8.2 IOMUX Controller (IOMUXC)

8.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

Figure 8-1 illustrates the IOMUX/IOMUXC connectivity in the system.

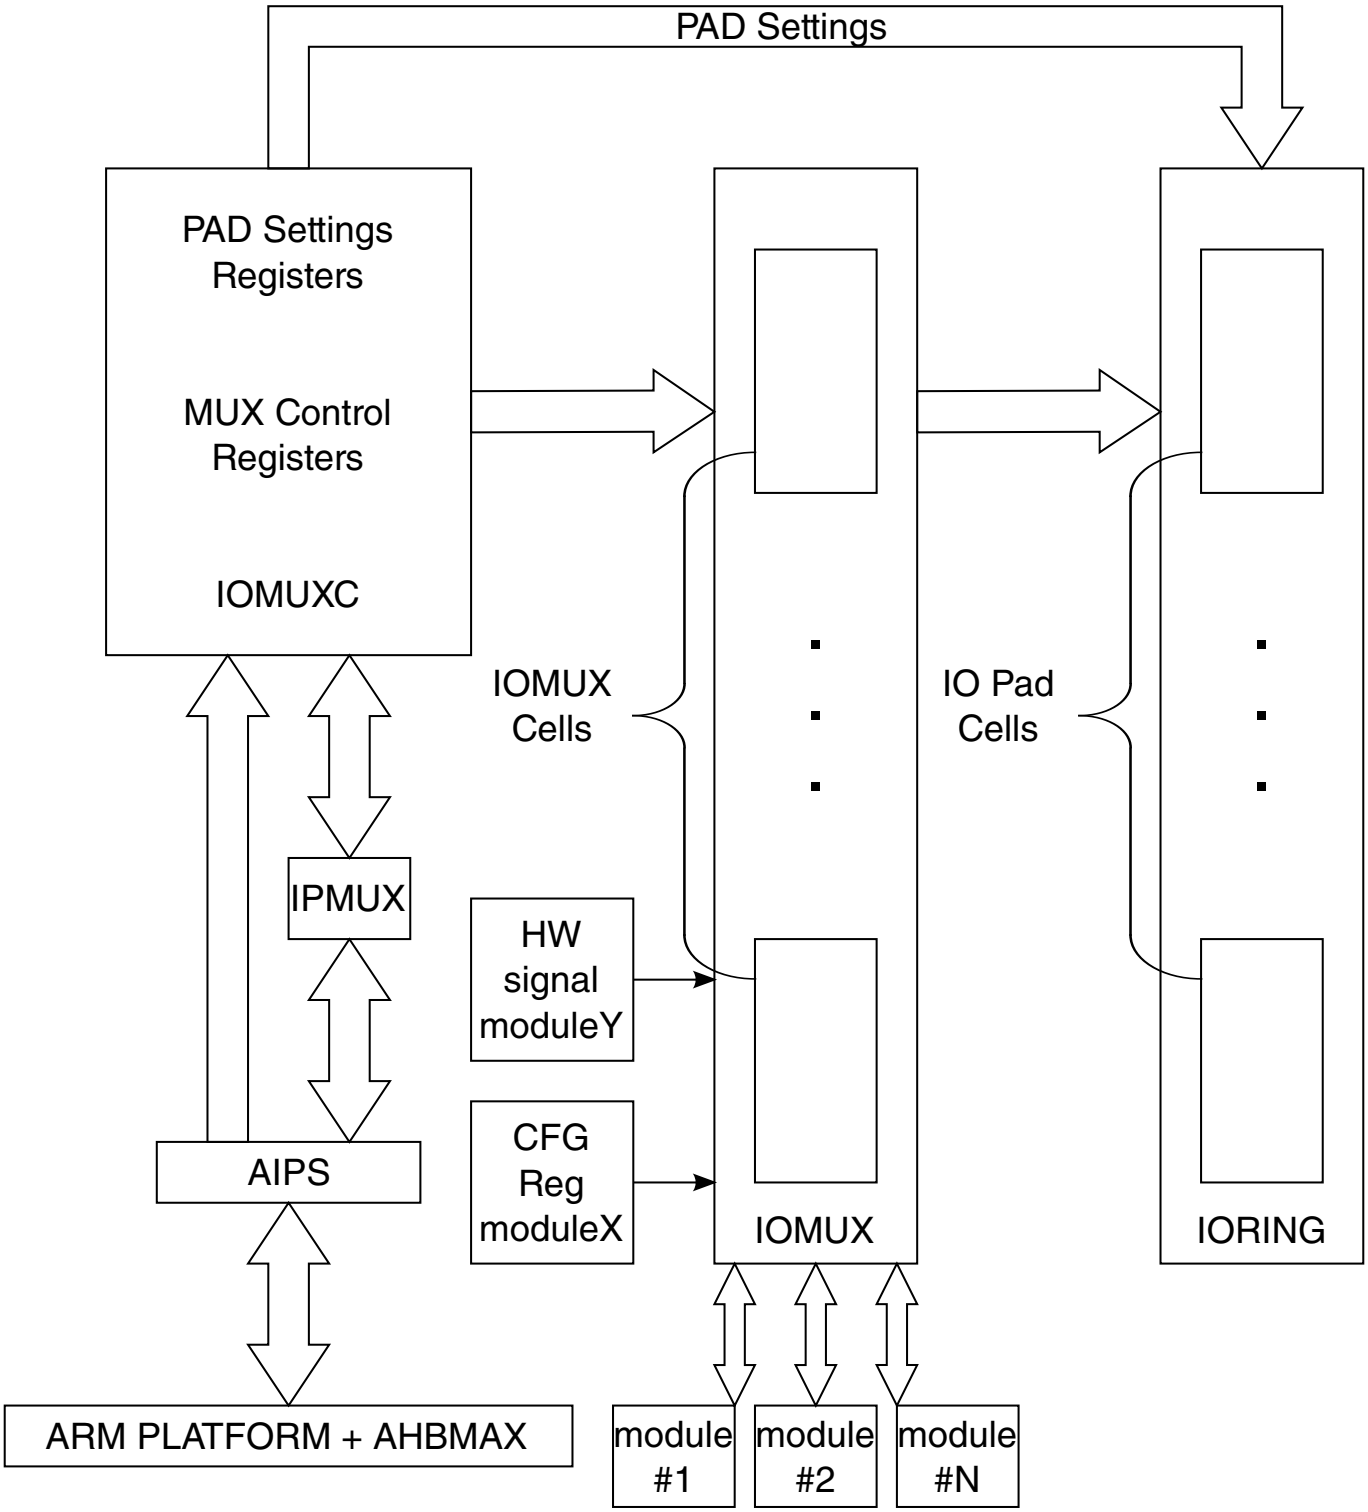

Figure 8-1. IOMUX SoC Level Block Diagram

8.2.1.1 Features

The IOMUXC features are:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX_MODE feilds of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - 14 (GPR0 to GPR13) 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

8.2.2 Clocks

The table found here describes the clock sources for IOMUXC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 8-1. IOMUXC Clocks

Clock name	Clock Root	Description
ipt_clk_io		IO clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.2.3 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC_REGISTERS includes all of the IOMUXC registers (see Features).
- IOMUXC_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure 8-2.

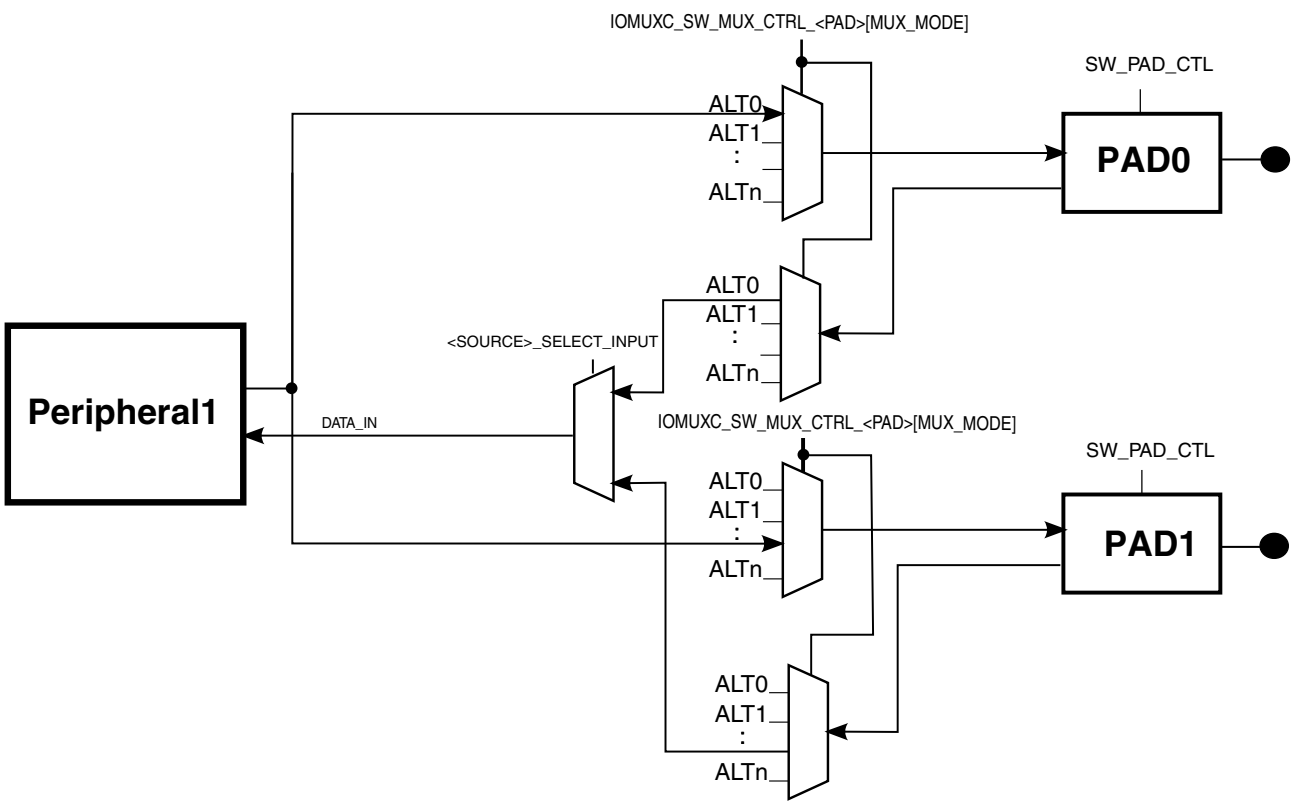

Figure 8-2. IOMUX Cell Block Diagram

8.2.3.1 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

8.2.3.2 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (ipp_ibe==1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.
- GPIO Capture - Module x drives the pad and the value is captured by GPIO.

8.2.3.3 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

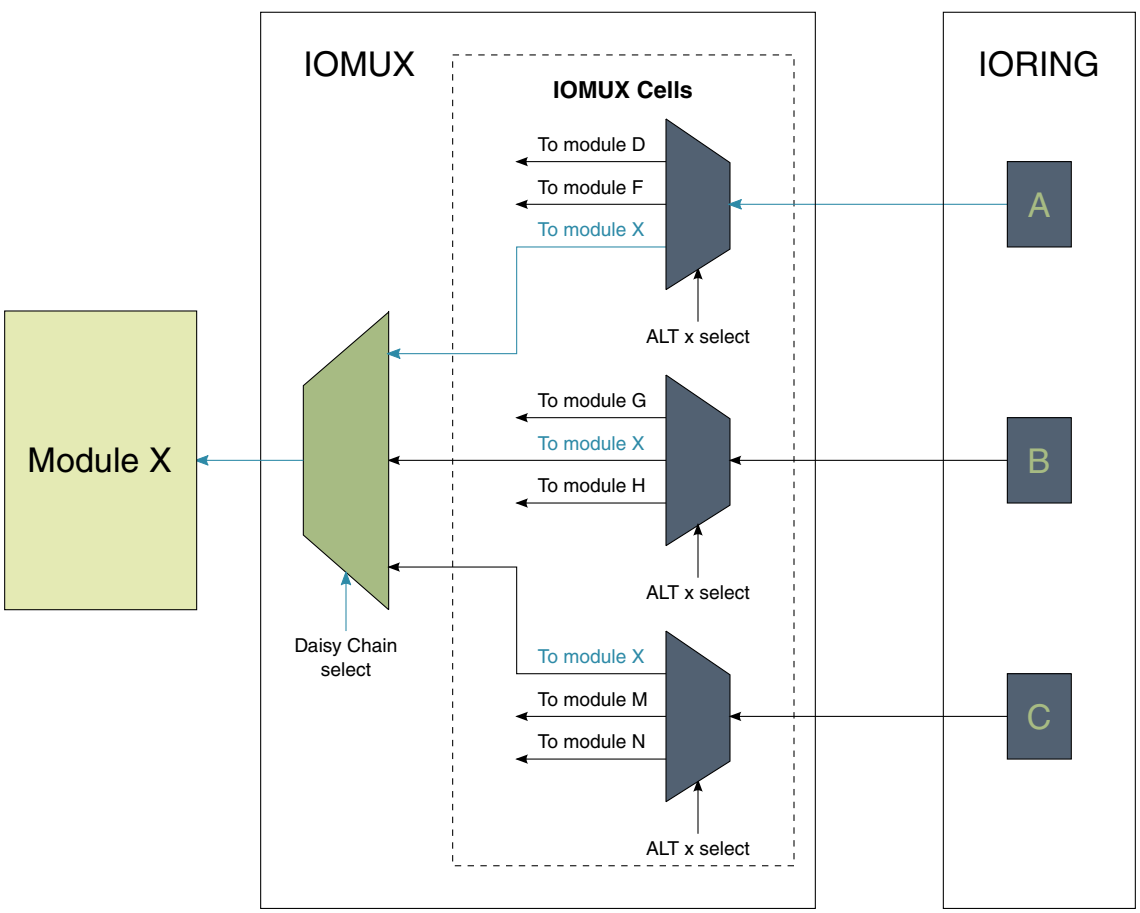

Figure 8-3. Daisy chain illustration

Field	Description
23 TZASC1_ SECURE_ BOOT_LOCK	TZASC-1 Secure Boot Lock 0 Secure boot lock is disabled 1 Secure boot lock is enabled
22 EXC_ERR_ RESP_EN	Security exclusive access error response enable for all security gaskets (on both AHB and AXI busses). Enables an ERR response on the AXI vs an OK response for an exclusive access error. 0 OK response on the AXI for an exclusive access error 1 ERR response on the AXI for an exclusive access error
21–19 -	This field is reserved. Reserved
18 -	This field is reserved. Reserved
17 ENET1_CLK_ DIR	ENET1_TX_CLK data direction control when ANATOP ENET_REF_CLK1 is selected (ALT1) 0 ENET1_TX_CLK output driver is disabled when configured for ALT1 1 ENET1_TX_CLK output driver is enabled when configured for ALT1
16 PAD_ADD_DS	Setting ADD_DS to 0 will make the output driver of the SD3 pins ~10% stronger at highest drive strength (DSE=111). This is for use if the I/O buffer operation at WCS and 200MHz is marginal. 0 output driver ~10% stronger 1 output driver is normal
15 -	This field is reserved. Reserved
14 -	This field is reserved. Reserved
13 ENET1_TX_ CLK_SEL	ENET1 reference clock mode select 0 Gets ENET1 TX reference clk. This clock is also output to pins via the IOMUX. ENET_REF_CLK1 function. 1 Gets ENET1 TX reference clk from the ENET1_TX_CLK pin. In this use case, an external OSC provides the clock for both the external PHY and the internal controller
12 IRQ	Interrupt signal which is connected to CPU IRQS[0]. Used to notify cores on exception condition while boot.
11–10 WEIM_ADDRS3	WEIM Address Space 3 Active Chip Select and Address Space. Each of the WEIM_ACT_CSx represents one of the four chip selects of the EIM. When ACT_CSx=1'b1, the corresponding chip select is active and has a valid address space according to its address space configuration determined by WEIM_ADDRSx[1:0] bits. WEIM_ADDRSx[1:0] is setting the space for each chip select which is active. The address space of the first active chip select must be the biggest one, the following active chip select address spaces may be equal or lower. Total address space size is 128 MByte. The supported configurations are: CS0(128M), CS1 (0M), CS2 (0M), CS3(0M) [default configuration]

4 S_RDATA_WAIT_EN	State Retention On-chip RAM read data wait state control For description, please refer to RDATA_WAIT_EN bit
3 WADDR_PIPE_EN	On-chip RAM write address pipeline enable When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, i.e., at most 1 more clock cycle for each write burst with multiple beats of data. When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle). 0 write address pipeline is disabled 0 write address pipeline is disabled 1 write address pipeline is enabled
2 WDATA_PIPE_EN	On-chip RAM write data pipeline enable When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, i.e., at most 1 more clock cycle for each write burst with multiple beats of data. When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

Table continues on the next page...

IOMUXC_GPR_GPR3 field descriptions (continued)

Field	Description
	0 write data pipeline is disabled 1 write data pipeline is enabled
1 RADDR_PIPE_EN	On-chip RAM read address pipeline enable When this feature is enabled, the read address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the read access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI read transaction, i.e., at most 1 more clock cycle for each read burst with multiple beats of data. When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait). 0 read address pipeline is disabled 1 read address pipeline is enabled
0 RDATA_WAIT_EN	On-chip RAM read data wait state control When the read data wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst). This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency. When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, i.e., get read data back in the next cycle of read request becomes valid on the bus. 0 read data wait state disabled 1 read data wait state enabled

12 GPIO1_IO13_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO13 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
11 GPIO1_IO13_ HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO13 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable
10 GPIO1_IO13_ SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO13 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
9–8 GPIO1_IO13_ DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO13 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6
7 GPIO1_IO12_ MUX_CTL	Mux control for PAD 0 Pad control from SOC IOMUX 1 Pad control from LPSR GPR
6–5 GPIO1_IO12_PS	Pull Select Field Select one out of next values for pad: GPIO1_IO12 00 PS_0_100K_PD — 100K PD 01 PS_1_5K_PU — 5K PU 10 PS_2_47K_PU — 47K PU 11 PS_3_100K_PU — 100K PU
4 GPIO1_IO12_PE	Pull Enable Field Select one out of next values for pad: GPIO1_IO12 0 PE_0_Pull_Disabled — Pull Disabled 1 PE_1_Pull_Enabled — Pull Enabled
3 GPIO1_IO12_ HYS	Hyst. Enable Field Select one out of next values for pad: GPIO1_IO12 0 HYS_0_Hysteresis_Disabled — Hysteresis Disabled 1 HYS_1_Hysteresis_Enabled — Hysteresis Enable
2 GPIO1_IO12_ SRE	Slew Rate Field Select one out of next values for pad: GPIO1_IO12 0 SRE_0_Fast_Slew_Rate — Fast Slew Rate 1 SRE_1_Slow_Slew_Rate — Slow Slew Rate
GPIO1_IO12_ DSE	Drive Strength Field Select one out of next values for pad: GPIO1_IO12 00 DSE_0_X1 — X1 01 DSE_1_X1 — X2 10 DSE_2_X1 — X4 11 DSE_3_X1 — X6

8.2.6.23 IOMUXC_LPSR General Purpose Register 22 (IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR22)

IOMUXC LPSR General Purpose Register

Address: 3027_0000h base + 58h offset = 3027_0058h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RO																GP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IOMUXC_LPSR_GPR_IOMUXC_LPSR_GPR22 field descriptions

Field	Description
31–16 RO	Read only bits, always 16'h0
GP	Common bits can be R/W freely

8.2.7 IOMUXC Memory Map/Register Definition

IOMUXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3033_0014	SW_MUX_CTL_PAD_GPIO1_IO08 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO08)	32	R/W	0000_0000h	8.2.7.1/ 1586
3033_0018	SW_MUX_CTL_PAD_GPIO1_IO09 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO09)	32	R/W	0000_0000h	8.2.7.2/ 1588

IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO08 field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 SION	Software Input On Field. Force the selected mux mode Input path no matter of MUX_MODE functionality. 1 **ENABLED** — Force input path of pad GPIO1_IO08 0 **DISABLED** — Input Path is determined by functionality
3 -	This field is reserved. Reserved
MUX_MODE	MUX Mode Select Field. Select 1 of 8 iomux modes to be used for pad: GPIO1_IO08. 000 **ALT0_GPIO1_IO8** — Select mux mode: ALT0 mux port: IO8 of instance: GPIO1 001 **ALT1_SD1_VSELECT** — Select mux mode: ALT1 mux port: VSELECT of instance: SD1 010 **ALT2_WDOG1_WDOG_B** — Select mux mode: ALT2 mux port: WDOG_B of instance: WDOG1 011 **ALT3_UART3_RX_DATA** — Select mux mode: ALT3 mux port: RX_DATA of instance: UART3 100 **ALT4_I2C3_SCL** — Select mux mode: ALT4 mux port: SCL of instance: I2C3 110 **ALT6_KPP_COL5** — Select mux mode: ALT6 mux port: COL5 of instance: KPP 111 **ALT7_PWM1_OUT** — Select mux mode: ALT7 mux port: OUT of instance: PWM1

8.3 General Purpose Input/Output (GPIO)

8.3.1 Overview

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO is one of the blocks controlling the IOMUX of the chip.

Figure 8-4 shows the chip multiplexing scheme.

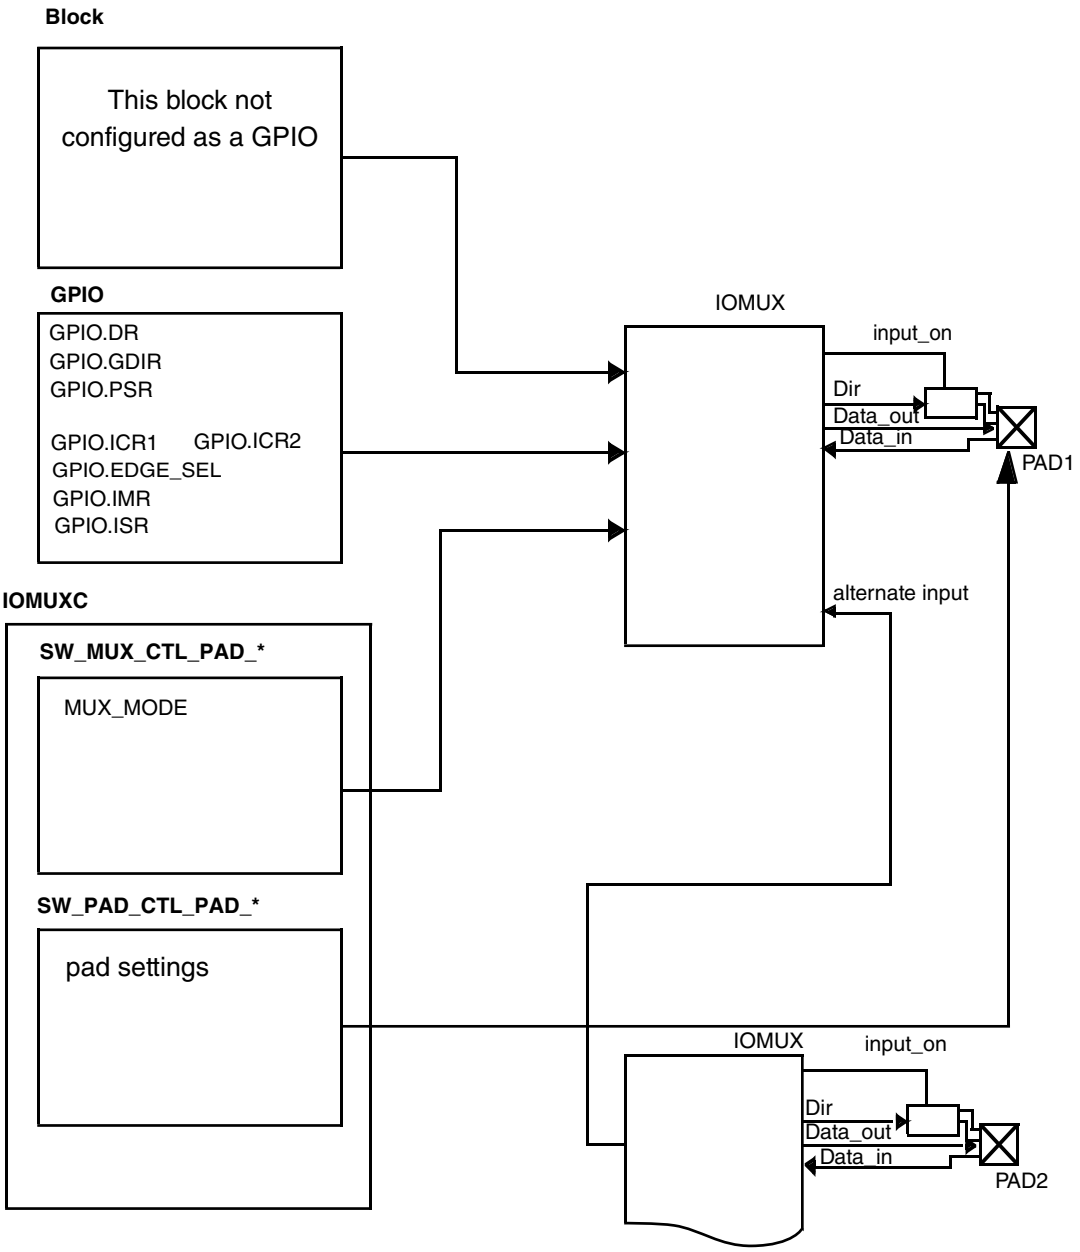

Figure 8-4. Chip IOMUX Scheme

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (GPIO_DR)
- GPIO direction register (GPIO_GDIR)
- Pad sample register (GPIO_PSR)
- Interrupt control registers (GPIO_ICR1, GPIO_ICR2)

- Edge select register (GPIO_EDGE_SEL)
- Interrupt mask register (GPIO_IMR)
- Interrupt status register (GPIO_ISR)

These registers are described in detail in GPIO Memory Map/Register Definition.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (GPIO_IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

In addition, GPIO1 provides visibility to each of its 8 low order interrupt sources (i.e. GPIO1 interrupt n, for n = 0 – 7). However, individual interrupt indications from other GPIOx are not available.

The GPIO edge detection is described further in Interrupt Control Unit.

The GPIO's overall functionality is described further in GPIO Functional Description.

8.3.1.1 Block Diagram

The GPIO subsystem contains 7 GPIO blocks which can generate and control up to 32 signals for general purpose.

A block diagram of the GPIO is shown in Figure 8-5 .

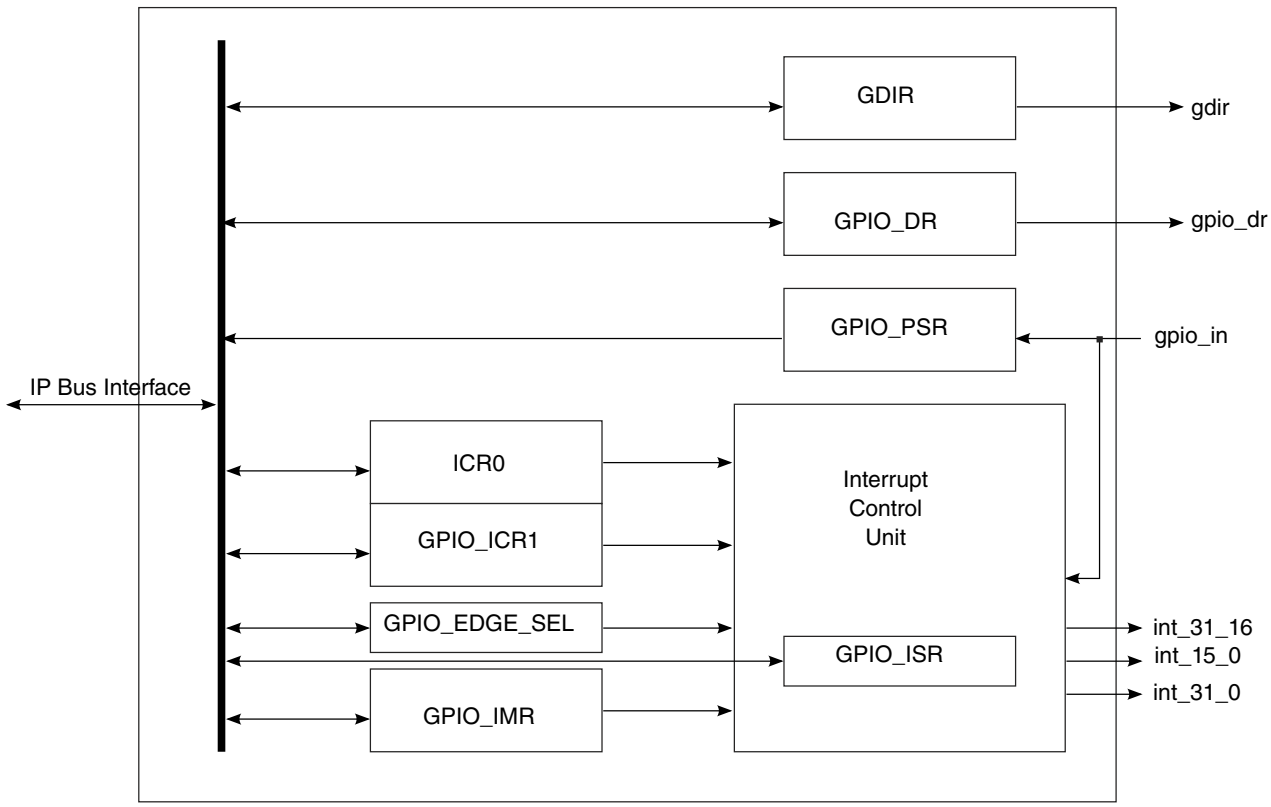

Figure 8-5. GPIO Block Diagram

8.3.1.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (GPIO_DR)
  - Controls the direction of the signal using the GPIO direction register (GPIO_GDIR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (GPIO_PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts

- Identifies interrupt edges
- Generates three active-high interrupts to the SoC interrupt controller

8.3.2 External Signals

The tables found here describe the external signals of GPIO.

Table 8-2. GPIO External Signals

Signal	Description	Pad	Mode	Direction

8.3.3 Clocks

The table found here describes the clock sources for GPIO.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 8-3. GPIO Clocks

Clock name	Clock Root	Description
ipg_clk_s	ipg_clk_root	Peripheral access clock

8.3.4 GPIO Functional Description

This section provides a complete functional description of the block.

8.3.4.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GPIO_GDIR).

When configured as an output (GPIO_GDIR bit = 1), the value in the data bit in the GPIO data register (GPIO_DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GPIO_GDIR bit = 0), the state of the input can be read from the corresponding GPIO_PSR bit.

8.3.4.2 GPIO Programming

8.3.4.2.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GPIO_GDIR[GDIR] set to 0b).
3. Read value from data reg*ister*/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

NOTE

While the GPIO direction is set to input (GPIO_GDIR = 0), a read access to GPIO_DR does not return GPIO_DR data. Instead, it returns the GPIO_PSR data, which is the corresponding input signal value.

8.3.4.2.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC), also enable SION if need to read loopback pad value through PSR
2. Configure GPIO direction register to output (GPIO_GDIR[GDIR] set to 1b).
3. Write value to data register (GPIO_DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback so we can capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

8.3.4.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (GPIO_ICR1 and GPIO_ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about GPIO_ICR1 and GPIO_ICR2 settings, see GPIO Memory Map/Register Definition.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

8.3.5 GPIO Memory Map/Register Definition

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

GPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3020_0000	GPIO data register (GPIO1_DR)	32	R/W	0000_0000h	8.3.5.1/ 2105

8.3.5.1 GPIO data register (GPIOx_DR)

The 32-bit GPIO_DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of GPIO_DR reflects the value of the corresponding signal.Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUXC input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.
- If GDIR[*n*] is set and IOMUXC input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is not GPIO, then reading DR[*n*] always returns zero.

Address: Base address + 0h offset

GPIOx_DR field descriptions

Field	Description
DR	Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading GPIO_DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0).

GPIOx_DR field descriptions (continued)

Field	Description
	NOTE: The I/O multiplexer must be configured to GPIO mode for the GPIO_DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

8.3.5.2 GPIO direction register (GPIOx_GDIR)

GPIO_GDIR functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPIOx_GDIR field descriptions

Field	Description
GDIR	GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** GPIO_GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO. 0 **INPUT** — GPIO is configured as input. 1 **OUTPUT** — GPIO is configured as output.

8.3.5.3 GPIO pad status register (GPIOx_PSR)

GPIO_PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

Address: Base address + 8h offset

GPIOx_PSR field descriptions

Field	Description
PSR	GPIO pad status bits (status bits). Reading GPIO_PSR returns the state of the corresponding input signal. Settings: **NOTE:** The IOMUXC must be configured to GPIO mode for GPIO_PSR to reflect the state of the corresponding signal.

8.3.5.4 GPIO interrupt configuration register1 (GPIOx_ICR1)

GPIO_ICR1 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Address: Base address + Ch offset

GPIOx_ICR1 field descriptions

Field	Description
31–30 ICR15	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 15. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
29–28 ICR14	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 14. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
27–26 ICR13	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 13. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
25–24 ICR12	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 12. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
23–22 ICR11	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 11. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
21–20 ICR10	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 10. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
19–18 ICR9	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 9. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
17–16 ICR8	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 8. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
15–14 ICR7	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 7. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
13–12 ICR6	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 6. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
11–10 ICR5	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 5. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
9–8 ICR4	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 4. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.

Table continues on the next page...

GPIOx_ICR1 field descriptions (continued)

Field	Description
7–6 ICR3	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 3. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
5–4 ICR2	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 2. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
3–2 ICR1	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 1. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.
ICR0	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for GPIO interrupt 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 **LOW_LEVEL** — Interrupt n is low-level sensitive. 01 **HIGH_LEVEL** — Interrupt n is high-level sensitive. 10 **RISING_EDGE** — Interrupt n is rising-edge sensitive. 11 **FALLING_EDGE** — Interrupt n is falling-edge sensitive.

8.3.5.5 GPIO interrupt configuration register2 (GPIOx_ICR2)

GPIO_ICR2 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Address: Base address + 10h offset

GPIOx_IMR field descriptions

Field	Description
IMR	Interrupt Mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Settings:

GPIOx_IMR field descriptions (continued)

Field	Description
	Bit IMR[n] (n=0...31) controls interrupt n as follows: 0 **UNMASKED** — Interrupt n is disabled. 1 **MASKED** — Interrupt n is enabled.

8.3.5.7 GPIO interrupt status register (GPIOx_ISR)

The GPIO_ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_ISR field descriptions

Field	Description
ISR	Interrupt status bits - Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in GPIO_IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

8.3.5.8 GPIO edge select register (GPIOx_EDGE_SEL)

GPIO_EDGE_SEL may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPIOx_EDGE_SEL field descriptions

Field	Description
GPIO_EDGE_SEL	Edge select. When GPIO_EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

Chapter 9
External Memory

9.1 External Memory Controllers

9.1.1 Overview

This chip has these external memory interfaces and controllers:

- Multi-Mode DDR Controller (MMDC)
- EIM-PSRAM/NOR flash controller

9.1.2 DDR controller (DDRC) overview and feature summary

The DDRC module is a DDR controller that supports several types of DDR memories.

Table 9-1. DDRC feature summary

Feature	Description
Supported standards	• DDR3/LPDDR2/LPDDR3 1ch x32

DDR interface	• Density of 256 MB - 2 GB
	  • Column size of 8-12 bits
	  • Row size of 11-16 bits
	• Supports burst length of 8 (aligned) for DDR3 and burst lengths of 4 for LPDDR2.

DDR performance	• Dynamic scheduling to optimize the bandwidth and latency. • Delayed writes for optimum bandwidth and latency. • For maximum SDRAM efficiency, commands are executed out of order. • Hardware configurable and software programmable QOS support. • Control options to avoid the starvation of lower priorities. • Write combine to allow multiple writes to the same address to be combined into a single write to the SDRAM. • Paging policy is selectable by the configuration registers. • Flexible address mapper logic to allow application-specific mapping of row, column, bank, and rank bits. • User-selectable refresh control options.

Table continues on the next page...

Table 9-1. DDRC feature summary (continued)

Feature	Description
AXI interface	• AXI bus compliant with a glueless interface to PL301 AXI network interconnect.
DDR calibration and delay-lines	• All calibrations can be done automatically by hardware or manually by software. • ZQ calibration for external DDR device (in DDR3 through the ZQ calibration command and in LPDDR2 through the MRW command).
DDR general	• Configurable timing parameters. • Configurable refresh scheme. • Supports dynamic voltage, frequency change, and low-power mode entry through the hardware negotiation with the system (req/ack handshake). • Suppors automatic self-refresh and power down entry and exit. • Supports fast and slow precharge power down in DDR3. • Supports various ODT control schemes. • Assertion/Deassertion of the ODT control per read or write accesses and for active or passive CS. • Supports MRW and MRR commands for LPDDR2. • Software control for moving to derated timing parameters and derated refresh rate according to the temperature variation.

9.1.3 EIM-PSRAM/NOR flash controller overview

EIM is an external interface module that manages the interface to external chip devices, including the generation of chip selects, clocks, and control for external peripherals and memory.

It provides asynchronous and synchronous access to devices with an SRAM-like interface.

9.1.3.1 EIM features

- Up to four (software configurable) chip selects for external devices
  - Flexible address decoding; each chip-select memory space is determined separately according to the GPR bits in IOMUXC.
  - Maximum supported density is 128 MB by default (AUS bit is cleared). When the AUS bit is set, the maximum supported density is 32 MB.
- Selectable write protection for each chip select
- Programmable wait-state generator for each chip select, for write and read accesses separately
- Asynchronous accesses with programmable setup and hold times for control signals
- Independent synchronous memory burst write mode support for PSRAM and NOR-flash memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNAND™ and utRAM™ from Samsung, and COSMORAM™from Toshiba)

- Supports NAND-flash devices with a NOR-flash interfaces - OneNAND™ (Samsung)
- Independent programmable variable/fix latency support for read and write synchronous (burst) mode
- Support for little-endian operation
- ARM AXI slave interface accesses are only handled in parallel for single AXI ID transactions
- External interrupt support using the RDY_INT signal function as an external interrupt pin
- Boot from external device support according to boot signals, using the RDY_INT signal
  - RDY signal support assertion after reset
  - INT signal support assertion after reset for OneNAND™ (Samsung) device
  - Supports little-endian mode only

9.1.3.2 EIM boot scenarios

EIM allows booting from NOR-flash devices. To select the NOR flash as the boot source, use either the boot mode and configuration GPIO pins or the internal boot-related fuses.

See Sytem Boot for more information.

9.1.3.3 EIM boot configuration

This table shows the EIM boot configuration:

Table 9-2. EIM boot configuration

EIM_BOOT_CFG bus	EIM affected bits	EIM register
12	NUM16_BYP_GRANT	CS0GCR2
11	DSZ[2]	CS0GCR1
10	AUS	CS0GCR1
[9:8]	CSREC[2:1]	CS0GCR1
[7:5]	RWSC[4:2]	CS0GCR1
	WWSC[4:2]	CS0WCR
4	ERRST	WCR
3	RAL	CS0RCR1
	WAL	CS0WCR
2	MUM	CS0GCR1
	OEA[1]	CS0RCR1
[1:0]	DSZ[1:0]	CS0GCR1

9.1.3.4 OneNAND requirements

By default, the Ready/Busy pin is not in use, perform these steps to configure the OneNAND:

- Poll the device to see whether it is ready; software performs a read from the device.
- Connect the Ready/Busy signal of the OneNAND device to any GPIO pin and use it as an interrupt that indicates the OneNAND device ready state.

9.2 DDR Controller (DDRC)

9.2.1 Introduction

The DDR Memory Controller (DDRMC) combined with DFI-compatible PHY is a complete memory interface solution for DDR memory subsystems. The DDRMC is a flexible and advanced solution for ASIC and System-on-Chip (SoC) designers who need very low power while achieving industry leading high-efficiency, low- latency and high-performance from their memory interface.

Supported SDRAM types include:

- DDR3
- LPDDR2
- LPDDR3

The DDRMC receives transactions from the SoC core. These transactions are queued internally and scheduled for access to the SDRAM while satisfying SDRAM protocol timing requirements, transaction priorities, and dependencies between the transactions. The DDRMC in turn issues commands on the DFI interface to the PHY module, which launches and captures data to and from the SDRAM.

9.2.2 General Overview

The DDRMC and the combine create a complete solution for connecting an SoC application bus to DDR memory devices. The combined DDRMC and solution enables the highest DDR performance and bandwidth, with the DDRMC initiating DDR commands to transfer data with the maximum efficiency.

The DDRMC SoC application bus interface supports an AMBA 3 AXI interface. The DDRMC has flexible address mapper logic to allow application-specific mapping of row, column, bank, bank group, and rank bits. The DDRMC includes a DFI interface that supports DDR3 (JEDEC JESD79-3*), LPDDR2 (JEDECJESD209-2*), and LPDDR3 (JEDEC 209-3*) standards.

9.2.2.1 Block diagram

The DDRMC converts system bus transactions into memory commands on the DFI interface that are compliant with the DDR protocols. The following figure is the block diagram of the DDRMC .

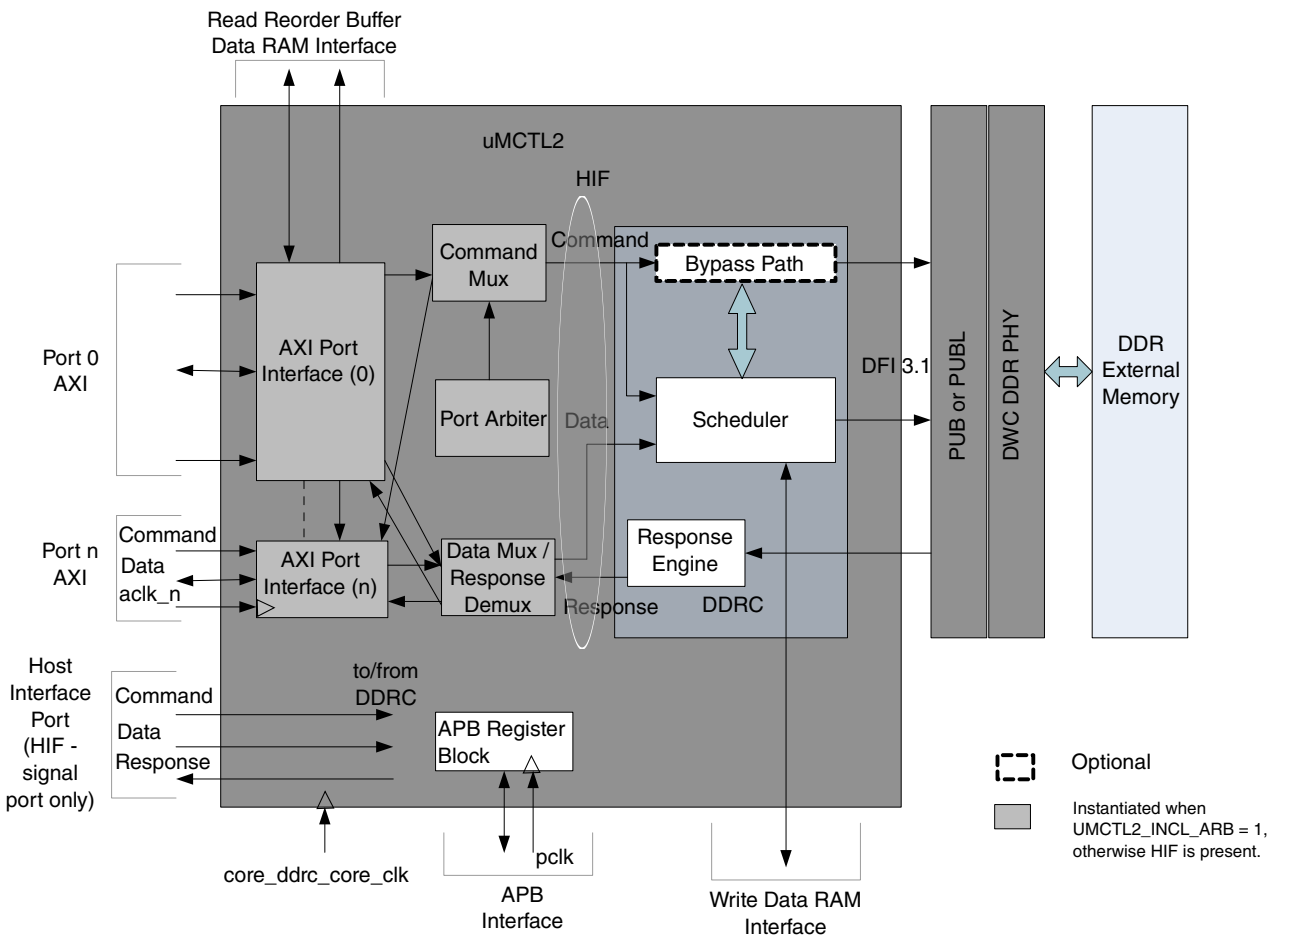

Figure 9-1. DDRMC Block Diagram

The DDRMC contains the following main architectural components:

- The AXI Port Interface (XPI) block: This block provides the interface to the application ports. It provides bus protocol handling, data buffering and reordering for read data, data bus size conversion (upsizing or downsizing), and memory burst address alignment.

- The Port Arbiter (PA) block: This block provides latency sensitive, priority based arbitration between the addresses issued by the XPIs (by the ports).
- The DDR Controller (DDRC) block: This block contains a logical CAM (Content Addressable Memory), which can be synthesized using standard cells. This holds information on the commands, which is used by the scheduling algorithms to optimally schedule commands to be sent to the PHY, based on priority, bank / rank status and DDR timing constraints. A bypass path is also provided (optionally).
- The APB Register Block: This block contains the software accessible registers.

9.2.2.2 Clocks

All application port clocks (ACLK_N) are independently configurable as asynchronous or synchronous with respect to the main DDRMC clock (CORE_DDRC_CORE_CLK). The APB interface clock (PCLK) is normally asynchronous to the CORE_DDRC_CORE_CLK. The interfaces that needs to be asynchronously configured, incur latency and area increase due to the additional clock domain crossing circuitry.

NOTE

PCLK frequency must be the same or less than CORE_DDRC_CORE_CLK frequency.

