.
gmacgrp_rxvlanframes_gb on page 17-724	0x1D8	32	RO	0x0	Register 118 (Receive Frame Count for Good and Bad VLAN Frames) This register maintains the number of received good and bad VLAN frames.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_rxwatchdo-gerror on page 17-725	0x1DC	32	RO	0x0	Register 119 (Receive Frame Count for Watchdog Error Frames) This register maintains the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes or value programmed in Register 55 (Watchdog Timeout Register)).
gmacgrp_rxrcverror on page 17-726	0x1E0	32	RO	0x0	Register 120 (Receive Frame Count for Receive Error Frames) This register maintains the number of frames received with error because of the GMII/MII RXER error.
gmacgrp_rxctrlframes_g on page 17-726	0x1E4	32	RO	0x0	Register 121 (Receive Frame Count for Good Control Frames Frames) This register maintains the number of good control frames received.

gmacgrp_l3_l4_control0 on page 17-762	0x400	32	RW	0x0	Register 256 (Layer 3 and Layer 4 Control Register 0) This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_layer4_address0 on page 17-768	0x404	32	RW	0x0	Register 257 (Layer 4 Address Register 0) You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option in coreConsultant. If the Layer 3 and Layer 4 Address Registers are configured to be double-synchronized to the Rx clock domains, then the synchroniza-tion is triggered only when Bits[31:24] (in little-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecu-tive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.
gmacgrp_layer3_addr0_reg0 on page 17-770	0x410	32	RW	0x0	Register 260 (Layer 3 Address 0 Register 0) For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_layer3_addr1_reg0 on page 17-771	0x414	32	RW	0x0	Register 261 (Layer 3 Address 1 Register 0) For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.
gmacgrp_layer3_addr2_reg0 on page 17-772	0x418	32	RW	0x0	Register 262 (Layer 3 Address 2 Register 0) For IPv4 frames, the Layer 3 Address 2 Register 0 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.
gmacgrp_layer3_addr3_reg0 on page 17-774	0x41C	32	RW	0x0	Register 263 (Layer 3 Address 3 Register 0) For IPv4 frames, the Layer 3 Address 3 Register 0 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.
gmacgrp_l3_l4_control1 on page 17-775	0x430	32	RW	0x0	Register 268 (Layer 3 and Layer 4 Control Register 1)

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address125_high on page 17-1157	0xB68	32	RW	0xFFFF	Register 729 (MAC Address125 High Register) The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address125 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address125 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address125_low on page 17-1158	0xB6C	32	RW	0xFFFFFFFF	Register 730 (MAC Address125 Low Register) The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address126_high on page 17-1159	0xB70	32	RW	0xFFFF	Register 731 (MAC Address126 High Register) The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address126 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address126 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address126_low on page 17-1161	0xB74	32	RW	0xFFFFFFFF	Register 732 (MAC Address126 Low Register) The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station.

Register	Offset	Width	Access	Reset Value	Description
gmacgrp_mac_address127_high on page 17-1161	0xB78	32	RW	0xFFFF	Register 733 (MAC Address127 High Register) The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address127 Low Register are written. For proper synchroniza-tion updates, consecu-tive writes to this MAC Address127 Low Register must be performed after at least four clock cycles in the destina-tion clock domain.
gmacgrp_mac_address127_low on page 17-1163	0xB7C	32	RW	0xFFFFFFFF	Register 734 (MAC Address127 Low Register) The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station.
dmagrp_bus_mode on page 17-1164	0x1000	32	RW	0x20101	Register 0 (Bus Mode Register) The Bus Mode register establishes the bus operating modes for the DMA.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_transmit_poll_demand on page 17-1171	0x1004	32	RW	0x0	Register 1 (Transmit Poll Demand Register) The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory. When this register is read, it always returns zero.
dmagrp_receive_poll_demand on page 17-1172	0x1008	32	RW	0x0	Register 2 (Receive Poll Demand Register) The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns. When this register is read, it always returns zero.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_receive_descriptor_list_address on page 17-1173	0x100C	32	RW	0x0	Register 3 (Receive Descriptor List Address Register) The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_transmit_descriptor_list_address on page 17-1175	0x1010	32	RW	0x0	Register 4 (Transmit Descriptor List Address Register) The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_status on page 17-1176	0x1014	32	RW	0x0	Register 5 (Status Register) The Status register contains all status bits that the DMA reports to the host. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).
dmagrp_operation_mode on page 17-1188	0x1018	32	RW	0x0	Register 6 (Operation Mode Register) The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization. This register is also present in the GMAC-MTL configuration with unused and reserved bits 24, 13, 2, and 1.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_interrupt_enable on page 17-1200	0x101C	32	RW	0x0	Register 7 (Interrupt Enable Register) The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.
dmagrp_missed_frame_and_buffer_overflow_counter on page 17-1206	0x1020	32	RO	0x0	Register 8 (Missed Frame and Buffer Overflow Counter Register) The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavail-able. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_receive_interrupt_watchdog_timer on page 17-1208	0x1024	32	RW	0x0	Register 9 (Receive Interrupt Watchdog Timer Register) This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)
dmagrp_axi_bus_mode on page 17-1210	0x1028	32	RW	0x110001	Register 10 (AXI Bus Mode Register)
dmagrp_ahb_or_axi_status on page 17-1214	0x102C	32	RO	0x0	Register 11 (AHB or AXI Status Register) This register provides the active status of the AHB master interface or AXI interface's read and write channels. This register is present and valid only in the GMAC-AHB and GMAC-AXI configurations. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.
dmagrp_current_host_transmit_descriptor on page 17-1215	0x1048	32	RO	0x0	Register 18 (Current Host Transmit Descriptor Register) The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_current_host_receive_descriptor on page 17-1216	0x104C	32	RO	0x0	Register 19 (Current Host Receive Descriptor Register) The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.
dmagrp_current_host_transmit_buffer_address on page 17-1217	0x1050	32	RO	0x0	Register 20 (Current Host Transmit Buffer Address Register) The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.
dmagrp_current_host_receive_buffer_address on page 17-1218	0x1054	32	RO	0x0	Register 21 (Current Host Receive Buffer Address Register) The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