9.2.3 Features

The DDRMC supports the following features:

- Complete, integrated, single-vendor DDR3, LPDDR2, LPDDR3 solution
- DDR PHY Interface (DFI) support for easy integration with industry standard DFI 3.1-compliant PHYs
  - All signals supported on control, write data, and read data interfaces
  - Low Power Interface
- Scalable 1:2 frequency ratio architecture
- For DDR3, LPDDR2 and LPDDR3 configurations, direct software request control or programmable internal control for ZQ short calibration cycles
- For DDR3, LPDDR2 and LPDDR3 configurations, support for ZQ long calibration after self- refresh exit
- For LPDDR2 and LPDDR3 configurations, support for ZQ Reset feature through software
- Dynamic scheduling to optimize bandwidth and latency
- Read and write buffers in fully associative CAMs, configurable in powers of two, up to 64 reads and 64 writes

- Delayed writes for optimum performance on SDRAM data bus
- For maximum SDRAM efficiency, commands are executed out-of-order
- Hardware configurable and software programmable Quality of Service (QoS) support:
  - Support for three traffic classes on read commands—high priority reads, variable priority reads and low priority reads
  - Support for two traffic classes on write commands—normal priority writes and variable priority writes
  - Support for port urgent and port throttling control
- Configurable maximum SDRAM data-bus width (denoted “full data-bus width” below)
- Programmable support for all of the following SDRAM data-bus widths:
  - The full data-bus width or
  - Half of the full data-bus width or
  - One quarter of the full data-bus width.
- Two priorities for read transactions, and one for writes
- Control options to avoid starvation of lower priorities
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) hazards
- Write combine to allow multiple writes to the same address to be combined into a single write to SDRAM; supported for same starting address
- Paging policy selectable by configuration registers as any of the following:
  - Leave pages open after accesses
  - Close page when there are no further accesses available in the controller for that page, or
  - Auto-precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Support automatic SDRAM power-down entry and exit caused by lack of transaction arrival for programmable time
- Support automatic Clock Stop (LPDDR2 / LPDDR3) entry and exit caused by lack of transaction arrival
- Support automatic power-down entry and exit caused by lack of transaction arrival for programmable time
- Support self-refresh entry and exit as follows:
  - Support automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
  - Support for self-refresh entry and exit under software control
  - Support for self-refresh entry and exit using dedicated DDRC hardware low power interface control (similar to the AMBA 3 AXI protocol low power control interface)

- Support for dynamically changing clock frequency while in self-refresh
  - DDR3 DLL-off mode supported
- Support for deep power-down entry and exit under software control (LPDDR2 / LPDDR3)
- Support for explicit SDRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column, bank, and rank bits
- User-selectable refresh control options:
  - Controller-generated auto-refreshes at programmable average intervals
  - Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increasing overall efficiency)
  - When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
  - Ability to disable controller-generated auto-refreshes
  - Ability to issue a refresh through direct software request
  - When LPDDR2 / LPDDR3 is used, user-selectable ability to perform per-bank refreshes rather than all-banks refreshes
- Advanced power-saving design includes no unnecessary toggling of command, address, and data pins (RAS / CAS / WE / BA / A hold last state after each command; DQ does not transition on writes when bytes are disabled)
- Low area, low power architecture
- 5-clock cycle typical command latency through the DDRMC (HIF interface)
  - Can be reduced to 4 cycles by choosing not to register DFI outputs (Configuration parameter)
  - 3-clock cycles for high priority read
- Leverages out of order requests with CAM to maximize throughput
- APB interface for the DDRMC software accessible registers

9.2.4 Functional Description

This chapter describes the functional about the DDRMC.

9.2.4.1 Functional overview

This section explains the functionality of the DDRMC. The DDRMC is composed of the following main architectural blocks:

- AXI Port Interface (XPI)
- DDR Controller (DDRC)
- Register Block

The DDRMC performs the following functions:

- Accepts requests from the SoC core with system addresses and associated data for writes.
- Performs address mapping from system addresses to SDRAM addresses (rank, bank, bank group, row).
- Prioritizes requests to minimize the latency of reads (especially high priority reads) and maximize page hits.
- Ensures that the SDRAM is properly initialized.
- Ensures that all requests made to the SDRAM are legal (accounting for associated SDRAM constraints).
- Ensures that refreshes and other SDRAM and PHY maintenance requests are inserted as required.
- Controls when the SDRAM enters and exits various power-saving modes appropriately.

9.2.4.2 Address mapper

Read and write requests are provided to the DDRMC with a system address. The system address is the command address of a transaction as presented on one of the data ports. The DDRMC converts this system address to a physical address. It maps the system address to the SDRAM rank, bank, row, and column addresses.

If the system address regions are enabled (DDRMC_A_NSAR > 0), the first part of the mapping is conversion of system address to AXI[1] byte address. The controller maps disjoint address regions to internal consecutive addresses. Otherwise, the controller assumes that the DRAM is always mapped as a monolithic block. For more information about this, see System address regions.

The second part of this mapping is conversion of AXI/AHB byte address to HIF word address. This is performed in the XPI block, and is applicable to AXI/AHB configurations only. For more information about this, see Application to HIF address mapping.

The last part is the conversion of HIF word address to SDRAM address. A flexible address mapper maps the HIF word address to the SDRAM rank / bank / bank group / row / column address. This address mapper is located within the DDRC.

The address mapping to be used depends on the use-case. The DDRMC provides a set of registers that allows flexible re-programming of logical to physical address mapping. For more information about this, see HIF address to SDRAM address mapping.

1. System Address Regions are only supported with AXI configurations.

The following figure explains the conversion of AXI to HIF to the SDRAM rank / bank / row / column / bank group addresses.

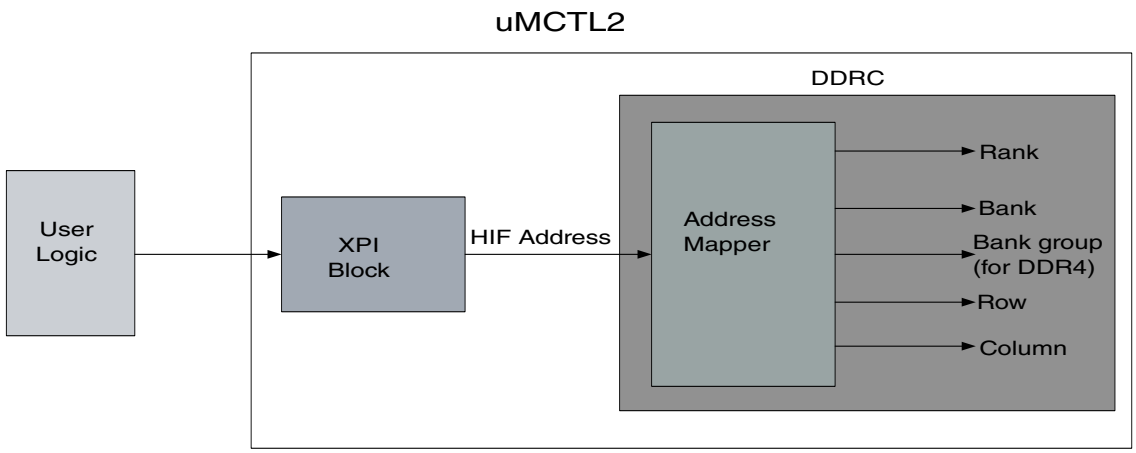

Figure 9-2. Conversion of AXI to HIF to SDRAM Rank / Bank / Row / Column / Bank Group Addresses

9.2.4.2.1 System address regions

The system address regions add the capability to define up to four disjoint memory regions mapping to the DRAM as consecutive addresses. The number of regions and minimum block size are determined by the hardware parameters DDRMC_A_NSAR and DDRMC_SARMINSIZE.

Each region is defined by:

- Base Address: Starting address of the region aligned to the minimum block size.
- Number of Blocks: Size of the region in multiples of minimum block size.

The base address of each region is specified by the register SARBASEn.base_addr and the total number of blocks is specified by the register SARSIZEn.nblocks (see SAR Size Register n (DDRC_MP_SARSIZE*n*)).

System address region specification is the same for all ports. Error response is not generated by the controller for addresses falling outside the specified address regions and the same address translation is applied from one base address to the next base address.

The base addresses must be specified so that they do not overlap. It is assumed that an outside agent can generate address decode errors if they happen to occur.

9.2.4.2.1.1 System address regions example

Consider the following example. The controller is set to have three system address regions (as specified on Table 9-3), with a minimum block size of 2 GB. Therefore, the DDRMC_SARMINSIZE parameter must be set to 4.

The system address bits [DDRMC_A_ADDRW-1:31] is used to represent the base addresses in the multiples of the minimum block size.

The registers must be programmed as follows:

- SARBASE0.base_addr = 1 (see SAR Base Address Register n (DDRC_MP_SARBASE*n*))
- SARBASE1.base_addr = 17
- SARBASE2.base_addr = 272
- SARSIZE0.nblocks = 0
- SARSIZE1.nblocks = 14
- SARSIZE2.nblocks = 15

The specifications in Table 9-3 translates to the register settings mentioned in Table 9-4.

Table 9-3. Address Region Mapping Example - Specification

Region	System Address (40-bit)	Offset	Internal Controller Address (36-bit)
Region 0 (2 GB)	0x00 8000 0000–0x00 FFFF FFFF	0x00 8000 0000	0x00 0000 0000–0x00 7FFF FFFF
Region 1 (30 GB)	0x08 8000 0000–0x0F FFFF FFFF	0x08 80000 0000	0x00 8000 0000–0x07 FFFF FFFF
Region 2 (32 GB)	0x88 0000 0000–0x8F FFFF FFFF	0x80 0000 0000	0x08 0000 0000–0x0F FFFF FFFF

Table 9-4. Example Base Addresses, Number of Blocks and Offset

Region	Base Address (Binary)	Register Value (base_addr)	Register Value (n blocks)	Calculated Base Address	Calculated Offset (Decimal / GB)
Region 0	9'b0_0000_0001	1	1	2 GB	1 / 2GB
Region 1	9'b0_0001_0001	17	15	34 GB	16 / 32GB
Region 2	9'b1_0001_0000	272	16	544 GB	256 / 512GB

Figure 9-3 shows the graphical illustration of the system address regions as specified in Table 9-3.

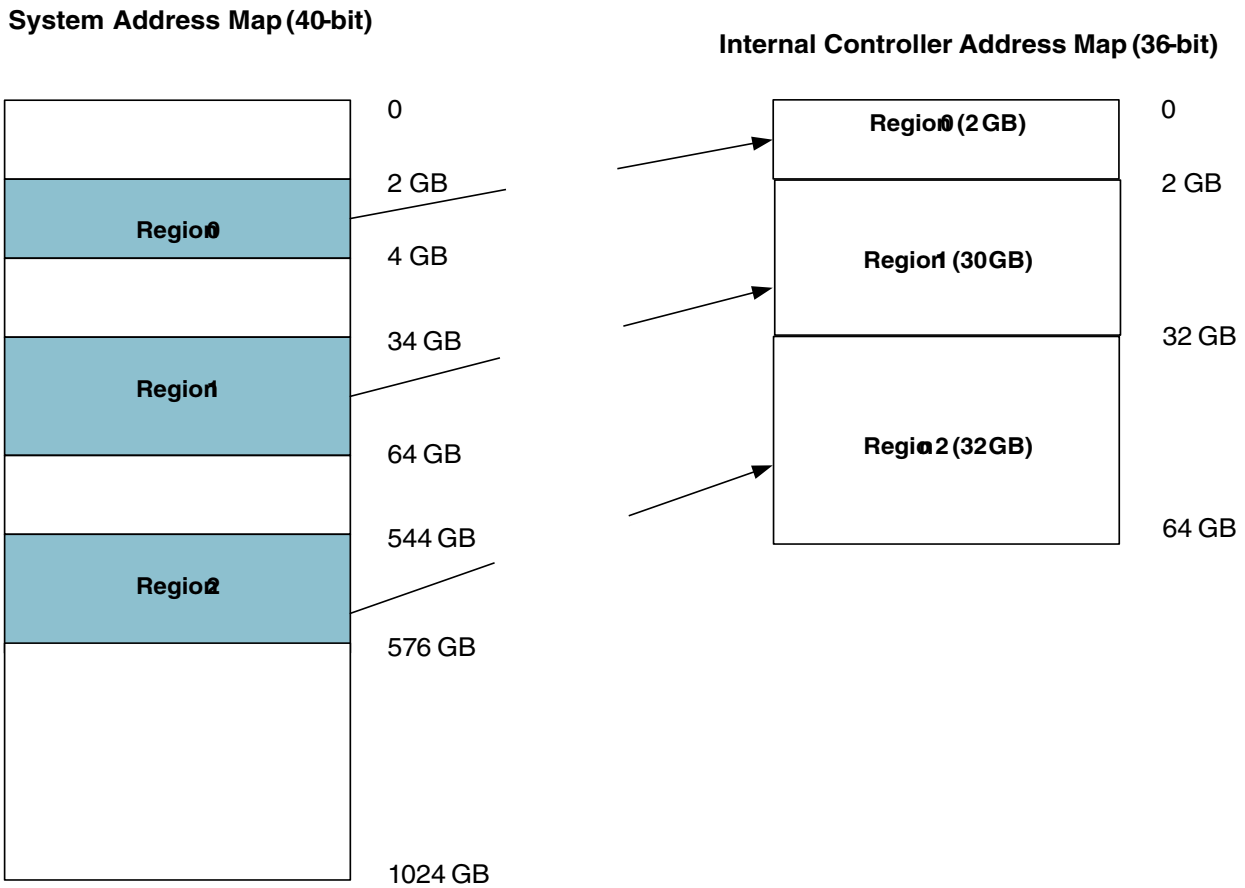

Figure 9-3. Address Region Mapping Example

NOTE

When DDRMC_AXI_BOUNDARY > DDRMC_SARMINSIZE + 27, portion of the address below the boundary can be changed by the conversion from system to AXI address. In this case, the user should ensure that the converted AXI address does not cross the boundary.

9.2.4.2.1.2 Application to HIF address mapping

The {ARADDR | AWADDR | HADDR} is a byte address. Based on the MEMC_BURST_LENGTH, XPI maps the MSB bits of the application address to the HIF address (hif_cmd_addr) in the following ways:

- HIF_CMD_ADDR [36: LOG2 (MEMC_BURST_LENGTH)] = {ARADDR | HADDR} [DDRMC_A_ADDRW - 1: LOG2 (MEMC_BURST_LENGTH) + LOG2 (MEMC_DRAM_DATA_WIDTH / 8]

- HIF_CMD_ADDR [LOG2 (MEMC_BURST_LENGTH) - 1: MEMC_FREQ_RATIO] is internally generated by XPI.
- HIF_CMD_ADDR [MEMC_FREQ_RATIO-1: 0] = 0

For example, if memory data width is 16, frequency ration is 1:1, and the application address width is 32:

- If MEMC_BURST_LENGTH = 8
  - HIF_CMD_ADDR [36:3] = {ARADDR | HADDR} [31:4]
  - HIF_CMD_ADDR [2:1] is internally generated by XPI.
  - HIF_CMD_ADDR [0] = 0
- If MEMC_BURST_LENGTH = 4
  - HIF_CMD_ADDR [36:2] = {ARADDR | AWADDR | HADDR} [31:3]
  - HIF_CMD_ADDR [1] is internally generated by XPI.
  - HIF_CMD_ADDR [0] = 0

9.2.4.2.1.3 HIF address to SDRAM address mapping

The address mapper maps HIF word addresses to SDRAM addresses by selecting the HIF address bit that maps to each and every applicable SDRAM address bit. While it is possible to map HIF address bits to a SDRAM address in any desired manner, the full available address space is accessible only when no two SDRAM address bits are determined by the same HIF address bit. Each SDRAM address bit has an associated register vector to determine its source.

Registers ADDRMAPx (x = 0 to 8) are used to program the address mapper. For more information on ADDRMAP registers, see DDRC.

The HIF address bit number is determined by adding the internal base of the ADDRMAPx (x = 0 to 8) register to the programmed value for that register, as described in the following equation:

HIF address bit number = [internal base] + [register value]

For example, for ADDRMAP3.addrmap_col_b7, the internal base is 7. When full data bus is in use, column bit 7 is determined by the following equation:

7 + [register value]

If this register is programmed to 2, the HIF address bit can be calculated by using following equation:

[HIF address bit number] = 7 + 2 = 9

In other words, the column address bit 7 sent to SDRAM would always be equal to hif_cmd_addr[9] of the corresponding HIF source address.

NOTE

- All of the column bits shift up 1 bit when only half of the data bus is in use. In this case, you need to look at ADDRMAP3.addrmap_col_b6 instead to determine the value of column address bit 7.
- All of the column bits shift up 2 bits when only a quarter of the data bus is in use. In this case, you need to look at ADDRMAP2.addrmap_col_b5 instead to determine the value of column address bit 7.
- All of the column bits shift up an additional 1 bit when the DDRMC is configured for BL8 mode (MEMC_BURST_LENGTH = 8).
- For Arbiter configurations (DDRMC_UNCL_ARB = 1) with mEMC_BURST_LENGTH = 8, it is required to program ADDRMAP2.addrmap_col_b2 = 0, so that the Arbiter can generate HIF address that are column aligned.
- If LPDDR2 or LPDDR3, or if MEMC_BURST_LENGTH = 8, it is required that HIF_CMD_ADDR [0] = 0, If DDRMC_INCL_ARB = 1, this is automatically the case. Otherwise, it is required that the HIF master generates HIF_CMD_ADDR [0] = 0.
- The register ADDRMAP5.addrmap_row_b2_10 maps multiple HIF address bits.
- For any address bits which cannot be in use in all cases, all bits of the associated address map register must be set to 1 when the associated SDRAM address bit is not in use.

The system address to physical address mapping can be completed by choosing any one of the possible combinations from the following figure. It explains the different possible ways to map the HIF address bits to the SDRAM rank / bank/ bank group / row / column address.

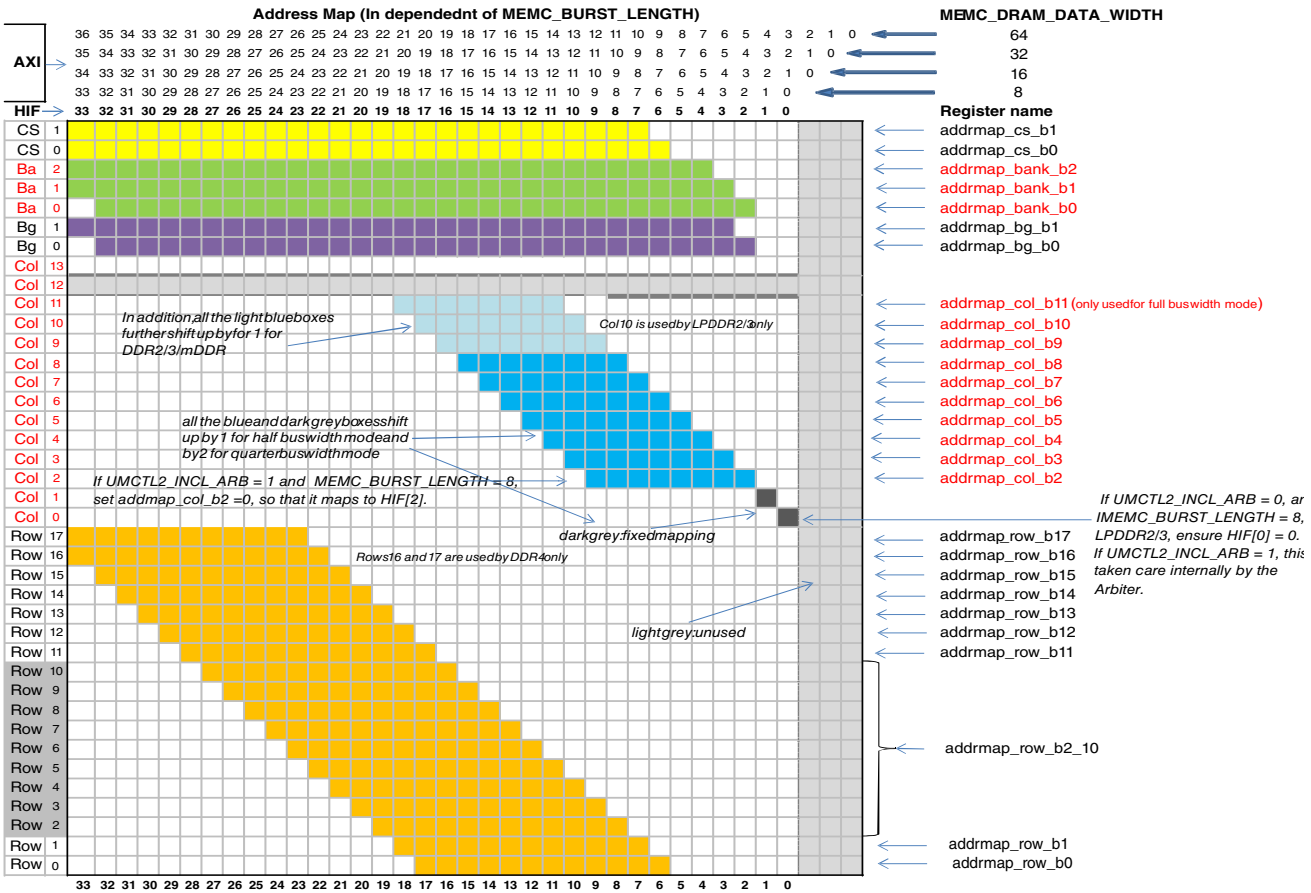

Figure 9-4. System Address to Physical Address Mapping (Independdent of MEMC_BURST_LENGTH)

NOTE

User should ensure that no two SDRAM address bits are determined by the same HIF address bit.

The following table shows some examples of address mapping schemes which might be used. This example assumes a full bus width, using an SDRAM with 10 column address bits (denoted “c” in the diagram), three bank address bits (denoted “b”) and 12 row address bits (denoted “r”). The non-interleaved example shows a simple address map where the lowest HIF address bits map to the SDRAM column addresses, the next three to the bank addresses, and the highest HIF address bits map to the row addresses. In the first interleaved example, the bank address bits are interleaved with the column address bits. In the last two examples, a more arbitrary mapping is shown. These examples are randomly selected to illustrate the flexibility of the DDRMC address mapper and they have no bearing on a typical system.

NOTE

The example "Non-Interleaved" and "Interleaved example1" are the same for both MEMC_BURST_LENGTH = 4 and MEMC_BURST_LENGTH = 8.

Table 9-5. Logical to Physical Address Mapping (Examples for DDR3)

	HIF Address Bits MEMC_BURST_LENGTH	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23	r10	ADDRMAP_ROW_B2_10	16	7
24	r11	ADDRMAP_ROW_B11	17	7

9.2.4.2.1.4 LPDDR3 6-Gb and 12-Gb device densities

LPDDR3 6Gb and 12Gb device densities do not support addresses which have both row bits 13 and 14 high (row[14:13] = 2'b11). Any attempt to read or write to this address space could result in memory misbehavior or the system hangs. When such devices are used, the user must set register ADDRMAP6.lpddr3_6gb_12gb to 1 (see Address Map Register 6 (DDRC_ADDRMAP6)). This prevents the DDRMC from accessing this address space when there is a read or write request from the user / SoC core.

When ADDRMAP6.lpddr3_6gb_12gb is set to 1, any write or RMW request with row[14:13] = 2'b11 is discarded, while the HIF output HIF_WDATA_PTR_ADDR_ERR is asserted. Also, any read request with row[14:13] = 2'b11 is executed (dummy read), by changing row[14:13] from 2'b11 to 2'b10. The return data for such reads are masked to zeros, while the HIF output HIF_RDATA_ADDR_ERR is asserted.

For AXI / AHB configurations, any assertion of HIF_WDATA_PTR_ADDR_ERR or HIF_RDATA_ADDR_ERR results also in SLVERR / ERROR response.

9.2.4.3 Transaction service control

The transaction service control allows the user to carefully manage the following:

- Costly read / write bus turn-arounds
- Priorities of read requests to generally favor high priority traffic while also preventing starvation of low priority traffic

This functionality is implemented in a simple 2-state machine for each traffic type with completely configurable controls. The states of the 2-state machine determine when reads / writes are serviced and the relative priority (high priority versus low priority reads) at any given moment.

Following is the list of registers related to transaction service control:

- Low priority read transaction store
  - PERFLPR1.lpr_max_starve (see Low Priority Read CAM Register 1 (DDRC_PERFLPR1))
  - PERFLPR1.lpr_xact_run_length
- High priority read transaction store
  - PERFHPR1.hpr_max_starve
  - PERFHPR1.hpr_xact_run_length
- Write transaction store
  - PERFWR1.w_max_starve
  - PERFWR1.w_xact_run_length
- Bus turn-around control
  - SCHED.prefer_write
  - SCHED.rdwr_idle_gap
- Variable priority read transaction grouping
  - PERFVPR1.vpr_timeout_range
- Variable priority write transaction grouping
  - PERFVPW1.vpw_timeout_range

9.2.4.3.1 Transaction stores

Transactions in the DDRMC are separated into five categories:

- Low Priority Reads (LPR)
- Variable Priority Reads (VPR)
- High Priority Reads (HPR)
- Normal Priority Writes (NPW)
- Variable Priority Writes (VPW)

NOTE

VPR and VPW categories are only supported when the multi port arbiter is configured (DDRMC_INC_ARB = 1). Hardware parameters DDRMC_INCL_ARB and DDRMC_VPRW_EN should be defined to enable the VPR / VPW feature.

9.2.4.3.1.1 Read transaction store

This section describes how LPR, VPR and HPR traffic classes work inside the DDRC. See Quality of service for information on how to map the AXI arqos value to LPR, VPR, and HPR traffic queues.

SCHED.lpr_num_entries register splits the Read CAM in the controller into LPR and HPR sections. The LPR and VPR commands are sent to the LPR section of the CAM, and the HPR commands are sent to the HPR section. The VPR commands come in with an associated ‘timeout’ value. The LPR and HPR commands do not have ‘timeout’ value associated with them. The ‘timeout’ value of the VPR commands are counted down every cycle in which the commands are pending in the LPR store. If any VPR command has not been serviced and its ‘timeout’ value reaches 0, the command is considered as expired-VPR command. When there are any expired-VPR commands in the DDRC, those commands are given higher priority than HPR and LPR commands.

A register, PERFVPR1.vpr_timeout_range, is used to indicate the range of the ‘timeout’ counter value to be considered when the priority is switched from VPR to expired-VPR. This feature is used to execute a group of VPR commands that are in the temporal vicinity together, thereby possibly improving the bus utilization. For example, if the register value is set to 0xF, it indicates that the priorities of all the VPR entries whose timeout counters are 15 or below are promoted to expired-VPR when any of the VPR commands timeout.

The Read CAM handles three traffic classes - LPR, VPR and HPR. But the Scheduling Engine that gets its input from the Read CAM, handles only two traffic classes - LPR and HPR. When there are no expired-VPR commands, all the VPR commands are treated as LPR. When there are any expired-VPR commands in DDRC, all expired-VPR commands are treated as HPR commands.

9.2.4.3.1.2 Write transaction store

This section describes how NPW and VPW traffic classes work inside the DDRC. See Quality of service for information on how to map the AXI awqos value to NPW and VPW traffic queues.

The NPW and VPW commands are sent to the Write CAM. VPW commands do not have reserved space in the Write CAM. The VPW commands come in with an associated ‘timeout’ value. The NPW commands do not have ‘timeout’ value associated with them. The ‘timeout’ value of the VPW commands are counted down every cycle in which the commands are pending in the WR store. If any VPW command has not been serviced and its ‘timeout’ value reaches 0, the command is considered as expired-VPW command. When there are any expired-VPW commands in the DDRC, those commands are given higher priority than NPW commands.

A register, PERFVPW1.vpw_timeout_range, is used to indicate the range of the ‘timeout’ counter value to be considered when the priority is switched from VPW to expired-VPW. This feature is used to execute a group of VPW commands that are in the temporal vicinity together, thereby possibly improving the bus utilization. For example, if the

register value is set to 0xF, it indicates that the priorities of all the VPW entries whose timeout counters are 15 or below are promoted to expired-VPW when any of the VPW commands timeout.

The Write CAM handles two traffic classes - NPW and VPW. But the Scheduling Engine that gets its input from the Write CAM, handles only one traffic class - NPW. When there are no expired-VPW commands, all the VPW commands are treated as NPW. When there are any expired-VPW commands in DDRC, all expired-VPW commands are given higher preference over NPW commands.

9.2.4.3.1.3 Transaction store state transitions

Each class of transaction store (LPR, HPR, or WR) can be in any one of the following two states:

- Normal: It is the state where the transaction store starts.
- Critical: It indicates that the transaction store must be prioritized for service.

The transaction stores move between these two states under the control of *_MAX_STARVE and *_XACT_RUN_LENGTH registers.

The following table describes the transaction store state transitions.

Table 9-7. Transaction Store State Transitions

Current State	Next State	State Transition
Normal	Critical	This transaction store is not serviced for a count of *_MAX_STARVE clock cycles, or if an address collision happens.
Critical	Normal	*_XACT_RUN_LENGTH number of transactions is serviced from this transaction store.

Taking the low priority read transaction store as an example, it is expected that the transaction store generally functions independently based on the following registers (see Low Priority Read CAM Register 1 (DDRC_PERFLPR1)):

- PERFLPR1.lpr_max_starve
- PERFLPR1.lpr_xact_run_length

In the normal mode of operation, the FSM moves from normal to critical state when the starvation timer times out. The store remains in Critical state until the number of transactions equal to what is indicated in PERFLPR1.lpr_xact_run_length are serviced, or when there are no more commands available for that store, whichever happens first.

The presence of any expired-VPR command in the DDRC makes the HPR queue to be in Critical state regardless of the value of its starvation timer. The HPR queue stays in Critical state until all the expired-VPR commands are served.

Similarly, the presence of any expired-VPW command in DDRC makes the WR queue to be in Critical state regardless of the value of its starvation timer. The WR queue stays in Critical state until all the expired-VPW commands are served.

When the DDRMC is configured as HIF-only (DDRMC_INCL_ARB = 0), it provides a feature where the SoC core can force this state transition using external signals. It is useful in cases where the SoC core may have additional information that is helpful in determining state transitions. For example, if the data stream has real-time requirements and the SoC core has knowledge about FIFO depths or time-till-failure, it can use this information to explicitly request the DDRMC to prioritize a particular data stream when it is critical to do so. The signals associated with this feature are HIF_GO2CRITICAL_LPR and HIF_GO2CRITICAL_WR.

In case of multi port arbiter configuration (DDRMC_INCL_ARB = 1), the HIF_GO2CRITICAL_* SIGNALS are driven by the Port Arbiter. The generation of three signals involved in this case - HIF_GO2CRITICAL_WR, HIF_GO2CRITICAL_LPR and HIF_GO2CRITICAL_HPR is described in VPR / VPW timeout and Urgent signalling.

The assertion of HIF_GO2CRITICAL_* SIGNALS cause their respective queue FSMs to go to Critical state. The change in Read / Write mode switching and the Read priority level selection based on the presence of the HIF_GO2CRITICAL_* SIGNALS is mentioned in the following section.

9.2.4.3.1.4 Read / Write turn-around

The following terminology is used to describe the Read / Write turn-around algorithm:

- Write / Read pending: A Write or a Read command is pending in the CAM.
- Write / Read collision: A Write collision indicates that a new Read command that arrived on the HIF bus is to the same address as a pending Write in the CAM and that the collided Write has to be now flushed before accepting the Read command into the CAM (vice versa for Read collision).
- Write / LPR / HPR critical: Indicates that the Write, LPR or HPR queue is in critical state due to starvation.
- Read / Write idle timeout: Read/Write idle timer based on the register SCHED.rdwr_idle_gap has expired.

The DDRC starts in the Read mode (servicing read requests) and then switches to Write mode (servicing write requests) in the following conditions:

- Write pending && (Write collision || Write critical) && ! Read collision && ! HPR critical && ! LPR critical, or

- No Read pending && (SCHED.prefer_write || (Write pending && Read/Write idle timeout)), or
- Expired-VPW pending and no Expired-VPR pending

The DDRC switches back to Read mode in the following conditions:

- Read pending && (hif_go2critical_hpr || hif_go2critical_lpr) && !Write collision
- Read pending && (Read collision || HPR critical || LPR critical) && ! Write collision && ! Write critical,
- No Write pending && (~SCHED.prefer_write || (Read pending && Read/Write idle timeout))
- Expired-VPR pending

The Read / Write idle timeout logic is as given below:

- If SCHED.prefer_write = 0, count down when Write pending and No Reads.
- If SCHED.prefer_write = 1, count down when Read pending and No Writes.

When both expired-VPR and expired-VPW are present at the same time, expired-VPR is given higher preference.

NOTE

- The normal programming is expected to be SCHED.prefer_write = 0. This implies that read requests are immediately serviced when the DDRMC is idle. Also, it is often desirable to set the SCHED.rdwr_idle_gap to a lower number (such as 0, 1, or 2). This ensures that writes do not go unserviced in an otherwise-idle DDRMC for any length of time, wasting the bandwidth. The trade-off is that reads received on the HIF immediately after these writes may incur additional latency. This is because time is needed to turn the bus around, service the writes, and then turn the bus around again to service the reads.
- Ordering between reads and writes to the same address is guaranteed on all requests issued to the DDRMC. Therefore, write latency is not be a concern to system design. In the event that write data is required by a subsequent read, the DDRMC automatically forces the write data out to SDRAM before servicing the read.

9.2.4.3.1.5 Read priority management

In a read mode, high priority read requests are preferred for service over low priority read requests. However, if the low priority read transaction store is in Critical state due to a transaction that is pending for a long time (see Transaction store state transitions) and the high priority read transaction store is not, the low priority read requests are preferred over high priority read requests. This prevents starvation of low priority reads.

The exceptions to the above rule are as follows:

- When there are any expired-VPR commands in DDRC, the HPR queue is given priority over LPR queue, even if LPR queue is in Critical state.
- If HIF_GO2CRITICAL_HPR is high, the HPR queue is given priority over LPR queue, even if LPR queue is in Critical state.
- If HIF_GO2CRITICAL_LPR is high and HIF_GO2CRITICAL_HPR is low, the LPR queue is given priority over HPR queue, even if HPR queue is in Critical state

9.2.4.3.2 Address collision handling

The DDRC can execute transactions out-of-order while ensuring that all transactions appear as if they are executed in the order in which they are received. Every transaction that requires a response from the DDRC arrives with a token number which is provided back to the SoC core as part of the response. Since the DDRC queues transactions prior to execution, it is possible that multiple transactions to the same SDRAM address can arrive before the first transaction to that address is issued.

To enforce ordering of accesses to the same address, the DDRC uses the following algorithm:

1. **New read colliding with queued read**: This collision causes no problems. The two reads can end up being executed out-of-order.
2. **New write colliding with queued write**: If write combine is enabled, the DDRC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine). For more information about this, see Write combine.
3. **New read (or write) colliding with queued write (or read) respectively**: In this case, the DDRC performs the following sequence:
   a. Holds the new transactions in a temporary buffer.
   b. Applies flow control back to the SoC core to prevent more transactions from arriving.
   c. Flushes the internal queue holding the colliding transaction until that transaction is serviced.
   d. Accepts the new transaction and removes flow control.

4. **New read colliding with both read and write**: This can happen when a read collides with a RMW command. In this case, the reads are flushed until the read collision is cleared, then the writes are flushed in the same manner as described in the step3.
5. **New write colliding with both read and write**: This can happen when a write collides with a RMW command. In this case, the new write is held in a temporary buffer until the read is completed. Then, it is combined with the queued write (if write combine is enabled).
6. **New RMW colliding with queued write**: In this case, the new RMW is stored in a temporary buffer until the queued write is completed.

9.2.4.3.3 Write combine

The write combine feature can combine multiple writes to the same address into a single write to SDRAM.

When a new write collides with a queued write in the CAM

- If write combine is enabled, the DDRC overwrites the data for the old write with that from the new write and only performs one write transaction (write combine).
- If write combine is disabled, the DDRC performs the following sequence:
  a. Holds the new write transaction in a temporary buffer.
  b. Applies flow control back to the SoC core to prevent more transactions from arriving.
  c. Flushes the internal queue holding the colliding transaction until that transaction is serviced.
  d. Accepts the new transaction and removes flow control.

9.2.4.3.4 Page policy

9.2.4.3.4.1 Explicit auto-precharge (Per command)

The explicit auto-precharge feature can enable auto-precharge on a per-command basis. If the HIF signal HIF_CMD_AUTOPRE is set during a valid command, then the auto-precharge bit for that command is set when it is sent to the SDRAM.

If you do not want to use the per-command auto-precharge feature, then this bit can be tied to 1’b1 or 1’b0. Tying it to 1’b1 causes all the commands to be executed with auto-precharge, and tying it to 1’b0 causes no commands to be executed with auto-precharge. For AXI configurations, HIF_CMD_AUTOPRE is tied to 0 internally, and is not accessible to the user.

In cases where a HIF transaction is translated into multiple DFI transactions, only the last DFI transaction is executed with auto-precharge. The earlier ones keep the page open, to allow subsequent transactions to benefit from the page hit. Also, if DBG0.dis_collision_page_opt (see Debug Register 0 (DDRC_DBG0)) is set to 0, the auto-precharge is automatically disabled for the flushed command in a collision case.

9.2.4.3.4.2 Intelligent precharges

The SCHED.pageclose register (see Scheduler Control Register (DDRC_SCHED)) enables precharge commands to be issued smartly via auto-precharges or explicit precharges. The exact functionality depends on the value programmed in SCHED1.pageclose_timer:

- If SCHED.pageclose is set to 1 and SCHED1.pageclose_timer = 0, a bank is kept open until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is executed with auto-precharge. Even if this register is set to 1, explicit precharge (and not auto-precharge) can be issued in some cases where there is a mode switch between write and read or between LPR and HPR. The read and write commands that are executed as part of the ECC scrub requests are also executed with explicit precharge if the page needs to be closed.
- SCHED.pageclose is set to 1 and SCHED1.pageclose_timer > 0, a bank is kept open until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is not executed with auto-precharge. Instead, a timer is started with pageclose_timer as the initial value. There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It resets to pageclose_timer value if the next read or write in the CAM to a bank is a page hit. Once the timer reaches zero, an explicit precharge is scheduled.
- If SCHED.pageclose is set to 0, the bank remains open only until there is a need to close it (to open a different page or for page timeout or refresh timeout). This is also known as open page policy. The open page policy can be overridden by setting the per command auto pre bit on the HIF interface (HIF_CMD_AUTOPRE) as described in Explicit auto-precharge (Per command). When the multi port arbiter is configured, the HIF signal hif_cmd_autopre is tied to 0 and the user has no control over it.

The intelligent precharge feature provides a midway between open and close page policies. SCHED1.pageclose_timer (see Scheduler Control Register 1 (DDRC_SCHED1)) gives user control over the time waited when there are no page hits to a bank in the CAM before auto-precharge or explicit precharge is scheduled. It is useful when the multi port arbiter is configured. This timer allows the page to be kept open for a configurable number of clock cycles after there are no commands pending in

the CAM to a bank. If there are pending commands higher up in the stream (for example, XPI / PA of multi port arbiter) to the same bank / page, it gives a chance to be scheduled by the DDRMC as an open page command.

The following table provides a summary of all paging policy options available in the DDRMC.

Table 9-8. Paging Policy Options

Paging Policy	Availability	Description
Open page policy	All configurations	Setting SCHED.pageclose to 0 enables the open page policy. In HIF configurations, the open page policy can be overridden by sending commands with HIF_CMD_AUTOPRE = 1.
Intelligent precharge(Midway between Closed page and Open page policy)	All configurations	Setting SCHED.pageclose to 1 enables this smart paging policy as described in Intelligent precharges. The exact functionality is dependent on SCHED1.pageclose_timer value. InHIF configurations, this paging policy can be overridden by sending commands with HIF_CMD_AUTOPRE = 1.
Closed page policy	Only in HIF configurations. Not in multi port configurations	Control the paging policy per-command by asserting or de-asserting the auto precharge signal on the HIF interface – HIF_CMD_AUTOPRE. If all commands are to be executed with auto-precharge, HIF_CMD_AUTOPRE can be tied to 1.

9.2.4.4 Quality of service

9.2.4.4.1 Traffic classes

The DDRMC supports different traffic classes that are distinguished from each other by the arqos signal:

9.2.4.4.1.1 Read classes

- Low Priority Read (LPR): It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. LPR is always treated as low priority in the PA and in the DDRC. There are timeout mechanisms that can be used to prevent starvation for both the PA and the DDRC. When there is a timeout in the PA, that port becomes the highest priority (priority0). When there is a timeout in the LPR store in the DDRC (in other words, LPR store becomes critical), the LPR entries are served before HPR entries.
- Variable Priority Read (VPR): It is also called as the maximum latency bound traffic for meeting real time deadlines in video or audio applications. VPR traffic shares the same resources with LPR in the DDRC. But, based on the configuration, it may have a dedicated queue (red or blue) in the XPI. It has the same priority as LPR, but lower priority than HPR for the PA. For the DDRC, VPR has the same initial priority as

LPR. Each command tagged as VPR has an associated latency timer. When expired, VPR transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

- High Priority Read (HPR): It has allocated resources. If the XPIs are configured to have dual read address queues, then the red queue can be allocated to HPR. For DDRC, HPR traffic goes to its own dedicated store. HPR traffic has higher priority than LPR. HPR is meant for latency critical but not real time applications such as CPU.

9.2.4.4.1.2 Write classes

- Normal Priority Write (NPW): It is also called as the best effort traffic. There is no resource allocation and it shares the resources with the other traffic types. It is always treated as normal priority in the PA and DDRC. There are timeout mechanisms that can be used to prevent starvation for the PA. When there is a timeout in the PA, that port becomes the highest priority (priority0).
- Variable Priority Write (VPW): It is also called as the maximum latency bound traffic to meet real time deadlines in video or audio applications. VPW traffic shares the same resources with NPW in the DDRC. For the DDRC, VPW has the same initial priority as NPW. Each command tagged as VPW has an associated latency timer. When expired, VPW transactions have the highest priority in the controller, both in the PA and in the DDRC. The purpose of this traffic class is to limit the maximum latency, where this latency bound is expected to be a few hundred clock cycles.

9.2.4.4.1.3 QoS mapping

The priority of an initiator (master) is susceptible to change by the intermediate agents (for example, interconnect) before reaching the destination slave depending on the service levels provided with respect to the required targets. Therefore, the relationship between the IDs and their class representations must be dynamically determined.

Arqos / awqos signal determines both port priorities and DDRC priorities dynamically. 16 QoS levels are divided to three regions for reads, two regions for writes. Each region can be assigned to any of the following traffic class—LPR, VPR, and HPR for reads, NPW and VPW for writes.

Region 0 and 1 are assigned to the blue address queue (See Dual read address queue). Typically, LPR / NPW and VPR / VPW may share this resource.

Region 2 is assigned to the red read address queue, this is not present for writes. The red address queue can be mapped to the HPR or VPR traffic. In the DDRC, LPR and VPR share the same CAM store called LPR store. HPR has its own store in the DDRC.

The regions are mapped per port using PCFGQOS0_n and PCFGWQOS0_n registers (see Port n Read QoS Configuration Register 0 (DDRC_MP_PCFGQOS0_0) and Port n Write QoS Configuration Register 0 (DDRC_MP_PCFGWQOS0_0)).

Fields for PCFGQOS0_n register are as follows:

- RQOS_MAP_LEVEL<x> (where x is 1 to 2) indicates two separation levels for three regions. Possible values 0 to 14 correspond to an arqos value. These registers indicate the upper end of the region. For example, if RQOS_MAP_LEVEL2 is set to 14, then Region 2 is identified as all transactions with arqos value of 15.
- RQOS_MAP_REGION<y> (where y is 0 to 2) for region identifier. This register indicates the traffic class of each of the three regions. RQOS_MAP_REGION2 is present only in dual read queue configurations.
  Valid values are:
  - 0–LPR
  - 1–VPR
  - 2–HPR

Fields for PCFGWQOS0_n register are as follows:

- WQOS_MAP_LEVEL indicates the separation level for two regions. Possible values 0 to 14 correspond to an awqos value. These registers indicate the upper end of the region. For example, if WQOS_MAP_LEVEL is set to 14, then Region 1 is identified as all transactions with awqos value of 15.
- WQOS_MAP_REGION<y> (where y is 0 to 1) for region identifier. This register indicates the traffic class of each of the two regions.
  Valid values are:
  - 0–NPW
  - 1–VPW

For dual read address queue configurations, Region 0 and Region 1 map to the blue queue, and Region 2 maps to the red queue. The blue queue can only be set to LPR, VPR or both. The red queue can only be set to VPR or HPR.

For single address queue configurations, Region 0 and Region 1 map to the blue queue. Being single queue, Region 2 is not present. In this case registers RQOS_MAP_LEVEL2 and RQOS_MAP_REGION2 don’t exist. In this case Region 0 can be set to HPR or VPR, Region 1 to VPR or LPR.

The following figure shows an example dynamic mapping from AXI QoS input to internal controller traffic classes.

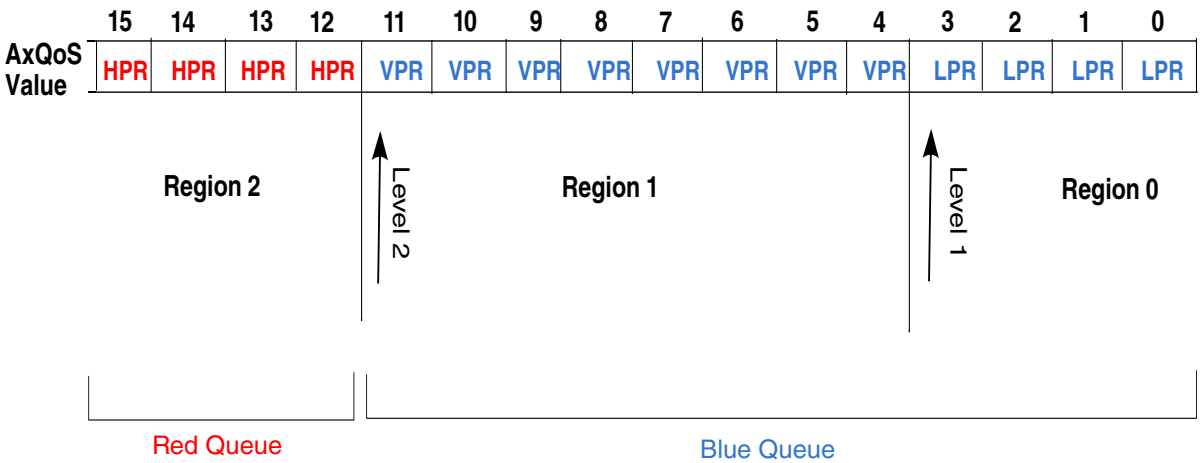

Figure 9-5. Example AxQoS Mapping to Traffic Classes

9.2.4.4.2 Dual read address queue

There are two separate read address queues in the XPI block—red and blue queue. They can be enabled by the parameter DDRMC_XPI_USE2RAQ_n for each port.

Both read queues request independently to the PA; therefore if enabled, maximum configurable number of XPI ports which is 16 is reduced. Each dual-queue XPI consumes two consecutive PA ports. The worst case is that there will be 8 ports where each XPI is configured to have dual read address queue.

Red queue can be used for one traffic class only and associated to Region 2 in the QoS mapper (HPR or VPR). Blue queue can be used for two traffic classes and associated to Region 0 and Region 1 in the QoS mapper (VPR and / or LPR).

There are separate time-outs for the blue and red queues. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command (see VPR / VPW timeout).

Optional retime block (register slice for pipelining) at the input of the XPI read address channel is enabled by DDRMC_XPI_USE_INPUT_RAR. Optional retime block at the output of the XPI read address channel (enabled by DDRMC_XPI_USE_RAR) cannot be used if dual queue is enabled.

9.2.4.4.2.1 ID collisions

Due to the dynamic nature of the QoS with respect to the IDs, two transactions of the same ID can potentially exist in two queues. The collisions can be classified as:

- Blue after Red (BAR): A command with ID x is presented to the blue queue where a command with the same ID x is outstanding in the red queue.
- Red after Blue (RAB): A command with ID x is presented to the red queue where a command with same ID x is outstanding in the blue queue.

In the XPI, for both collision types, the ordering consistency within a given ID is preserved by stalling the incoming transaction to be pushed into the address queue it is mapped to until the colliding transaction in the opposite queue exists. This is required for functional correctness.

In case of any ID collision, the DDRMC does not speed up the drain of the stored transactions in the address queue causing collision even if the incoming transaction is HPR. In other words, address queues request arbitration to the Port Arbiter with their normal mapped priorities.

9.2.4.4.3 VPR / VPW timeout

There are separate timeouts for the blue and red queues for read transactions, and one timeout for write transactions. Timers are started to down count when the transaction is accepted in the XPI, which are then forwarded to DDRC together with the command.

Timeouts are set per port and queue using PCFGQOS1_n and PCFGWQOS1_n registers (see Port n Read QoS Configuration Register 1 (DDRC_MP_PCFGQOS1_0) and Port n Write QoS Configuration Register 1 (DDRC_MP_PCFGWQOS1_0)).

For PCFGQOS1_n register:

- RQOS_MAP_TIMEOUTB: Specifies the timeout value for transactions mapped to the blue queue.
- RQOS_MAP_TIMEOUTR: Specifies the timeout value for transactions mapped to the red queue.

For PCFGWQOS1_n register:

- WQOS_MAP_TIMEOUT: Specifies the timeout value for write transactions.

When expired, VPR/VPW transactions from XPI are tagged as expired-VPR or expired-VPW instead of LPR/NPW during normal priority transaction flow. The Port Arbiter treats these transactions with the highest priority (priority0). In addition, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits available (LPR store of the read CAM is full) when an expired-VPR port is pending, and hif_go2critical_wr signal to the DDRC if there are no write credits available when an expired-VPW is pending. If an expired-VPW is issued as RMW at the HIF interface, the Port Arbiter asserts hif_go2critical_lpr signal to the DDRC if there are no LPR credits,

and / or hif_go2critical_wr signal if there are no write credits available. If both hif_go2critical_lpr and hif_go2critical_wr are asserted at the same time, priority in the DDRC is given to the read.

If VPR / VPW timeout registers are set to 0, the VPR / VPW transactions expire immediately as they enter the DDRMC, thereby making them the highest priority transaction class within the device. If multiple VPR / VPW transactions expire at the same time in the XPI, they are executed by the PA in round robin order.

To understand how the DDRC handles the VPR/VPW transactions, see Transaction service control. In addition to the registers mentioned in this section, PERFVPR1.vpr_timeout_range and PERFVPW1.vpw_timeout_range registers are also used by the DDRC and are related to the QoS.

9.2.4.4.3.1 Head of line blocking

Blue queue can be assigned to LPR and / or VPR if single or dual queue is selected, HPR and / or VPR if single queue is selected. Head of line blocking can occur in the XPI if more than one traffic class is mapped to the same address queue.

If a VPR expires inside the read address queue there can be two scenarios:

- Expired-VPR is blocked by one or more LPR transactions (single or dual queue configuration)
- Expired-VPR is blocked by one or more HPR transactions (only single queue configuration)

In case an LPR is blocking, that port becomes the highest priority (priority0) and if there are no LPR credits available, hif_go2critical_lpr is asserted.

In case an HPR is blocking, that port becomes the highest priority (priority0) and if there are no HPR credits available, hif_go2critical_hpr is asserted.

If a VPW expires inside the write address queue, expired-VPW may be blocked by one or more NPW transactions.

In case an NPW is blocking, that port becomes the highest priority (priority0) and if there are no write credits available, hif_go2critical_wr is asserted.

This behavior allows the queue where the VPR / VPW is expired to be flushed as quickly as possible.

This mechanism is applied only for the expired-VPR and expired-VPW commands.

For single read address queue configurations, HPR commands may be blocked by LPR or VPR commands (not-expired); in this case, the port priority is not increased.

9.2.4.4.4 Urgent signalling

AXI sideband signals per port, arurgent (arurgentb, arurgentr when DDRMC_XPI_USE2RAQ_n is defined) and awurgent, when asserted (and as long as asserted), set a given port to the highest priority (priority0) and when applicable- cause the read/write direction to switch immediately in the Port Arbiter if enabled by PCFGR_n.rd_port_urgent_en and PCFGW_n.wr_port_urgent_en registers (see Port n Configuration Read Register (DDRC_MP_PCFGR_0) and Port n Configuration Write Register (DDRC_MP_PCFGW_0)).

Urgent signals also cause the hif_go2critical_wr / hif_go2critical_lpr / hif_go2critical_hpr signals to be asserted at the HIF interface, which in turn force the read/write direction switching in the DDRC, if enabled by the PCFG.go2critical_en register. Urgent signals are ignored by the PA if there are no requesters from the asserted address channel and port. Similarly, hif_go2critical* signals are ignored by the DDRC if the corresponding store is empty.

9.2.4.5 Refresh controls

Refresh can be issued using the auto-refresh feature in the DDRMC or using the direct software request of refresh command. The RFSHCTL3.dis_auto_refresh register bit selects the refresh method (see Refresh Control Register 0 (DDRC_RFSHCTL3)). When this bit is set to ‘1’, the DDRMC uses direct software request of refresh command and when it is set to ‘0’, the internal auto-refresh feature is used.

This section describes the following topics about refresh controls:

- Refresh using direct software request of refresh command
- Refresh using auto refresh feature inside the DDRMC

9.2.4.5.1 Refresh using direct software request of refresh command

Follow these steps to put the DDRMC in direct software request of refresh command mode:

1. Set the RFSHCTL3.dis_auto_refresh bit to 1. When the register bit set, the DDRMC checks for any pending refreshes. Any pending refreshes are issued right away using the ‘critical refresh’ feature inside the DDRMC. After these refreshes are issued, all the refresh timers inside the DDRMC are reset to 0. They are re-activated only when the auto-refresh feature is enabled.
2. The SoC core must keep track of the refresh requirements of the SDRAM.
3. The refresh command can be issued by setting the register bits DBGCMD.rank*_refresh to 1 (see Command Debug Register (DDRC_DBGCMD)). When the rank*_refresh request is stored in the DDRMC, the corresponding register

bit is automatically cleared. The SoC core can initiate a rank*_refresh operation only if DBGSTAT.rank*_refresh_busy is low. The DDRMC issues refresh to the SDRAM at the earliest.

4. Software-driven refresh commands for each rank are loaded into a 9-entry buffer, and are issued by the DDRMC on the DFI as soon as it is legal to do so (the DDRMC controller must wait tRFC(min) between each refresh request). If the buffer saturates, the DBGSTAT.rank*_refresh_busy remains asserted to prevent software from initiating further refreshes.
5. Refresh control through direct software request is not allowed when the controller is in DDR4 mode and Fine Granularity Refresh (FGR) operation is turned on. In this case, RFSHCTL3.dis_auto_refresh bit should be set to 0 and refresh control should be done using the auto-refresh feature.

NOTE

It is possible to give a burst of back-to-back refresh commands without polling the DBGSTAT.rank*_refresh_busy register field to reduce the time between the software refresh commands to a minimum with the following risk:

- If the refresh buffer is not empty when the burst starts or the burst is longer than 9 refresh commands, the buffer saturates (DBGSTAT.rank*_refresh_busy is asserted) and some APB writes given in the burst are not added to the buffer. This means that the number of APB writes do not reflect the number of REF commands sent out to the memory.

9.2.4.5.2 Refresh using auto refresh feature inside the DDRMC

The DDRMC provides advanced refresh controls. Besides fully-configurable refresh constraints (tRFC(min) and tREFI), the DDRMC can also be programmed to gather refreshes to each rank of SDRAM to reduce the bandwidth consumed by refreshes and to increase the likelihood that refreshes can be serviced during an idle period.

Fine-gain control of the refreshes ensures these benefits can be balanced against worst case latencies associated with servicing refreshes together. Staggered refresh timers for multi-rank configurations of the DDRMC allow transactions to continue to other ranks while refreshes are taking place to just one rank.

Following signals are related to refresh controls:

- RFSHCTL0.refresh_burst (see Refresh Control Register 0 (DDRC_RFSHCTL0))
- RFSHCTL0.per_bank_refresh (LPDDR2/LPDDR3 feature)
- RFSHCTL0.refresh_margin
- RFSHCTL0.refresh_to_x32.

- RFSHCTL1.refresh_timer0_start_value_x32
- RSHCTL1.refresh_timer1_start_value_x32
- RFSHCTL2.refresh_timer2_start_value_x32
- RFSHCTL2._refresh_timer3_start_value_x32
- RFSHCTL3.refresh_update_level
- RFSHCTL3.dis_auto_refresh

For more information on “x32” register fields, refer to Computation for all the registers in units of 32, 1024, or 4096 clocks .

The purposes of refresh control are to:

- Reduce the bandwidth impact of refresh cycles
- Increase the likelihood of refreshes being serviced during idle periods
- Provide fine-gain control of the trading-off the above benefits (to gather refreshes) versus the increased worst case latencies associated with gathering refreshes
- Allow traffic to flow to other ranks while a given rank is being refreshed (for multi-rank configurations of the DDRMC only)

To minimize the worst case impact of a forced refresh cycle, the DDRMC can be programmed to issue single refreshes at a time by forcing RFSHCTL0.refresh_burst = 0 (see Refresh Control Register 0 (DDRC_RFSHCTL0)). It can be programmed to burst up to 8 refreshes (RFSHCTL0.refresh_burst = 7) in non-DDR4 modes. Burst refresh can be used to minimize the bandwidth lost to closing pages for refresh and to increase the likelihood that refreshes can be serviced during idle periods. It can also be programmed to any number in between to trade-off the benefits of each.

9.2.4.5.2.1 Single refresh

When using single refresh (RFSHCTL0.refresh_burst = 0), the DDRMC issues refreshes every time the refresh timer (t_{REFI}) expires. This is the optimal mode of operation for systems that minimize the maximum latency associated with refresh cycles.

9.2.4.5.2.2 Burst refresh

When burst refresh is enabled (RFSHCTL0.refresh_burst > 0), the DDRMC issues refreshes in bursts of (RFSHCTL0.refresh_burst + 1) refreshes at one time. Bursting refreshes reduces the total latency associated with those refreshes by reducing the number of pre-charges and activates required for refresh, as banks must be precharged only once to perform the entire group of refreshes, instead of once for each refresh.

9.2.4.5.2.2.1 Speculative refresh

When burst refresh is enabled (RFSHCTL0.refresh_burst > 0), the user can also make use of a feature called speculative refresh.

Burst refresh is implemented by counting the number of times t_{REFI} expires and issuing a group of refreshes when that number reaches the refresh burst number. Once t_{REFI} has expired at least once, the DDRMC can also perform speculative refreshes. This is done by automatically inserting refreshes when the DDRMC is idle.

The RFSHCTL0.refresh_to_x32 register determines how long the DDRMC must be idle before considering inserting these speculative refreshes. Each time a speculative refresh is performed, the count of t_{REFI} expirations is decremented, and thereby increasing the time before a burst of refreshes is required. This also ensures that speculative refreshes never occur more often than is required to keep the SDRAM properly refreshed.

If a new read or write transaction is accepted by the DDRMC during speculative refresh, the DDRMC services it as soon as legally possible. Most often it entails waiting for the required NOP cycles after a refresh before performing an activate and then servicing the read or write. If the DDRMC has begun closing pages for a speculative refresh but has not yet issued the refresh when the new transaction arrives, the speculative refresh is cancelled.

9.2.4.5.2.3 Per-bank refresh (LPDDR2/LPDDR3 only)

If RFSHCTL0.per_bank_refresh is set to 1 (see Refresh Control Register 0 (DDRC_RFSHCTL0)), the DDRMC performs per-bank refreshes instead of all-bank refreshes. In this case, RFSHTMG.t_rfc_nom_x32 and RFSHTMG.t_rfc_min should be set to the appropriate values for per-bank refresh (tREFIpb and tRFCpb respectively). In this mode, the DDRMC keeps track of which bank is being refreshed at any time, and is able to schedule commands to other banks immediately before and after the per-bank refresh commands, resulting in potential efficiency gains.

9.2.4.6 ZQ calibration

This feature is applicable for DDR3 and LPDDR2 / LPDDR3. The DDRMC uses ZQ calibration command to calibrate SDRAM RON (Resistor ON) and ODT (On-Die Termination) values over PVT (Process, Voltage, Temperature). DDR3 SDRAMs need more time to calibrate R_{ON} and ODT at initialization and relatively less time to perform periodic calibrations. For more information, refer to DDR3 (JEDEC JESD79-3*), LPDDR2 (JEDEC JESD209-2*) and LPDDR3 (JEDEC JESD209-3*) Specifications.

9.2.4.6.1 DDR3 devices

ZQCL (ZQ Calibration Long) command is used as follows:

- To perform the initial calibration during the power-up initialization sequence. This command is allowed a timing period of tZQinit determined by INIT5. dev_zqinit_x32 (see SDRAM Initialization Register 5 (DDRC_INIT5)) to perform full calibration and the transfer of values.
- To perform long ZQ Calibration after exiting from self-refresh. This command is allowed a timing period of tZQOPER, determined by ZQCTL0._t_zq_long_nop. This command is automatically issued when ZQCTL0.dis_srx_zqcl (ZQCL0.dis_mpsmx_zqcl) is set to 0. To disable issuing ZQCL after self-refresh exit , set ZQCTL0.dis_srx_zqcl (ZQCTL0.dis_mpsmx_zqcl) to 1.

ZQCS (ZQ Calibration Short) command is used to perform periodic calibration to account for VT (Voltage / Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter tZQCS (determined by ZQCTL0._t_zq_short_nop). ZQCS can be performed automatically on a regular interval or through direct software request. For more information about this, see Automatic and software initiated ZQCs.

In DDR3 mode, the ZQ Calibration commands are sent out encoded on the DFI command bus as mentioned in the JEDEC Specification. The DDRMC performs no other activities for the duration of tZQinit, tZQOPER and tZQCS. The quiet time on the SDRAM channel helps in accurate calibration of SDRAM R_{ON} and ODT. All banks are precharged and tRP met before the DDRMC issues the ZQ Calibration commands.

9.2.4.6.2 LPDDR2 / LPDDR3 devices

The DDRMC supports the ZQ Calibration commands that are supported by the JEDEC Specification.

ZQInit (ZQ Initial Calibration) command performs the initial calibration during the power-up initialization sequence. This command is allowed a time period of tZQinit (determined by INIT5.dev_zqinit_x32).

ZQCL (ZQ Long Calibration) command performs long ZQ Calibration after exiting from self-refresh mode. This command is allowed a timing period of tZQCL (determined by ZQCTL0._t_zq_long_nop). This command is issued automatically when ZQCTL0. dis_srx_zqcl is set to 0. To disable issuing of ZQCL after self-refresh exit, set ZQCTL0. dis_srx_zqcl to 1.

ZQCS (ZQ Short Calibration) command is used to perform periodic calibration to account for VT (Voltage/Temperature) variations. A shorter timing window is provided to perform calibration and transfer of values as defined by the timing parameter tZQCS

(determined by ZQCTL0._t_zq_short_nop). ZQCS can be performed automatically on a regular interval or through direct software request. For more information about this, see Automatic and software initiated ZQCs.

ZQReset (ZQ Calibration Reset) command is used to reset the R_{ON} calibration to a default accuracy of ±30% across process, voltage and temperature. This command is used to ensure R_{ON} accuracy of ±30% when ZQCS and ZQCL are not used and is allowed a time period of tZQRESET, determined by ZQCTL1.t_zq_reset_nop. The command is issued by using the registers ZQCTL2.zq_reset and ZQSTAT.zq_reset_busy (see ZQ Control Register 2 (DDRC_ZQCTL2) and ZQ Status Register (DDRC_ZQSTAT)). For more information about this, see LPDDR2 / LPDDR3 ZQ reset command.

In LPDDR2 / LPDDR3 mode, ZQ Calibration commands are sent out as Mode Register Write commands to the DRAM. The MRW is done to MR10 and the calibration codes for the different commands are as follows: ZQInit – 0xFF, ZQCL – 0xAB, ZQCS – 0x56, and ZQRest – 0xC3.

NOTE

For LPDDR2 / LPDDR3, it is possible to perform ZQ commands from software using the mode register interface (see Mode register reads and writes). However, the DDRMC does not implement the correct timing for such a command, so it is recommended not to do this, and instead to use either of the two methods mentioned below.

9.2.4.6.3 Automatic and software initiated ZQCs

The DDRMC issues a ZQCS command in the following two ways:

- **Automatic ZQCS by the DDRMC** : In this case, the DDRMC sends ZQCS commands to the SDRAM periodically. The interval is determined by ZQCTL1.t_zq_short_interval_x1024. This method is used if ZQCTL0.dis_auto_zq is set to 0 (see ZQ Control Register 0 (DDRC_ZQCTL0)).
- **ZQCS using direct software request**: In this case, the SoC core sends a ZQCS command through software by setting DBGCMD.zq_calib_short to 1. When the ZQCS request is stored in the DDRMC, the register bit is automatically cleared. It is recommended not to set DBGCMD.zq_calib_short signal in init, self-refresh, deep power-down operating modes or maximum power saving mode (MPSM). The SoC core can initiate a ZQCS operation only if DBGSTAT.zq_calib_short_busy is low. The DBGSTAT.zq_calib_short_busy signal goes high in the clock after the DDRMC accepts a ZQCS request. It goes low when the ZQCS operation is initiated in the DDRMC. For proper SDRAM operation, user/SoC core should schedule this command frequently. This method is used if ZQCTL0.dis_auto_zq is set to 1.

9.2.4.6.4 LPDDR2 / LPDDR3 ZQ reset command

In LPDDR2/LPDDR3 mode, ZQ Reset command is issued by setting ZQCTL2.zq_reset to 1 (see ZQ Control Register 2 (DDRC_ZQCTL2)). When the ZQ Reset operation is complete, the DDRMC automatically clears this register bit. It is recommended not to set this signal in init, self-refresh or deep power-down operating modes. The SoC core can initiate a ZQ Reset operation only if ZQSTAT.zq_reset_busy is low. This signal goes high in the clock after the DDRMC accepts a ZQ Reset request. It goes low when the ZQ reset command is issued to the SDRAM and the associated NOP period is completed. It is recommended not to perform ZQ Reset command when the ZQSTAT.zq_reset_busy signal is high.

9.2.4.7 SDRAM initialization sequence

A specific command sequence must be followed to properly initialize SDRAM modules. Much of the sequence is standard, but parts of it must be controlled differently according to the system configuration, clock speeds, and specific SDRAM parts in use. For this reason, the DDRMC provides a great deal of flexibility in how the initialization sequence is performed.

This section describes the initialization sequence and programmability provided by the DDRMC.

The list of registers associated with SDRAM initialization sequence are as follows:

- MSTR.ddr3
- MSTR.lpddr2
- MSTR.lpddr3
- INIT0.skip_dram_init
- INIT0.pre_cke_x1024
- INIT0.post_cke_x1024
- DRAMTMG3.t_mrd
- DRAMTMG3.t_mod (This is only used for DDR3 SDRAMs)
- INIT1.reg_ddrc_pre_ocd_x32
- INIT1.final_wait_x32
- INIT3.mr
- INIT3.emr
- INIT4.emr2
- INIT4.emr3
- INIT5.dev_zqinit_x32. This is used for DDR3 and LPDDR2/LPDDR3 SDRAMs.

For LPDDR2 / LPDDR3 configurations, the following registers are used for the SDRAM initialization sequence:

- INIT2.min_stable_clock_x1
- INIT2.idle_after_reset_x32
- INIT5.max_auto_init_x1024
- DRAMTMG3.t_mrw

When user / SoC core appropriately sets the inputs listed above, the DDRMC automatically performs the necessary sequence to properly initialize the DDR SDRAM devices. These registers must be set before bringing the DDRMC out of reset.

NOTE

In addition to initializing the SDRAM after a hard reset, the initialization sequence can also be used to bring the SDRAM out of self-refresh mode (see Self-refresh).

9.2.4.7.1 DDR3 initialization sequence

For DDR3, the DDRMC initialization state machine executes the following initialization sequence:

1. Power-up.
2. Maintain dfi_reset_n low for duration specified by INIT1.dram_rstn_x1024. Specification requires at least 200 us with stable power.
3. Issue NOP / deselect for duration specified by INIT0.pre_cke_x1024. Specification requires at least 500 µs.
4. Assert CKE and issue NOP/deselect for INIT0.post_cke_x1024 (specification requires at least t_{XPR}).
5. Issue MRS (mode register set) command to load MR2 with INIT4.emr2 value followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
6. Issue MRS command to load MR3 with INIT4.emr3 followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
7. Issue MRS command to load MR1 with INIT4.emr followed by NOP/deselect for duration of DRAMTMG3.t_mrd.
8. Issue MRS command to load MR0 with INIT3.mr followed by NOP/deselect for duration of DRAMTMG3.t_mod.
9. Issue ZQCL command to start ZQ calibration and wait for INIT5.dev_zqinit_x32.
10. Wait for INIT5.dev_zqinit_x32 counting to finish. Ensure wait from Step 8 is larger than t_{DLLK}.
11. DDR3 SDRAM is now ready for normal operation.

9.2.4.7.2 LPDDR2 / LPDDR3 initialization sequence

For LPDDR2 / LPDDR3, the DDRMC initialization state machine executes the following initialization sequence:

1. Power-up.
2. CKE is held low for a duration specified by INIT0.pre_cke_x1024. The clock is checked to be stable for duration specified by INIT2.min_stable_clock_x1 (minimum of 5 clock cycles) prior to the first low to high transition of CKE.
3. Assert CKE for INIT0.post_cke_x1024 (specification requires at least 200 µs).
4. A MRW (Reset) command is issued to MRW63 register. Values of MA<7:0> = 3FH and OP<7:0> = 00H is used for this command. The MRW reset command brings the device to the device auto-initialization (resetting) state in the power-on initialization sequence.
5. Issue NOP / deselect for duration specified by INIT2.idle_after_reset_x32 (specification requires 1 us minimum) and INIT5.max_auto_init_x1024 (specification requires maximum time of 10 µs).
6. An MRW ZQ initialization calibration command is issued to the memory to register MR10 to initiate the ZQ calibration. Values of MA<7:0> = 0AH and OP<7:0> = FFH is used for this command.
7. Issue NOP / deselect for duration specified by INIT5.dev_zqinit_x32 (specification requires a minimum time of 1 µs).
8. Program MR2 register by setting MR2 register to INIT3.emr followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
9. Program MR1 register by setting MR1 register to INIT5.mr followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
10. Program MR3 register by setting MR3 register to INIT4.emr2 followed by a NOP / deselect for a duration specified by DRAMTMG3.t_mrw (typical value of 5 clock cycles).
11. Schedule multiple all bank refresh.
12. Begin normal operation.

9.2.4.8 ODT control

By default, ODT to memories (dfi_odt) is driven to all zeroes. Figure 9-6 shows the timing diagram for ODT writes.

The register inputs control the following:

- **ODTMAP.rank*_wr_odt**: The value desired for ODT following a write command (see ODT / Rank Map Register (DDRC_ODTMAP)).

- **ODTCFG.wr_odt_delay**: The number of cycles to delay following a write command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- **ODTCFG.wr_odt_hold**: The number of cycles to hold the programmed write value after it is first driven.
- **ODTMAP.rank*_rd_odt**: The value desired for ODT following a read command.
- **ODTCFG.rd_odt_delay**: The number of cycles to delay following a read command before driving the programmed values for write ODT, which depends primarily on CAS latency.
- **ODTCFG.rd_odt_hold**: The number of cycles to hold the programmed read value after it is first driven.

NOTE

- ODT for memories is not required for mDDR / LPDDR2. It is a DDR2/DDR3 specific feature. For mDDR/LPDDR2, set ODTMAP.rank*_wr_odt to all zeroes.

All of these must be set by the SoC core before taking the DDRMC out of reset. They are then applied to every read or write issued by the DDRMC.

The recommended settings for ODT related registers in each protocol are given in ODT Configuration Register (DDRC_ODTCFG).

To avoid overlap of ODT for reads and writes, the following constraints must be enforced:

- ODTCFG.wr_odt_hold ≤ MEMC_FREQ_RATIO * RANKCTL.diff_rank_wr_gap + MSTR.burst_rdwr
  - If burst chop is enabled (MSTR.burstchop = 1), use burst_rdwr / 2 in the above equation
- ODTCFG.rd_odt_hold ≤ MEMC_FREQ_RATIO*RANKCTL.diff_rank_rd_gap + MSTR.burst_rdwr
  - If burst chop is enabled (MSTR.burstchop = 1), use burst_rdwr / 2 in the above equation
- ODTCFG.wr_odt_delay + ODTCFG.wr_odt_hold ≤ ODTCFG.rd_odt_delay + MEMC_FREQ_RATIO * DRAMTMG2.wr2rd
- ODTCFG.rd_odt_delay + ODTCFG.rd_odt_hold ≤ ODTCFG.wr_odt_delay + MEMC_FREQ_RATIO * DRAMTMG2.rd2wr

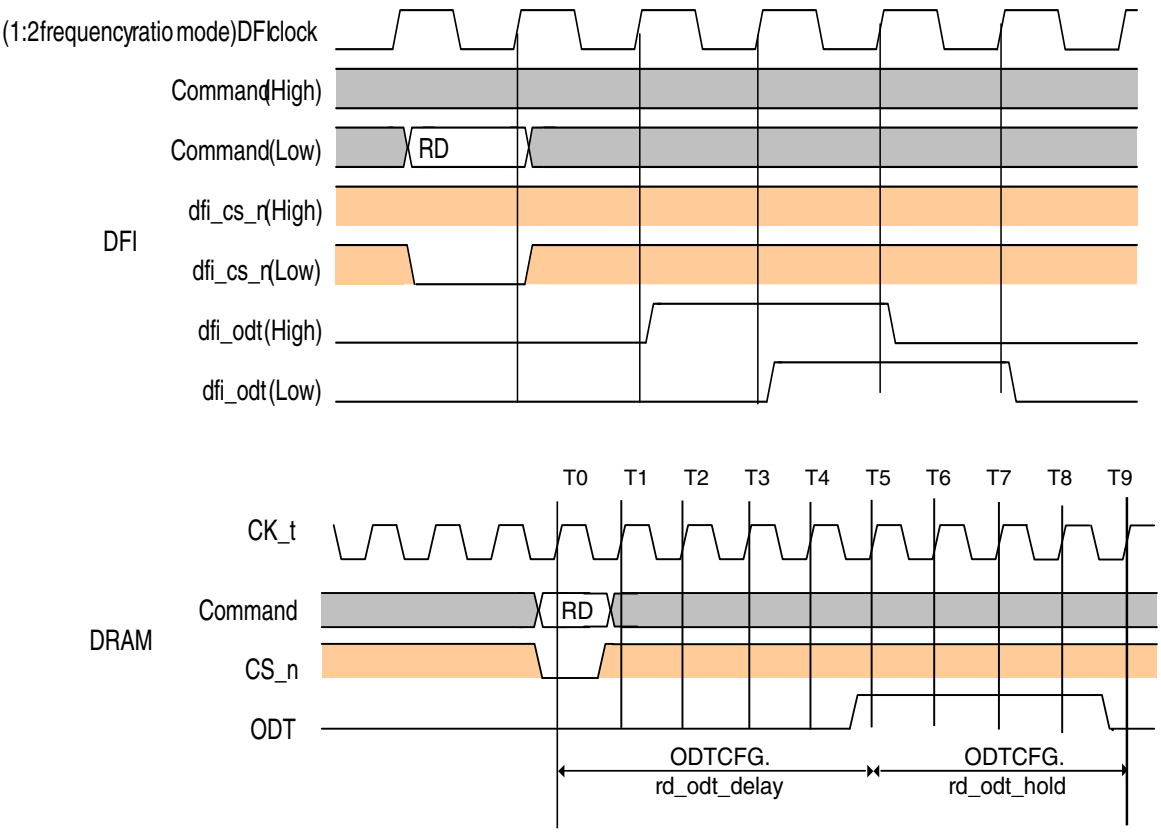

Figure 9-7. RD ODT Timing Diagram

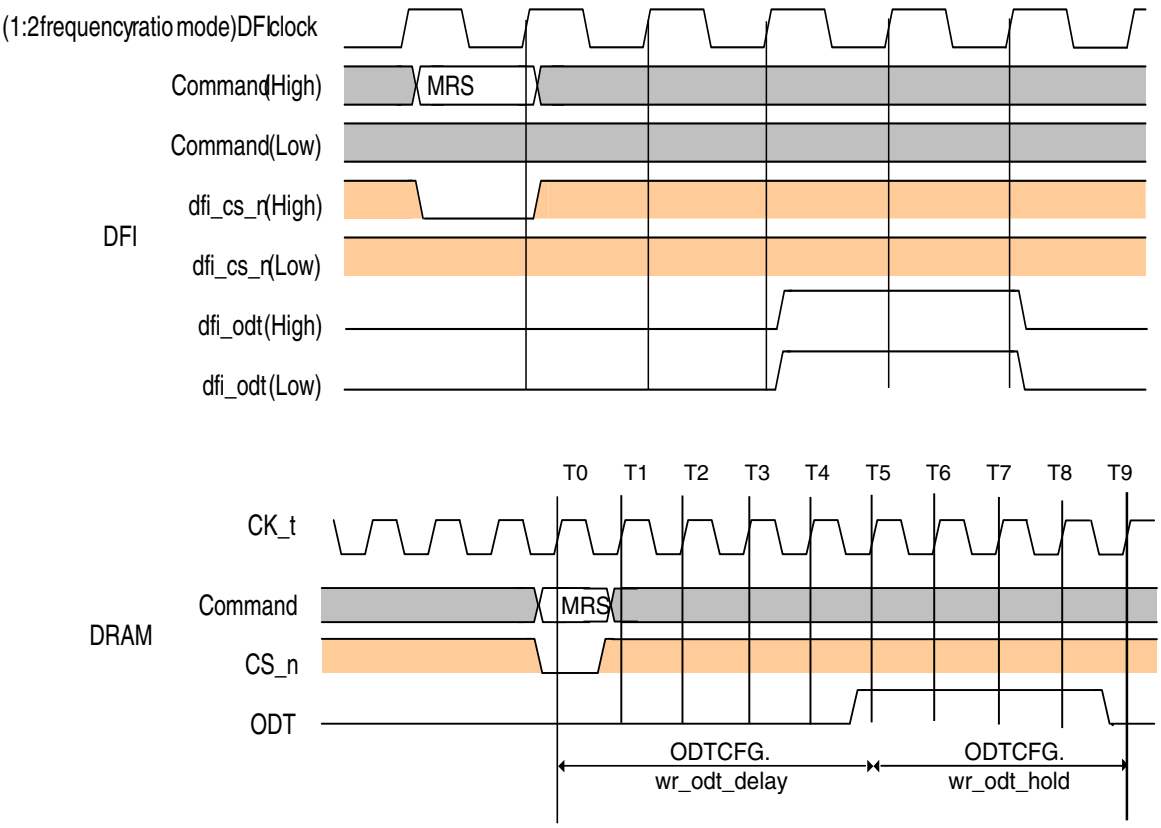

Figure 9-8. PDA ODT Timing Diagram

9.2.4.9 Power saving features

The DDRMC supports various methods to save power within the system:

- Power saving opportunities within the SDRAM. For more information about this, see SDRAM power saving features.

9.2.4.9.1 SDRAM power saving features

The DDRMC supports various SDRAM power-saving modes—precharge power-down, self-refresh, deep power-down, maximum power saving mode, and support for disabling clock to the DRAM via DFI_DRAM_CLK_DISABLE.

This section describes the following power-saving modes:

- Precharge power-down
- Self-refresh

- Deep power-down
- Assertion of dfi_dram_clk_disable

In multi-rank systems, these power-saving modes cannot be applied on a per-rank basis. If applied, they are always applied globally.

When enabled, the DDRMC automatically enters and exits precharge power-down mode based on a programmable idle timeout period.

Self-refresh can be entered/exited via three ways:
- Based on a programmable idle timeout period (similar to precharge power-down idle timeout)
- Explicitly controlled by the user via software
- Via the hardware low power interface(s)

In addition, DFI_DRAM_CLK_DISABLE can be asserted to disable the clocks to the DRAM. This can be done in self-refresh, power-down, deep power-down, and maximum power saving mode. It also includes clock stop if mDDR / LPDDR2 / LPDDR3 is used.

In relation to the hardware low power interface, optional support is provided to drive cactive_ddrc low under idle conditions in normal or power-down or automatic self-refresh modes. Optional support for power-down, self-refresh, and clock stop to be forcefully exited via CACTIVE_IN_DDRC = 1 is also provided.

Following registers are related to power saving features:
- DRAMTMG5.t_cke
- Precharge power-down controls:
  - PWRCTL.powerdown_en
  - PWRTMG.powerdown_to_x32
  - DRAMTMG1.t_xp
- Self-refresh controls:
  - PWRCTL.selfref_sw
  - PWRCTL.selfref_en
  - HWLPCTL.hw_lp_en
  - Hardware low power interface: csysreq_* / csysack_* / cactive_*
  - PWRTMG.selfref_to_x32
  - STAT.selfref_type
- Hardware low power interface:
  - HWLPCTL.hw_lp_exit_idle_en
  - HWLPCTL.hw_lp_idle_x32
- Deep power-down controls:
  - PWRCTL.deeppowerdown_en
  - PWRTMG.t_dpd_x4096
- Maximum power saving mode controls:

    - PWRCTL.mpsm_en
    - DRAMTMG11.t_mpx_lh
    - DRAMTMG11.t_mpx_s
    - DRAMTMG11.t_ckmpe
- Assertion of dfi_dram_clk_disable to disable the clocks to the DRAM controls:
    - PWRCTL.en_dfi_dram_clk_disable
    - DFITMG1.dfi_t_dram_clk_disable
    - DFITMG1.dfi_t_dram_clk_enable
    - DRAMTMG5.t_cksre
    - DRAMTMG5.t_cksrx
    - DRAMTMG6.t_ckpde
    - DRAMTMG6.t_ckpdx
    - DRAMTMG6.t_ckdpde
    - DRAMTMG6.t_ckdpdx
    - DRAMTMG6.t_ckcsx

For all the above power saving features, STAT.operating_mode signal can be used to monitor the current operating mode of the DDRMC.

NOTE

For more information on “x32 and x1024” register fields, refer to Computation for all the registers in units of 32, 1024, or 4096 clocks.

9.2.4.9.1.1 Precharge power-down

This section explains the following topics:

- Entering precharge power-down
- Exiting precharge power-down

9.2.4.9.1.1.1 Entering precharge power-down

When PWRCTL.powerdown_en = 1 (see Low Power Control Register (DDRC_PWRCTL)), the DDRMC automatically enters precharge power-down when the period specified by PWRTMG.powerdown_to_x32 has passed while the DDRMC is idle (except for issuing refreshes).

Entering precharge power-down mode involves the following steps:

1. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
2. Waiting for tRP (row precharge) idle period.

3. Issuing the command to enter precharge power-down (NOP / deselect with CKE = 0).
4. This step occurs only if DFI low power interface for power-down is enabled (DFILPCFG0.dfi_lp_en_pd). Attempts an entry to low power mode via DFI low power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_pd.

If the DDRMC receives a read or write request from the SoC core during Step 1 or Step 2 above, the power- down entry is immediately aborted. The same is true if PWRCTL.powerdown_en is driven to '0' during Step 1 or Step 2 . Once the power-down entry command is issued then proper power-down exit is required, as described in Exiting precharge power-down.

9.2.4.9.1.1.2 Exiting precharge power-down

Once the DDRMC has put the DDR SDRAM device(s) in precharge power-down mode, the DDRMC automatically performs the precharge power-down exit sequence for any of the following reasons:

- A refresh cycle is required to any rank in the system.
- The DDRMC receives a new request from the SoC core.
- A self-refresh entry is requested.
- PWRCTL.powerdown_en is set to '0' (see Low Power Control Register (DDRC_PWRCTL))

The DDRMC follows these steps when exiting precharge power-down mode:

1. Inserting any NOP / deselect commands required to satisfy the t_{CKE} requirement after entering precharge power-down.
2. This step occurs only if DFI low power mode entry during power-down entry is successful. Performs an exit from DFI low power mode.
3. Issuing the power-down exit command (NOP/deselect with CKE = 1). For multi-rank systems, all chip-selects are asserted so that all ranks exit precharge power-down simultaneously.
4. Issuing NOP/deselect for the period defined by t_{XP}.

NOTE

- DDR2: Fast Exit versus Slow Exit Active Power-down The DDR2 Specification describes two different variations on active power-down exit, depending on the programmed value of MR bit 12. As the DDRMC uses precharge power-down rather than active power-down, this programming has no effect on the DDRMC or the SDRAM devices.
- DDR3: Fast Exit versus Slow Exit Precharge Power-down The DDR3 Specification describes two different variations on precharge power-down exit, depending on the

programmed value of MR0 bit 12. If slow precharge power-down is used (MR0[12] = 0), DRAMTMG1.t_xp should be set to tXPDLL. If fast precharge power-down is used (MR0[12] = 1), DRAMTMG1.t_xp should be set to tXP.

- Other supported DDR protocols do not specify the difference between fast and slow power- down exit.

9.2.4.9.1.2 Self-refresh

This section explains the following topics:

- Entering self-refresh
- Exiting self-refresh

9.2.4.9.1.2.1 Entering self-refresh

The DDRMC puts the DDR SDRAM device(s) into self-refresh mode in the following cases:

- When the PWRCTL. selfref_en bit is set (see Low Power Control Register (DDRC_PWRCTL)) and no reads or writes are pending in the DDRMC for the period specified by PWRTMG.selfref_to_x32. This is referred to as automatic self-refresh. Dynamic changing of the PWRTMG.selfref_to_x32 register field is not allowed except when the DDRC is in reset (core_ddrc_rstn = 0).
- When the PWRCTL.selfref_sw bit is set. This is referred to as software self-refresh entry. The DDRC's hif_cmd_stall is driven high to stop new HIF commands from being accepted and existing core commands in DDRC are performed before sequence below . Note that, for arbiter configurations (MEMC_INCL_ARB = 1), commands mayoccurs be accepted by the AXI/AHB interface, but they do not enter the DDRC via the HIF as hif_cmd_stall = 1.
- When a hardware low power entry request occurs (on csysreq_ddrc / csysack_ddrc) with cactive_in_ddrc = 0, no outstanding commands, and as long as the DDRMC is in not in init or deep power-down or maximum power saving mode. This is referred to as an accepted hardware low power self-refresh entry. When accepted, the DDRC's hif_cmd_stall is driven high to stop new commands from being accepted and existing core commands in the DDRC are performed before the sequence mentioned below occurs.

Entering self-refresh mode involves the following steps:

1. If there is a self-refresh exit previously, wait for at least one refresh command (or 8 per-bank refresh commands if LPDDR2 / LPDDR3 per-bank refresh is enabled) to all active ranks. Auto-refresh logic must be enabled, or refresh should be issued using direct software requests of refresh command via DBGCMD.rank*_refresh.
2. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
3. Waiting for t_{RP} (row precharge) idle period. If a new command is received on the HIF during this time, the self-refresh entry is aborted.
4. Issuing the command to enter self-refresh mode
5. This step occurs only if DFI low power interface for self-refresh is enabled (DFILPCFG0.dfi_lp_en_sr). Attempts an entry to low power mode via DFI low power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_sr.

NOTE

STAT.selfref_type register field is 2'b11 if automatic self-refresh feature is the only cause of self- refresh. If software self-refresh or hardware low power self-refresh occurs, STAT.selfref_type = 2'b10.

Automatic self-refresh has lowest priority and is superseded by both software and hardware low power self-refresh. A software self-refresh entry means that a self-refresh exit occurs only if a software self-refresh exit occurs. Similarly, a hardware low power self-refresh entry means a self-refresh exit occurs only if a hardware low power self-refresh exit occurs. If both software and hardware low power self-refresh entry occurs, self-refresh exit occurs only if both software and hardware low power self-refresh exits occur.

9.2.4.9.1.2.2 Exiting self-refresh

The DDRMC takes the DDR SDRAM out of self-refresh mode under the following conditions:

- Whenever the PWRCTL.selfref_en input is de-asserted (see Low Power Control Register (DDRC_PWRCTL)), or new commands are received by the DDRMC, as long as automatic self-refresh is only cause for self-refresh entry (STAT.selfref_auto_flag = 1).
- Whenever the PWRCTL.selfref_sw bit is de-asserted. This is referred to as software self-refresh exit.
- When a hardware low power exit request occurs (on csysreq_ddrc / csysack_ddrc). This is referred to as hardware low power self-refresh exit.

Exiting self-refresh mode involves the following steps:

1. Inserting any NOP / deselect commands required to satisfy the t_{CKE} / t_{CKERSR} requirements after entering self-refresh.

2. This step occurs only if DFI low power mode entry during self-refresh entry is successful. Performs an exit from DFI low power mode.
3. Issuing the self-refresh exit command (refresh with CKE = 1).
4. Issuing NOP / deselect for the period defined by tX_{SDLL} / t_{XSNR} / t_{XSRD}.

9.2.4.9.1.3 Deep power-down

This power saving mode is applicable for LPDDR and LPDDR2 devices only. This section explains the following topics:

- Entering deep power-down
- Exiting deep power-down

9.2.4.9.1.3.1 Entering deep power-down

By setting the PWRCTL.deeppowerdown_en bit (see Low Power Control Register (DDRC_PWRCTL)), the user can put the SDRAM device(s) into deep power-down mode, if all the following conditions are true:

- The period specified by PWRTMG.powerdown_to_x32 has passed while the DDRMC is idle (except for issuing refreshes)
- PWRCTL.selfref_sw = 0
- PWRCTL.selfref_en = 0
- If HWLPCTL.hw_lp_en = 1, DPD is entered only when the hardware low power interface has completed a self-refresh exit. (This can be checked by observing STAT.operating_mode and STAT.selfref_type).
- If HWLPCTL.hw_lp_exit_idle_en = 1, DPD is entered only when all bits of

cactive_in_ddrc = 0 Entering Deep power-down involves the following steps:

1. Precharging (closing) all open pages. Pages are closed one-at-a-time in no specified order.
2. Waiting for tRP (row precharge) idle period.
3. Issuing the command to enter deep power-down. For multi-rank systems, all chip-selects are asserted so that all ranks enter deep power-down simultaneously. The deep power-down entry commands are as follows:

   Command for mDDR: CKE = 0, CSN = 0, RAS = 1, CAS = 1, WE = 0

   Command for LPDDR2 / LPDDR3: CKE = 0, CSN = 0, CA0 = 1, CA1 = 1, CA2 = 0

4. This step occurs only if DFI low power interface for deep power-down is enabled (DFILPCFG0.dfi_lp_en_dpd). It attempts an entry to low power mode via DFI low power interface with dfi_lp_wakeup set by DFILPCFG0.dfi_lp_wakeup_dpd.

If the DDRMC receives a read or write request from the SoC core during Step 1 or Step 2 above, the deep power-down entry is immediately aborted. The same is true if PWRCTL.deep_powerdown_en is driven to ‘0’ during Step 1 or Step 2 . Once the deep power-down entry command is issued, proper deep power-down exit is required, as described in the following section.

NOTE

Contents of SDRAM may be lost upon entry into deep power-down mode.

9.2.4.9.1.3.2 Exiting deep power-down

Once the DDRMC puts the DDR SDRAM device(s) in deep power-down mode, the DDRMC automatically exits deep power-down and re-runs the initialization sequence when PWRCTL.deeppowerdown_en is reset to ‘0’ (see Low Power Control Register (DDRC_PWRCTL)). An exit from DFI low power mode is performed prior to exiting deep power-down (this occurs only if DFI low power mode entry during deep power-down entry is successful).

9.2.4.9.1.4 Assertion of dfi_dram_clk_disable

Assertion of dfi_dram_clk_disable occurs only if PWRTL.en_dfi_dram_clk_disable = 1. dfi_dram_clk_disable is also dependent on the operating mode:

- In DDR2 / DDR3, dfi_dram_clk_disable can be asserted only in self-refresh mode.
- In mDDR / LPDDR2 / LPDDR3, dfi_dram_clk_disable can be asserted in the following modes:
  - In Self-refresh
  - In Power-down
  - In Deep power-down
  - In Normal mode. This is “Clock Stop” feature.

The timing of the assertion and de-assertion of dfi_dram_clk_disable in various modes is as follows:

- In Self-refresh:
  - Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG5.t_cksre - DFITMG1.dfi_t_dram_clk_disable cycles after SRE command.
  - Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG5.t_cksrx - DFITMG0.dfi_t_ctrl_delay cycles before SRX command.

■ In Power-down:

- Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG7.t_ckpde - DFITMG1.dfi_t_dram_clk_disable cycles after PDE command.
- Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG7.t_ckpdx - DFITMG0.dfi_t_ctrl_delay cycles before PDX command.

■ In Deep power-down:

- Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG6.t_ckdpde - DFITMG1.dfi_t_dram_clk_disable cycles after DPDE command.
- Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckdpdx - DFITMG0.dfi_t_ctrl_delay cycles before DPDX command.

- In Normal mode (Clock Stop):
  - Asserted at least DFITMG0.dfi_t_ctrl_delay - DFITMG0.dfi_t_dram_clk_disable cycles after any command other than SRE / PDE / DPDE.
  - Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG6.t_ckcsx - DFITMG0.dfi_t_ctrl_delay cycles before any command other than SRX / PDX / DPDX.
- In Maximum power saving mode:
  - Asserted at least DFITMG0.dfi_t_ctrl_delay + DRAMTMG11.t_ckmpe - DFITMG1.dfi_t_dram_clk_disable cycles after MPSME.
  - Deasserted at least DFITMG1.dfi_t_dram_clk_enable + DRAMTMG5.t_cksrx - DFITMG0.dfi_t_ctrl_delay cycles before MPSMX.

9.2.4.9.1.5 DLL-off mode (DDR3)

DLL-off mode enables DDR3 SDRAMs to be operated at low frequencies. The DDRMC supports DLL-off mode, and transitions between DLL-on and DLL-off mode, under software control. To enable DLL-off mode from initialization, the following register fields must be set:

- INIT3.emr[0], so that the SDRAM mode register is set for DLL-off mode
- MSTR.dll_off_mode = 1
- If using the Synopsys DWC DDR PHY, it should be put in PLL-bypass mode

To perform a transition between DLL-off and DLL-on modes, the software must implement the sequence specified in the JEDEC specification. Full details of the software sequence is provided in the User Guide.

NOTE

DBI, geardown and programmable preamble are not supported in DLL-off mode. Also, geardown, C/A parity and CAL mode must be disabled when moving from DLL-off to DLL-on.

9.2.4.9.2 Software sequence for removal of clocks

Software can be used to keep the SDRAM in self-refresh. The AXI and DDRC clocks can be removed when in self-refresh by following the sequence described in the Table 9-9.

Table 9-9. Software Clock Removal Sequence

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI port(s) from taking anymore transactions
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Wait unit all AXI ports are idle
3	Write 0 to SBRCTL.scrub_en	Disable SBR, only required if SBR instantiated
4	Poll SBRSTAT.scrub_busy=0	Indicates that there are no outstanding SBR read commands, only required if SBR instantiated
5	Write 1 to PWRCTL.selfref_sw	Cause system to move to self-refresh state
6	Poll STAT.selfref_type= 2'b10	Wait until self-refresh state entered
7	Remove AXI clock(s)	
8[1]	Remove DDRC core clock	

1. Prior to this step, if PHY allows, it is recommended to disable generation of PHY initiated Update requests (dfi_phyupd_req). This avoids the possibility of the DDRMC missing dfi_phyupd_req assertions while its clock has been removed. The DDRMC cannot respond via dfi_phyupd_ack as its clock has been removed. If using a Synopsys PHY, this can be done via the PUB's DSGCR.PUREN.

The clocks should be re-enabled by following the sequence described in Table 9-10.

Table 9-10. Re-enabling the Clocks

Step	Description	Comment
1	Enable AXI clock(s)	
2[1]	Enable DDRC core clock	
3	Write 0 to PWRCTL.selfref_sw	Cause system to exit from self-refresh state
4	Poll STAT.selfref_type = 2'b00	Wait until self-refresh state is exited
5	Write 1 to PCTRL_n.port_en	AXI port(s) are no longer blocked from taking transactions
6	Write 1 to SBRCTL.scrub_en	Enable SBR if desired, only required if SBR instantiated

1. After this step, it is recommended to re-enable generation of PHY initiated Update requests (dfi_phyupd_req). If using a Synopsys PHY, this can be done via the PUB's DSGCR.PUREN.