Register	Offset	Width	Access	Reset Value	Description
dmagrp_hw_feature on page 17-1218	0x1058	32	RO	0xF0D69BF	Register 22 (HW Feature Register) This register indicates the presence of the optional features or functions of the DWC_gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks. Note: All bits are set or reset as per the selection of features during the DWC_gmac configuration.

gmacgrp_mac_configuration Fields

Bit	Name	Description	Access	Reset
31	reserved_31_28	Reserved	RO	0x0
27	twokpe	IEEE 802.3as Support for 2K Packets When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (JE) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (JE) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 is set, setting this bit has no effect on Giant Frame status.	RW	0x0
26	sfterr	SMII Force Transmit Error When set, this bit indicates to the PHY to force a transmit error in the SMII frame being transmitted.	RO	0x0

Bit	Name	Description	Access	Reset
25	cst	CRC Stripping for Type Frames When this bit is set, the last 4 bytes (FCS) of all frames of Ether type (Length/Type field greater than or equal to 1,536) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. This function is valid when Type 2 Checksum Offload Engine is enabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
24	tc	Transmit Configuration in RGMII, SGMII, or SMII When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII, SMII, or SGMII port. When this bit is reset, no such information is driven to the PHY. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0

Bit	Name	Description	Access	Reset
23	wd	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow a receive frame which more than 2,048 bytes (10,240 if JE is set high) or the value programmed in Register 55 (Watchdog Timeout Register). The MAC cuts off any bytes received after the watchdog limit number of bytes. **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0
22	jd	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission. **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0

Bit	Name	Description	Access	Reset
21	be	Frame Burst Enable When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. This bit is reserved (and RO) in the 10/100 Mbps only or full-duplex-only configurations. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
20	je	Jumbo Frame Enable When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
19:17	ifg	Inter-Frame Gap These bits control the minimum IFG between frames during transmission. * 000: 96 bit times * 001: 88 bit times * 010: 80 bit times * ... * 111: 40 bit times In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 64 bit times (and above). **Value** — **Description** 0x0 — IFG96BITTIMES 0x1 — IFG88BITTIMES 0x2 — IFG80BITTIMES 0x3 — IFG72BITTIMES 0x4 — IFG64BITTIMES 0x5 — IFG56BITTIMES 0x6 — IFG48BITTIMES 0x7 — IFG40BITTIMES	RW	0x0

Bit	Name	Description	Access	Reset
16	dcrs	Disable Carrier Sense During Transmission When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. This bit is reserved (and RO) in the full-duplex-only configurations. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15	ps	Port Select This bit selects the Ethernet line speed: * 0: For 1000 Mbps operations * 1: For 10 or 100 Mbps operations In 10 or 100 Mbps operations, this bit, along with FES bit, selects the exact line speed. In the 10 or 100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only with the appropriate value. In default 10, 100, or 1000 Mbps configuration, this bit is R_W. The mac_portselect_o signal reflects the value of this bit. **Value** **Description** 0x0 GMII1000SEL 0x1 MII10100SEL	RW	0x0

Bit	Name	Description	Access	Reset
14	fes	Speed This bit selects the speed in the MII, RMII, SMII, RGMII, SGMII, or RevMII interface * 0: 10 Mbps * 1: 100 Mbps This bit is reserved (RO) by default and is enabled only when the parameter SPEED_SELECT = Enabled. This bit generates link speed encoding when Bit 24 (TC) is set in the RGMII, SMII, or SGMII mode. This bit is always enabled for RGMII, SGMII, SMII, or RevMII interface. In configurations with RGMII, SGMII, SMII, or RevMII interface, this bit is driven as an output signal (mac_speed_o[0]) to reflect the value of this bit in the mac_speed_o signal. In configurations with RMII, MII, or GMII interface, you can optionally drive this bit as an output signal (mac_speed_o[0]) to reflect its value in the mac_speed_o signal. **Value** — **Description** 0x0 — SPEED10 0x1 — SPEED100	RW	0x0