.

9.2.4.9.3 Power removal flow

Table 9-11. Power Removal

Step	Description	Comment
1	Write 0 to PCTRL_n.port_en	Blocks AXI port(s) from taking anymore transactions

Table continues on the next page...

Table 9-11. Power Removal (continued)

Step	Description	Comment
2	Poll PSTAT.rd_port_busy_n = 0 Poll PSTAT.wr_port_busy_n = 0	Wait unit all AXI ports are idle
3	Write 0 to SBRCTL.scrub_en	Disable SBR, only required if SBR instantiated
4	Poll SBRSTAT.scrub_busy = 0	Indicates that there are no outstanding SBR read commands, only required if SBR instantiated
5	Write 1 to PWRCTL.selfref_sw	Cause system to move to self-refresh state
6	Poll STAT.selfref_type= 2'b10	Wait until self-refresh state entered
7	Place IOs in retention mode	Refer to relevant PHY databook for more information
8	Remove power	

Table 9-12. Re-enabling the power

Step	Description	Comment
1	Enable Power	
2	Reset controller / PHY by driving core_ddrc_rstn = 1'b0, aresetn_n = 1'b0, presetn = 'b0	
3	Remove APB reset, presetn = 1'b1, and re-reprogram the registers to pre-power removal values	
4	Program INIT0.skip_dram_init = 2'b11	Skips the DRAM init routine and starts up in self-refresh mode
5	Programs PWRCTL.selfref_sw = 1'b1	Keeps the controller in self-refresh mode
6	Program DFIMISC.dfi_init_complete_en to 1'b0	PHY initialization needs to be rerun so set to 0 until initialization complete
7	Remove the core reset core_ddrc_rstn = 1'b1 aresetn_n = 1'b1	
8	Remove IOs from retention mode	Refer to relevant PHY databook for more information
9	Run PHY initialization / training as required	Refer to relevant PHY databook for more information
10	Program DFIMISC.dfi_init_complete_en to 1'b1	Indicates to controller that PHY has completed re- training / initialization
11	Program PWRCTL.selfref_sw = 1'b0	trigger self-refresh exit
12	Poll STAT.selfref_type = 2'b00	Wait until self-refresh state is exited
13	Poll STAT.operating_mode for Normal Mode entry	
14	Write PCTRL.port_en = 1	AXI port(s) are no longer blocked from taking transactions
15	Write 1 to SBRCTL.scrub_en	Enable SBR if desired, only required if SBR instantiated

9.2.4.10 Mode register reads and writes

This section explains how to perform mode register reads and writes via software. Mode Register Reads (MRR) are applicable only to LPDDR2 / LPDDR3, and are used to read configuration and status data from mode registers in the SDRAM. Mode Register Writes (MRW or MRS) are applicable to all supported DDR protocols, and are used to write configuration data to mode registers in the SDRAM.

Access to the mode register is initiated by programming the MRCTRL0 and MRCTRL1 registers (see Mode Register Read / Write Control Register 0 (DDRC_MRCTRL0) and Mode Register Read / Write Control Register 1 (DDRC_MRCTRL1)). This must be done in three steps:

1. Poll MRSTAT.mr_wr_busy until it is '0'. This checks that there is no outstanding MR transaction. No writes should be performed to MRCTRL0 and MRCTRL1 if MRSTAT.mr_wr_busy = 1.
2. Write the MRCTRL0.mr_type, MRCTRL0.mr_addr, MRCTRL0.mr_rank and (for MRWs) MRCTRL1.mr_data to define the MR transaction.
3. In a separate APB transaction, write the MRCTRL0.mr_wr to 1. This bit is self-clearing, and triggers the MR transaction. The DDRMC then asserts the MRSTAT.mr_wr_busy while it performs the MR transaction to SDRAM, and no further accesses can be initiated until it is deasserted.

Some additional notes on mode register transactions are as follows:

- MRW transactions can be specified for either any single rank, or any combination of several ranks, by programming MRCTRL1.mr_rank.
- MRR transactions should only be performed to one rank at a time, to avoid bus contention.
- When a MRR is performed, the mode register contents are available on hif_mrr_data[7:0], qualified by hif_mrr_data_valid, after the mode register read command is issued by the DDRMC to the SDRAM.

9.2.4.10.1 Mode register write

The Mode Register Write (MRW) command is used to write configuration data to mode registers.

For non-LPDDR2 / non-LPDDR3 SDRAMs, MRW on <MR addr> with <MR Data> is triggered by writing MRCTRL0.mr_wr = '1', MRCTRL0.mr_type = '0', MRCTRL0.mr_addr = <MR addr>, MRCTRL1.mr_data = <MR Data> and MRCTRL0.mr_rank = <MR rank> for one clock.

For LPDDR2 / LPDDR3 SDRAMs, MRW on <MR addr> with <MR Data> is triggered by writing MRCTRL0.mr_wr = ‘1’, MRCTRL0.mr_type = ‘0’, MRCTRL1.mr_data[15:8] = <MR addr>, MRCTRL1.mr_data[7:0] = <MR Data> and MRCTRL0.mr_rank = <MR rank> for one clock.

In both the cases, the signal MRSTAT.mr_wr_busy is asserted by the DDRMC while the mode register access is performed, and no further accesses can be initiated until it is deasserted.

For user-initiated MR writes, the user can request mode registers programming operation for either any single rank / all even ranks / all odd ranks only. To implement this, a NUM_RANKS bits wide register is provided to indicate the rank of mode registers programming operation (MRCTRL1.mr_rank [NUM_RANKS - 1: 0]).

9.2.5 Register Descriptions

9.2.5.1 Description introduction

All registers are addressable on 32-bit boundaries; each unused bit or address location is reserved for future use and read back as 0. The register access abbreviations are as follows:

- R – Read only
- W – Write only
- R/W – Read / Write
- R/W1C - Read / Write 1 to clear
- R/WSC – Read / Write Self Clear. When a R/WSC bit is set to 1, the bit remains set until it is cleared by hardware after an internal event.

Some register fields might use the following optional attribute.

Table 9-13. Optional Attributes

Attribute	Description
Testable	As defined by the IP-XACT specification. Possible values are unconstrained, untestable, read only, write as read, restore. Untestablemeans that this field is untestable by a simple automated register test. For example, the read-write access of the register is controlled by a pin or another register. Read only means that you should not write to this register; only read from it. This might apply for a register that modifies the contents of another register.

NOTE

Computation for all the registers in units of 32, 1024, or 4096 clocks

This note refers to register fields whose names include “x32”, “x1024”, or “x4096”.

The DDRMC contains a timer which issues a pulse once every 32 clock cycles, another which issues a pulse once every 1024 clock cycles and another which issues a pulse once every 4096 clock cycles. “x32” register fields count pulses of the 32-cycle timer, “x1024” register fields count pulses of the 1024-cycle timer, and “x4096” register fields count pulses of the 4096-cycle timer. These timers are shared by the logic for all of these register fields, and the various periods start without any guaranteed relation to the phase of this timer.

Therefore for “x32” register fields:

- A programmed value of 0 gives 0 clock cycles
- A programmed value of 1 gives a 1 to 32 cycle delay
- A programmed value of 2 gives a 33 to 64 cycle delay and so on

For “x1024” register fields:

- A programmed value of 0 gives no delay
- A programmed value of 1 gives a 1 to 1,024 cycle delay
- A programmed value of 2 gives a 1,025 to 2,048 cycle delay and so on

For “x4096” register fields:

- A programmed value of 0 gives no delay
- A programmed value of 1 gives a 1 to 4,096 cycle delay
- A programmed value of 2 gives a 4,097 to 8,192 cycle delay and so on

For minimum delays, the control signal must be set to the smallest number for which the resulting delay is ALWAYS ≥ the required delay; for maximum delays or nominal refresh, this must be set such that the delay is ALWAYS ≤ the required delay.

This scheme is used to reduce the gate count that would be required to enforce these constraints more precisely.

NOTE

Most of the SDRAM timing registers are in terms of clock cycles. But the value given in an SDRAM datasheet may be in terms of ns / ps. These are primarily minimum timings. Before

using them to calculate value to program in the register, it is expected that these are divided by tCK (SDRAM clock period) and rounded up to the next integer value if division does not result in a whole integer value.

Exceptions to this rule are related to maximum timings, where these should be rounded down rather than rounded up, if division does not result in a whole integer value.

These include:

- RFSHTMG.t_rfc_nom_x32
- DRAMTMG0.t_ras_max

Certain SDRAM timing registers clarify this by using the following functions in their descriptions:

- RoundUp (X / Y) means that if X divided by Y does not result in a whole integer value, the result should be rounded up to the next integer value. For example, RoundUp (1000 / 150) = 7, RoundUp (1050 / 150) = 7.
- RoundDown (X / Y) means that if X divided by Y does not result in a whole integer value, the result should be rounded down to the next integer value. For example, RoundDown (1000 / 150) = 6, RoundDown (1050 / 150) = 7.

9.2.5.2 DDRC Registers

DDRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

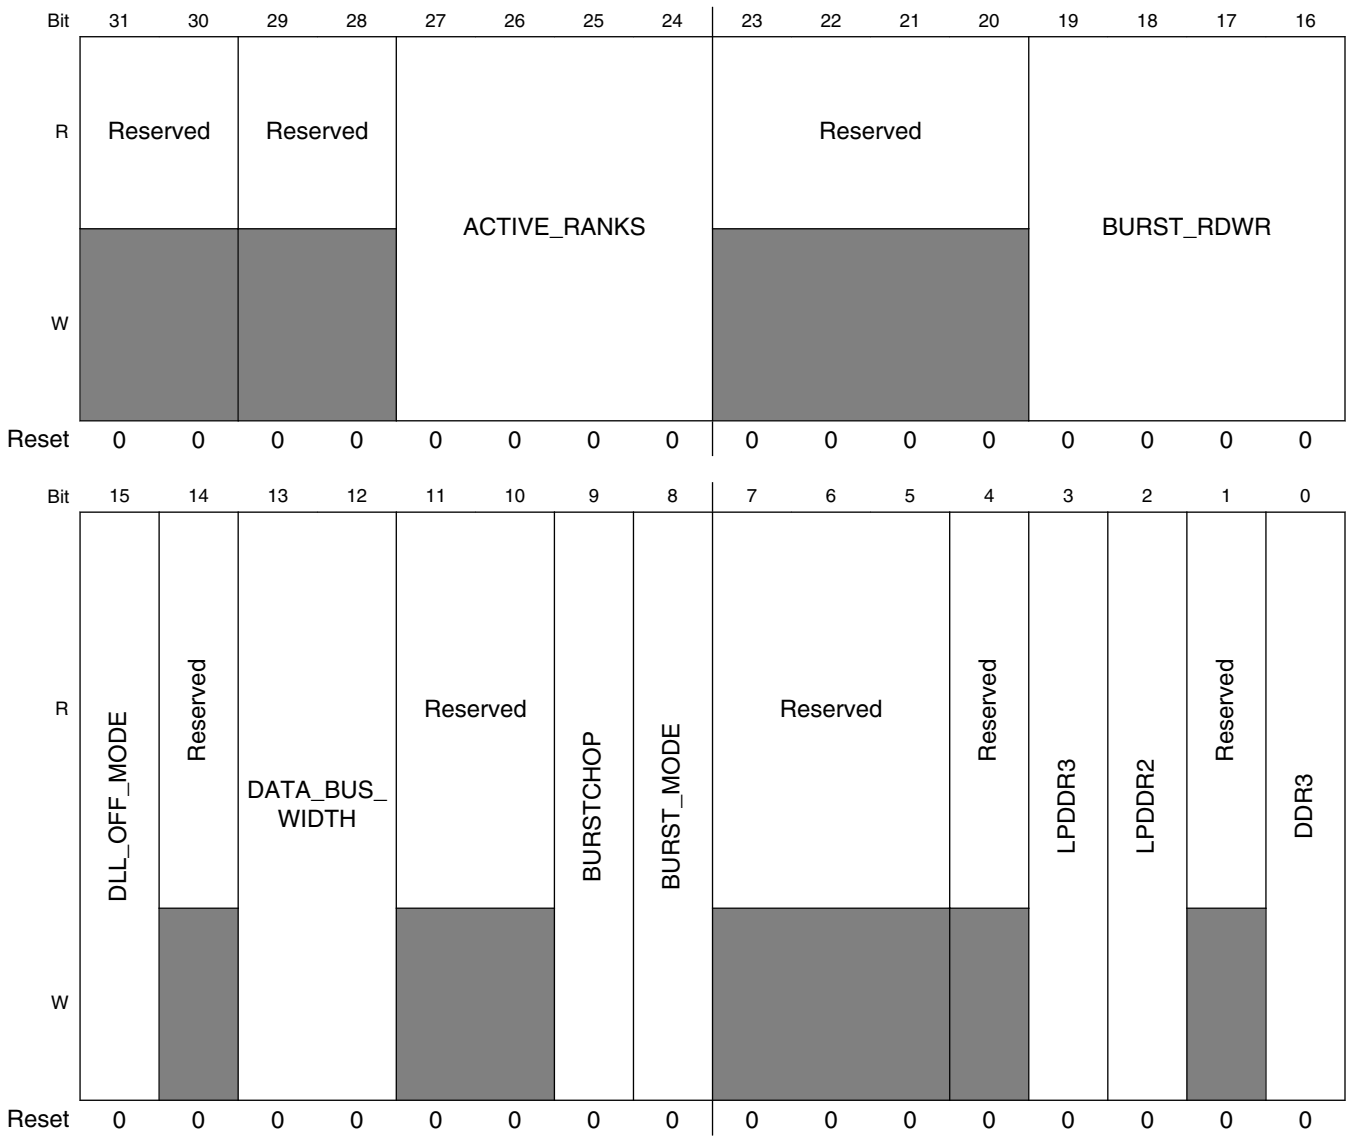
9.2.5.2.1 Master Register (DDRC_MSTR)

Address: 307A_0000h base + 0h offset = 307A_0000h



DDRC_MSTR field descriptions

Field	Description
31–30 Reserved	This field is reserved. Reserved for future use
29–28 Reserved	This field is reserved. Reserved for future use
27–24 ACTIVE_RANKS	Only present for multi-rank configurations. Each bit represents one rank. For two-rank configurations, only bits [25:24] are present. • 1 - populated • 0 - unpopulated

Table continues on the next page...

DDRC_MSTR field descriptions (continued)

Field	Description
	LSB is the lowest rank number. For 2 ranks following combinations are legal: • 01 - One rank • 11 - Two ranks • Others - Reserved. For 4 ranks following combinations are legal: • 0001 - One rank • 0011 - Two ranks • 1111 - Four ranks **Value After Reset**: "(MEMC_NUM_RANKS == 4) ? 0xF :((MEMC_NUM_RANKS == 2) ? 0x3 : 0x1)" **Exists**: MEMC_NUM_RANKS > 1
23–20 Reserved	This field is reserved. Reserved for future use
19–16 BURST_RDWR	All other values are reserved. This controls the burst size used to access the SDRAM. This must match the burst length mode register setting in the SDRAM. Burst length of 2 is not supported with AXI ports when MEMC_BURST_LENGTH is 8. **Value After Reset**: 0x4 **Exists**: Always SDRAM burst length used: 0001 Burst length of 2 (only supported for mDDR) 0010 Burst length of 4 0100 Burst length of 8 1000 Burst length of 16 (only supported for mDDR and LPDDR2)
15 DLL_OFF_MODE	Set to 1 when the DDRC and DRAM has to be put in DLL-off mode for low frequency operation. Set to 0 to put DDRC and DRAM in DLL-on mode for normal frequency operation. **Value After Reset**: 0x0 **Exists**:MEMC_DDR3 == 1
14 Reserved	This field is reserved. Reserved for future use
13–12 DATA_BUS_ WIDTH	Note that half bus width mode is only supported when the SDRAM bus width is a multiple of 16, and quarter bus width mode is only supported when the SDRAM bus width is a multiple of 32 and the configuration parameter MEMC_QBUS_SUPPORT is set. Bus width refers to DQ bus width (excluding any ECC width). **Value After Reset**: 0x0 **Exists**: Always Selects proportion of DQ bus width that is used by the SDRAM: 00 Full DQ bus width to SDRAM 01 Half DQ bus width to SDRAM 10 Quater DQ bus width to SDRAM 11 Reserved
11–10 Reserved	This field is reserved.

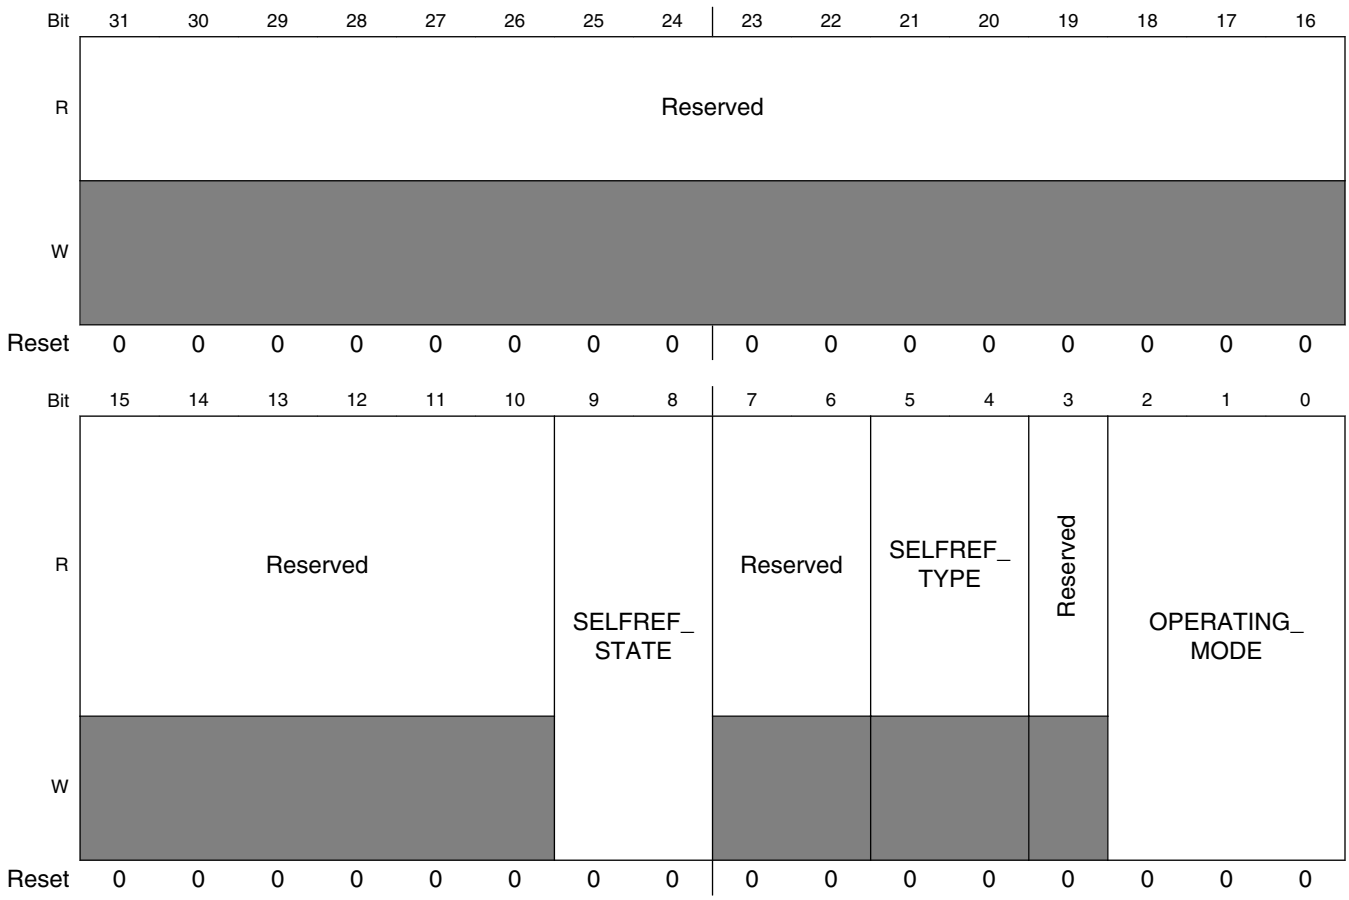
Table continues on the next page...

DDRC_MSTR field descriptions (continued)

Field	Description
9 BURSTCHOP	When set, enable burst-chop in DDR3. This is only supported in HIF configurations (DDRC_INCL_ARB not set) using full bus width mode (MSTR.data_bus_width = 00).**Value After Reset**: 0x0 **Exists**: MEMC_DDR3 == 1
8 BURST_MODE	Indicates Burst Mode **Value After Reset**: 0x0 **Exists**: DDRC_INCL_ARB == 0 0 Sequential burst mode 1 Interleaved burst mode
7–5 Reserved	This field is reserved. Reserved for future use
4 Reserved	This field is reserved.
3 LPDDR3	Select LPDDR3 SDRAM Present only in designs configured to support LPDDR3. **Value After Reset**: 0x0 **Exists**:MEMC_LPDDR3 == 1 1 LPDDR3 SDRAM device in use 0 Non-LPDDR3 device in use
2 LPDDR2	Select LPDDR2 SDRAM Present only in designs configured to support LPDDR2. **Value After Reset**: 0x0 **Exists**:MEMC_LPDDR2 == 1 1 LPDDR2 SDRAM device in use 0 Non-LPDDR2 device in use
1 Reserved	This field is reserved. Reserved for future use
0 DDR3	Only present in design that support DDR3. **Value After Reset**: "(MEMC_DDR3 == 1) ? 0x1 : 0x0" **Exists**:MEMC_DDR3 == 1 Select DDR3 SDRAM 1 DDR3 SDRAM device in use 0 Non-DDR3 device in use

9.2.5.2.2 Operating Mode Status Register (DDRC_STAT)

Address: 307A_0000h base + 4h offset = 307A_0004h



DDRC_STAT field descriptions

Field	Description
31–10 Reserved	This field is reserved. Reserved for future use
9–8 SELFREF_ STATE	Self refresh state This indicates self refresh or self refresh power down state for LPDDR4. This register is used for frequency change and MRR / MRW access during self-refresh. **Value After Reset**:0x0 **Exists**: MEMC_LPDDR4==1 00 SDRAM is not in Self Refresh. 01 Self refresh 1 10 Self refresh power down 11 Self refresh 2
7–6 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_STAT field descriptions (continued)

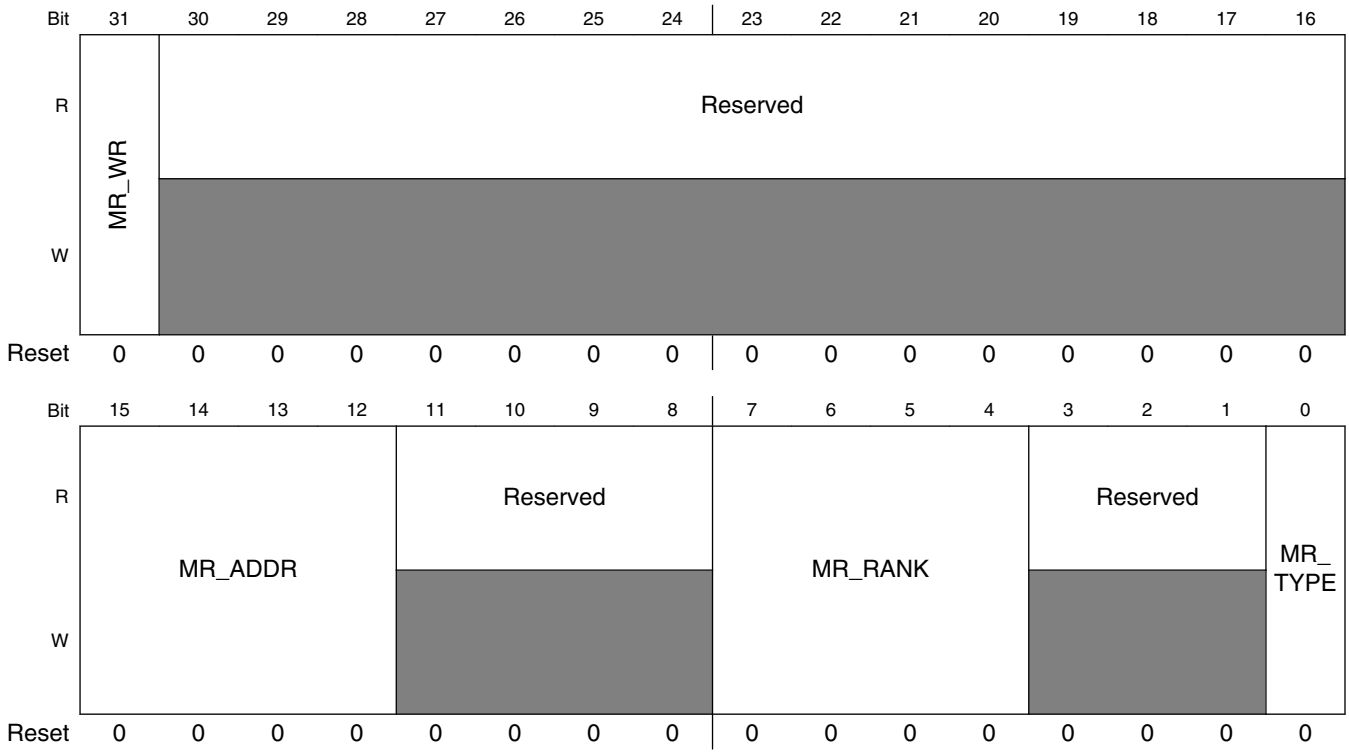
Field	Description
5–4 SELFREF_TYPE	Flags if self-refresh is entered. If it is under automatic, it is self-refresh control only or not.**Value After Reset**: 0x0 **Exists**: Always 00 SDRAM is not in self-refresh. If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates SRE command is still in parity error window or retry is in-progress. 11 SDRAM is in self-refresh and self-refresh is caused by automatic self-refresh only. If retry is enabled, this guarantees SRE command is executed correctly without parity error. 10 SDRAM is in self-refresh and self-refresh is not caused solely under automatic self-refresh control. It could have been caused by Hardware Low Power Interface and/or Software (reg_ddrc_selfref_sw). If retry is enabled, this guarantees SRE command is executed correctly without parity error.
3 Reserved	This field is reserved. Reserved for future use
OPERATING_ MODE	Operating Mode This is 3-bits wide in configurations with mDDR / LPDDR2 / LPDDR3 support and 2-bits in all other configurations.Non-mDDR / LPDDR2 / LPDDR3 and non-DDR4 designs: • 00 - Init • 01 - Normal • 10 - Power-down • 11 - Self-refresh mDDR / LPDDR2 / LPDDR3 or DDR4 designs: • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self-refresh • 1XX - Deep power-down / Maximum Power Saving Mode **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.3 Mode Register Read / Write Control Register 0 (DDRC_MRCTRL0)

NOTE

Do not enable more than one of the following fields simultaneously:
- RCD_INIT_EN
- PDA_EN
- MPR_EN

Address: 307A_0000h base + 10h offset = 307A_0010h



DDRC_MRCTRL0 field descriptions

Field	Description
31 MR_WR	Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the DDRC automatically clears this bit. The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep power-down or MPSM operating modes. **Value After Reset**: 0x0 **Exists**: Always
30–16 Reserved	This field is reserved. Reserved for future use
15–12 MR_ADDR	Address of the mode register that is to be written to Do not Care for LPDDR2 / LPDDR3 (see MRCTRL1.mr_data formode register addressing in LPDDR2 / LPDDR3).This signal is also used for writing to control words of RDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM **Value After Reset**: 0x0 **Exists**: Always 0000 MR0 0001 MR1 0010 MR2 0011 MR3 0100 MR4 0101 MR5 0110 MR6 0111 MR7

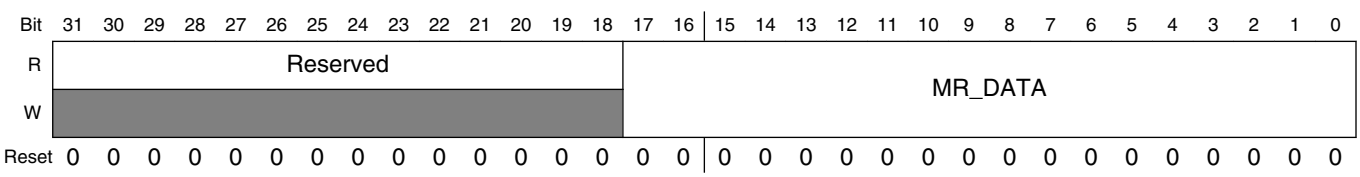
Table continues on the next page...

DDRC_MRCTRL0 field descriptions (continued)

Field	Description
11–8 Reserved	This field is reserved. Reserved for future use
7–4 MR_RANK	Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1. However, for multi-rank UDIMMs / RDIMMs which implement address mirroring, it may be necessary to access ranks individually. Examples (assume DDRC is configured for 4 ranks): • 0x1 - select rank 0 only • 0x2 - select rank 1 only • 0x5 - select ranks 0 and 2 • 0xA - select ranks 1 and 3 • 0xF - select ranks 0, 1, 2 and 3 **Value After Reset**: "(MEMC_NUM_RANKS == 4) ? 0xF :((MEMC_NUM_RANKS == 2) ? 0x3 : 0x1)" **Exists**: Always
3–1 Reserved	This field is reserved.
0 MR_TYPE	Indicates whether the mode register operation is read or write. Only used for LPDDR2 / LPDDR3.**Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2 == 1 0 Write 1 Read

9.2.5.2.4 Mode Register Read / Write Control Register 1 (DDRC_MRCTRL1)

Address: 307A_0000h base + 14h offset = 307A_0014h

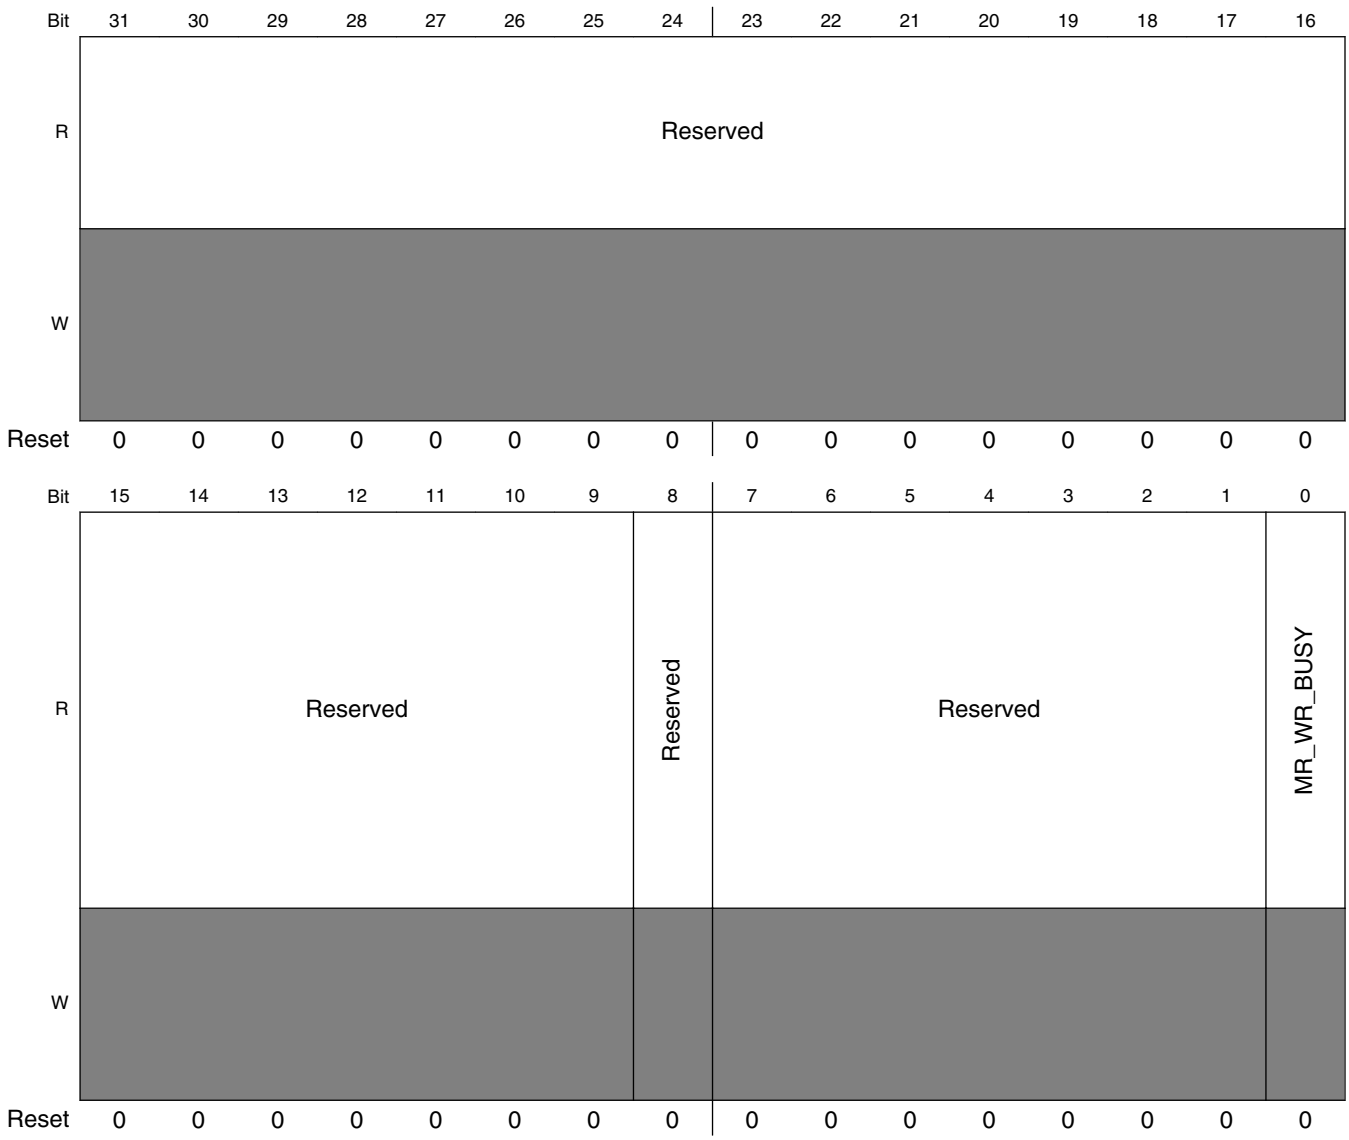


DDRC_MRCTRL1 field descriptions

Field	Description
31–18 Reserved	This field is reserved. Reserved for future use
MR_DATA	Mode register write data for all non- LPDDR2 / non-LPDDR3 modes. For LPDDR2 / LPDDR3, MRCTRL1 [15:0] are interpreted as [15:8] MR Address. [7:0] MR data for writes, do not care for reads. This is 18-bit wide in configurations with support and 16-bit in all other configurations. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.5 Mode Register Read / Write Status Register (DDRC_MRSTAT)

Address: 307A_0000h base + 18h offset = 307A_0018h



DDRC_MRSTAT field descriptions

Field	Description
31–9 Reserved	This field is reserved. Reserved for future use
8 Reserved	This field is reserved.
7–1 Reserved	This field is reserved. Reserved for future use
0 MR_WR_BUSY	The SoC core may initiate a MR write operation only if this signal is low.This signal goes high in the clock after the DDRC accepts the MRW / MRR request. It goes low when the MRW / MRR command is issued

Table continues on the next page...

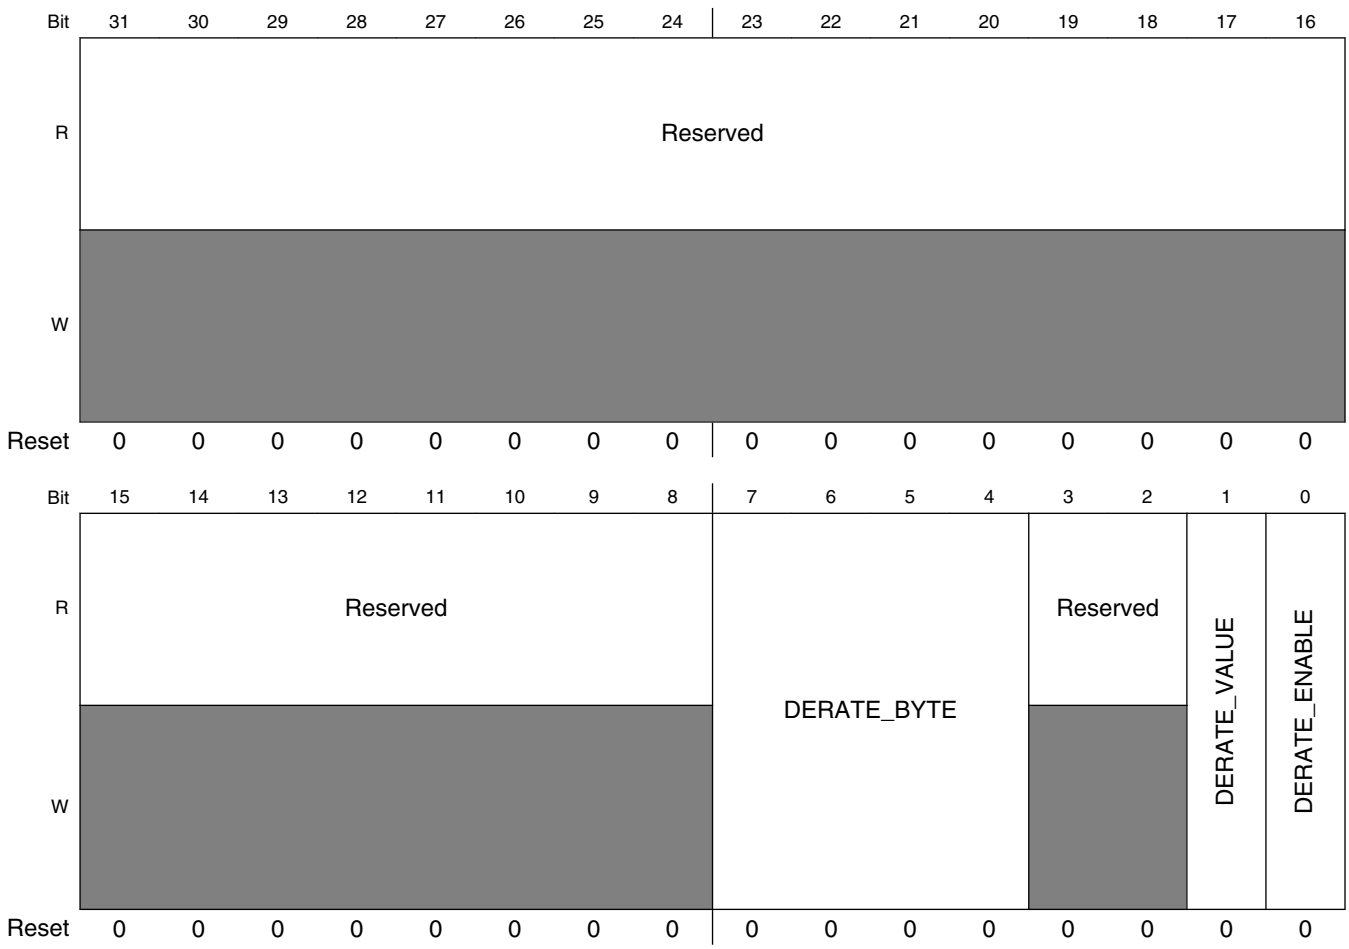
DDRC_MRSTAT field descriptions (continued)

Field	Description
	to the SDRAM. It is recommended not to perform MRW / MRR commands when 'MRSTAT.mr_wr_busy' is high. **Value After Reset**: 0x0 **Exists**: Always 0 Indicates that the SoC core can initiate a mode register write operation 1 Indicates that mode register write operation is in progress

9.2.5.2.6 Temperature Derate Enable Register (DDRC_DERATEEN)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 20h offset = 307A_0020h



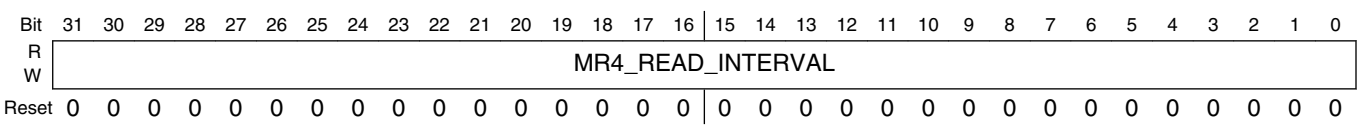
DDRC_DERATEEN field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved for future use
7–4 DERATE_BYTE	Derate byte present only in designs configured to support LPDDR2 or LPDDR3 indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH. **Value After Reset**: 0x0 **Exists**: MEMC_LPDdR2==1
3–2 Reserved	This field is reserved. Reserved for future use.
1 DERATE_VALUE	Derate Value Present only in designs configured to support LPDDR2 or LPDDR3 Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period. It can be 0 or 1 for LPDDR3, depending if +1.875 ns is less than a core_ddrc_core_clk period or not. **Value After Reset**: 0x0 **Exists**:MEMC_LPDDR2==1 0 Derating uses + 1 1 Derating uses + 2
0 DERATE_ ENABLE	Enable Derating Present only in designs configured to support LPDDR2 / LPDDR3. This field must be set to '0' for non-LPDDR2 / LPDDR3 mode. **Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2==1 0 Timing parameter derating is disabled 1 Timing parameter derating is enabled using MR4 read value

9.2.5.2.7 Temperature Derate Interval Register (DDRC_DERATEINT)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 24h offset = 307A_0024h

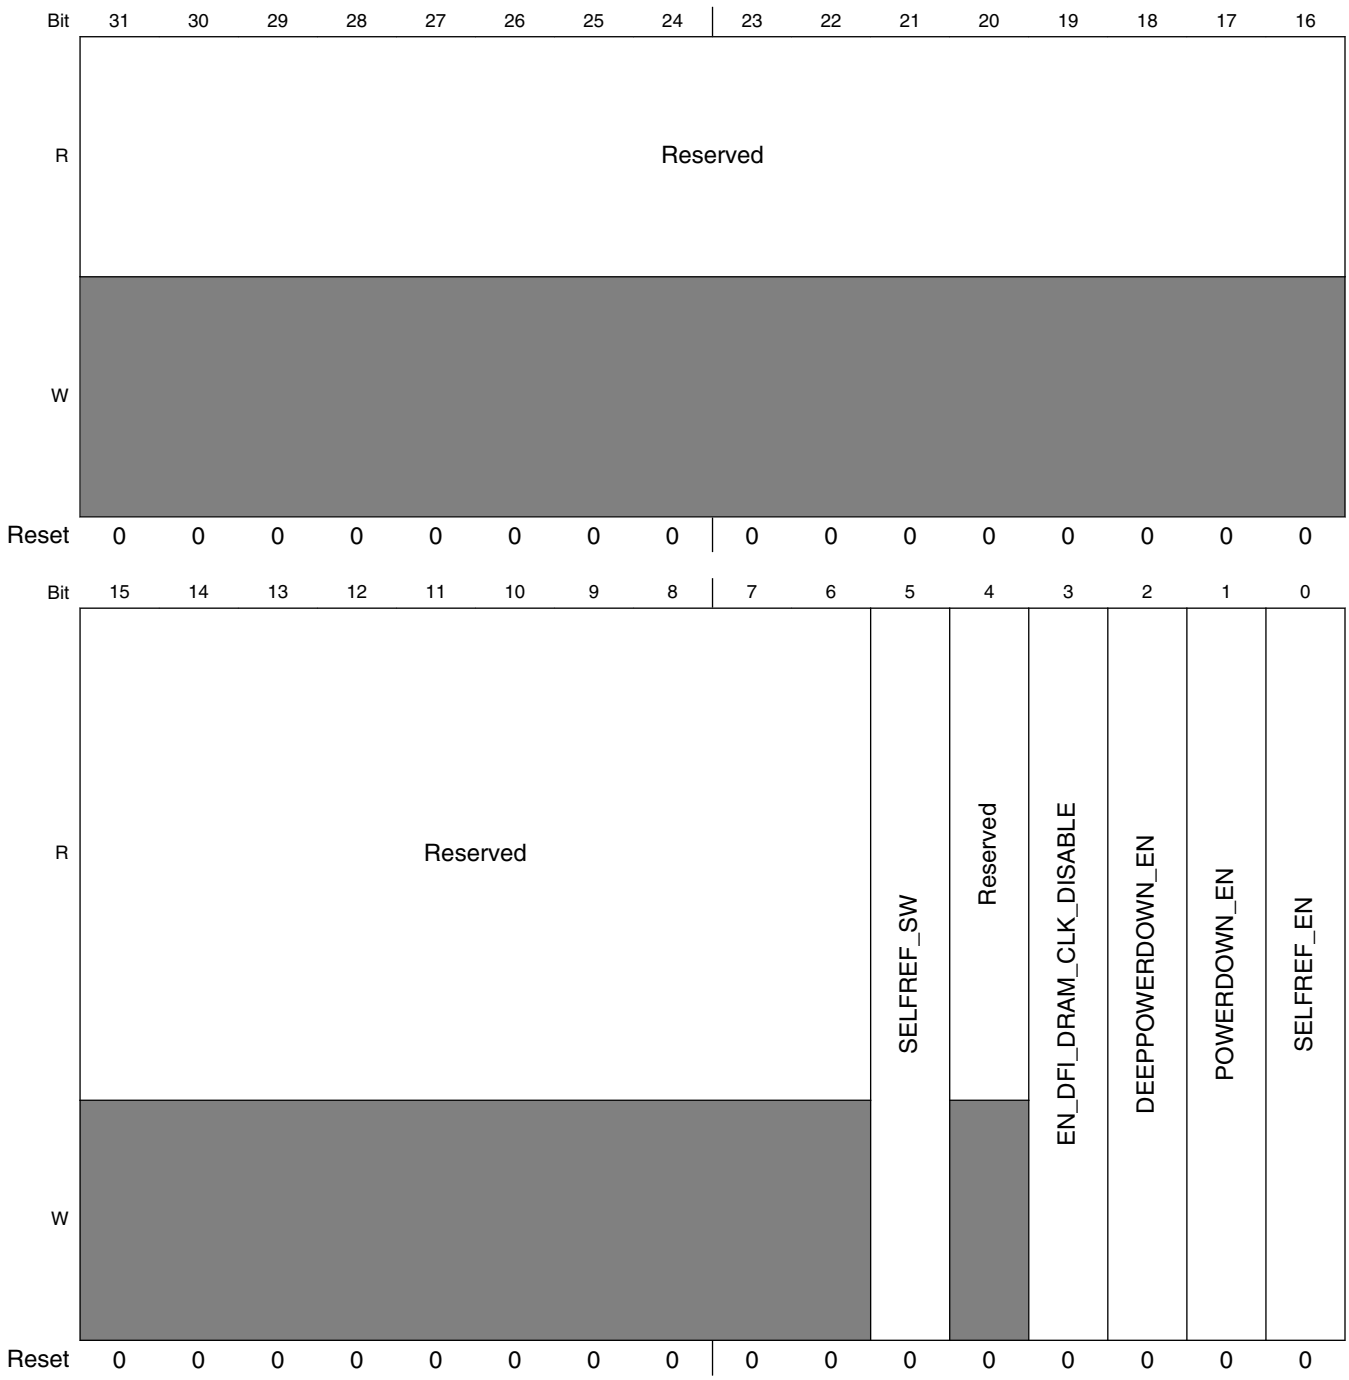


DDRC_DERATEINT field descriptions

Field	Description
MR4_READ_ INTERVAL	Interval between two MR4 reads, used to derate the timing parameters. Present only in designs configured to support LPDDR2 / LPDDR3. This register cannot not be set to zero.**Value After Reset**: 0x800000 **Exists**: MEMC_LPDDR2 == 1

9.2.5.2.8 Low Power Control Register (DDRC_PWRCTL)

Address: 307A_0000h base + 30h offset = 307A_0030h



DDRC_PWRCTL field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_PWRCTL field descriptions (continued)

Field	Description
5 SELFREF_SW	A value 0 of 1 to this register causes system to move to self-refresh state immediately, as long as it is not in INIT or DPD / MPSM operating_mode. This is referred to as Software Entry / Exit to Self-refresh.**Value After Reset**: 0x0 **Exists**: Always 1 Software Entry to Self-refresh 0 Software Exit from Self-refresh
4 Reserved	This field is reserved.
3 EN_DFI_DRAM_CLK_DISABLE	Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM. If set to 0, dfi_dram_clk_disable is never asserted. Assertion of dfi_dram_clk_disable is as follows: In DDR2 / DDR3, can only be asserted in self-refresh.**Value After Reset**: 0x0 **Exists**: Always
2 DEEPPOWERDOWN_EN	When this is 1, DDRC puts the SDRAM into deep power-down mode when the transaction store is empty. This register must be reset to '0' to bring DDRC out of deep power-down mode. Controller performs automatic SDRAM initialization on deep power-down exit. Present only in designs configured to support mDDR or LPDDR2 or LPDDR3. FOR PERFORMANCE ONLY. **Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2 == 1
1 POWERDOWN_EN	If true then the DDRC goes into power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32). This register bit may be re-programmed during the course of normal operation. **Value After Reset**: 0x0 **Exists**: Always
0 SELFREF_EN	If true then the DDRC puts the SDRAM into Self Refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.9 Low Power Timing Register (DDRC_PWRTMG)

Address: 307A_0000h base + 34h offset = 307A_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRC_PWRTMG field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use

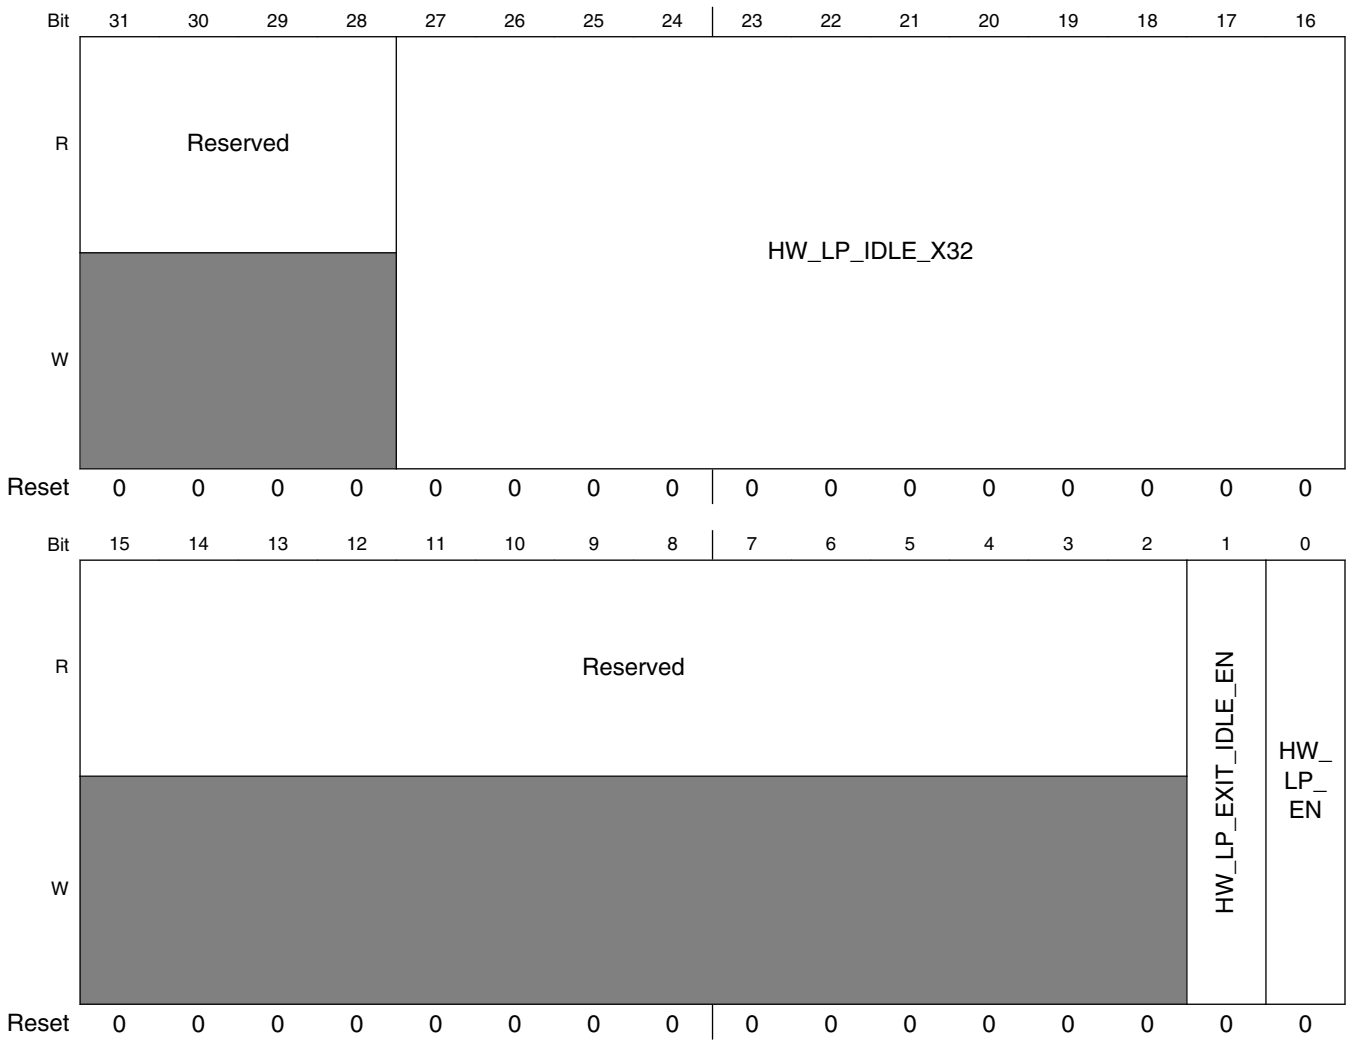
Table continues on the next page...