Bit	Name	Description	Access	Reset
13	do	Disable Receive Own When this bit is set, the MAC disables the reception of frames when the phy_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. This bit is reserved (RO with default value) if the MAC is configured for the full-duplex-only operation. **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0
12	lm	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input (clk_rx_i) is required for the loopback to work properly, because the Transmit clock is not looped-back internally. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
11	dm	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configuration. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
10	ipc	Checksum Offload When this bit is set, the MAC calculates the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
9	dr	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode and is reserved (RO with default value) in the full-duplex-only configuration. **Value** **Description** 0x0 ENABLED 0x1 DISABLED	RW	0x0
8	lud	Link Up or Down This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface: * 0: Link Down * 1: Link Up **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0

Bit	Name	Description	Access	Reset
7	acs	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0
6:5	bl	Back-Off Limit The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. * 00: k = min (n, 10) * 01: k = min (n, 8) * 10: k = min (n, 4) * 11: k = min (n, 1) where n = retransmission attempt. The random integer r takes the value in the range 0 <= r < kth power of 2 **Value** — **Description** 0x0 — BACKLIMTR10 0x1 — BACKLIMIRT8 0x2 — BACKLIMITR4 0x3 — BACKLIMITR1	RW	0x0

Bit	Name	Description	Access	Reset
4	dc	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0 and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. **Value** — **Description** 0x0 — DISABLED 0x1 — ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
3	te	Transmitter Enable When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
2	re	Receiver Enable When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
1:0	prelen	Preamble Length for Transmit Frames These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. * 2'b00: 7 bytes of preamble * 2'b01: 5 byte of preamble * 2'b10: 3 bytes of preamble * 2'b11: 1 byte of preamble **Value** **Description** 0x0 PREAM7BYTES 0x1 PREAM5BYTES 0x2 PREAM3BYTES 0x3 PREAM1BYTE	RW	0x0

gmacgrp_mac_frame_filter

Register 1 (MAC Frame Filter)

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800004
i_emac_emac1	0xFF802000	0xFF802004
i_emac_emac2	0xFF804000	0xFF804004

Offset: 0x4

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

gmacgrp_mac_frame_filter Fields

Bit	Name	Description	Access	Reset
31	ra	Receive All When this bit is set, the MAC Receiver module passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes only those frames to the Application that pass the SA or DA address filter. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
30:22	reserved_30_22	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
21	dntu	Drop non-TCP/UDP over IP Frames When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. **Value** **Description** 0x0 NODROP 0x1 DROP	RW	0x0
20	ipfe	Layer 3 and Layer 4 Filter Enable When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 fields. **Value** **Description** 0x0 NODROP 0x1 DROP	RW	0x0
19:17	reserved_19_17	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
16	vtfe	VLAN Tag Filter Enable When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag. **Value** **Description** 0x0 NODROP 0x1 DROP	RW	0x0
15:11	reserved_15_11	Reserved	RO	0x0
10	hpf	Hash or Perfect Filter When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0

Bit	Name	Description	Access	Reset
9	saf	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved and set to 0. However, in DWC_gmac, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
8	saif	SA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter. When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
7:6	pcf	Pass Control Frames These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames).	RW	0x0

Bit	Name	Description	Access	Reset
		• 00: MAC filters all control frames from reaching the application. • 01: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. • 10: MAC forwards all control frames to application even if they fail the Address Filter. • 11: MAC forwards control frames that pass the Address Filter. The following conditions should be true for the PAUSE control frames processing: • Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting Bit 2 (RFE) of Register 6 (Flow Control Register) to 1. • Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when Bit 3 (UP) of the Register 6 (Flow Control Register) is set. • Condition 3: The Type field of the received frame is 0x8808 and the OPCODE field is 0x0001. **Note:** This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application). **Value** — **Description** 0x0 — MACFLTALLCFR 0x1 — MACFWDXPAUSE 0x2 — MACFWDFAIL 0x3 — MACFWDPASS		

Bit	Name	Description	Access	Reset
5	dbf	Disable Broadcast Frames When this bit is set, the AFM module filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast frames. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
4	pm	Pass All Multicast When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
3	daif	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
2	hmc	Hash Multicast When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0
1	huc	Hash Unicast When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0

Bit	Name	Description	Access	Reset
0	pr	Promiscuous Mode When this bit is set, the Address Filter module passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

gmacgrp_gmii_address

Register 4 (GMII Address Register)

The GMII Address register controls the management cycles to the external PHY through the management interface.