DDRC_PWRTMG field descriptions (continued)

Field	Description
23–16 SELFREF_TO_X32	After this many clocks of NOP or deselect the DDRC automatically puts the SDRAM into Self Refresh. This must be enabled in the PWRCTL.selfref_en.Unit: Multiples of 32 clocks. FOR PERFORMANCE ONLY. **Value After Reset**: 0x40 **Exists**: Always
15–8 T_DPD_X4096	Minimum deep power-down timeFor mDDR, value from the JEDEC specification is 0 as mDDR exits from deep power-down mode immediately after PWRCTL.deeppowerdown_en is de-asserted. For LPDDR2 / LPDDR3, value from the JEDEC specification is 500 µs. Unit: Multiples of 4096 clocks. Present only in designs configured to support mDDR, LPDDR2 or LPDDR3. FOR PERFORMANCE ONLY. **Value After Reset**: "(MEMC_MOBILE_OR_LPDDR2_EN) ? 0x20 : 0x0" **Exists**: MEMC_LPDDR2 == 1
7–5 Reserved	This field is reserved. Reserved for future use
POWERDOWN_TO_X32	After this many clocks of NOP or deselect the DDRC automatically puts the SDRAM into power-down. This must be enabled in the PWRCTL.powerdown_en. Unit: Multiples of 32 clocks FOR PERFORMANCE ONLY. **Value After Reset**: 0x10 **Exists**: Always

9.2.5.2.10 Hardware Low Power Control Register (DDRC_HWLPCTL)

Address: 307A_0000h base + 38h offset = 307A_0038h



DDRC_HWLPCTL field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–16 HW_LP_IDLE_X32	Hardware idle period. The cactive_ddrc output is driven low if the system is idle for hw_lp_idle * 32 cycles if not in INIT or DPD / MPSM operating_mode. The hardware idle function is disabled when hw_lp_idle_x32 = 0. Unit: Multiples of 32 clocks. FOR PERFORMANCE ONLY. **Value After Reset**: 0x0 **Exists**: Always
15–2 Reserved	This field is reserved. Reserved for future use

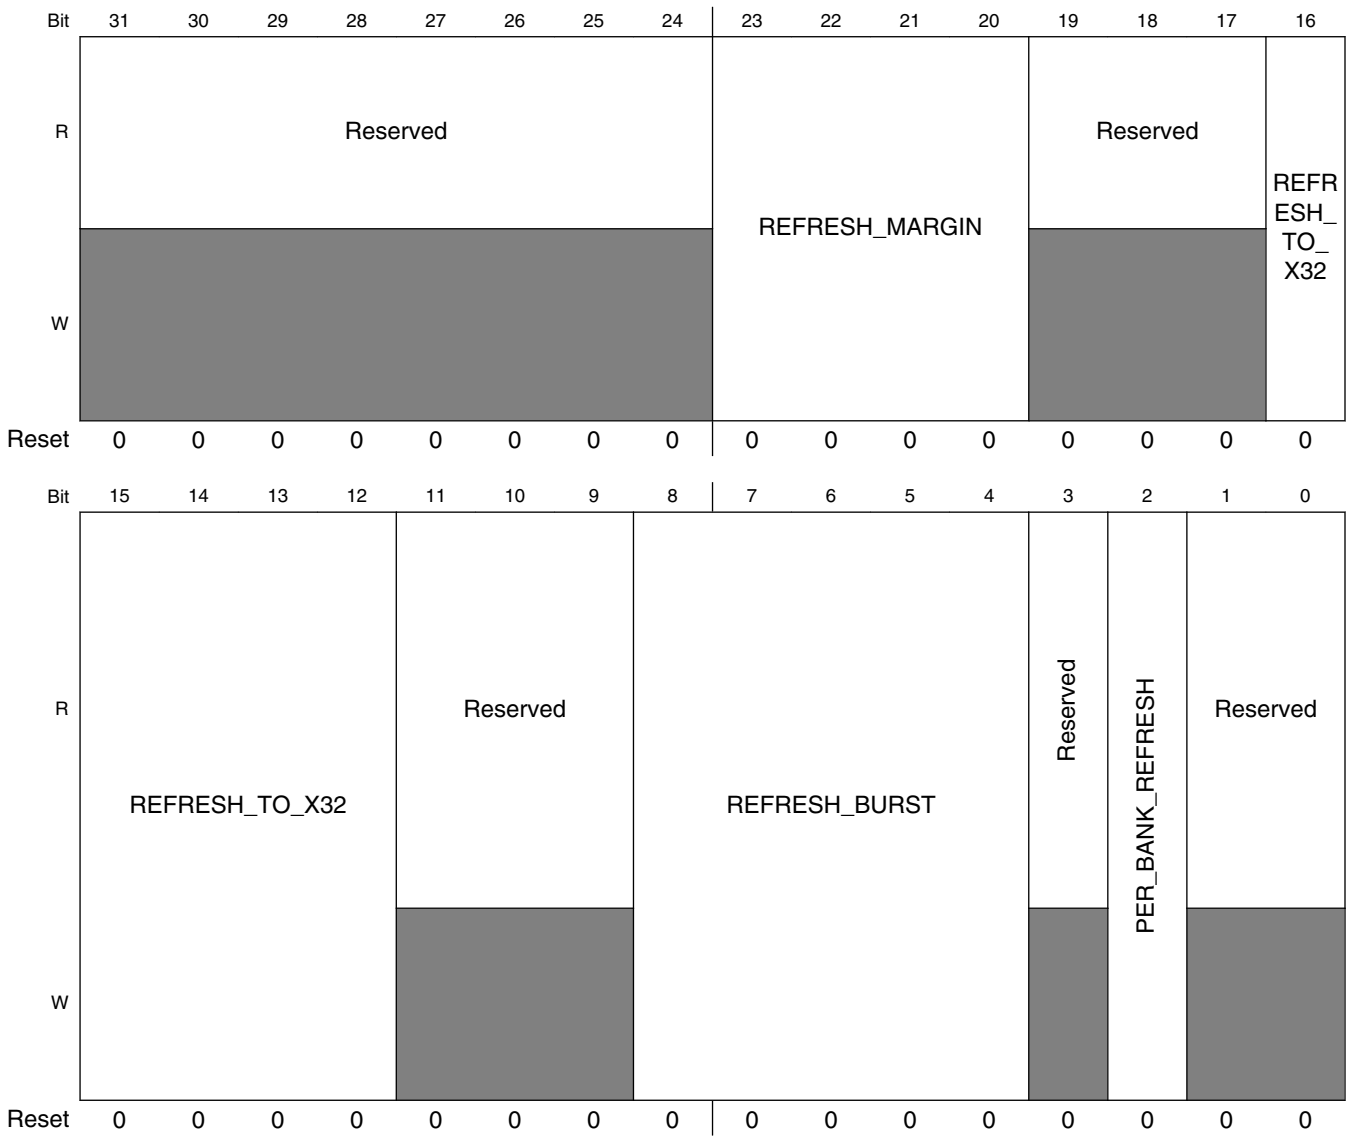
Table continues on the next page...

DDRC_HWLPCTL field descriptions (continued)

Field	Description
1 HW_LP_EXIT_IDLE_EN	When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the automatic clock stop, automatic power down or automatic self-refreshmodes. **NOTE:** It will not cause exit of Self-Refresh that is caused by Hardware Low Power Interface and / or Software (PWRCTL.selfref_sw). **Value After Reset**: 0x1 **Exists**: Always
0 HW_LP_EN	Enable for Hardware Low Power Interface **Value After Reset**: 0x1 **Exists**: Always

9.2.5.2.11 Refresh Control Register 0 (DDRC_RFSHCTL0)

Address: 307A_0000h base + 50h offset = 307A_0050h



DDRC_RFSHCTL0 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–20 REFRESH_MARGIN	Threshold value in number of clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom_x32. Note that, in LPDDR2 / LPDDR3, internally used t_rfc_nom_x32 may be equal to RFSHTMG.t_rfc_nom_x32 >> 2 if derating is enabled (DERATEEN.derate_enable = 1). Otherwise, internally used t_rfc_nom_x32 will be equal to RFSHTMG.t_rfc_nom_x32. Unit: Multiples of 32 clocks. **Value After Reset**: 0x2

Table continues on the next page...

DDRC_RFSHCTL0 field descriptions (continued)

Field	Description
	Exists: Always
19–17 Reserved	This field is reserved. Reserved for future use
16–12 REFRESH_TO_X32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst + 1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by thisRFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. **Value After Reset**: 0x10 **Exists**: Always
11–9 Reserved	This field is reserved. Reserved for future use
8–4 REFRESH_BURST	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes. For information on burst refresh feature refer to section 3.9 of DDR2 JEDEC specification - JESD79-2F.pdf. For DDR2 / DDR3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over 8 * t_{REFI} cycles using the burst refresh feature. **Value After Reset**: 0x0 **Exists**: Always 0 Single refresh 1 Burst-of-2 refresh 7 Burst-of-8 refresh
3 Reserved	This field is reserved. Reserved for future use
2 PER_BANK_REFRESH	Per bank refresh allows traffic to flow to other banks. Per bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3 devices. Present only in designs configured to support LPDDR2 / LPDDR3.**Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2 == 1 1 Per bank refresh 0 All bank refresh
Reserved	This field is reserved. Reserved for future use

9.2.5.2.12 Refresh Control Register 1 (DDRC_RFSHCTL1)

Exists: MEMC_NUM_RANKS > 1

Address: 307A_0000h base + 54h offset = 307A_0054h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
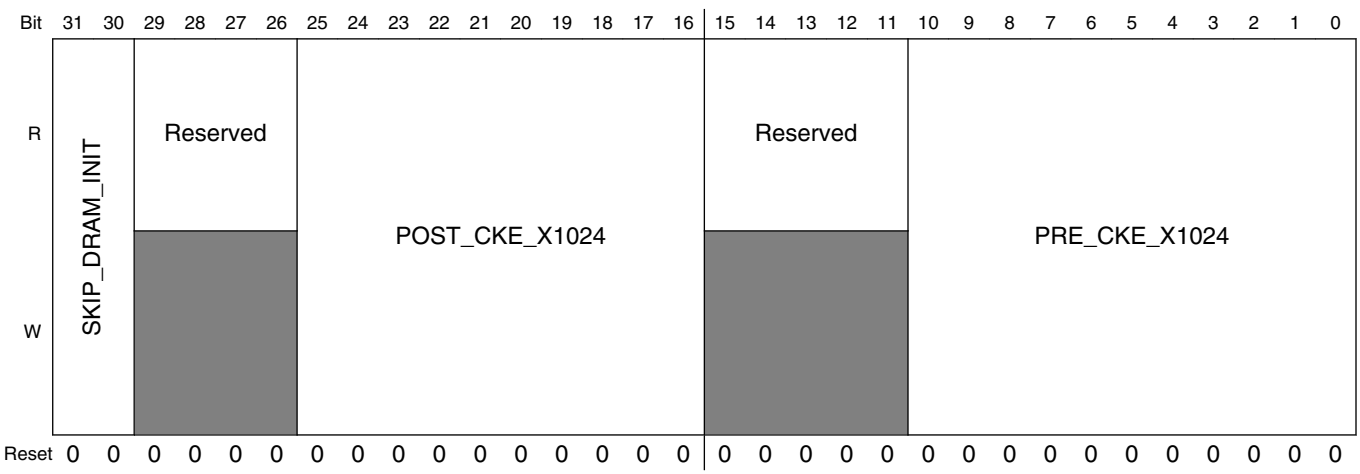
	Unit: Clocks. **Value After Reset**: 0x8c **Exists**: Always

9.2.5.2.15 SDRAM Initialization Register 0 (DDRC_INIT0)

Exists: Always

Address: 307A_0000h base + D0h offset = 307A_00D0h



DDRC_INIT0 field descriptions

Field	Description
31–30 SKIP_DRAM_INIT	If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed. **Value After Reset**: 0x0 **Exists**: Always 00 SDRAM Intialization routine is run after power-up. 01 SDRAM Intialization routine is skipped after power- up. Controller starts up in Normal Mode. 11 SDRAM Intialization routine is skipped after power- up. Controller starts up in Self-refresh Mode. 10 SDRAM Intialization routine is run after power-up.
29–26 Reserved	This field is reserved. Reserved for future use
25–16 POST_CKE_X1024	Cycles to wait after driving CKE high to start the SDRAM initialization sequence. Unit: 1024 clocks. DDR2 typically requires a 400 ns delay, requiring this value to be programmed to 2 at all clock speeds. LPDDR2 / LPDDR3 typically requires this to be programmed for a delay of 200 us.

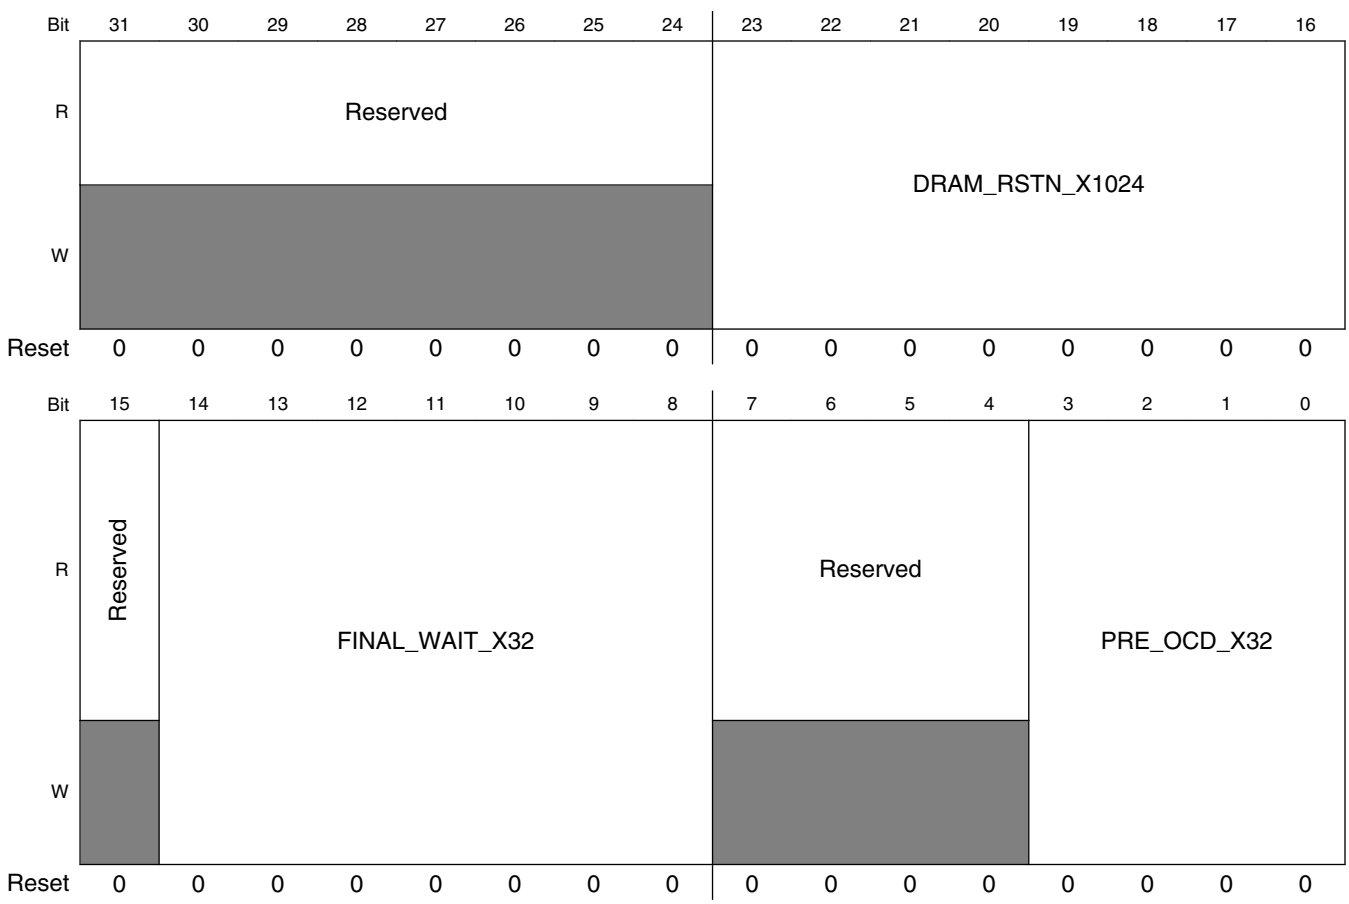
Table continues on the next page...

DDRC_INIT0 field descriptions (continued)

Field	Description
	For configurations with MEMC_FREQ_RATIO = 2, program this to JEDEC spec value divided by 2, and round it up to next integer value. **Value After Reset**: 0x2 **Exists**: Always
15–11 Reserved	This field is reserved. Reserved for future use
PRE_CKE_X1024	Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence. Unit: 1024 clock cycles. DDR2 specifications typically require this to be programmed for a delay of ≥ 200 µs. LPDDR2 / LPDDR3: tINIT1 of 100 ns (min) For configurations with MEMC_FREQ_RATIO = 2, program this to JEDEC spec value divided by 2, and round it up to next integer value. **Value After Reset**: 0x4e **Exists**: Always

9.2.5.2.16 SDRAM Initialization Register 1 (DDRC_INIT1)

Address: 307A_0000h base + D4h offset = 307A_00D4h



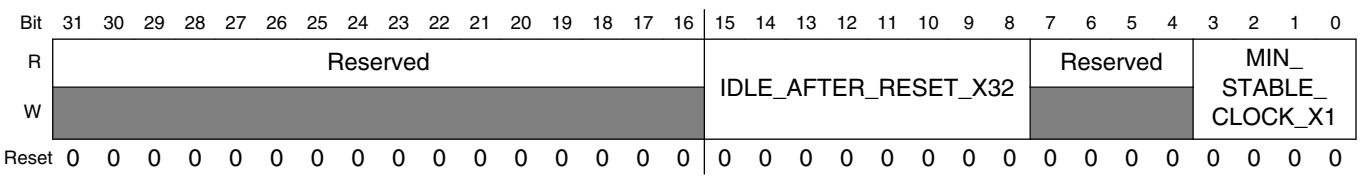
DDRC_INIT1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–16 DRAM_RSTN_X1024	Number of cycles to assert SDRAM reset signal during init sequence. This is only present for designs supporting DDR3 devices. **Value After Reset**: 0x0 **Exists**: MEMC_DDR3 == 1
15 Reserved	This field is reserved. Reserved for future use
14–8 FINAL_WAIT_X32	Cycles to wait after completing the SDRAM initialization sequence before starting the dynamic scheduler. Unit: Counts of a global timer that pulses every 32 clock cycles. There is no known specific requirement for this; it may be set to zero. **Value After Reset**: 0x0 **Exists**: Always
7–4 Reserved	This field is reserved. Reserved for future use
PRE_OCD_X32	Wait period before driving the OCD complete command to SDRAM. Unit: Counts of a global timer that pulses every 32 clock cycles. There is no known specific requirement for this; it may be set to zero. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.17 SDRAM Initialization Register 2 (DDRC_INIT2)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + D8h offset = 307A_00D8h



DDRC_INIT2 field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved for future use
15–8 IDLE_AFTER_RESET_X32	Idle time after the reset command, tINIT4. Present only in designs configured to support LPDDR2. Unit: 32 clock cycles.

Table continues on the next page...

DDRC_INIT2 field descriptions (continued)

Field	Description
	Value After Reset: (MEMC_LPDDR2) ? 0xd : 0x0 **Exists**: MEMC_LPDDR2 == 1
7–4 Reserved	This field is reserved. Reserved for future use
MIN_STABLE_ CLOCK_X1	Time to wait after the first CKE high, tINIT2. Present only in designs configured to support LPDDR2 / LPDDR3. Unit: 1 clock cycle. LPDDR2 / LPDDR3 typically requires 5 x tCK delay. **Value After Reset**: (MEMC_LPDDR2) ? 0x5 : 0x0 **Exists**: MEMC_LPDDR2 == 1

9.2.5.2.18 SDRAM Initialization Register 3 (DDRC_INIT3)

Address: 307A_0000h base + DCh offset = 307A_00DCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRC_INIT5 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–16 DEV_ZQINIT_X32	ZQ initial calibration, tZQINIT. Present only in designs configured to support DDR3 or LPDDR2 / LPDDR3. Unit: 32 clock cycles. DDR3 typically requires 512 clocks.

Table continues on the next page...

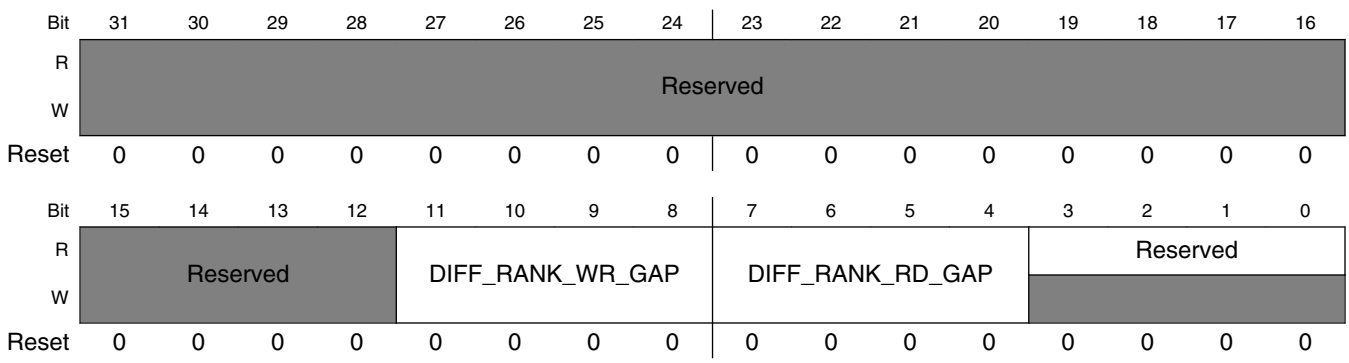
DDRC_INIT5 field descriptions (continued)

Field	Description
	LPDDR2 / LPDDR3 requires 1 µs. **Value After Reset**: 0x10 **Exists**: MEMC_DDR3 == 1 || MEMC_LPDDR2 == 1
15–10 Reserved	This field is reserved. Reserved for future use
MAX_AUTO_ INIT_X1024	Maximum duration of the auto initialization, tINIT5. Present only in designs configured to support LPDDR2 / LPDDR3. LPDDR2 / LPDDR3 typically requires 10 µs. **Value After Reset**: (MEMC_LPDDR2) ? 0x4 : 0x0 **Exists**: MEMC_LPDDR2 == 1

9.2.5.2.21 Rank Control Register (DDRC_RANKCTL)

Exists: MEMC_NUM_RANKs > 1

Address: 307A_0000h base + F4h offset = 307A_00F4h



DDRC_RANKCTL field descriptions

Field	Description
31–12 Reserved	This field is reserved. Reserved for future use
11–8 DIFF_RANK_ WR_GAP	**Description**: Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive writes to different ranks. This is used to switch the delays in the PHY to match the rank requirements. The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during writes. For configurations with MEMC_FREQ_RATIO = 2, program this to (N / 2) and round it up to the next integer value. N is value required by PHY, in terms of PHY clocks. If write preamble is set to 2tCK (DDR4 only), it increases by 1. For configurations with MEMC_FREQ_RATIO = 1, program this to N + 1.

Table continues on the next page...

DDRC_RANKCTL field descriptions (continued)

Field	Description
	For configurations with MEMC_FREQ_RATIO = 2, program this to ((N + 1) / 2) and round it up to the next integer value. **Value After Reset**: 0x6 **Exists**: MEMC_NUM_RANKS > 1
7–4 DIFF_RANK_ RD_GAP	**Description**: Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive reads to different ranks. This is used to switch the delays in the PHY to match the rank requirements. The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during reads. For configurations with MEMC_FREQ_RATIO = 2, program this to (N / 2) and round it up to the next integer value. N is value required by PHY, in terms of PHY clocks. If read preamble is set to 2tCK (DDR4 only), it increases by 1. For configuration with MEMC_FREQ_RATIO = 1, program this to N + 1. For configuration with MEMC_FREQ_RATIO = 2, program this to ((N + 10 / 2) and round it up to the next integer value. **Value After Reset**: 0x6 **Exists**: MEMC_NUM_RANKS > 1

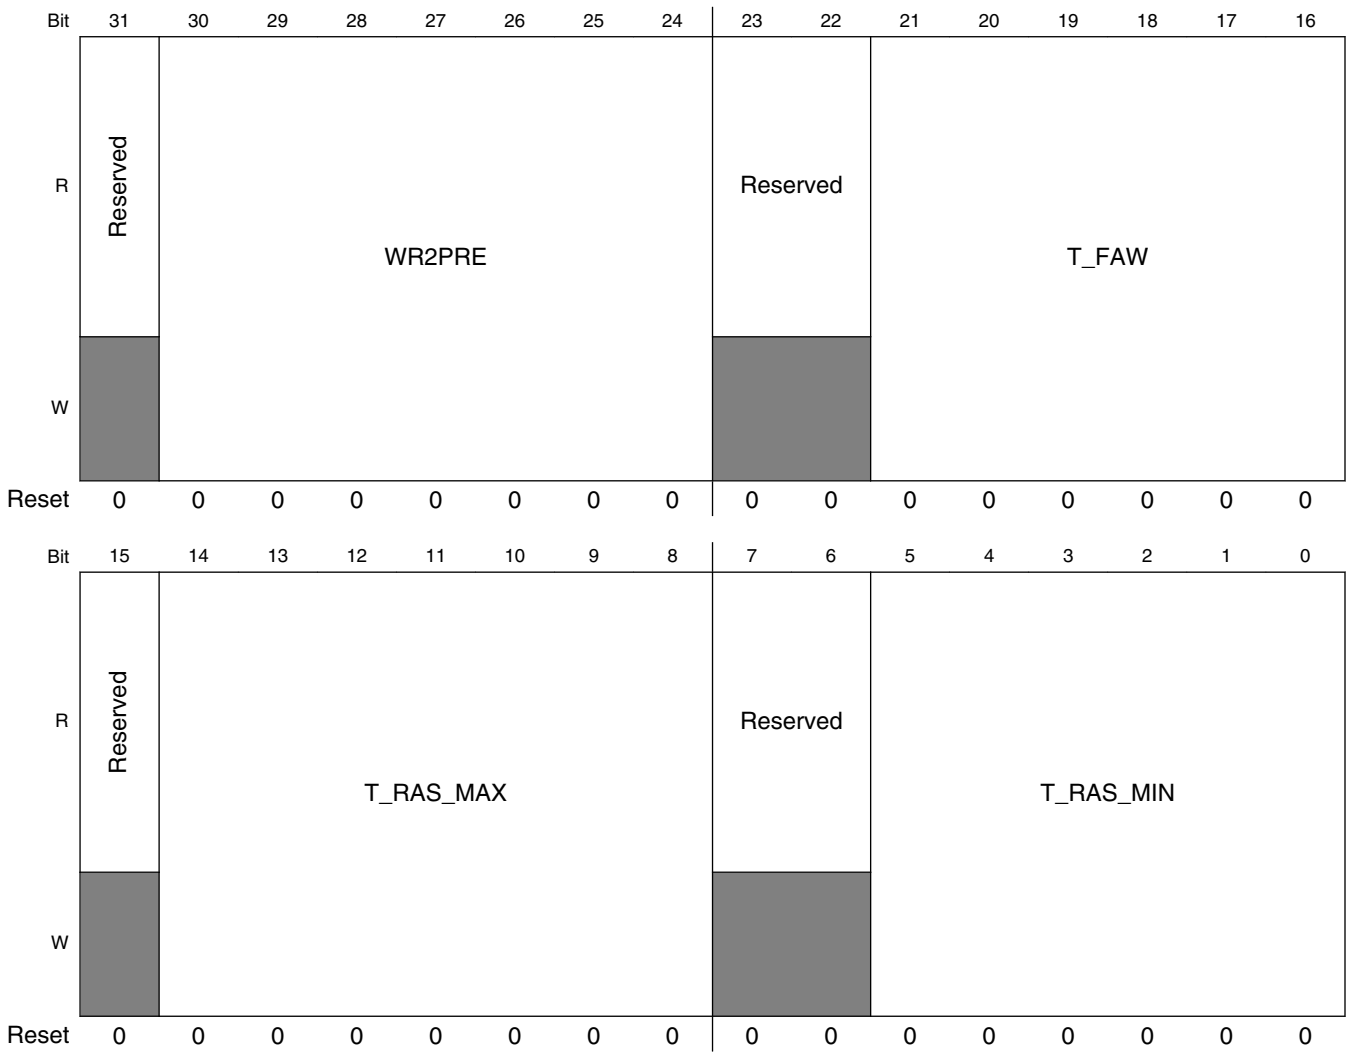
9.2.5.2.22 SDRAM Timing Register 0 (DDRC_DRAMTMG0)

Address: 307A_0000h base + 100h offset = 307A_0100h



DDRC_DRAMTMG0 field descriptions

Field	Description
31 Reserved	This field is reserved. Reserved for future use
30–24 WR2PRE	Minimum time between write and precharge to same bank Unit: Clocks Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @ 400 MHz and less for lower frequencies where: • WL = write latency • BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present. • tWR = Write recovery time. This comes directly from the SDRAMspecification.

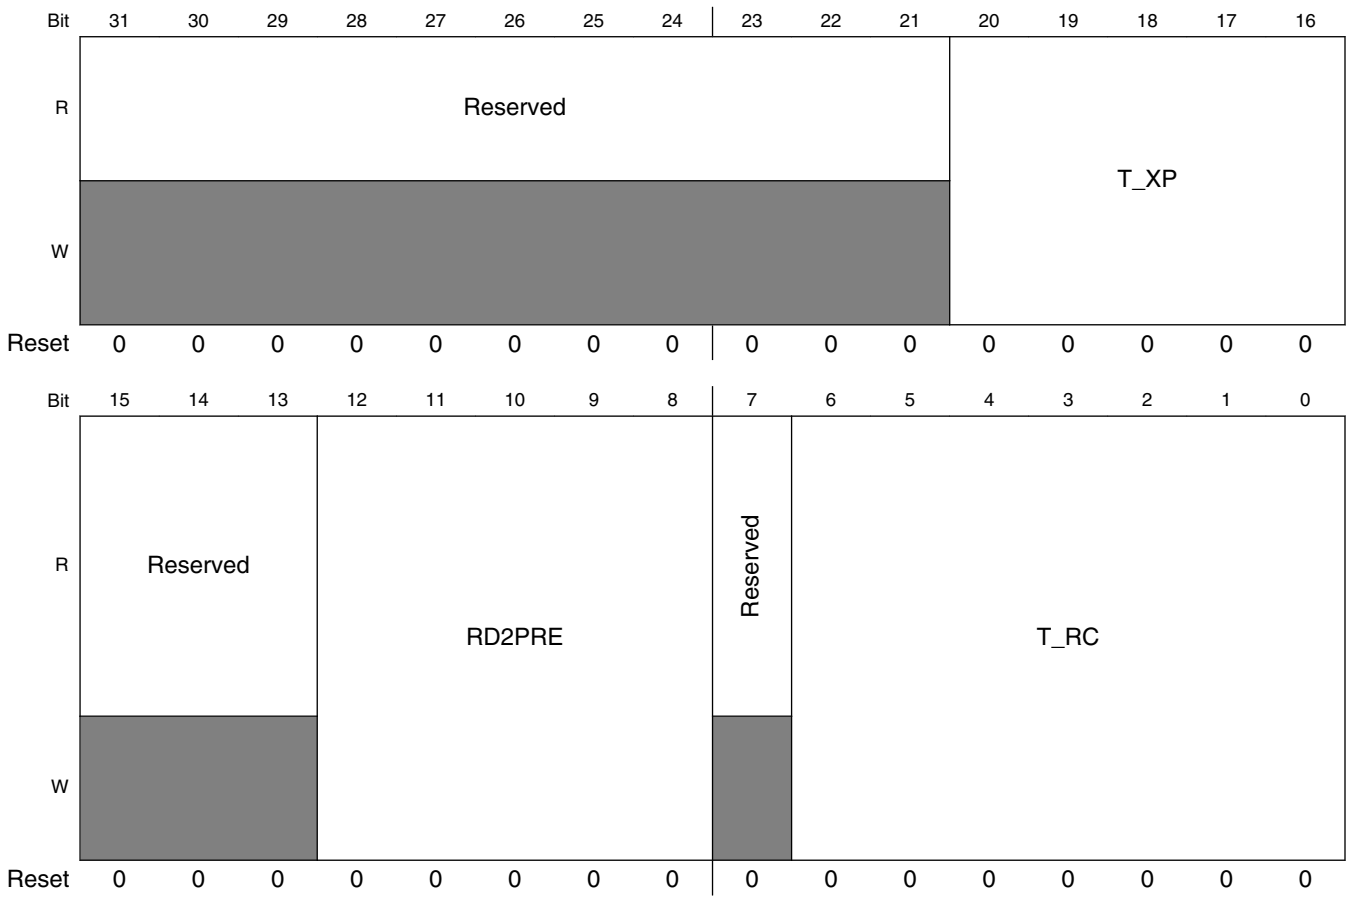
Table continues on the next page...

DDRC_DRAMTMG0 field descriptions (continued)

Field	Description
	Add one extra cycle for LPDDR2/LPDDR3 for this parameter. For configurations with MEMC_FREQ_RATIO = 2, 1T mode, divide the above value by 2. No rounding up. For configurations with MEMC_FREQ_RATIO = 2, 2T mode, divide the above value by 2 and add 1. No rounding up. **Value After Reset**: 0xf **Exists:**Always
23–22 Reserved	This field is reserved. Reserved for future use
21–16 T_FAW	tFAW Valid only when 8 or more banks (or banks x bank groups) are present. In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles. For configurations with MEMC_FREQ_RATIO = 2, program this to (tFAW / 2) and round up to next integer value. In a 4-bank design, set this register to 0x1 independent of the MEMC_FREQ_RATIO configuration. Unit: Clocks **Value After Reset**: 0x10 **Exists**: Always
15 Reserved	This field is reserved. Reserved for future use
14–8 T_RAS_MAX	tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open. Minimum value of this register is 1. Zero is invalid. For configurations with MEMC_FREQ_RATIO = 2, program this to (tRAS (max) - 1) / 2. No rounding up. Unit: Multiples of 1024 clocks. **Value After Reset**: 0x1b **Exists**: Always
7–6 Reserved	This field is reserved. Reserved for future use
T_RAS_MIN	tRAS (min): Minimum time between activate and precharge to the same bank. For configurations with MEMC_FREQ_RATIO = 2, 1T mode, program this to tRAS(min) / 2. No rounding up. For configurations with MEMC_FREQ_RATIO = 2, 2T mode, program this to (tRAS (min) / 2 + 1). No rounding up of the division operation. Unit: Clocks **Value After Reset**: 0xf **Exists**: Always

9.2.5.2.23 SDRAM Timing Register 1 (DDRC_DRAMTMG1)

Address: 307A_0000h base + 104h offset = 307A_0104h



DDRC_DRAMTMG1 field descriptions

Field	Description
31–21 Reserved	This field is reserved. Reserved for future use
20–16 T_XP	tXP: Minimum time after power-down exit to any operation. For DDR3, this should be programmed to tXPDLL if slow powerdown exit is selected in MR0[12]. Units: Clocks **Value After Reset**: 0x8 **Exists**: Always
15–13 Reserved	This field is reserved. Reserved for future use
12–8 RD2PRE	tRTP: Minimum time from read to precharge of same bank. • DDR3: tAL + max (tRTP, 4) • DDR4: Max of following two equations: tAL + max (tRTP, 4) or, RL + BL / 2 - tRP. • LPDDR2: Depends on if it's LPDDR2-S2 or LPDDR2-S4: • LPDDR3: BL / 2 + max (tRTP, 4) - 4

Table continues on the next page...

For configurations with MEMC_FREQ_RATIO = 2, divide the value calculated using the above equation by 2, and round it up to next integer. This register field is not required for DDR2 and DDR3 as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols Unit: clocks **Value After Reset**: 0x5 **Exists**: MEMC_MOBILE==1 || MEMC_LPDDR2==1 || MEMC_DDR4==1 || MEMC_TRAINING==1
15–14 Reserved	This field is reserved. Reserved for future use
13–8 RD2WR	DDR2/3/mDDR: RL + BL / 2 - WL DDR4: RL + BL / 2 + 1 +WR_PREAMBLE - WL LPDDR2/LPDDR3: RL + BL / 2 + RU (tDQSCKmax / tCK) + 1 - WL. Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Unit: Clocks. Where • WL = write latency • BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. • RL = read latency = CAS latency • WR_PREAMBLE = write preamble. This is unique to DDR4. For configurations with MEMC_FREQ_RATIO = 2, divide the value calculated using the above equation by 2, and round it up to next integer. Value After Reset: 0x6 Exists: Always
7–6 Reserved	This field is reserved. Reserved for future use
WR2RD	DDR4: CWL + PL + BL / 2 + tWTR_L Others: CWL + BL / 2 + tWTR In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Unit: Clocks. Where: • CWL = CAS write latency

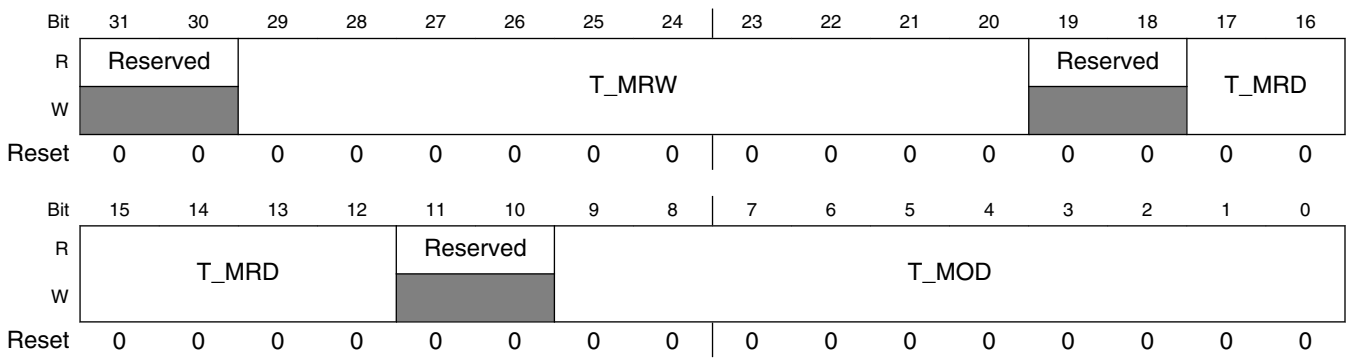
Table continues on the next page...

DDRC_DRAMTMG2 field descriptions (continued)

Field	Description
	• PL = Parity latency • BL = Burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. • tWTR_L = Internal write to read command delay for same bank group. This comes directly from the SDRAM specification. • tWTR = Internal write to read command delay. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR2 / LPDDR3 operation. For configurations with MEMC_FREQ_RATIO = 2, divide the value calculated using the above equation by 2, and round it up to next integer. **Value After Reset**: 0xd **Exists**: Always

9.2.5.2.25 SDRAM Timing Register 3 (DDRC_DRAMTMG3)

Address: 307A_0000h base + 10Ch offset = 307A_010Ch



DDRC_DRAMTMG3 field descriptions

Field	Description
31–30 Reserved	This field is reserved. Reserved for future use
29–20 T_MRW	Time to wait after a mode register write or read (MRW or MRR). Present only in designs configured to support LPDDR2 / LPDDR3. LPDDR2 typically requires value of 5. LPDDR3 typically requires value of 10. **Value After Reset**: (MEMC_LPDDR2 == 1) ? 0x5 : 0x0 **Exists**: MEMC_LPDDR2 == 1
19–18 Reserved	This field is reserved. Reserved for future use
17–12 T_MRD	tMRD: Cycles between loadmode commands. If MEMC_DDR3 = 0, this parameter is also used to define the cycles between load mode command and following non-load mode command.

Table continues on the next page...

DDRC_DRAMTMG3 field descriptions (continued)

Field	Description
	For configurations with MEMC_FREQ_RATIO = 2, program this to (tMRD / 2) and round it up to the next integer value. If C/A parity for DDR4 is used, set to tMRD_PAR (tMOD + PL) instead. **Value After Reset**: 0x4 **Exists**: Always
11–10 Reserved	This field is reserved. Reserved for future use
T_MOD	tMOD: Present if MEMC_DDR3_OR_4 = 1. Cycles between loadmode command and following non-load mode command. This is required to be programmed even when a design that supports DDR3 / DDR4 is running in DDR2 mode. Set to tMOD if MEMC_FREQ_RATIO = 1, or tMOD / 2 (rounded up to next integer) if MEMC_FREQ_RATIO = 2. Note that if using RDIMM, depending on the PHY, it may be necessary to use a value of tMOD + 1 or (tMOD + 1) / 2 to compensate for the extra cycle of latency applied to mode register writes by the RDIMM chip. **Value After Reset**: (MEMC_DDR3 == 1) ? 0xc : 0x0 **Exists**: MEMC_DDR3 == 1

9.2.5.2.26 SDRAM Timing Register 4 (DDRC_DRAMTMG4)

Exists: Always

Address: 307A_0000h base + 110h offset = 307A_0110h

Field	Description
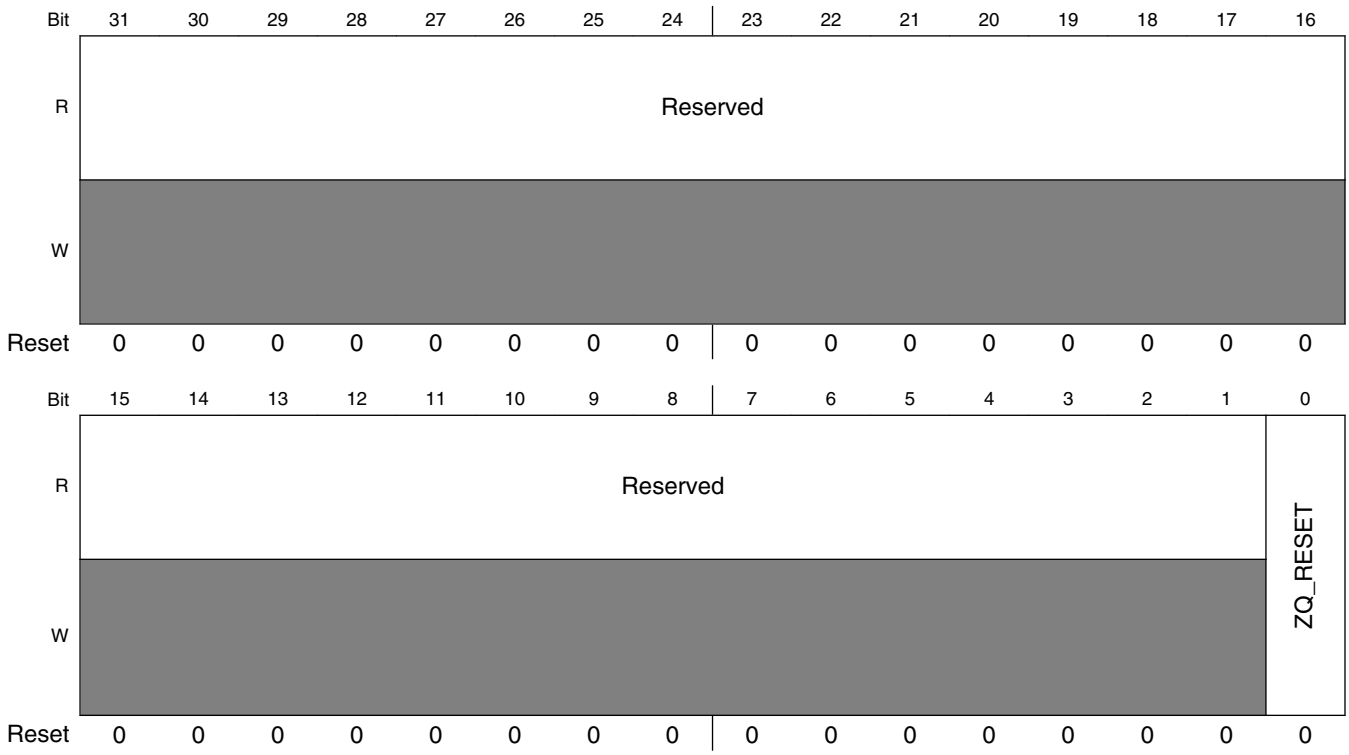
31–30 Reserved	This field is reserved. Reserved for future use
29–20 T_ZQ_RESET_NOP	tZQReset: Number of cycles of NOP required after a ZQReset (ZQ calibration Reset) command is issued to SDRAM. For configurations with MEMC_FREQ_RATIO = 2, program this to tZQReset / 2 and round it up to the next integer value. Unit: Clock cycles. This is only present for designs supporting LPDDR2 / LPDDR3 devices. **Value After Reset**: 0x20 **Exists**: MEMC_LPDDR2 == 1
T_ZQ_SHORT_INTERVAL_X1024	Average interval to wait between automatically issuing ZQCS (ZQ calibration short) commands to DDR3 / LPDDR2 / LPDDR3 devices. Meaningless, if ZQCTL0.dis_auto_zq = 1. Unit: 1024 clock cycles. This is only present for designs supporting DDR3 or LPDDR2/LPDDR3 devices. **Value After Reset**: 0x100 **Exists**: MEMC_DDR3 == 1 || MEMC_LPDDR2 == 1

9.2.5.2.33 ZQ Control Register 2 (DDRC_ZQCTL2)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 188h offset = 307A_0188h



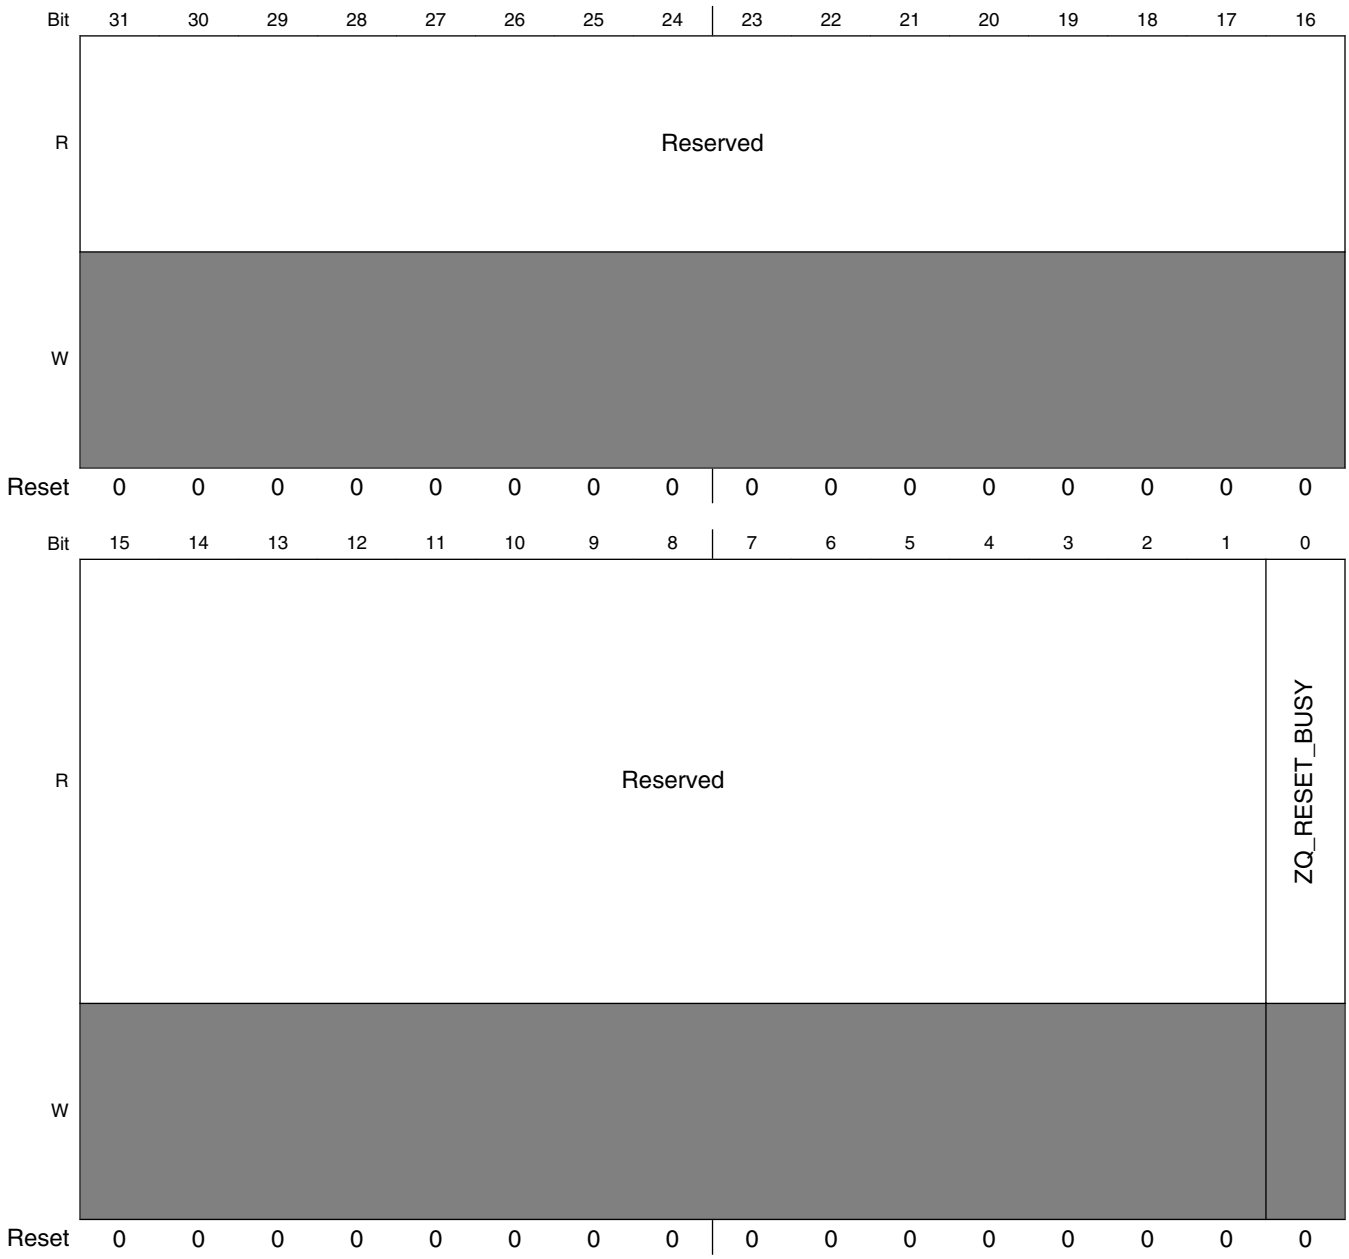
DDRC_ZQCTL2 field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 ZQ_RESET	Setting this register bit to 1 triggers a ZQ Reset operation.When the ZQ Reset operation is complete, the DDRC automatically clears this bit. It is recommended NOT to set this signal if in Init, Self-Refresh or Deep power- down operating modes. This is only present for designs supporting LPDDR2 / LPDDR3 devices. **Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2 == 1

9.2.5.2.34 ZQ Status Register (DDRC_ZQSTAT)

Exists: MEMC_LPDDR2==1

Address: 307A_0000h base + 18Ch offset = 307A_018Ch



DDRC_ZQSTAT field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use

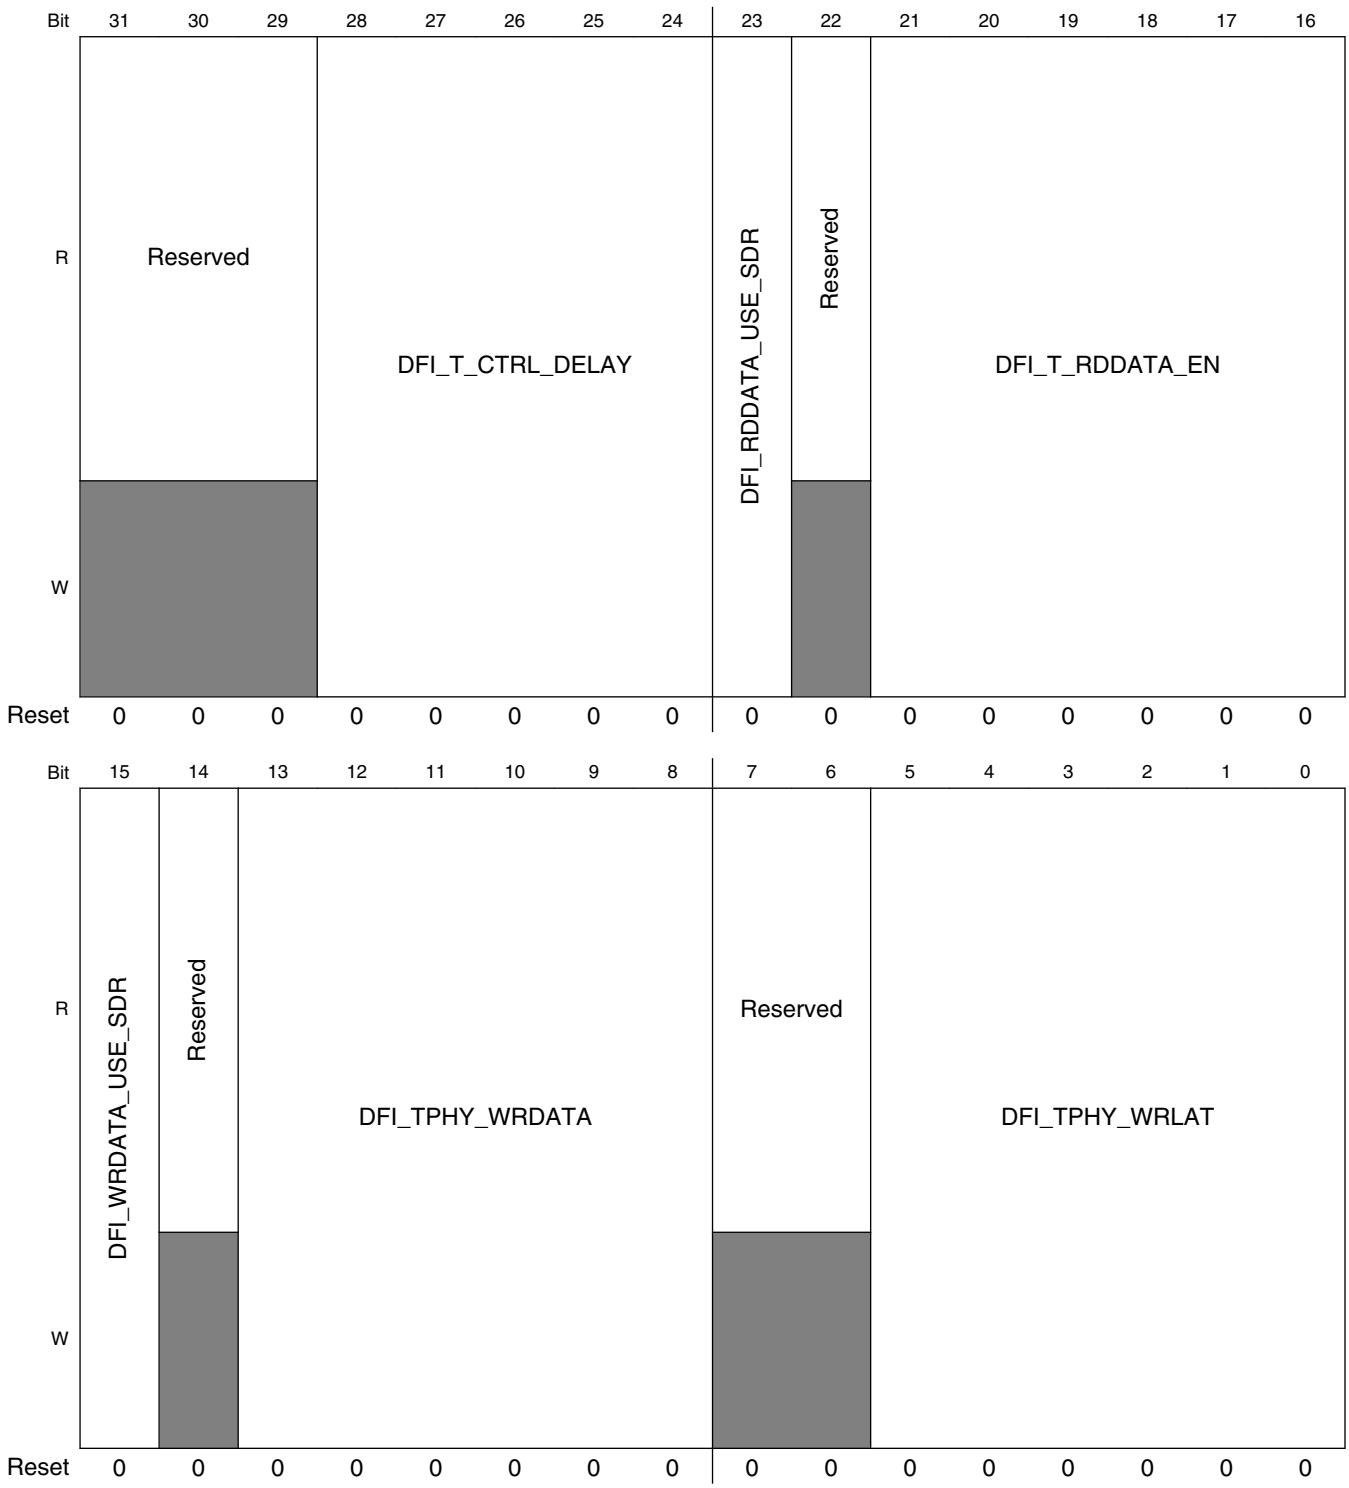
Table continues on the next page...

DDRC_ZQSTAT field descriptions (continued)

Field	Description
0 ZQ_RESET_ BUSY	SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high. **Value After Reset**: 0x0 **Exists**: Always 0 Indicates that the SoC core can initiate a ZQ Reset operation. 1 Indicates that ZQ Reset operation is in progress.

9.2.5.2.35 DFI Timing Register 0 (DDRC_DFITMG0)

Address: 307A_0000h base + 190h offset = 307A_0190h



DDRC_DFITMG0 field descriptions

Field	Description
31–29 Reserved	This field is reserved. Reserved for future use
28–24 DFI_T_CTRL_DELAY	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or deassertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value **Value After Reset**: 0x7. **Exists**: Always
23 DFI_RDDATA_USE_SDR	Defines whether dfi_rddata_en / dfi_rddata / dfi_rddata_valid is generated using HDR or SDR values Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of SDR or HDR clock cycles. **Value After Reset**: 0x0 **Exists**: MEMC_FREQ_RATIO == 2 0 In terms of HDR clock cycles 1 In terms of SDR clock cycles Refer to PHY specification for correct value.
22 Reserved	This field is reserved. Reserved for future use
21–16 DFI_T_RDDATA_EN	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM, it may be necessary to use the value (CL + 1) in the calculation of trddata_en. This is to compensate for the extra cycle of latency through the RDIMM. Unit: Clocks **Value After Reset**: 0x2 **Exists**: Always
15 DFI_WRDATA_USE_SDR	Defines whether dfi_wrdata_en / dfi_wrdata / dfi_wrdata_mask is generated using HDR or SDR values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of SDR or HDR clock cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of SDR or HDR clock cycles. Refer to PHY specification for correct value. **Value After Reset**: 0x0 **Exists**: MEMC_FREQ_RATIO==2 0 In terms of HDR clock cycles 1 In terms of SDR clock cycles
14 Reserved	This field is reserved. Reserved for future use
13–8 DFI_TPHY_WRDATA	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. **NOTE:** The max supported value is 8. Unit: Clocks **Value After Reset**: 0x0 **Exists**: Always
7–6 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_DFITMG0 field descriptions (continued)

Field	Description
DFI_TPHY_ WRLAT	Write latency Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat. Refer to PHY specification for correct value.Note that, depending on the PHY, if using RDIMM, it may be necessary to use the value (CL + 1) in the calculation of tphy_wrlat. This is to compensate for the extra cycle of latency through the RDIMM. **Value After Reset**: 0x2 **Exists**: Always

9.2.5.2.36 DFI Timing Register 1 (DDRC_DFITMG1)

Address: 307A_0000h base + 194h offset = 307A_0194h

Field	Description
31–26 Reserved	This field is reserved. Reserved for future use
25–24 Reserved	This field is reserved.
23–21 Reserved	This field is reserved. Reserved for future use
20–16 DFI_T_ WRDATA_ DELAY	Specifies the number of DFI clocks between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In FREQ_RATIO = 2, divide PHY's value by 2 and round up to next integer. If usingDFITMG0.dfi_wrdata_use_sdr = 1, add 1 to the value. Unit: Clocks **Value After Reset**: 0x0 **Exists**: Always
15–12 Reserved	This field is reserved. Reserved for future use

Table continues on the next page...

DDRC_DFITMG1 field descriptions (continued)

Field	Description
11–8 DFI_T_DRAM_CLK_DISABLE	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value. **Value After Reset**: 0x4 **Exists**: Always
7–4 Reserved	This field is reserved. Reserved for future use
DFI_T_DRAM_CLK_ENABLE	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value. **Value After Reset**: 0x4 **Exists**: Always

9.2.5.2.37 DFI Low Power Configuration Register 0 (DDRC_DFILPCFG0)

Address: 307A_0000h base + 198h offset = 307A_0198h

DDRC_DFILPCFG0 field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–24 DFI_TLP_RESP	Setting for DFI's tlp_resp time. Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes. DFI 2.1 specification onwards, recommends using a fixed value of 7 always. **Value After Reset**: 0x7 **Exists**: Always
23–20 DFI_LP_ WAKEUP_DPD	Value to drive on dfi_lp_wakeup signal when Deep Power Down mode is entered. Determines the DFI's tlp_wakeup time. This is only present for designs supporting mDDR or LPDDR2 / LPDDR3 devices. **Value After Reset**: 0x0 **Exists**: MEMC_MOBILE == 1 ||MEMC_LPDDR2 == 1 0x0 16 cycles 0x1 32 cycles 0x2 64 cycles 0x3 128 cycles 0x4 256 cycles 0x5 512 cycles 0x6 1024 cycles 0x7 2948 cycles 0x8 4096 cycles 0x9 8192 cycles 0xA 16384 cycles 0xB 32768 cycles 0xC 65536 cycles 0xD 131072 cycles 0xE 262144 cycles 0xF Unlimited
19–17 Reserved	This field is reserved. Reserved for future use
16 DFI_LP_EN_ DPD	Enables DFI Low Power interface handshaking during Deep Power Down Entry / Exit. This is only present for designs supporting mDDR or LPDDR2 / LPDDR3 devices. **Value After Reset**: 0x0 **Exists**: MEMC_LPDDR2 == 1 0 Disabled 1 Enabled
15–12 DFI_LP_ WAKEUP_SR	Value to drive on dfi_lp_wakeup signal when Self Refresh mode is entered. Determines the DFI's tlp_wakeup time. **Value After Reset**: 0x0 **Exists**: Always

DDRC_DFILPCFG0 field descriptions (continued)

Field	Description
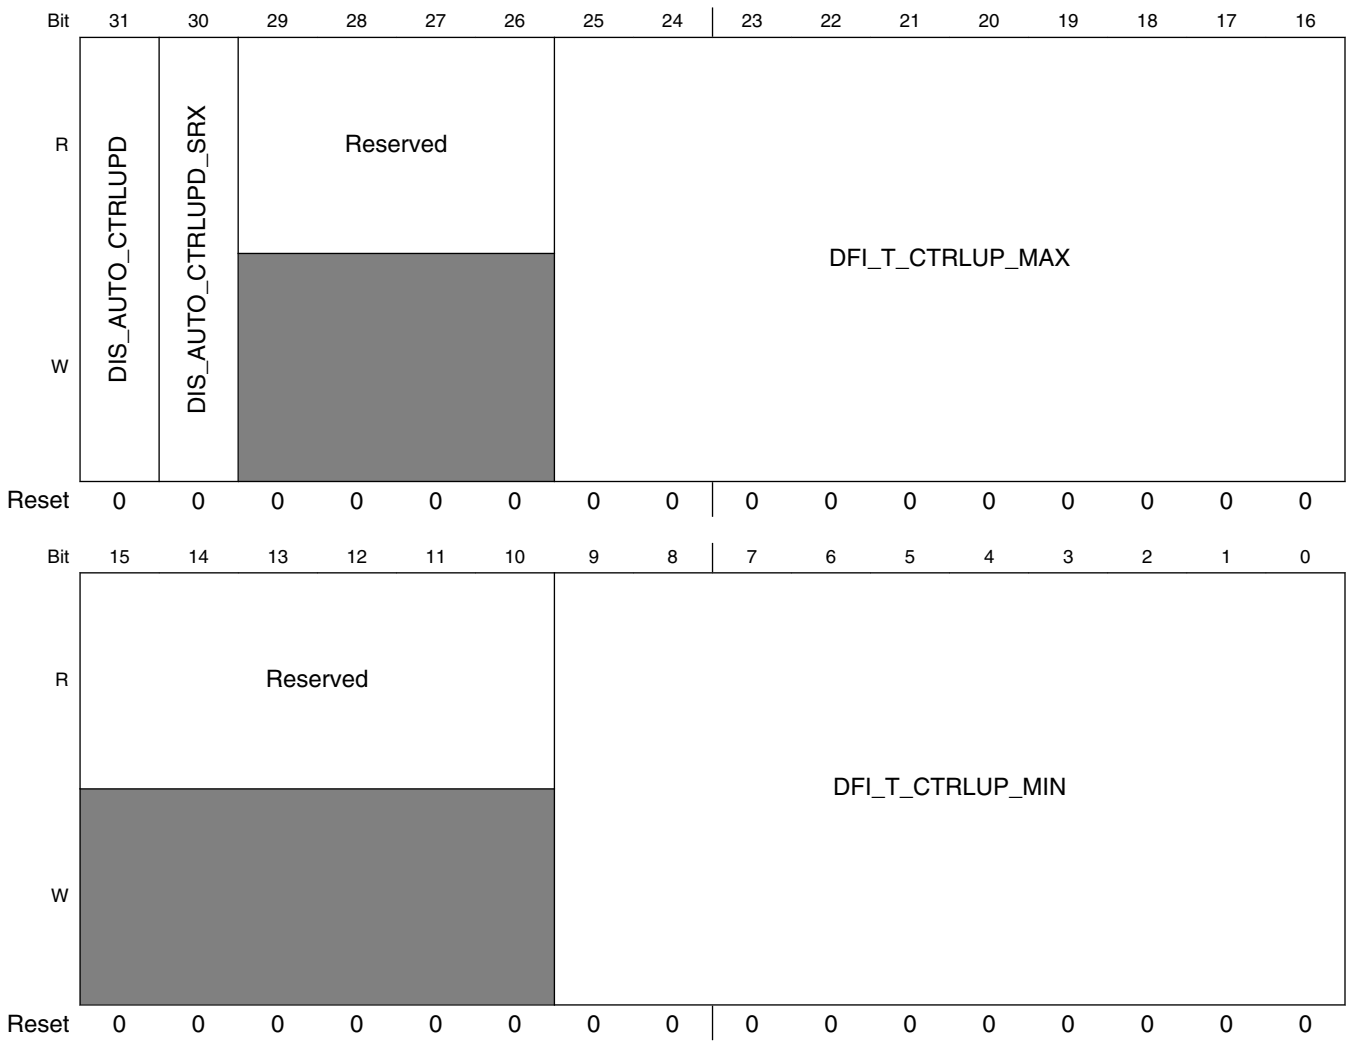
3–1 Reserved	This field is reserved. Reserved for future use
0 DFI_LP_EN_PD	Enables DFI Low Power interface handshaking during Power Down Entry / Exit. **Value After Reset**: 0x0 **Exists**: Always 0 Disabled 1 Enabled

9.2.5.2.38 DFI Update Register 0 (DDRC_DFIUPD0)

Address: 307A_0000h base + 1A0h offset = 307A_01A0h

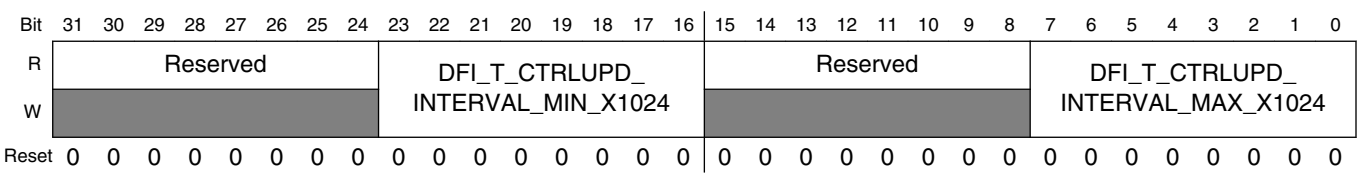


DDRC_DFIUPD0 field descriptions

Field	Description
31 DIS_AUTO_ CTRLUPD	When '1', disable the automatic dfi_ctrlupd_req generation by the DDRC. The core must issue the dfi_ctrlupd_req signal using register reg_ddrc_ctrlupd. This register field is changeable on the fly. When '0', DDRC issues dfi_ctrlupd_req periodically. **Value After Reset**: 0x0 **Exists**: Always
30 DIS_AUTO_ CTRLUPD_SRX	When '1', disable the automatic dfi_ctrlupd_req generation by the DDRC following a self-refresh exit. The core must issue the dfi_ctrlupd_req signal using register reg_ddrc_ctrlupd. This register field is changeable on the fly. When '0', DDRC issues a dfi_ctrlupd_req after exiting self- refresh. **Value After Reset**: 0x0 **Exists**: Always
29–26 Reserved	This field is reserved. Reserved for future use
25–16 DFI_T_CTRLUP_ MAX	Specifies themaximum number of clock cycles that the dfi_ctrlupd_req signal can assert. The lowest value to assign to this variable is 0x40. Unit: Clocks **Value After Reset**: 0x40 **Exists**: Always
15–10 Reserved	This field is reserved. Reserved for future use
DFI_T_CTRLUP_ MIN	Specifies the minimum number of clock cycles that the dfi_ctrlupd_req signal must be asserted. The DDRC expects the PHY to respond within this time. If the PHY does not respond, the DDRC will de-assert dfi_ctrlupd_req after dfi_t_ctrlup_min + 2 cycles. Lowest value to assign to this variable is 0x3. Unit: Clocks **Value After Reset**: 0x3 **Exists**: Always

9.2.5.2.39 DFI Update Register 1 (DDRC_DFIUPD1)

Address: 307A_0000h base + 1A4h offset = 307A_01A4h



DDRC_DFIUPD1 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Reserved for future use
23–16 DFI_T_ CTRLUPD_	This is the minimum amount of time between DDRC initiated DFI update requests (which is executed whenever the DDRC is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the DDRC is idle.

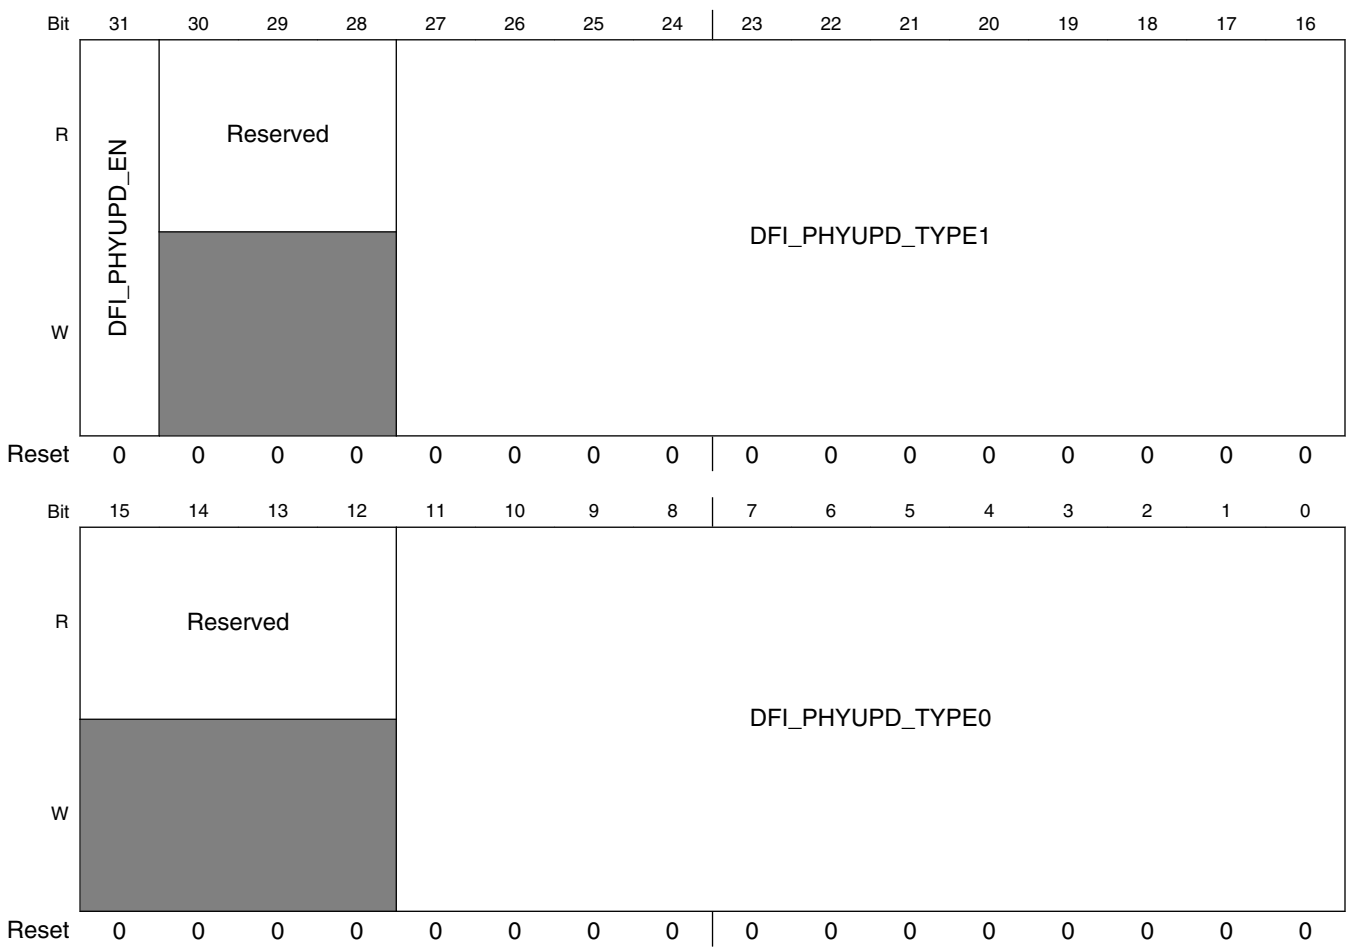
Table continues on the next page...

DDRC_DFIUPD1 field descriptions (continued)

Field	Description
INTERVAL_MIN_X1024	Unit: 1024 clocks **Value After Reset**: 0x0 **Exists**: Always
15–8 Reserved	This field is reserved. Reserved for future use
DFI_T_CTRLUPD_INTERVAL_MAX_X1024	This is the maximum amount of time between DDRC initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. **NOTE:** Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024. Unit: 1024 clocks **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.40 DFI Update Register 2 (DDRC_DFIUPD2)

Address: 307A_0000h base + 1A8h offset = 307A_01A8h

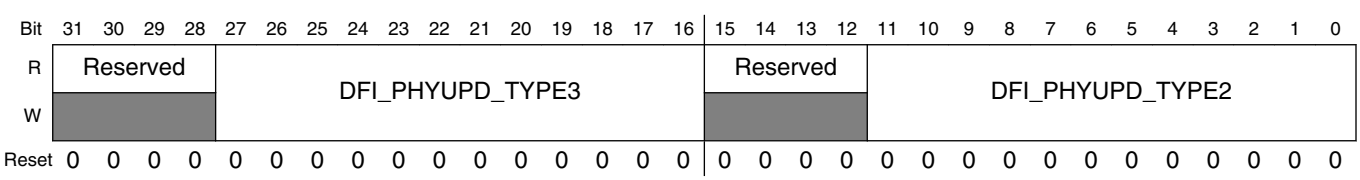


DDRC_DFIUPD2 field descriptions

Field	Description
31 DFI_PHYUPD_EN	Enables the support for acknowledging PHY- initiated updates. **Value After Reset**: 0x1 **Exists**: Always 0 Disabled 1 Enabled
30–28 Reserved	This field is reserved. Reserved for future use
27–16 DFI_PHYUPD_TYPE1	Specifies the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 2'b01. Is used in conjunction with value defined via DFIUPD4.dfi_phyupd_type1_mult. The dfi_phyupd_req signal may de-assert at any cycle after the assertion of the dfi_phyupd_ack signal. **Value After Reset**: 0x10 **Exists**: Always
15–12 Reserved	This field is reserved. Reserved for future use
DFI_PHYUPD_TYPE0	Specifies the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 2'b00. Is used in conjunction with value defined via DFIUPD4.dfi_phyupd_type0_mult. The dfi_phyupd_req signal may de-assert at any cycle after the assertion of the dfi_phyupd_ack signal. **Value After Reset**: 0x10 **Exists**: Always

9.2.5.2.41 DFI Update Register 3 (DDRC_DFIUPD3)

Address: 307A_0000h base + 1ACh offset = 307A_01ACh



DDRC_DFIUPD3 field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–16 DFI_PHYUPD_TYPE3	Specifies the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 2'b11. Is used in conjunction with value defined via DFIUPD4.dfi_phyupd_type3_mult. The dfi_phyupd_req signal may de-assert at any cycle after the assertion of the dfi_phyupd_ack signal. **Value After Reset**: 0x10 **Exists**: Always

Table continues on the next page...

DDRC_DFIUPD3 field descriptions (continued)

Field	Description
15–12 Reserved	This field is reserved. Reserved for future use
DFI_PHYUPD_TYPE2	Specifies the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 2'b10. Is used in conjunction with value defined via DFIUPD4.dfi_phyupd_type2_mult. The dfi_phyupd_req signal may de-assert at any cycle after the assertion of the dfi_phyupd_ack signal. **Value After Reset**: 0x10 **Exists**: Always

9.2.5.2.42 DFI Miscellaneous Control Register (DDRC_DFIMISC)

Address: 307A_0000h base + 1B0h offset = 307A_01B0h

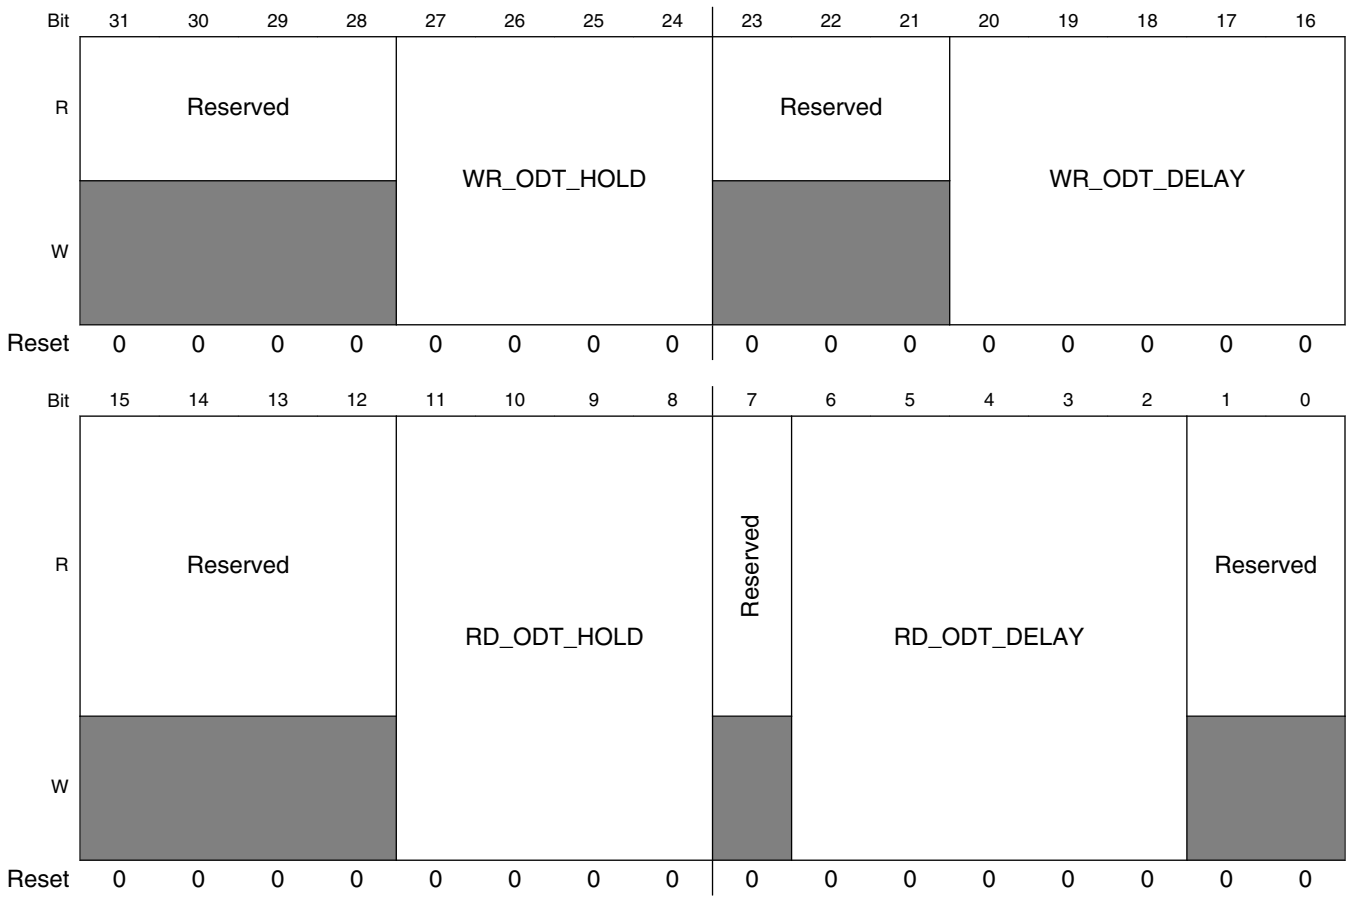
DDRC_ADDRMAP6 field descriptions (continued)

Field	Description
	The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 15, row address bit 15 is set to 0. **Value After Reset**: 0x0 **Exists**: Always
23–20 Reserved	This field is reserved. Reserved for future use
19–16 ADDRMAP_ ROW_B14	Selects the HIF address bit used as row address bit 14. Valid Range: 0 to 11, and 15 Internal Base: 20 The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 15, row address bit 14 is set to 0. **Value After Reset**: 0x0 **Exists**: Always
15–12 Reserved	This field is reserved. Reserved for future use
11–8 ADDRMAP_ ROW_B13	Selects the HIF address bit used as row address bit 13. Valid Range: 0 to 11, and 15 Internal Base: 19 The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 15, row address bit 13 is set to 0. **Value After Reset**: 0x0 **Exists**: Always
7–4 Reserved	This field is reserved. Reserved for future use
ADDRMAP_ ROW_B12	Selects the HIF address bit used as row address bit 12. Valid Range: 0 to 11, and 15 Internal Base: 18 The selected HIF address bit is determined by adding the internal base to the value of this field. If set to 15, row address bit 12 is set to 0. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.50 ODT Configuration Register (DDRC_ODTCFG)

Address: 307A_0000h base + 240h offset = 307A_0240h



DDRC_ODTCFG field descriptions

Field	Description
31–28 Reserved	This field is reserved. Reserved for future use
27–24 WR_ODT_HOLD	Cycles to hold ODT for a write command. The minimum supported value is 2. DDR3: • BL8 - 0x6 • BL4 - 0x4 **Value After Reset**: 0x4 **Exists**: Always
23–21 Reserved	This field is reserved. Reserved for future use
20–16 WR_ODT_ DELAY	The delay, in clock cycles, from issuing a write command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRC. ODT is used only in DDR3 designs. Recommended values: DDR3 - 0

Table continues on the next page...

DDRC_ODTCFG field descriptions (continued)

Field	Description
	Value After Reset: 0x0 **Exists**: Always
15–12 Reserved	This field is reserved. Reserved for future use
11–8 RD_ODT_HOLD	Cycles to hold ODT for a read command. The minimum supported value is 2. Recommended values: DDR3: • BL8 - 0x6 • BL4 - 0x4 **Value After Reset**: 0x4 **Exists**: Always
7 Reserved	This field is reserved. Reserved for future use
6–2 RD_ODT_ DELAY	The delay, in clock cycles, from issuing a read command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRC. Recommended values: DDR3: • (CL - CWL) **Value After Reset**: 0x0 **Exists**: Always
Reserved	This field is reserved. Reserved for future use

9.2.5.2.51 ODT / Rank Map Register (DDRC_ODTMAP)

Address: 307A_0000h base + 244h offset = 307A_0244h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRC_ODTMAP field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved for future use

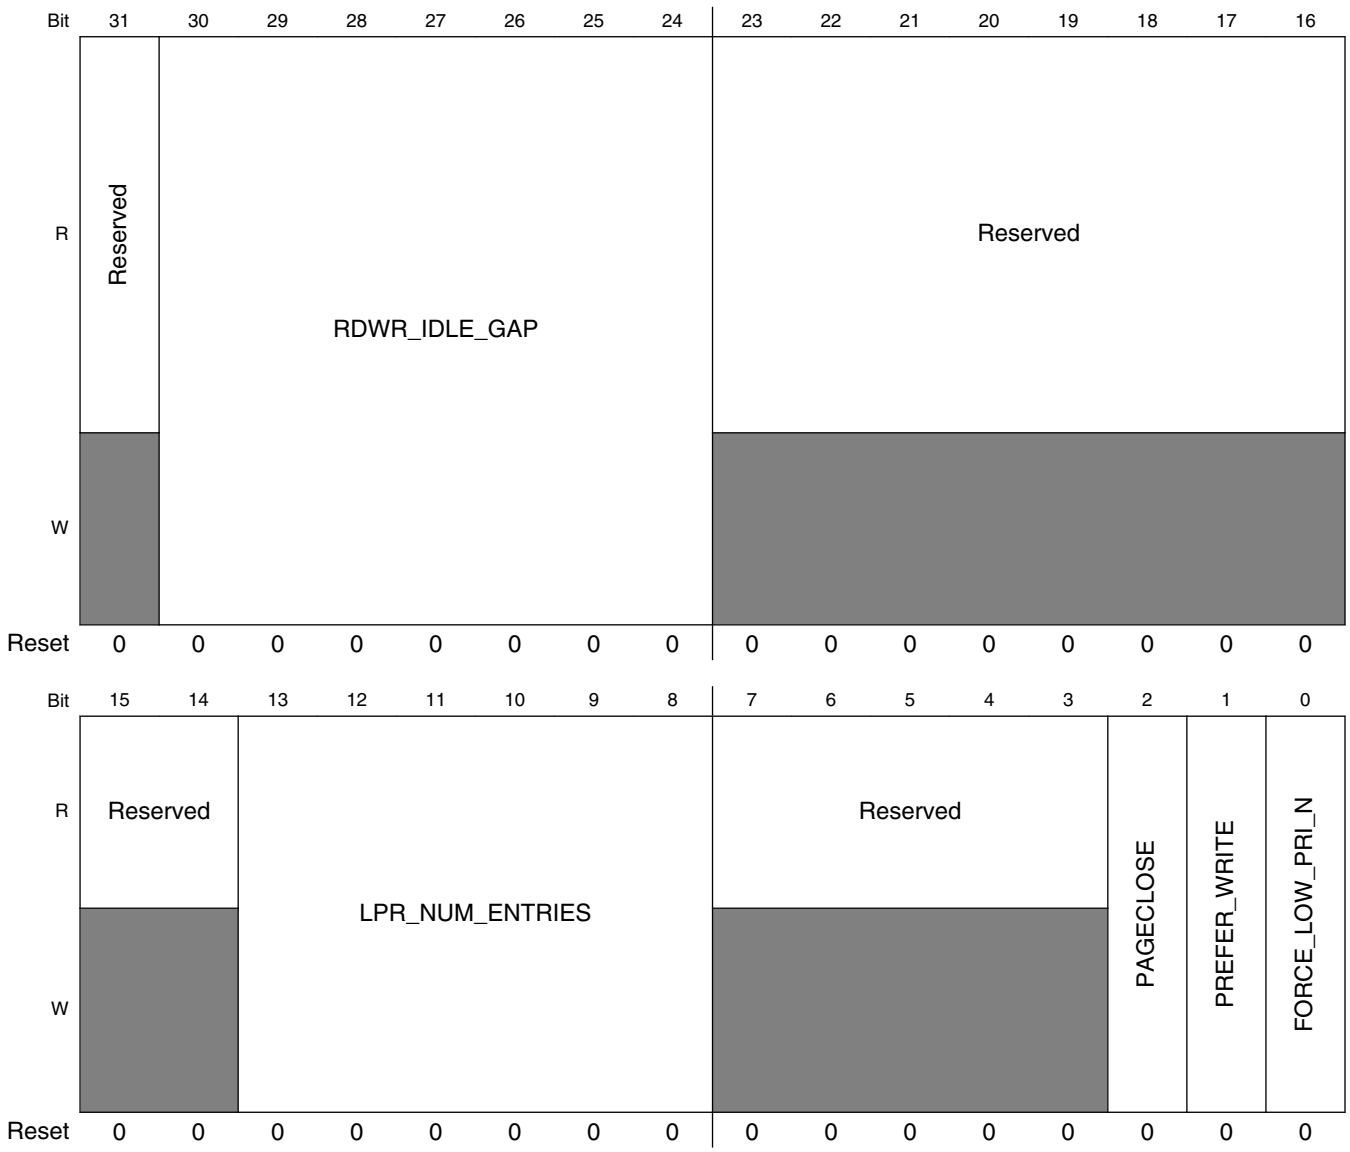
Table continues on the next page...