Note: This register is present for all PHY interface when you select the Station Management (MDIO) feature in coreConsultant.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800010
i_emac_emac1	0xFF802000	0xFF802010
i_emac_emac2	0xFF804000	0xFF804010

Offset: 0x10

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

gmacgrp_gmii_address Fields

Bit	Name	Description	Access	Reset
31:16	reserved_31_16	Reserved	RO	0x0
15:11	pa	Physical Layer Address This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII module.	RW	0x0
10:6	gr	GMII Register These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.	RW	0x0
5:2	cr	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design. The suggested range of CSR clock frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. • 0000: The frequency of the CSR clock is 60-100 MHz and the MDC clock is CSR clock/42. • 0001: The frequency of the CSR clock is 100-150 MHz and the MDC clock is CSR clock/62. • 0010: The frequency of the CSR clock is 20-35 MHz and the MDC clock is CSR clock/16. • 0011: The frequency of the CSR clock is 35-60 MHz and the MDC clock is CSR clock/26.	RW	0x0

Bit	Name	Description	Access	Reset
		• 0100: The frequency of the CSR clock is 150-250 MHz and the MDC clock is CSR clock/102. • 0100: The frequency of the CSR clock is 250-300 MHz and the MDC clock is CSR clock/124. • 0110 and 0111: Reserved When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Program the following values only if the interfacing chips support faster MDC clocks: • 1000: CSR clock/4 • 1001: CSR clock/6 • 1010: CSR clock/8 • 1011: CSR clock/10 • 1100: CSR clock/12 • 1101: CSR clock/14 • 1110: CSR clock/16 • 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface. **Value** — **Description** 0xa — DIV8 0xb — DIV10 0xc — DIV12 0xd — DIV14 0xe — DIV16AGAIN 0xf — DIV18 0x0 — DIV42 0x1 — DIV62 0x2 — DIV16 0x3 — DIV26 0x4 — DIV102 0x5 — DIV124 0x8 — DIV4		

Bit	Name	Description	Access	Reset
		Value **Description** 0x9 DIV6		
1	gw	GMII Write When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
0	gb	GMII Busy This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

gmacgrp_gmii_data

Register 5 (GMII Data Register)

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800014
i_emac_emac1	0xFF802000	0xFF802014

gmacgrp_flow_control

```
Register 6 (Flow Control Register)

The Flow Control register controls the generation and reception of
the Control (Pause Command) frames by the MAC's Flow control module.
A Write to a register with the Busy bit set to '1' triggers the Flow
Control block to generate a Pause Control frame. The fields of the
control frame are selected as specified in the 802.3x specification,
and the Pause Time value from this register is used in the Pause Time
field of the control frame. The Busy bit remains set until the
control frame is transferred onto the cable. The Host must make sure
```

that the Busy bit is cleared before writing to the register.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800018
i_emac_emac1	0xFF802000	0xFF802018
i_emac_emac2	0xFF804000	0xFF804018

Offset: 0x18

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_flow_control Fields

Bit	Name	Description	Access	Reset
31:16	pt	Pause Time This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.	RW	0x0
15:8	reserved_15_8	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
7	dzpq	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
6	reserved_6	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
5:4	plt	Pause Low Threshold This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The following list provides the threshold values for different values: - 00: The threshold is Pause time minus 4 slot times (PT - 4 slot times). - 01: The threshold is Pause time minus 28 slot times (PT - 28 slot times). - 10: The threshold is Pause time minus 144 slot times (PT - 144 slot times). - 11: The threshold is Pause time minus 256 slot times (PT - 256 slot times). The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. **Value** **Description** 0x0 PAUSETIME_4 0x1 PAUSETIME_28 0x2 PAUSETIME_144 0x3 PAUSETIME_256	RW	0x0

Bit	Name	Description	Access	Reset
3	up	Unicast Pause Frame Detect A pause frame is processed when it has the unique multicast address specified in the IEEE Std 802.3. When this bit is set, the MAC can also detect Pause frames with unicast address of the station. This unicast address should be as specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC only detects Pause frames with unique multicast address. Note: The MAC does not process a Pause frame if the multicast address of received frame is different from the unique multicast address. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
2	rfe	Receive Flow Control Enable When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
1	tfe	Transmit Flow Control Enable In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
0	fca_bpa	Flow Control Busy or Backpressure Activate This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

gmacgrp_vlan_tag

Register 7 (VLAN Tag Register)

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify

the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes.
If the VLAN Tag register is configured to be double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF80001C
i_emac_emac1	0xFF802000	0xFF80201C
i_emac_emac2	0xFF804000	0xFF80401C