DDRC_ODTMAP field descriptions (continued)

Field	Description
15–12 RANK1_RD_ODT	Indicates which remote ODTs must be turned on during a read from rank 1. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. Present only in configurations that have 2 or more ranks **Value After Reset**: "(MEMC_NUM_RANKS > 1) ? 0x2 : 0x0" **Exists**: MEMC_NUM_RANKS > 1
11–8 RANK1_WR_ODT	Indicates which remote ODTs must be turned on during a write to rank 1. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. Present only in configurations that have 2 or more ranks **Value After Reset**: "(MEMC_NUM_RANKS > 1) ? 0x2 : 0x0" **Exists**: MEMC_NUM_RANKS > 1
7–4 RANK0_RD_ODT	Indicates which remote ODTs must be turned on during a read from rank 0. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. **Value After Reset**: 0x1 **Exists**: Always
RANK0_WR_ODT	Indicates which remote ODTs must be turned on during a write to rank 0. Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here. Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc. For each rank, set its bit to 1 to enable its ODT. **Value After Reset**: 0x1 **Exists**: Always

9.2.5.2.52 Scheduler Control Register (DDRC_SCHED)

Address: 307A_0000h base + 250h offset = 307A_0250h



DDRC_SCHED field descriptions

Field	Description
31 Reserved	This field is reserved. Reserved for future use
30–24 RDWR_IDLE_GAP	When the preferred transaction store is empty for these many clock cycles, switch to the alternate transaction store if it is non-empty. The read transaction store (both high and low priority) is the default preferred transaction store and the write transaction store is the alternative store. When prefer write over read is set this is reversed. 0x0 is a legal value for this register. When set to 0x0, the transaction store switching will happen immediately when the switching conditions become true.

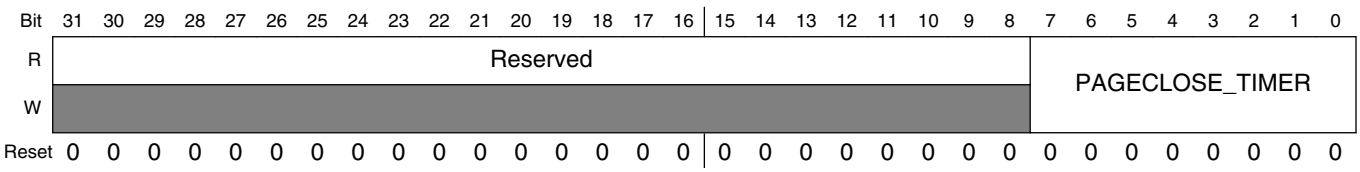
Table continues on the next page...

DDRC_SCHED field descriptions (continued)

Field	Description
	FOR PERFORMANCE ONLY **Value After Reset**: 0x0 **Exists**: Always
23–14 Reserved	This field is reserved. Reserved for future use
13–8 LPR_NUM_ENTRIES	Number of entries in the low priority transaction store is this value + 1. (MEMC_NO_OF_ENTRY - (SCHED.lpr_num_entries + 1)) is the number of entries available for the high priority transaction store. Setting this to maximum value allocates all entries to low priority transaction store. Setting this to 0 allocates 1 entry to low priority transaction store and the rest to high priority transaction store. **Value After Reset**: "MEMC_NO_OF_ENTRY / 2" **Exists**: Always
7–3 Reserved	This field is reserved. Reserved for future use
2 PAGECLOSE	If true, bank is kept open only until there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit will be executed with auto-precharge if SCHED1.pageclose_timer = 0. Even if this register set to 1 and SCHED1.pageclose_timer is set to 0, explicit precharge (and not auto-precharge) may be issued in some cases where there is a mode switch betweenWrite and Read or between LPR and HPR. The Read andWrite commands that are executed as part of the ECC scrub requests are also executed without auto-precharge. If false, the bank remains open until there is a need to close it (to open a different page, or for page timeout or refresh timeout) - also known as open page policy. The open page policy can be overridden by setting the per-command- autopre bit on the HIF interface (hif_cmd_autopre). The pageclose feature provids a midway between Open and Close page policies. FOR PERFORMANCE ONLY. **Value After Reset**: 0x1 **Exists**: Always
1 PREFER_WRITE	If set then the bank selector prefers writes over reads. FOR DEBUG ONLY. **Value After Reset**: 0x0 **Exists**: Always
0 FORCE_LOW_PRI_N	Active low signal.When asserted ('0'), all incoming transactions are forced to low priority. This implies that all High Priority Read (HPR) and Variable Priority Read commands (VPR) will be treated as Low Priority Read (LPR) commands. On the write side, all Variable PriorityWrite (VPW) commands will be treated as Normal PriorityWrite (NPW) commands. Forcing the incoming transactions to low priority implicitly turns off Bypass path for read commands. FOR PERFORMANCE ONLY. **Value After Reset**: 0x1 **Exists**: Always

9.2.5.2.53 Scheduler Control Register 1 (DDRC_SCHED1)

Address: 307A_0000h base + 254h offset = 307A_0254h

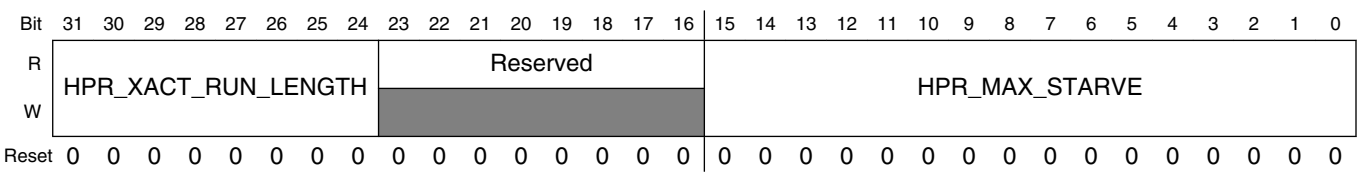


DDRC_SCHED1 field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved for future use
PAGECLOSE_ TIMER	This field works in conjunction with SCHED.pageclose. It only has meaning if SCHED.pageclose == 1. If SCHED.pageclose == 1 and pageclose_timer == 0, then an auto-precharge may be scheduled for last read or write command in the CAM with a bank and page hit. Note, sometimes an explicit precharge is scheduled instead of the auto-precharge. See SCHED.pageclose for details of when this may happen. If SCHED.pageclose == 1 and pageclose_timer > 0, then an auto-precharge is not scheduled for last read or write command in the CAM with a bank and page hit. Instead, a timer is started, with pageclose_timer as the initial value. There is a timer on a per bank basis. The timer decrements unless the next read or write in the CAM to a bank is a page hit. It gets reset to pageclose_timer value if the next read or write in the CAM to a bank is a page hit. Once the timer has reached zero, an explcit precharge will be attempted to be scheduled. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.54 High Priority Read CAM Register 1 (DDRC_PERFHPR1)

Address: 307A_0000h base + 25Ch offset = 307A_025Ch



DDRC_PERFHPR1 field descriptions

Field	Description
31–24 HPR_XACT_ RUN_LENGTH	Number of transactions that are serviced once the HPR queue goes critical is the smaller of: • This number • Number of transactions available. Unit: Transaction FOR PERFORMANCE ONLY. **Value After Reset**: 0xf

Table continues on the next page...

DDRC_PERFHPR1 field descriptions (continued)

Field	Description
	Exists: Always
23–16 Reserved	This field is reserved.
HPR_MAX_ STARVE	Number of clocks that the HPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies. Unit: Clock cycles. FOR PERFORMANCE ONLY. **Value After Reset**: 0x1 **Exists**: Always

9.2.5.2.55 Low Priority Read CAM Register 1 (DDRC_PERFLPR1)

Address: 307A_0000h base + 264h offset = 307A_0264h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

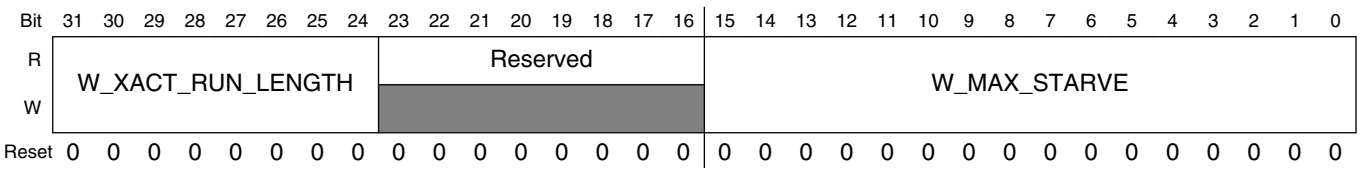
DDRC_PERFLPR1 field descriptions

Field	Description
31–24 LPR_XACT_ RUN_LENGTH	Number of transactions that are serviced once the LPR queue goes critical is the smaller of: 1. This number 2. Number of transactions available Unit: Transaction. FOR PERFORMANCE ONLY. **Value After Reset**: 0xf **Exists**: Always
23–16 Reserved	This field is reserved. Reserved for future use
LPR_MAX_ STARVE	Number of clocks that the LPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies. Unit: Clock cycles. FOR PERFORMANCE ONLY. **Value After Reset**: 0x7f **Exists**: Always

9.2.5.2.56 Write CAM Register 1 (DDRC_PERFWR1)

Address: 307A_0000h base + 26Ch offset = 307A_026Ch



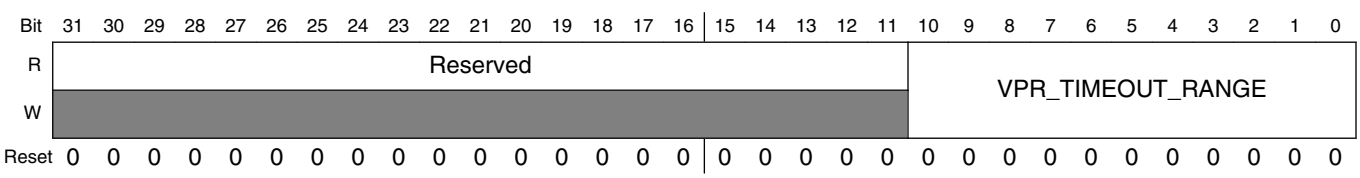
DDRC_PERFWR1 field descriptions

Field	Description
31–24 W_XACT_RUN_LENGTH	Number of transactions that are serviced once the WR queue goes critical is the smaller of: 1. This number 2. Number of transactions available Unit: Transaction. FOR PERFORMANCE ONLY. **Value After Reset**: 0xf **Exists**: Always
23–16 Reserved	This field is reserved. Reserved for future use
W_MAX_STARVE	Number of clocks that the WR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 will disable the starvation functionality; during normal operation, this function should not be disabled as it will cause excessive latencies. Unit: Clock cycles. FOR PERFORMANCE ONLY. **Value After Reset**: 0x7f **Exists**: Always

9.2.5.2.57 Variable Priority Read CAM Register 1 (DDRC_PERFVPR1)

Exists: DDRC_VPR_EN==1

Address: 307A_0000h base + 274h offset = 307A_0274h



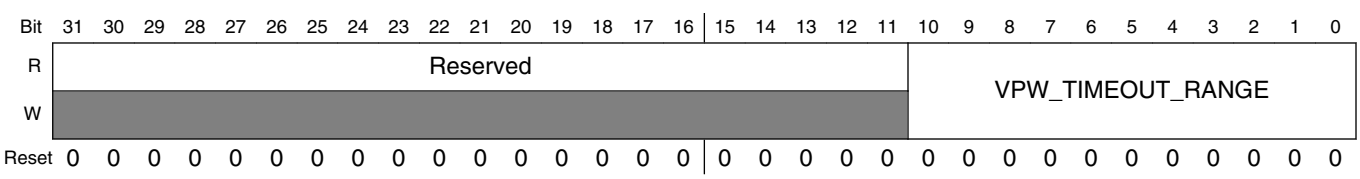
DDRC_PERFVPR1 field descriptions

Field	Description
31–11 Reserved	This field is reserved. Reserved for future use
VPR_TIMEOUT_RANGE	Indicates the range of the timeout value that is used for grouping the expired VPR commands in the CAM in DDRC. For example, if the register value is set to 0xF, then the priorities of all the VPR commands whose timeout counters are 15 or below will be considered as expired-VPR commands when the timeout value of any of the VPR commands reach 0. The expired-VPR commands, when present, are given higher priority than HPR commands. The VPR commands are expected to consist of largely page hit traffic and by grouping them together the bus utilization is expected to increase. This register applies to transactions inside the DDRC only. The Max value for this register is 0x7FF and the Min value is 0x0. When programmed to the Max value of 0x7FF, all the VPR commands that come in to DDRC will time-out right-away and will be considered as expired-VPR. When programmed to the Min value of 0x0, the timer of each command would have to reach a value of 0 before it will be considered as expired-VPR. Unit: Clock cycles. FOR PERFORMANCE ONLY. **Value After Reset**: 0x0 **Exists**: DDRC_VPR_EN == 1

9.2.5.2.58 Variable Priority Write CAM Register 1 (DDRC_PERFVPW1)

Exists: DDRC_VPW_EN==1

Address: 307A_0000h base + 278h offset = 307A_0278h



DDRC_PERFVPW1 field descriptions

Field	Description
31–11 Reserved	This field is reserved. Reserved for future use
VPW_TIMEOUT_RANGE	Indicates the range of the timeout value that is used for grouping the expired VPW commands in the CAM in DDRC. For example, if the register value is set to 0xF, then the priorities of all the VPW commands whose timeout counters are 15 or below will be considered as expired-VPW commands when the timeout value of any of the VPW commands reach 0. The expired-VPW commands, when present, are given higher priority than normalWrite commands. The VPW commands are expected to consist of largely page hit traffic and by grouping them together the bus utilization is expected to increase. This register applies to transactions inside the DDRC only. The Max value for this register is 0x7FF and the Min value is 0x0.

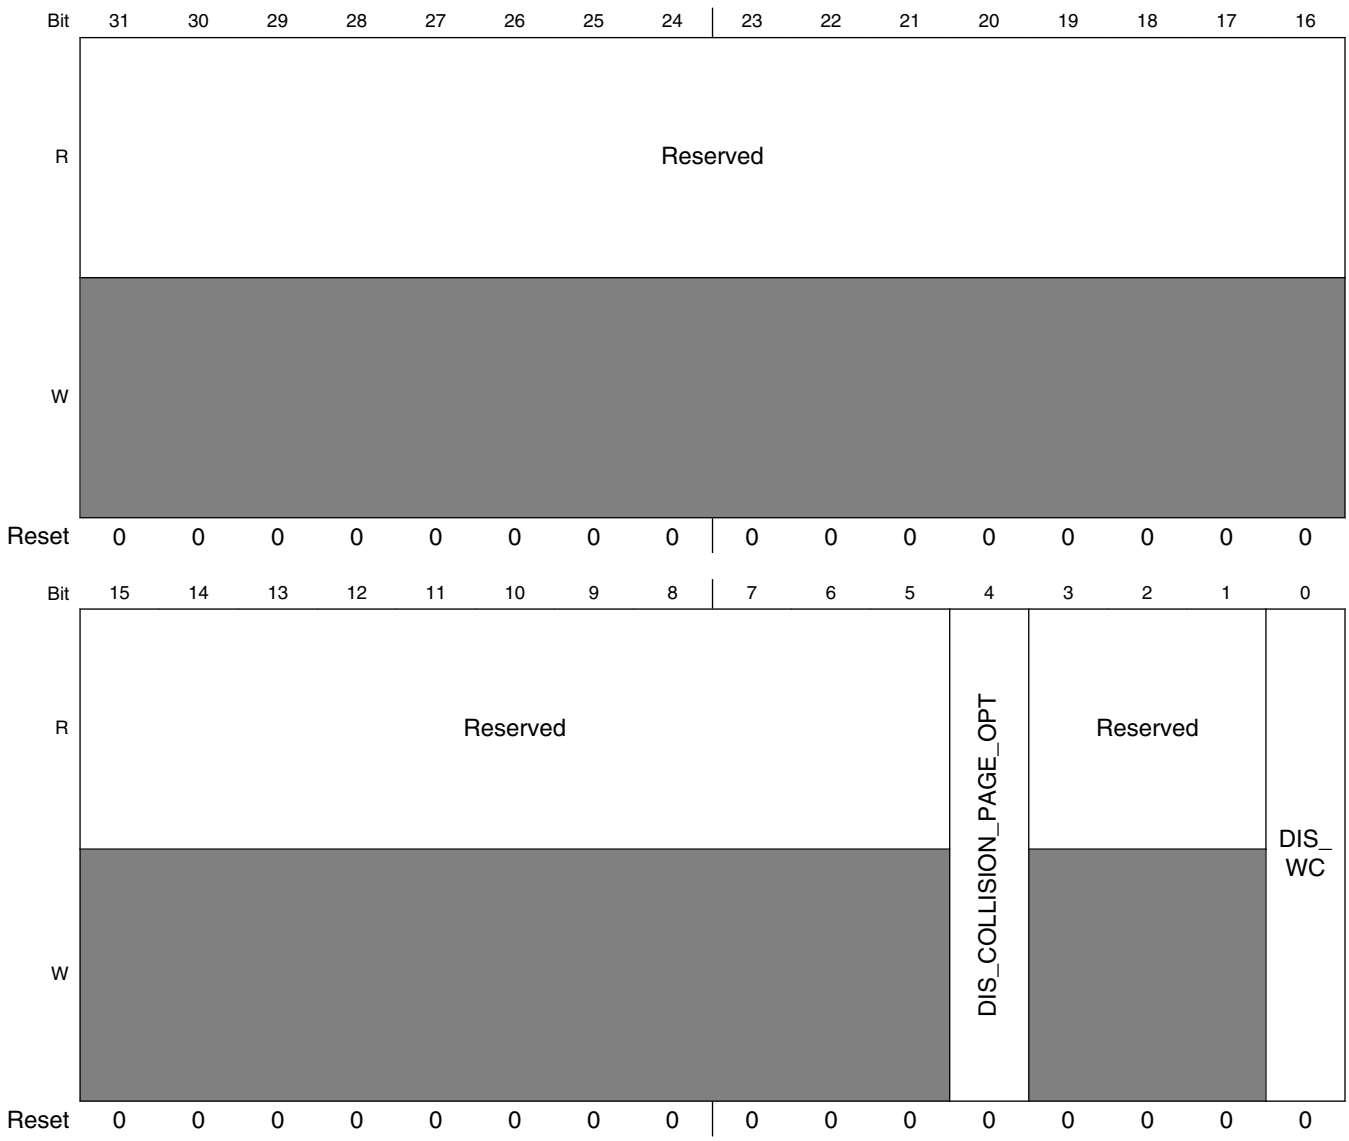
Table continues on the next page...

DDRC_PERFVPW1 field descriptions (continued)

Field	Description
	When programmed to the Max value of 0x7FF, all the VPW commands that come in to DDRC will time-out right-away and will be considered as expired-VPW. When programmed to the Min value of 0x0, the timer of each command would have to reach a value of 0 before it will be considered as expired-VPW. Unit: Clock cycles. FOR PERFORMANCE ONLY. **Value After Reset**: 0x0 **Exists**: DDRC_VPW_EN == 1

9.2.5.2.59 Debug Register 0 (DDRC_DBG0)

Address: 307A_0000h base + 300h offset = 307A_0300h

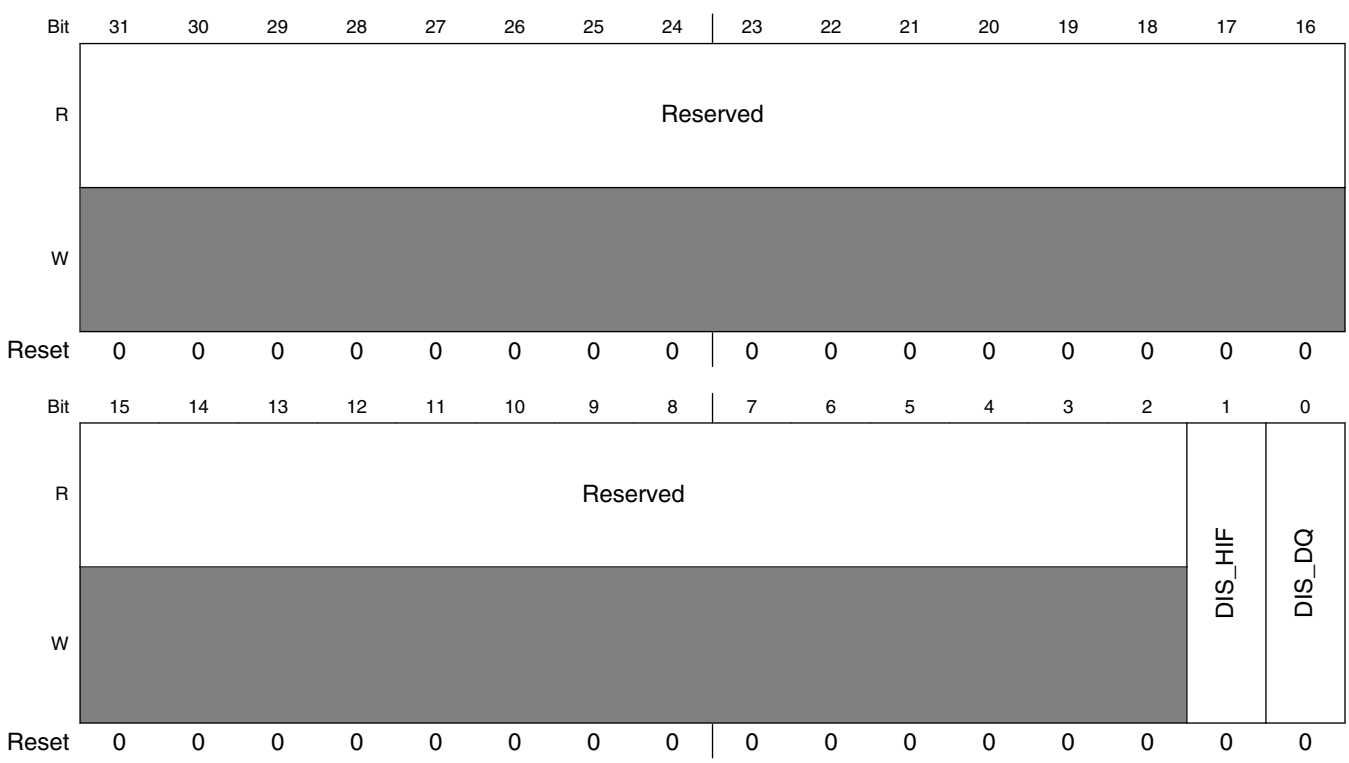


DDRC_DBG0 field descriptions

Field	Description
31–5 Reserved	This field is reserved. Reserved for future use
4 DIS_ COLLISION_ PAGE_OPT	When this is set to '0', auto-precharge is disabled for the flushed command in a collision case. Collision cases are write followed by read to same address, read followed by write to same address, or write followed by write to same address with DBG0.dis_wc bit = 1 (where same address comparisons exclude the two address bits representing critical word). FOR DEBUG ONLY. **Value After Reset**: 0x0 **Exists**: Always
3–1 Reserved	This field is reserved. Reserved for future use
0 DIS_WC	When the value is 1, disable write combine. FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.60 Debug Register 1 (DDRC_DBG1)

Address: 307A_0000h base + 304h offset = 307A_0304h

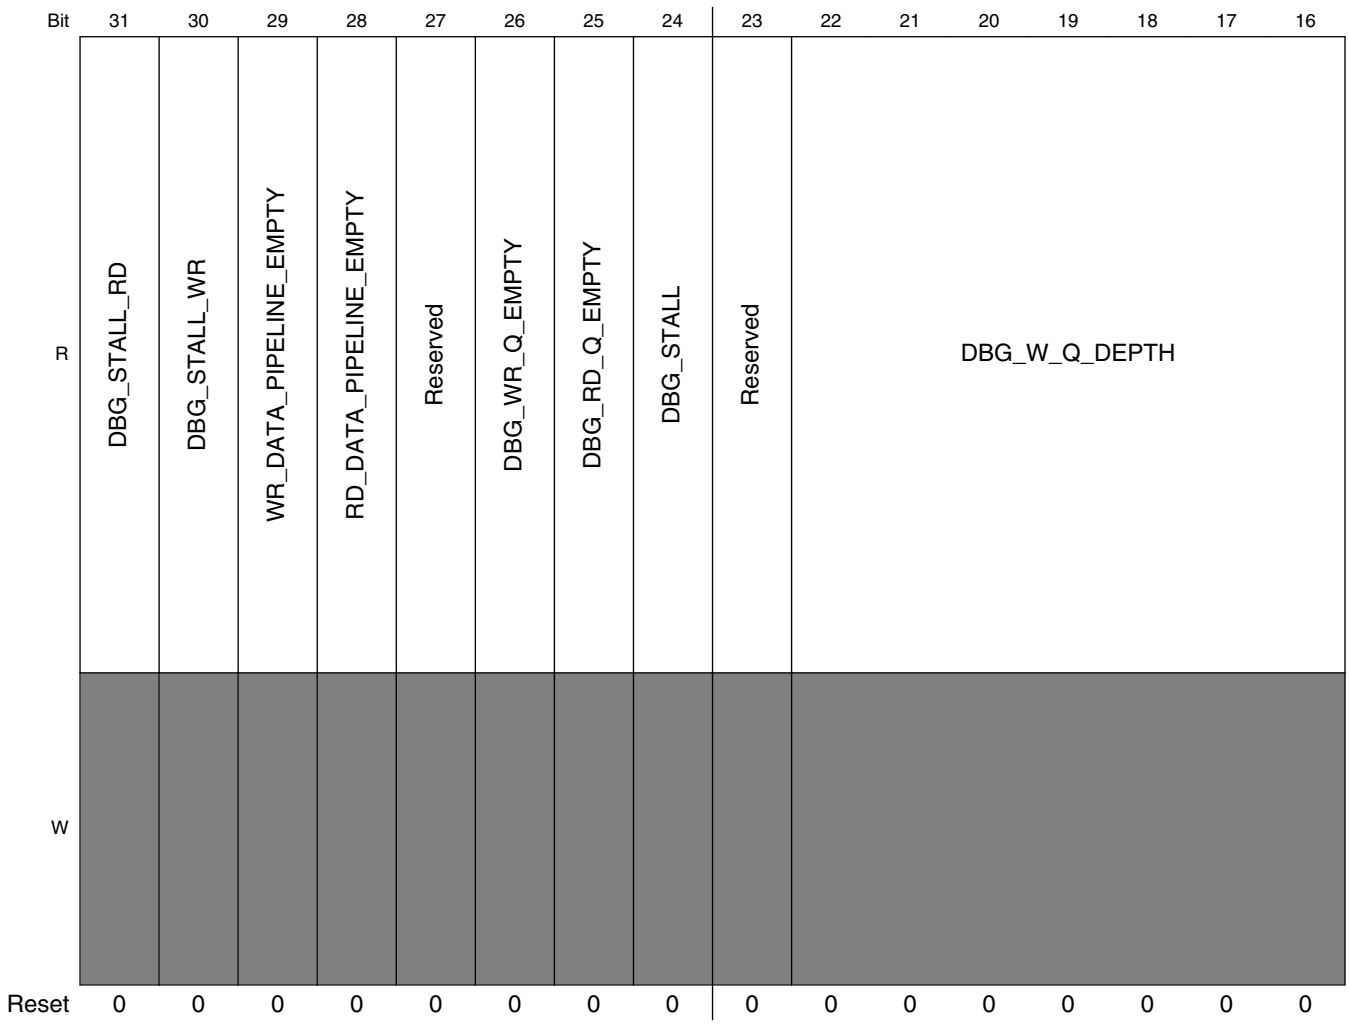


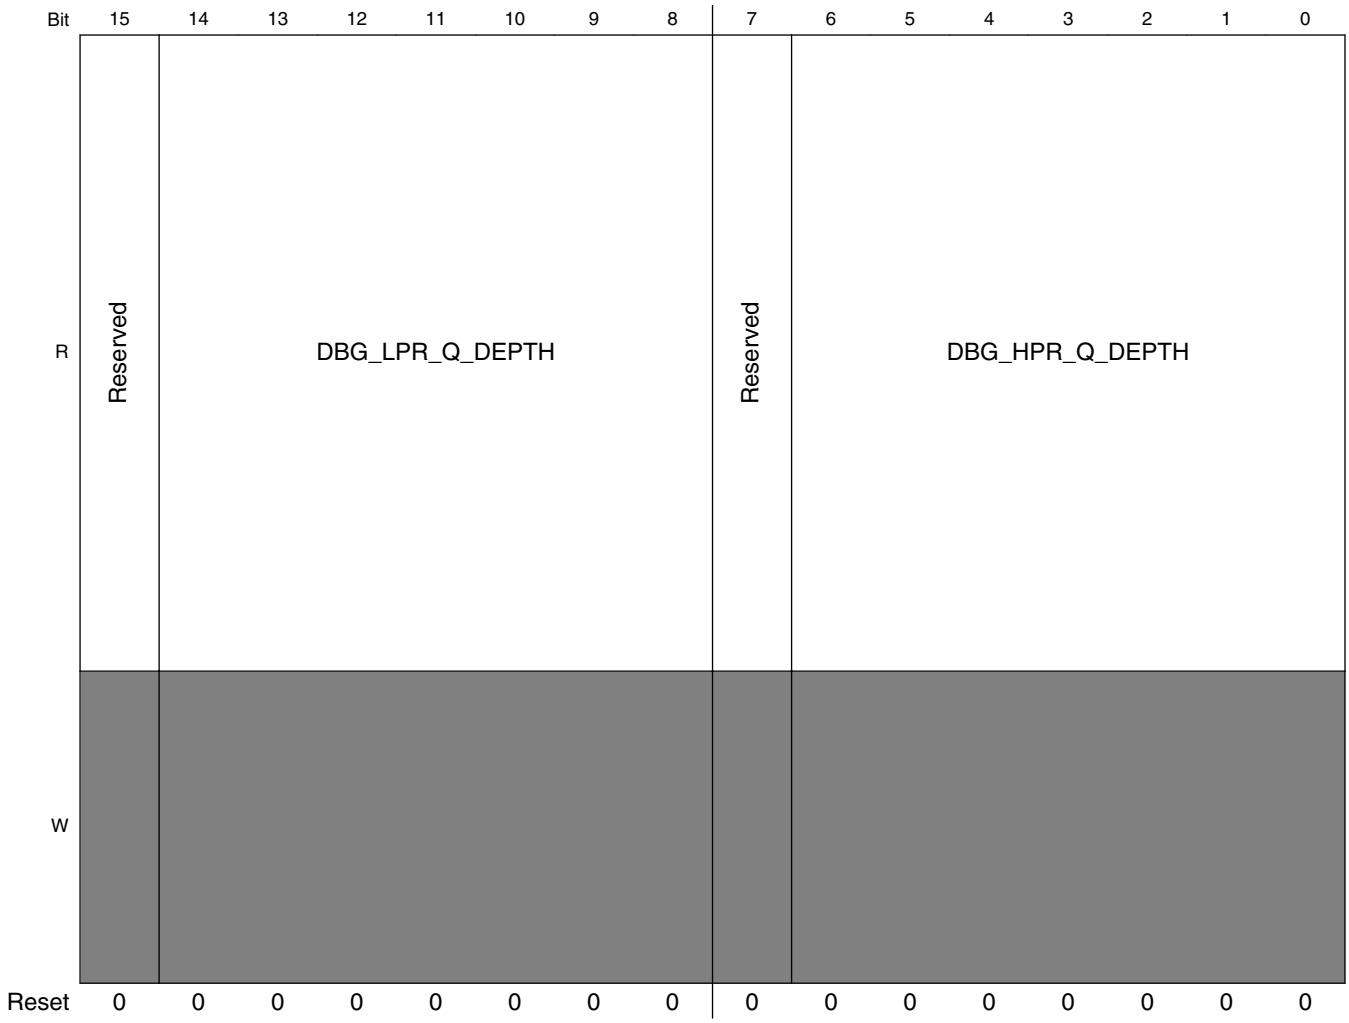
DDRC_DBG1 field descriptions

Field	Description
31–2 Reserved	This field is reserved. Reserved for future use
1 DIS_HIF	When 1, the DDRC asserts the HIF command signal hif_cmd_stall. The DDRC will ignore the hif_cmd_valid and all other associated request signals. This bit is intended to be switched on-the-fly. **Value After Reset**: 0x0 **Exists**: Always
0 DIS_DQ	When 1, DDRC will not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted. This bit may be used to prevent reads or writes being issued by the DDRC, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, beforemaking changes to any registers which affect reads and writes. This will ensure that the relevant logic in the DDRC is idle. This bit is intended to be switched on-the-fly. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.61 CAM Debug Register (DDRC_DBGCAM)

Address: 307A_0000h base + 308h offset = 307A_0308h





DDRC_DBGCAM field descriptions

Field	Description
31 DBG_STALL_RD	Stall for Read channel FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: DDRC_DUAL_PA_1 == 1
30 DBG_STALL_WR	Stall for Write channel FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: DDRC_DUAL_PA_1 == 1
29 WR_DATA_PIPELINE_EMPTY	This bit indicates that the write data pipeline on the DFI interface is empty. This register is intended to be polled after setting DBG1.dis_dq, to ensure that all remaining commands / data have completed. **Value After Reset**: 0x0 **Exists**: Always

Table continues on the next page...

DDRC_DBGCAM field descriptions (continued)

Field	Description
28 RD_DATA_ PIPELINE_ EMPTY	This bit indicates that the read data pipeline on the DFI interface is empty. This register is intended to be polled after setting DBG1.dis_dq, to ensure that all remaining commands / data have completed. **Value After Reset**: 0x0 **Exists**: Always
27 Reserved	This field is reserved. Reserved for future use
26 DBG_WR_Q_ EMPTY	When 1, all theWrite command queues and Write data buffers inside DDRC are empty. This register is to be used for debug purpose. An example use-case scenario:When Controller enters Self- Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time. FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always
25 DBG_RD_Q_ EMPTY	When 1, all the Read command queues and Read data buffers inside DDRC are empty. This register is to be used for debug purpose. An example use-case scenario:When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time. FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always
24 DBG_STALL	Stall FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always
23 Reserved	This field is reserved. Reserved for future use
22–16 DBG_W_Q_ DEPTH	Write Queue Depth FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always
15 Reserved	This field is reserved. Reserved for future use
14–8 DBG_LPR_Q_ DEPTH	Low Priority Read Queue Depth FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always
7 Reserved	This field is reserved. Reserved for future use

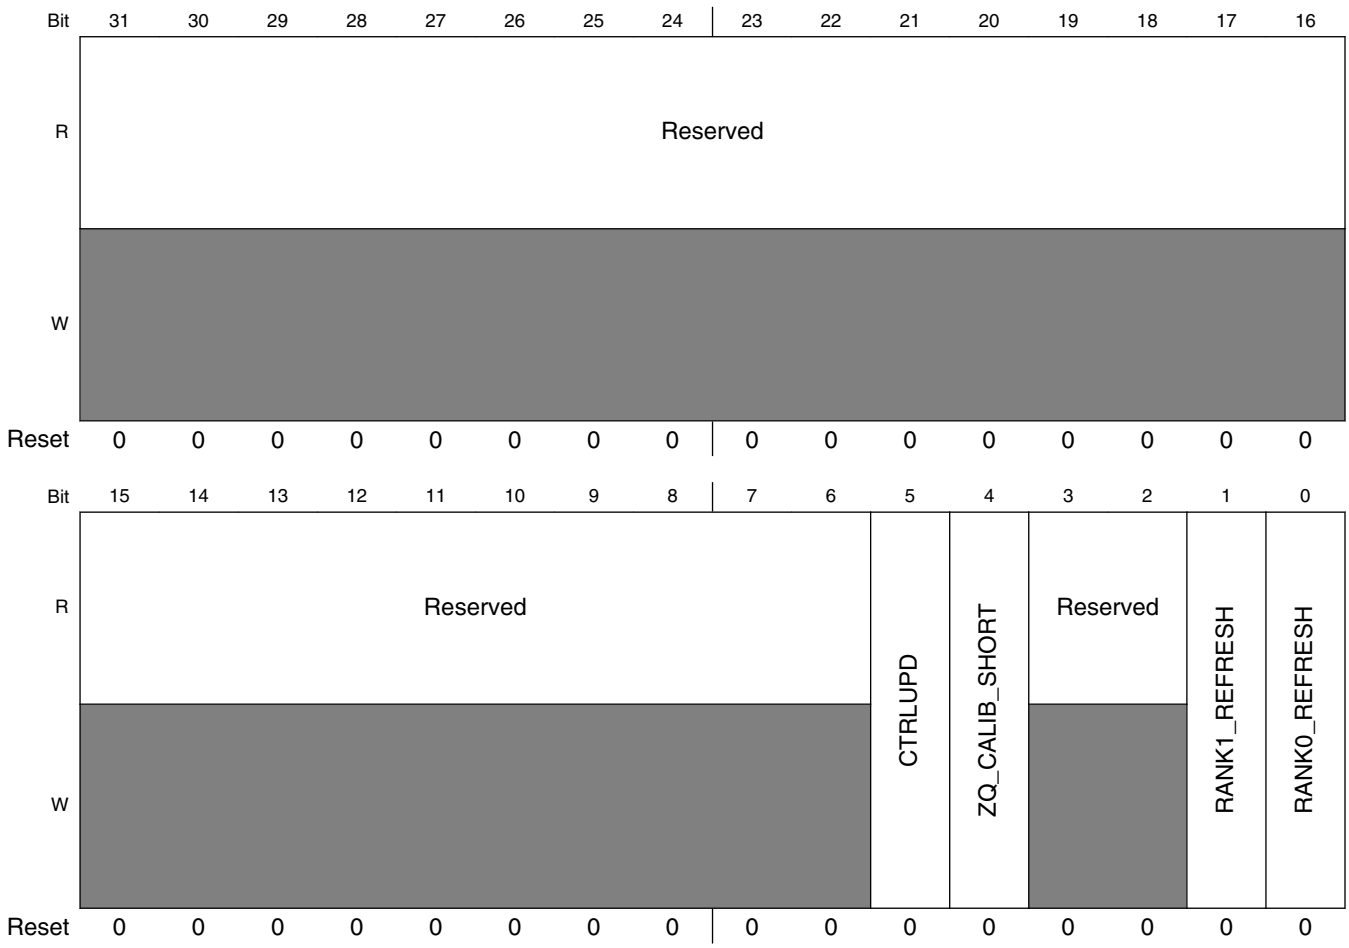
Table continues on the next page...

DDRC_DBGCAM field descriptions (continued)

Field	Description
DBG_HPR_Q_DEPTH	High Priority Read Queue Depth FOR DEBUG ONLY **Value After Reset**: 0x0 **Exists**: Always

9.2.5.2.62 Command Debug Register (DDRC_DBGCMD)

Address: 307A_0000h base + 30Ch offset = 307A_030Ch



DDRC_DBGCMD field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use
5 CTRLUPD	Setting this register bit to 1 indicates to the DDRC to issue a dfi_ctrlupd_req to the PHY. When this request is stored in the DDRC, the bit is automatically cleared. This operation must only be performed when DFIUPD0.dis_auto_ctrlupd = 1.

Table continues on the next page...

DDRC_DBGCMD field descriptions (continued)

Field	Description
	Value After Reset: 0x0 **Exists**: Always **Testable**: Read only
4 ZQ_CALIB_ SHORT	Setting this register bit to 1 indicates to the DDRC to issue a ZQCS (ZQ calibration short) command to the SDRAM. When this request is stored in the DDRC, the bit is automatically cleared. This operation can be performed only when ZQCTL0.dis_auto_zq = 1. It is recommended NOT to set this register bit if in Init operating mode. This register bit is ignored when in Self-Refresh and Deep power-down operating modes and Maximum Power Saving Mode. **Value After Reset**: 0x0 **Exists**: MEMC_DDR3_OR_4_OR_LPDDR2 == 1 **Testable**: Read only
3–2 Reserved	This field is reserved. Reserved for future use
1 RANK1_ REFRESH	Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 1.Writing to this bit causes DBGSTAT.rank1_refresh_busy to be set. When DBGSTAT.rank1_refresh_busy is cleared, the command has been stored in the DDRC. This operation can be performed only when RFSHCTL3.dis_auto_refresh = 1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode. **Value After Reset**: 0x0 Exists:MEMC_NUM_RANKS > 1 **Testable**: Read only
0 RANK0_ REFRESH	Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 0.Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in the DDRC. This operation can be performed only when RFSHCTL3.dis_auto_refresh = 1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode. **Value After Reset**: 0x0 **Exists**: Always **Testable**: Read only

9.2.5.2.63 Status Debug Register (DDRC_DBGSTAT)

Address: 307A_0000h base + 310h offset = 307A_0310h

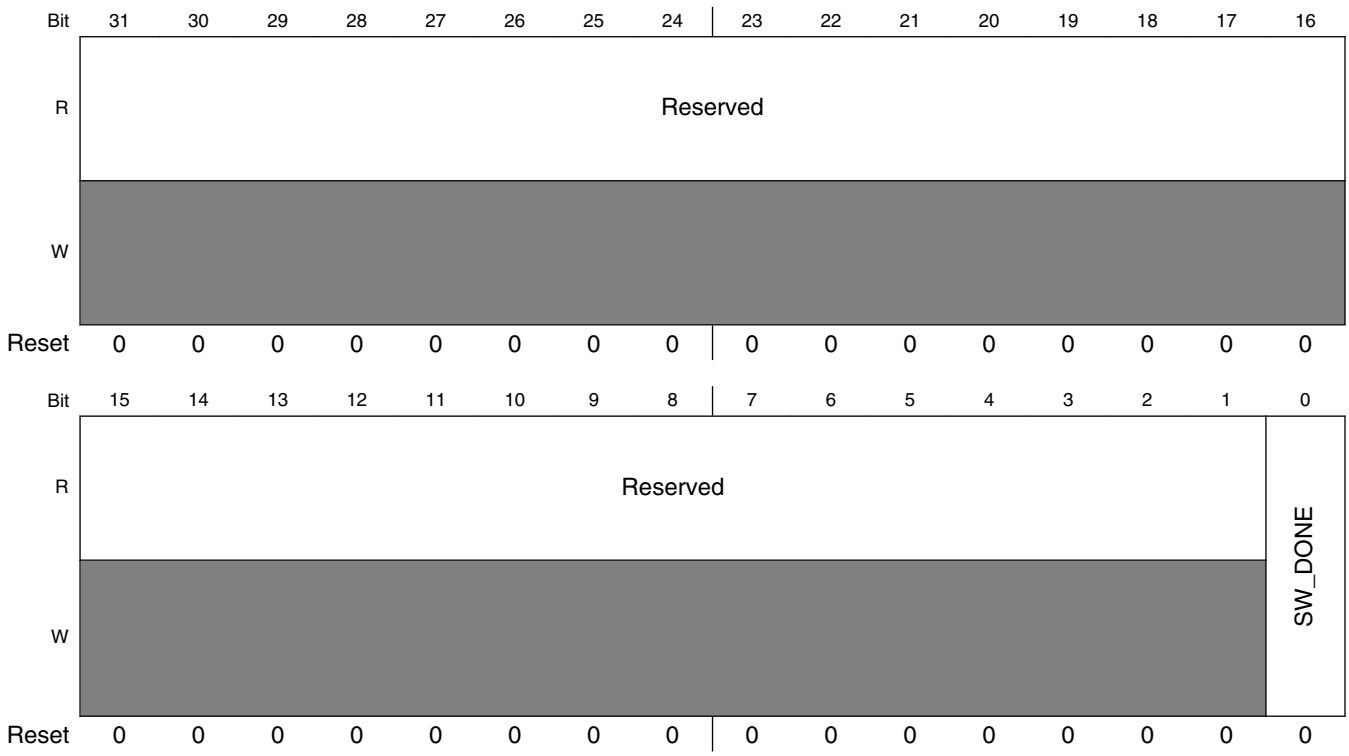
DDRC_DBGSTAT field descriptions

Field	Description
31–6 Reserved	This field is reserved. Reserved for future use
5 CTRLUPD_ BUSY	SoC coremay initiate a ctrlupd operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ctrlupd request. It goes low when the ctrlupd operation is initiated in the DDRC. It is recommended not to perform ctrlupd operations when this signal is high. **Value After Reset**: 0x0 **Exists**: Always 0 Indicates that the SoC core can initiate a ctrlupd operation 1 Indicates that ctrlupd operation has not been initiated yet in the DDRC
4 ZQ_CALIB_ SHORT_BUSY	SoC core may initiate a ZQCS (ZQ calibration short) operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQCS request. It goes low when the ZQCS operation is initiated in the DDRC. It is recommended not to perform ZQCS operations when this signal is high. **Value After Reset**: 0x0 **Exists**: MEMC_DDR3_OR_LPDDR2 == 1
3–2 Reserved	This field is reserved. Reserved for future use
1 RANK1_ REFRESH_ BUSY	SoC core may initiate a rank1_refresh operation (refresh operation to rank 1) only if this signal is low. This signal goes high in the clock after DBGCMD.rank1_refresh is set to one. It goes low when the rank1_refresh operation is stored in the DDRC. It is recommended not to performrank1_refresh operationswhen this signal is high. **Value After Reset**: 0x0 **Exists**: MEMC_NUM_RANKS > 1 0 Indicates that the SoC core can initiate a rank1_refresh operation 1 Indicates that rank1_refresh operation has not been stored yet in the DDRC
0 RANK0_ REFRESH_ BUSY	SoC core may initiate a rank0_refresh operation (refresh operation to rank 0) only if this signal is low. This signal goes high in the clock after DBGCMD.rank0_refresh is set to one. It goes low when the rank0_refresh operation is stored in the DDRC. It is recommended not to performrank0_refresh operationswhen this signal is high. **Value After Reset**: 0x0 **Exists**: Always 0 Indicates that the SoC core can initiate a rank0_refresh operation 1 Indicates that rank0_refresh operation has not been stored yet in the DDRC

9.2.5.2.64 Software Register Programming Control Enable (DDRC_SWCTL)

Address: 307A_0000h base + 320h offset = 307A_0320h

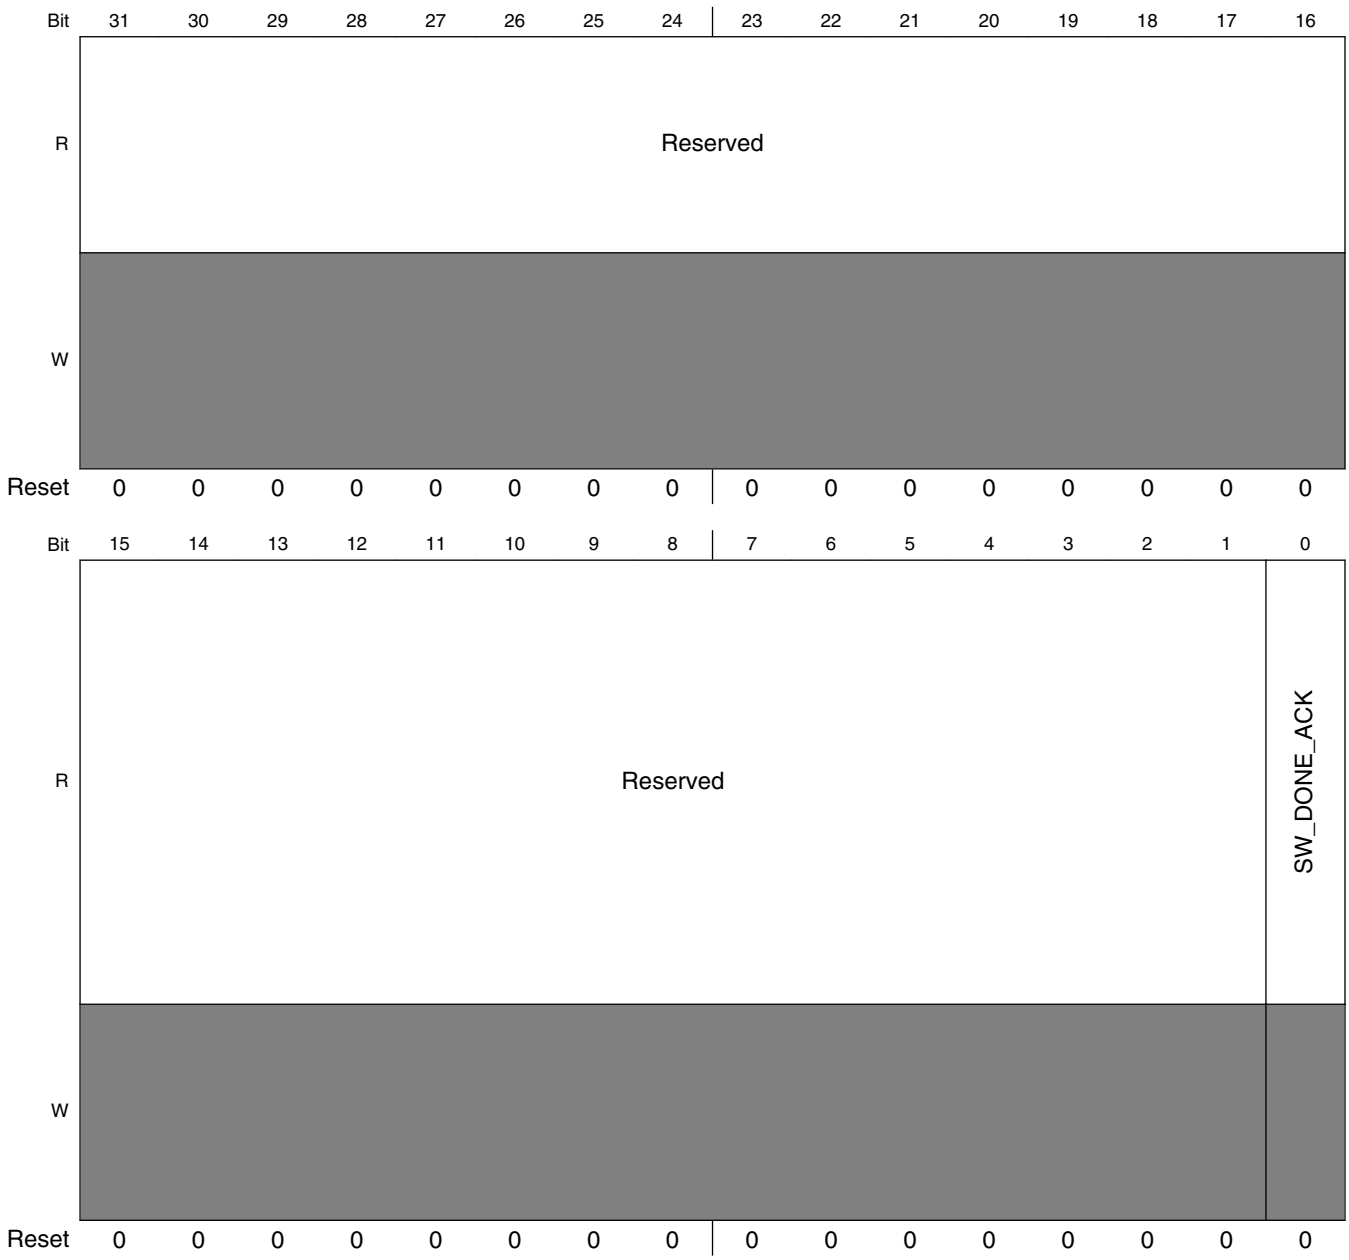


DDRC_SWCTL field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 SW_DONE	Enable quasi dynamic register programming outside reset. Program register to 0 to enable quasi dynamic programming. Set back register to 1 once programming is done. **Value After Reset**: 0x1 **Exists**: Always

9.2.5.2.65 Software Register Programming Control Status (DDRC_SWSTAT)

Address: 307A_0000h base + 324h offset = 307A_0324h



DDRC_SWSTAT field descriptions

Field	Description
31–1 Reserved	This field is reserved. Reserved for future use
0 SW_DONE_ACK	Register programming done

Table continues on the next page...