Offset: 0x1C

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

Bit Fields

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
vl RW 0x0															

gmacgrp_vlan_tag Fields

Bit	Name	Description	Access	Reset
31:20	reserved_31_20	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
19	vthm	VLAN Tag Hash Table Match Enable When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RO	0x0
18	esvl	Enable S-VLAN When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0
17	vtim	VLAN Tag Inverse Match Enable When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0

Bit	Name	Description	Access	Reset
16	etv	Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15:0	vl	VLAN Tag Identifier for Receive Frames This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

gmacgrp_version

Register 8 (Version Register)

The Version registers identifies the version of the DWC_gmac.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800020
i_emac_emac1	0xFF802000	0xFF802020
i_emac_emac2	0xFF804000	0xFF804020

Offset: 0x20

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_lpi_control_status Fields

Bit	Name	Description	Access	Reset
31:20	reserved_31_20	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
19	lpitxa	LPI TX Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending descriptors in system memory that the DMA must process have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
18	plsen	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII receive paths to be used for activating the LPI LS TIMER. When set, the MAC uses the link-status bits of Register 54 (SGMII/RGMII/SMII Status Register) and Bit 17 (PLS) for the LPI LS Timer trigger. When cleared, the MAC ignores the link-status bits of Register 54 and takes only the PLS bit. This bit is RO and reserved if you have not selected the RGMII, SGMII, or SMII PHY interface. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0
17	pls	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (okay) at least for the time indicated by the LPI LS TIMER. When set, the link is considered to be okay (up) and when reset, the link is considered to be down. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
16	lpien	LPI Enable When set, this bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
15:10	reserved_15_10	Reserved	RO	0x0
9	rlpist	Receive LPI State When set, this bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
8	tlpist	Transmit LPI State When set, this bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
7:4	reserved_7_4	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
3	rlpiex	Receive LPI Exit When set, this bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of CSR clock. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
2	rlpien	Receive LPI Entry When set, this bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of CSR clock. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

Bit	Name	Description	Access	Reset
1	tlpiex	Transmit LPI Exit When set, this bit indicates that the MAC transmitter has exited the LPI state after the user has cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0
0	tlpien	Transmit LPI Entry When set, this bit indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register. **Value** **Description** 0x0 INACTIVE 0x1 ACTIVE	RO	0x0

gmacgrp_lpi_timers_control

Register 13 (LPI Timers Control Register)

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800034
i_emac_emac1	0xFF802000	0xFF802034

Bit	Name	Description	Access	Reset
31:26	reserved_31_26	Reserved	RO	0x0
25:16	lst	LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	twt	LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

gmacgrp_interrupt_status

Register 14 (Interrupt Register)

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding feature is enabled during operation. Therefore, these bits are reserved when the corresponding features are not present in the core.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800038
i_emac_emac1	0xFF802000	0xFF802038

gmacgrp_mac_address0_high

Register 16 (MAC Address0 High Register)

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800040
i_emac_emac1	0xFF802000	0xFF802040
i_emac_emac2	0xFF804000	0xFF804040

Offset: 0x40

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mac_address7_high

Register 30 (MAC Address7 High Register)

The MAC Address7 High register holds the upper 16 bits of the eighth 6-byte MAC address of the station.
If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address7 Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800078
i_emac_emac1	0xFF802000	0xFF802078

gmacgrp_mac_address11_high

Register 38 (MAC Address11 High Register)

The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station.
If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address11 Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800098
i_emac_emac1	0xFF802000	0xFF802098
i_emac_emac2	0xFF804000	0xFF804098

gmacgrp_mac_address15_high

Register 46 (MAC Address15 High Register)

The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station.
If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this MAC Address15 Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF8000B8
i_emac_emac1	0xFF802000	0xFF8020B8

Bit	Name	Description	Access	Reset
31:25	reserved_31_x	Reserved	RO	0x0
24	gpit	GPI Type When set, this bit indicates that the corresponding GPIS is of latched-low (LL) type. When reset, this bit indicates that the corresponding GPIS is of latched-high (LH) type. The number of bits available in this field depend on the GP Input Signal Width option. Other bits are not used (reserved and always reset).	RW	0x0
23:17	reserved_23_x	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
16	gpie	GPI Interrupt Enable When this bit is set and the programmed event (LL or LH) occurs on the corresponding GPIS bit, Bit 11 (GPIIS) of Register 14 (Interrupt Status Register) is set. Accordingly, the interrupt is generated on the mci_intr_o or sbd_intr_o. The GPIIS bit is cleared when the host reads the Bits[7:0] of this register. When reset, Bit 11 (GPIIS) of Register 14 (Interrupt Status Register) is not set when any event occurs on the corresponding GPIS bits. The number of bits available in this field depend on the GP Input Signal Width option. Other bits are not used (reserved and always reset).	RW	0x0
15:9	reserved_15_x	Reserved	RO	0x0
8	gpo	General Purpose Output When this bit is set, it directly drives the gpo_o output ports. When this bit is reset, it does not directly drive the gpo_o output ports. The number of bits available in this field depend on the GP Output Signal Width option. Other bits are not used (reserved and always reset).	RW	0x0
7:1	reserved_7_x	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
0	gpis	General Purpose Input Status This field gives the status of the signals connected to the gpi_i input ports. This field is of the following types based on the setting of the corresponding GPIT field of this register: * Latched-low (LL): This field is cleared when the corresponding gpi_i input becomes low. This field remains low until the host reads this field. After this, this field reflects the current value of the gpi_i input. * Latched-high (LH) : This field is set when the corresponding gpi_i input becomes high. This field remains high until the host reads this field. After this, this field reflects the current value of the gpi_i input. The number of bits available in this field depend on the GP Input Signal Width option. Other bits are not used (reserved and always reset).	RO	0x0

gmacgrp_mmc_control

Register 64 (MMC Control Register)

The MMC Control register establishes the operating mode of the management counters.

Note:
The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800100
i_emac_emac1	0xFF802000	0xFF802100

Module Instance	Base Address	Register Address
i_emac_emac2	0xFF804000	0xFF804100

Offset: 0x100

Access: RW

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mmc_control Fields

Bit	Name	Description	Access	Reset
31:9	reserved_31_9	Reserved	RO	0x0
8	ucdbc	Update MMC Counters for Dropped Broadcast Frames When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0
7:6	reserved_7_6	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
5	cntprstlvl	Full-Half Preset When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. **Value** **Description** 0x0 ALMOSTHALF 0x1 ALMOSTFULL	RW	0x0
4	cntprst	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
3	cntfreez	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
2	rstonrd	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
1	cntstopro	Counters Stop Rollover When this bit is set, after reaching maximum value, the counter does not roll over to zero. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

Bit	Name	Description	Access	Reset
0	cntrst	Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0

gmacgrp_mmc_receive_interrupt

Register 65 (MMC Receive Interrupt Register)

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens:
 * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter).
 * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).
When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800104
i_emac_emac1	0xFF802000	0xFF802104
i_emac_emac2	0xFF804000	0xFF804104

Offset: 0x104

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mmc_transmit_interrupt

Register 66 (MMC Transmit Interrupt Register)

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800108
i_emac_emac1	0xFF802000	0xFF802108
i_emac_emac2	0xFF804000	0xFF804108

Offset: 0x108

Access: RO

Important: The value of a reserved bit must be maintained in software. When you modify registers containing reserved bit fields, you must use a read-modify-write operation to preserve state and prevent indeterminate system behavior.

gmacgrp_mmc_transmit_interrupt_mask Fields

Bit	Name	Description	Access	Reset
31:26	reserved_31_26	Reserved	RO	0x0
25	txosizegfim	MMC Transmit Oversize Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txoversize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
24	txvlangfim	MMC Transmit VLAN Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txvlanframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
23	txpausfim	MMC Transmit Pause Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txpauseframes counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
22	txexdeffim	MMC Transmit Excessive Deferral Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txexcessdef counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
21	txgfrmim	MMC Transmit Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txframecount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
20	txgoctim	MMC Transmit Good Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
19	txcarerfim	MMC Transmit Carrier Error Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txcarriererror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
18	txexcolfim	MMC Transmit Excessive Collision Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txexcesscol counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
17	txlatcolfim	MMC Transmit Late Collision Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txlatecol counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
16	txdeffim	MMC Transmit Deferred Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txdeferred counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
15	txmcolgfim	MMC Transmit Multiple Collision Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
14	txscolgfim	MMC Transmit Single Collision Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
13	txuflowerfim	MMC Transmit Underflow Error Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
12	txbcgbfim	MMC Transmit Broadcast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcast-frames_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
11	txmcgbfim	MMC Transmit Multicast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticast-frames_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
10	txucgbfim	MMC Transmit Unicast Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txunicastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
9	tx1024tmaxoctgbfim	MMC Transmit 1024 to Maximum Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx1024tomaxoc-tets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
8	tx512t1023octgbfim	MMC Transmit 512 to 1023 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
7	tx256t511octgbfim	MMC Transmit 256 to 511 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
6	tx128t255octgbfim	MMC Transmit 128 to 255 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
5	tx65t127octgbfim	MMC Transmit 65 to 127 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
4	tx64octgbfim	MMC Transmit 64 Octet Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
3	txmcgfim	MMC Transmit Multicast Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txmulticast-frames_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

Bit	Name	Description	Access	Reset
2	txbcgfim	MMC Transmit Broadcast Good Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txbroadcast-frames_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
1	txgbfrmim	MMC Transmit Good Bad Frame Counter Interrupt Mask Setting this bit masks the interrupt when the txframecount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0
0	txgboctim	MMC Transmit Good Bad Octet Counter Interrupt Mask Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 NOMASKINTR 0x1 MASKINTR	RW	0x0

gmacgrp_txoctetcount_gb

Register 69 (Transmit Octet Count for Good and Bad Frames)

This register maintains the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes.

Module Instance	Base Address	Register Address

gmacgrp_mmc_ipc_receive_interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

gmacgrp_layer4_address0

Register 257 (Layer 4 Address Register 0)

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option in coreConsultant. If the Layer 3 and Layer 4 Address Registers are configured to be double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

2	l3sam3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 4 (L3DAM3) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen3	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM3 or L3DAM3 bit is set high.	RW	0x0

gmacgrp_layer4_address3

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

gmacgrp_layer3_addr3_reg3 Fields

Bit	Name	Description	Access	Reset
31:0	l3a33	When Bit 0 (L3PEN3) and Bit 2 (L3SAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN3) and Bit 4 (L3DAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

gmacgrp_hash_table_reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash

filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values.
Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Hash Table Register X registers are written.

Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Bit	Name	Description	Access	Reset
17:16	vlc	VLAN Tag Control in Transmit Frames * 2'b00: No VLAN tag deletion, insertion, or replacement * 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted frames with VLAN tags. * 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the frame after inserting the Type value (0x8100/0x88a8) in bytes 13 and 14. This operation is performed on all transmitted frames, irrespective of whether they already have a VLAN tag. * 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted frames (Bytes 13 and 14 are 0x8100/0x88a8). Note: Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value.	RW	0x0
15:0	vlt	VLAN Tag for Transmit Frames This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority, Bit 12 is the CFI/DEI, and Bits[11:0] are the VLAN tag's VID field.	RW	0x0

gmacgrp_vlan_hash_table_reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame

is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.
The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper four bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) of this register are written.

Notes:
 * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

gmacgrp_timestamp_control

Register 448 (Timestamp Control Register)

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver.

Note:
 * Bits[5:1] are reserved when External Timestamp Input feature is enabled.
 * Bits[19:8] are reserved and read-only when Advanced Timestamp feature is not enabled.
 * Bits[28:24] are reserved and read-only when Auxiliary Snapshot feature is not enabled.
 * Release 3.60a onwards, the functions of Bits 17 and 16 (SNAPTYPSEL) have changed. These functions are not backward compatible with the functions described in release 3.50a.

Bit	Name	Description	Access	Reset
31:29	reserved_31_29	Reserved	RO	0x0
28	atsen3	Auxiliary Snapshot 3 Enable This field controls capturing the Auxiliary Snapshot Trigger 3. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[3] input is enabled. When this bit is reset, the events on this input are ignored.	RO	0x0
27	atsen2	Auxiliary Snapshot 2 Enable This field controls capturing the Auxiliary Snapshot Trigger 2. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[2] input is enabled. When this bit is reset, the events on this input are ignored.	RO	0x0

Bit	Name	Description	Access	Reset
26	atsen1	Auxiliary Snapshot 1 Enable This field controls capturing the Auxiliary Snapshot Trigger 1. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[1] input is enabled. When this bit is reset, the events on this input are ignored.	RO	0x0
25	atsen0	Auxiliary Snapshot 0 Enable This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0
24	atsfc	Auxiliary Snapshot FIFO Clear When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RO	0x0
23:19	reserved_23_19	Reserved	RO	0x0

Bit	Name	Description	Access	Reset
18	tsenmacaddr	Enable MAC address for PTP Frame Filtering When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
17:16	snaptypsel	Select PTP packets for Taking Snapshots These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.	RW	0x0
15	tsmstrena	Enable Snapshot for Messages Relevant to Master When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. **Value** **Description** 0x0 SLAVE 0x1 MASTER	RW	0x0

Bit	Name	Description	Access	Reset
14	tsevntena	Enable Timestamp Snapshot for Event Messages When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
13	tsipv4ena	Enable Processing of PTP Frames Sent over IPv4-UDP When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. **Value** **Description** 0x0 NO_PROCESS_PTP 0x1 PROCESS_PTP	RW	0x1
12	tsipv6ena	Enable Processing of PTP Frames Sent Over IPv6-UDP When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets. **Value** **Description** 0x0 NO_PROCESS_PTP 0x1 PROCESS_PTP	RW	0x0

Bit	Name	Description	Access	Reset
11	tsipena	Enable Processing of PTP over Ethernet Frames When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets. **Value** **Description** 0x0 NO_PROCESS_PTP 0x1 PROCESS_PTP	RW	0x0
10	tsver2ena	Enable PTP packet Processing for Version 2 Format When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format. **Value** **Description** 0x0 PTP_1588_VER1 0x1 PTP_1588_VER2	RW	0x0
9	tsctrlssr	Timestamp Digital or Binary Rollover Control When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit. **Value** **Description** 0x0 NOTIMESTAMP_LOW_ROLL_MAX 0x1 TIMESTAMP_LOW_ROLL_1NS	RW	0x0

Bit	Name	Description	Access	Reset
8	tsenall	Enable Timestamp for All Frames When set, the timestamp snapshot is enabled for all frames received by the MAC. **Value** **Description** 0x0 DISABLED 0x1 ENABLED	RW	0x0
7:6	reserved_7_6	Reserved	RO	0x0
5	tsaddreg	Addend Reg Update When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it. **Value** **Description** 0x0 NOTIMESTAMP_ADDEND_UPDATED 0x1 TIMESTAMP_ADDEND_UPDATED	RO	0x0
4	tstrig	Timestamp Interrupt Trigger Enable When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt. **Value** **Description** 0x0 NOTIMESTAMP_INTR_TRIG_EN 0x1 TIMESTAMP_INTR_TRIG_EN	RO	0x0

Bit	Name	Description	Access	Reset
3	tsupdt	Timestamp Update When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register is not updated. **Value** — **Description** 0x0 — NOTIMESTAMP_UPDATED 0x1 — TIMESTAMP_UPDATED	RO	0x0
2	tsinit	Timestamp Initialize When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register can only be initialized. **Value** — **Description** 0x0 — NOTIMESTAMP_INIT 0x1 — TIMESTAMP_INIT	RO	0x0

Bit	Name	Description	Access	Reset
1	tscfupdt	Timestamp Fine or Coarse Update When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method. **Value** **Description** 0x0 TIMESTAMP_COARSE 0x1 TIMESTAMP_FINE	RO	0x0
0	tsena	Timestamp Enable When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set. **Value** **Description** 0x0 NOTIMESTAMP 0x1 TIMESTAMP	RW	0x0

gmacgrp_sub_second_increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800704
i_emac_emac1	0xFF802000	0xFF802704

gmacgrp_sub_second_increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

gmacgrp_system_time_seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
29:25	atsns	This field indicates the number of Snapshots available in the FIFO. A value of 16 (equal to the depth of the FIFO) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set.	RO	0x0
24	atsstm	This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. **Value** — **Description** 0x0 — NOTFULL 0x1 — FULL	RO	0x0
19:16	atsstn	These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list: * Bit 16: Auxiliary trigger 0 * Bit 17: Auxiliary trigger 1 * Bit 18: Auxiliary trigger 2 * Bit 19: Auxiliary trigger 3 The software can read this register to find the triggers that are set when the timestamp is taken.	RO	0x0

Bit	Name	Description	Access	Reset
3	tstrgterr	This bit is set when the target time, being programmed in Target Time Registers, is already elapsed. This bit is cleared when read by the application. **Value** **Description** 0x0 RESET 0x1 SET	RO	0x0
2	auxtstrig	This bit is set high when the auxiliary snapshot is written to the FIFO. **Value** **Description** 0x0 RESET 0x1 SET	RO	0x0
1	tstargt	When set, this bit indicates that the value of system time is greater or equal to the value specified in the Register 455 (Target Time Seconds Register) and Register 456 (Target Time Nanoseconds Register). **Value** **Description** 0x0 RESET 0x1 SET	RO	0x0
0	tssovf	When set, this bit indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. **Value** **Description** 0x0 RESET 0x1 SET	RO	0x0

gmacgrp_pps_control Fields

Bit	Name	Description	Access	Reset
6:5	trgtmodsel0	This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal Value: Description 0x0: TRGTINTERONLY 0x2: TRGTINTPPS0 0x3: TRGTNOINTER	RW	0x0
4	ppsen0	When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD. Value: Description 0x0: PPSCTRL 0x1: PPSCMD	RW	0x0

Bit	Name	Description	Access	Reset

3:0	ppsctrl_ppscmd	PPSCTRL0: PPS0 Output Frequency Control
		This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:
		• 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
		• 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
		• 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
		• 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.
		• ...
		• 1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz.
		Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies.
		In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:
		• When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
		• When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of:
		  • One clock of 50 percent duty cycle and 537 ms period>
		  • Second clock of 463 ms period (268 ms low and 195 ms high)
		• When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of:
		  • Three clocks of 50 percent duty cycle and 268 ms period
		  • Fourth clock of 195 ms period (134 ms low and 61 ms high)
		This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register).
		Flexible PPS0 Output (ptp_pps_o[0]) Control
			RW	0x0

Bit	Name	Description	Access	Reset
		Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: • 0000: No Command • 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. • 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. • 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. • 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. • 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). • 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. • 0111-1111: Reserved		

gmacgrp_auxiliary_timestamp_nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read.

Module Instance	Base Address	Register Address

gmacgrp_mac_address19_high

Register 518 (MAC Address19 High Register)

The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address19 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800818

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then
the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address26 Low Register must be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address
i_emac_emac0	0xFF800000	0xFF800850
i_emac_emac1	0xFF802000	0xFF802850
i_emac_emac2	0xFF804000	0xFF804850

Offset: 0x850

Access: RW