DDRC_SWSTAT field descriptions (continued)

Field	Description
	This register is the echo of SWCTL.sw_done.Wait for sw_done value 1 to propagate to sw_done_ack at the end of the programming sequence to ensure that the correct registers values are propagated to the destination clock domains. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.3 DDRMC multi port registers

The following n and m is always 0 in the register.

Field	Description
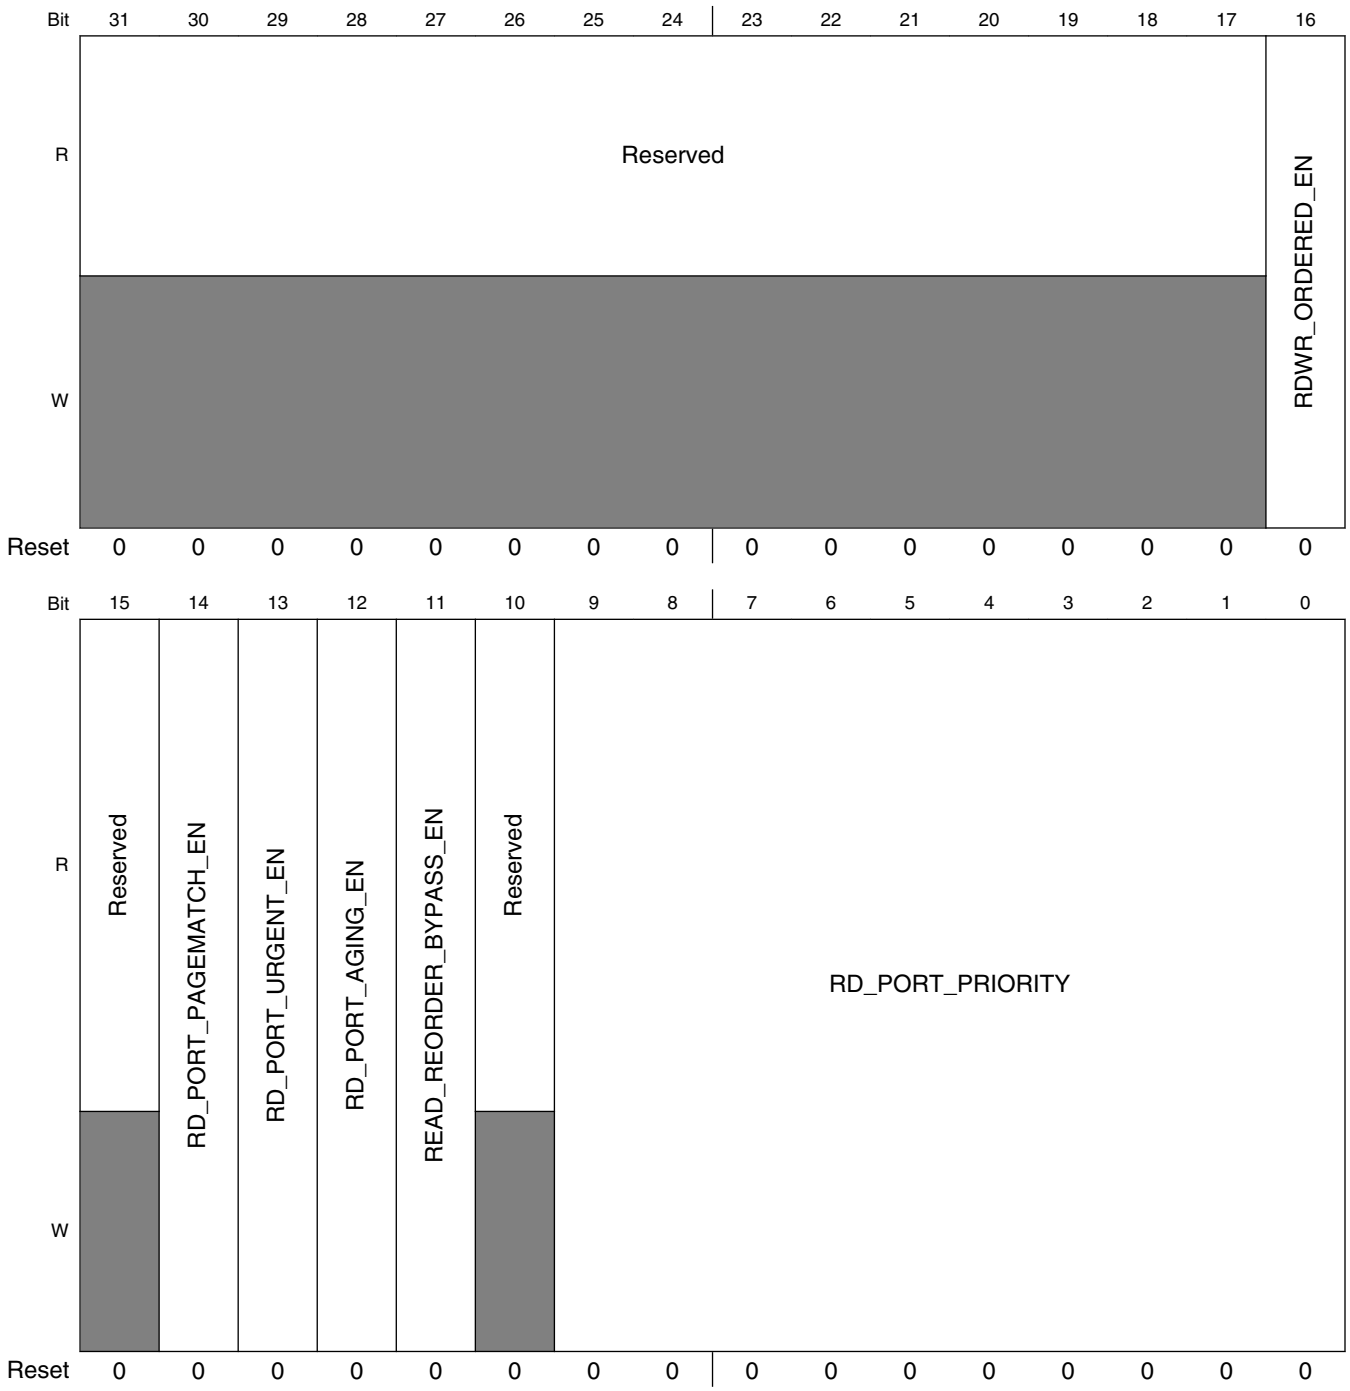
4 PAGEMATCH_LIMIT	Page Match Four Limit If set to 1, limits the number of consecutive same page DDRC transactions that can be granted by the Port Arbiter to four when Page Match feature is enabled. If set to 0, there is no limit imposed on number of consecutive same page DDRC transactions. **Value After Reset**: 0x0 **Exists**: Always
3–1 Reserved	This field is reserved. Reserved for future use
0 GO2CRITICAL_EN	If set to 1 (enabled), sets hif_go2critical_wr and hif_go2critical_lpr / hif_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from AXI master. If set to 0 (disabled), hif_go2critical_wr and hif_go2critical_lpr / hif_go2critical_hpr signals at DDRC are driven to 1b'0. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.3.3 Port n Configuration Read Register (DDRC_MP_PCFGR_0)

Exists: DDRC_INCL_ARB==1 && DDRC_PORT_n==1

Address: 307A_0000h base + 404h offset = 307A_0404h



DDRC_MP_PCFGR_0 field descriptions

Field	Description
31–17 Reserved	This field is reserved. Reserved for future use
16 RDWR_ ORDERED_EN	Enable ordered read / writes. If set to 1, preserves the ordering between read transaction and write transaction issued to the same address, on a given port. In other words, the controller ensures that all same address read and write commands from the application port interface are transported to the DFI interface in the order of acceptance. This feature is useful in cases where software coherency is desired for masters issuing back-to-back read / write transactions without waiting for write/read responses. **NOTE:** This register has an effect only if necessary logic is instantiated via the DDRC_RDWR_ORDERED_0 parameter. **Value After Reset**: 0x0 **Exists**: DDRC_A_RDWR_ORDERED_0 == 1 && DDRC_A_AXI_0 == 1
15 Reserved	This field is reserved. Reserved for future use
14 RD_PORT_ PAGEMATCH_ EN	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. **Value After Reset**:0x1 **Exists**: Always
13 RD_PORT_ URGENT_EN	If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and hif_go2critical_lpr / hif_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. **NOTE:** Arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). **Value After Reset**: 0x0 **Exists**: Always
12 RD_PORT_ AGING_EN	If set to 1, enables aging function for the read channel of the port. **Value After Reset**: 0x0 **Exists**: Always
11 READ_ REORDER_ BYPASS_EN	If set to 1, read transactions with ID not covered by any of the virtual channel ID mapping registers are not reordered. **Value After Reset**: 0x0 **Exists**: DDRC_PORT_CHm_0 == 1
10 Reserved	This field is reserved. Reserved for future use
RD_PORT_ PRIORITY	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bit of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bit of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this

Table continues on the next page...

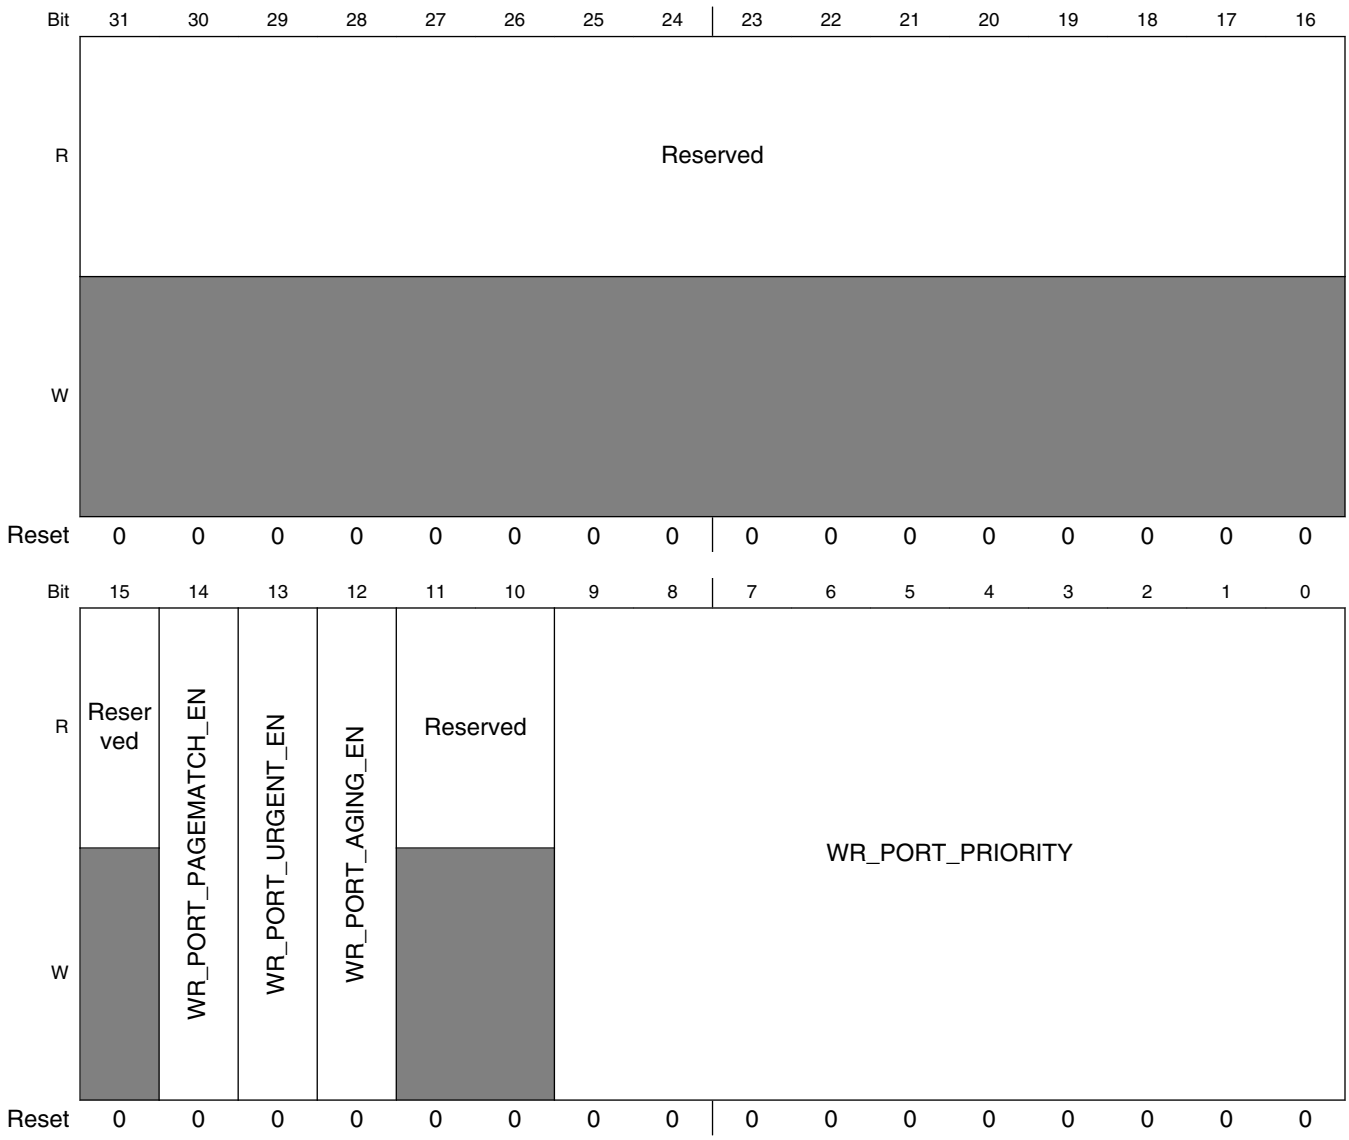
Address: 307A_0000h base + 408h offset = 307A_0408h



DDRC_MP_PCFGW_0 field descriptions

Field	Description
31–15 Reserved	This field is reserved. Reserved for future use
14 WR_PORT_ PAGEMATCH_ EN	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register. **Value After Reset**: 0x1 **Exists**: Always
13 WR_PORT_ URGENT_EN	If set to 1, enables the AXI urgent sideband signal (awurgent). When enabled and awurgent is asserted by the master, that port becomes the highest priority and hif_go2critical_wr signal to DDRC is asserted if enabled in PCCFG.go2critical_enregister. **NOTE:** Awurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command). **Value After Reset**: 0x0 **Exists**: Always
12 WR_PORT_ AGING_EN	If set to 1, enables aging function for the write channel of the port. **Value After Reset**: 0x0 **Exists**: Always
11–10 Reserved	This field is reserved. Reserved for future use
WR_PORT_ PRIORITY	Determines the initial load value of write aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bit of the write aging counter sets the initial priority of the write channel of a given port. Port's priority will increase as the higher significant 5-bit of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level. For multi port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (awqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. **NOTE:** Two LSBs of this register field are tied internally to 2'b00. **Value After Reset**: 0x0 **Exists**: Always

9.2.5.3.5 Port n Channel m Configuration ID Mask Register (DDRC_MP_PCFGIDMASKCH_*n*0)

M signifies the number of the virtual channel for the Port n where m = 0 to 15.

Exists: DDRC_PORT_CH m_0==1

Address: 307A_0000h base + 410h offset + (8d × i), where i=0d to 15d

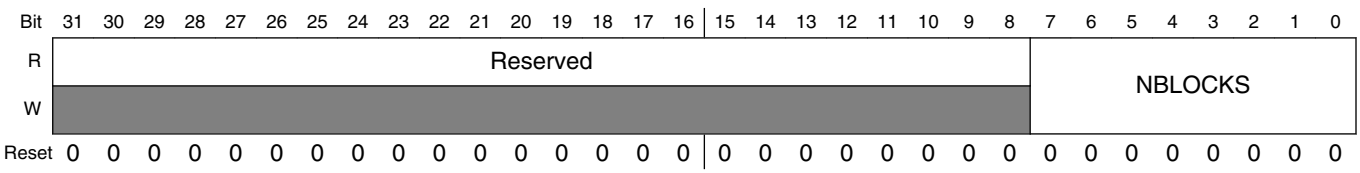
Exists: DDRC_INCL_ARB==1 && DDRC_A_SAR_n==1

Address: 307A_0000h base + F08h offset + (8d × i), where i=0d to 3d



DDRC_MP_SARSIZE*n* field descriptions

Field	Description
31–8 Reserved	This field is reserved. Reserved for future use
NBLOCKS	Number of blocks for address region n. This register determines the total size of the region in multiples of minimum block size as specified by the hardware parameter DDRC_SARMINSIZE. The register value is encoded as number of blocks = nblocks + 1. For example, if register is programmed to 0, region will have 1 block. **Value After Reset**: 0x0 **Exists**: Always

9.3 DDR PHY (DDRP)

9.3.1 Overview

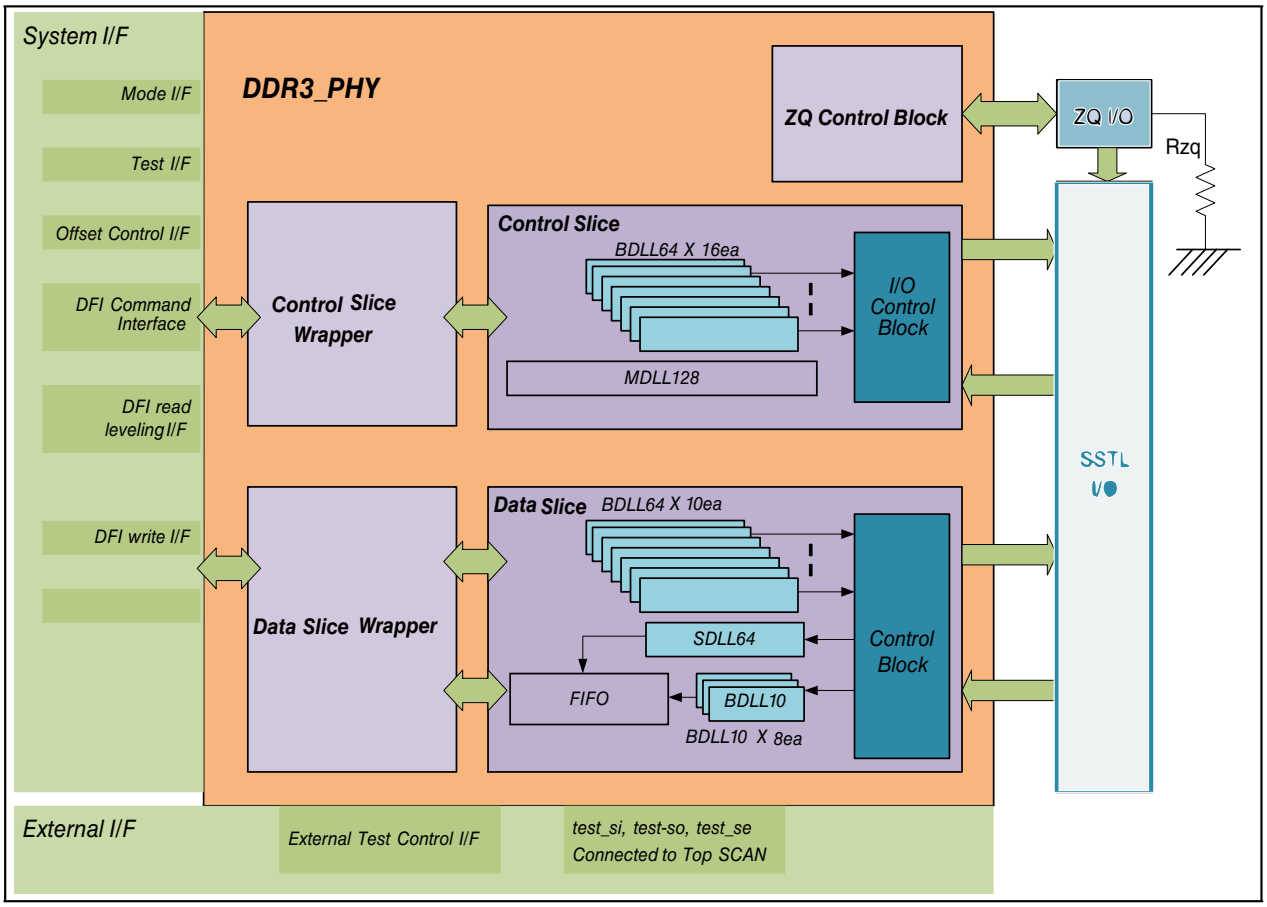


Figure 9-9. LPDDR3 HPHY

9.3.1.1 Features

The DDR3 PHY (V6R0) provides the following features:

- Fully supports DDR3, LPDDR2, LPDDR3 memory types.
- Fully digital DLL for 90° phase shift of strobe signal.
- FIFO (width:16-bit / depth:16 per 8-bit data slice) for programmable read timing.
- Provide feedback loop-back test scheme for at-speed data and control channel test.

NOTE

- RL should be greater than 4. If PHY is used with the dual-rank configurations, RL (Read Latency) and BL (Burst Length) should be used as the same value for those two ranks.
- ODT is not supported for LPDDR3.

9.3.2 Block diagram description

9.3.2.1 DLL and CONTROL I/F

9.3.2.1.1 DLL

DLL detects one clock period and generates delay line control signal. Delay line consists of 128 delay cells and is controlled by control logic. Delay line delays input clock and phase detector compares input clock and delayed clock. After phase comparison, phase detector detects whether delayed clock is lag or lead and generates INC / DEC signals to increase or decrease the delay amount of the delay line.

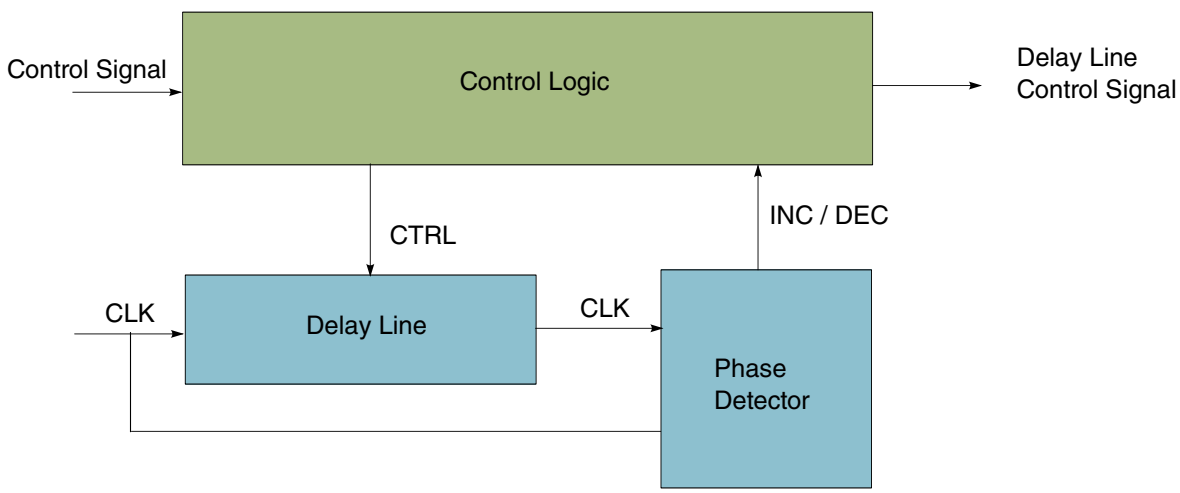

Figure 9-10. Block Diagram of DLL

9.3.2.1.2 Control

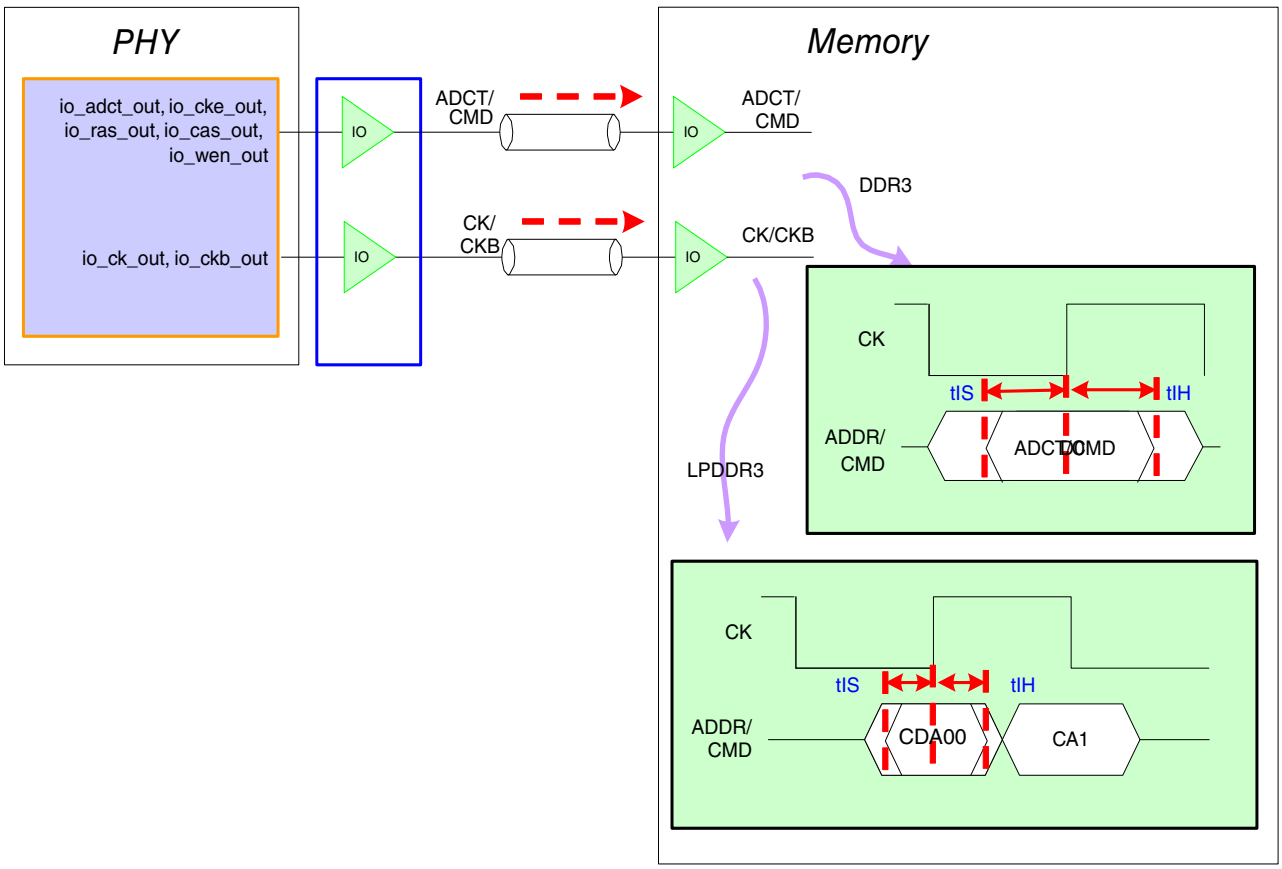

Figure 9-11. Block Diagram of the Control Path

The control block generates address, control, and clock signals that are sent to the I/O pads. ADCT[24:0] are the address traces that consist of Reset (RSN), ODT, Address[15:0], Bank Address[2:0], and Chip Selects[1:0] (chip selects [3:2] are not used in this implementation. Command signals consist of RAS, CAS, and WE. CK and CKB are differential clock signals. Address and control signals are center aligned at rising CK edge to maximize address / control signal setup / hold timing.

9.3.2.2 DATA I/F

9.3.2.2.1 Write path

Data I/F block generates data, mask and strobe signals to interface memory for memory write transaction. DQs are 8-bit width data signals, DM is data mask signal and DQS is strobe signal. Therefore, to interface 32-bit memory, 4 data slices are required.

DQS is edge-aligned signal to CK / CKB and DQs / DM are center-aligned signals to the edge of CK / CKB.

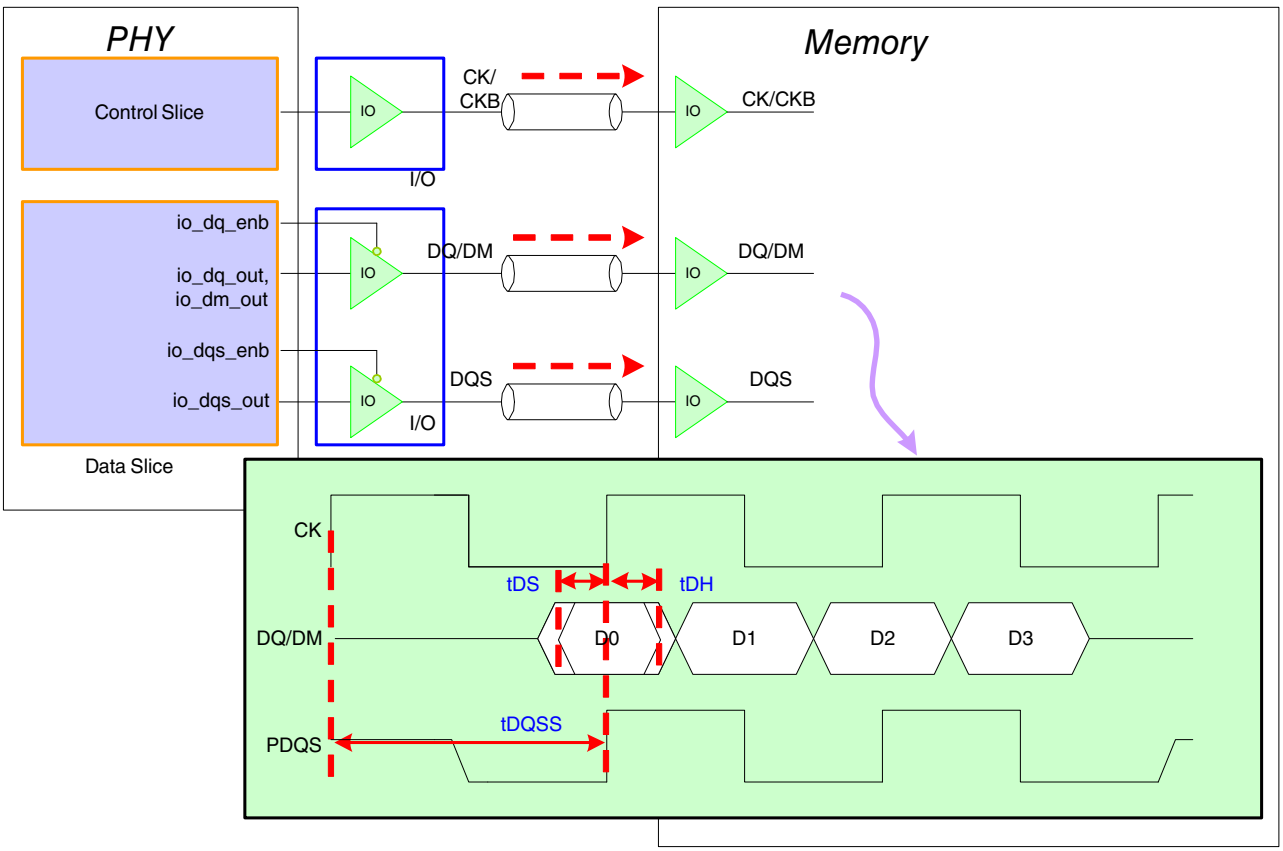

Figure 9-12. Block Diagram of the Write Path

9.3.2.2.2 Read path

Read blocks capture valid data using strobe signal which come from memory for read transaction. DQs are 8-bit width data signals, DQS is strobe signal.

DQs and DQS from memory are edge aligned to CK edge. Therefore, to capture DQs using DQS, DQS should be delayed to make 90° phase shifted DQS, i.e. DQs should be center aligned to the edge of delayed DQS and captured DQs are stored in the FIFO.

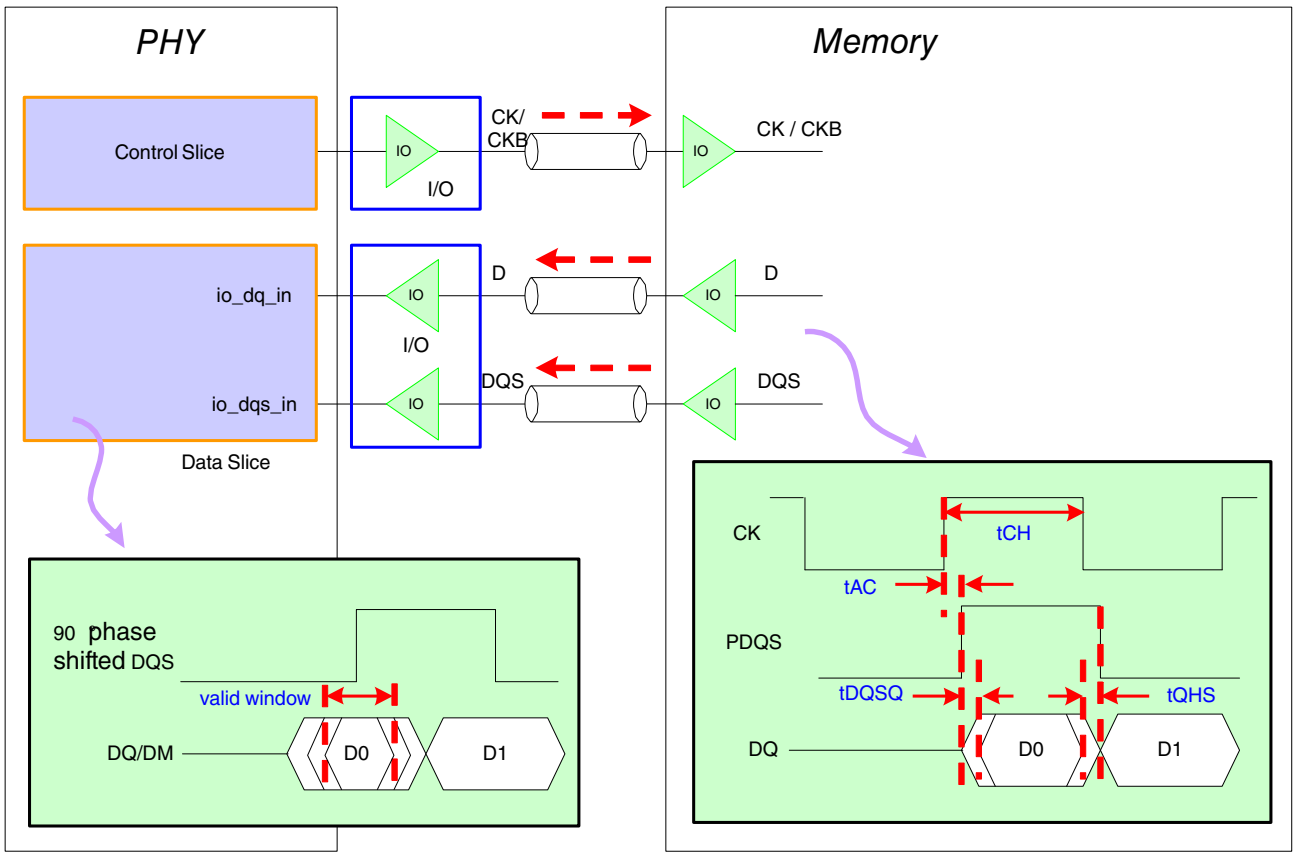

Figure 9-13. Block Diagram of the Read Path

9.3.2.2.3 ZQ CALIBRATION I/O

ZQ_IO calibrates the output and termination impedance and passes through impedance control signals to each I/O cells. RZQ should be 240 ohm.

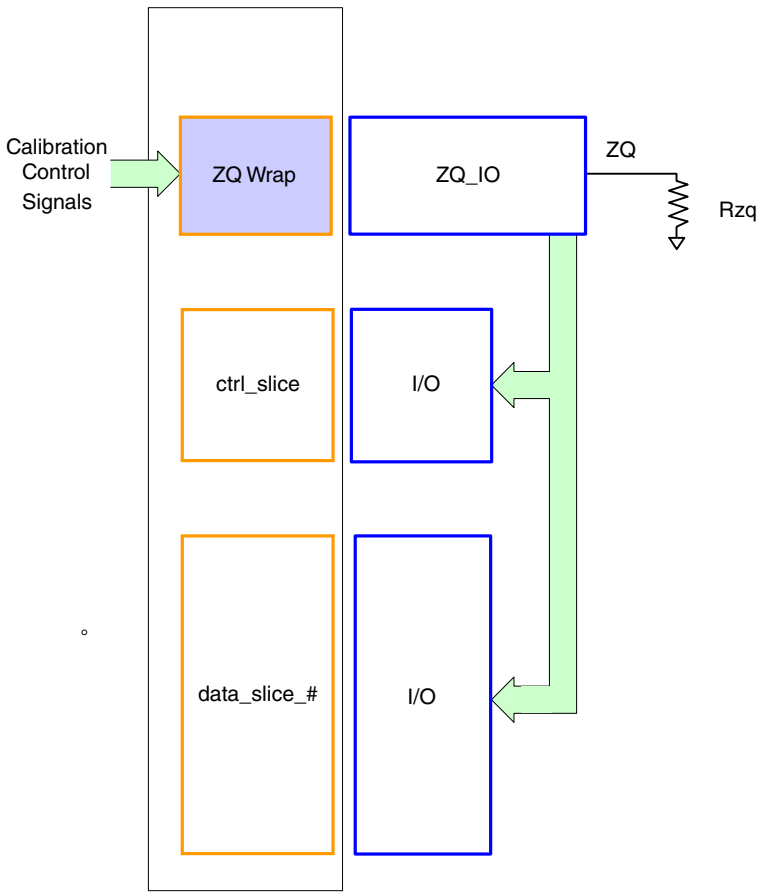

Figure 9-14. Connectivity Between ZQ I/O and the other I/Os

9.3.3 Functional description

9.3.3.1 DATAPATH

The timing parameters tphy_wrlat and tphy_wrdata define the delay from the write command to the dfi_wrdata_en_pN signal, and from the dfi_wrdata_en_pN signal to when data will be driven on the dfi_wrdata_pN signal respectively. These timing parameters are defined in terms of DFI PHY clocks.

- tphy_wrlat = WL - 1, tphy_wrdata = 2, for example ifWL = 4, tphy_wrlat = 3, tphy_wrdata = 2 (LPDDR3)
- tphy_wrlat = WL - 2, tphy_wrdata = 2, for example ifWL = 8, tphy_wrlat = 6, tphy_wrdata = 2(DDR3)

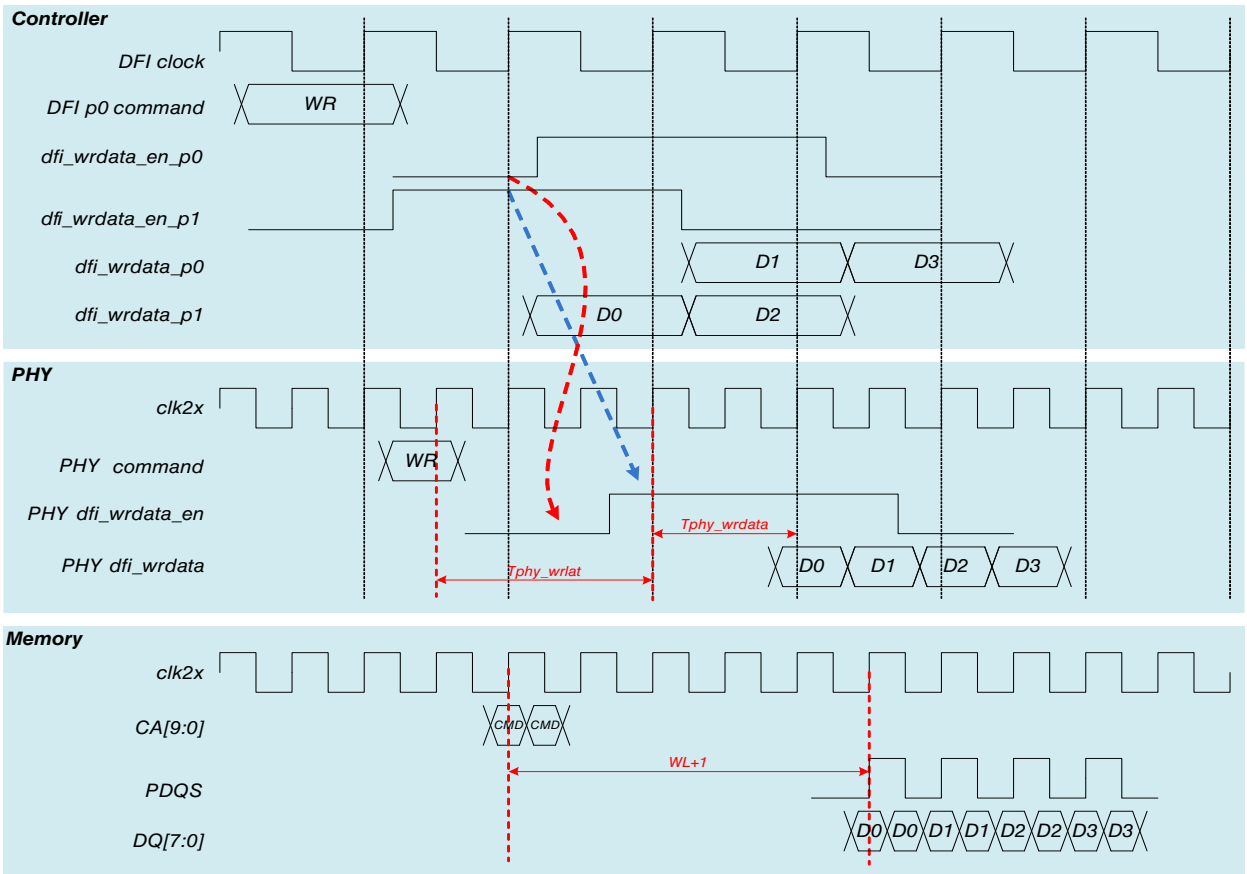

Figure 9-15. Data write Timing Diagram with phase 0 command (1:2 frequency ratio, LPDDR3)

Signal interface timing for data write is shown in the following figure. dfi_wrdata_en_p0/p1 is enable signal to indicate dfi_wrdata_p0/p1 and dfi_mask_p0/p1 are valid.

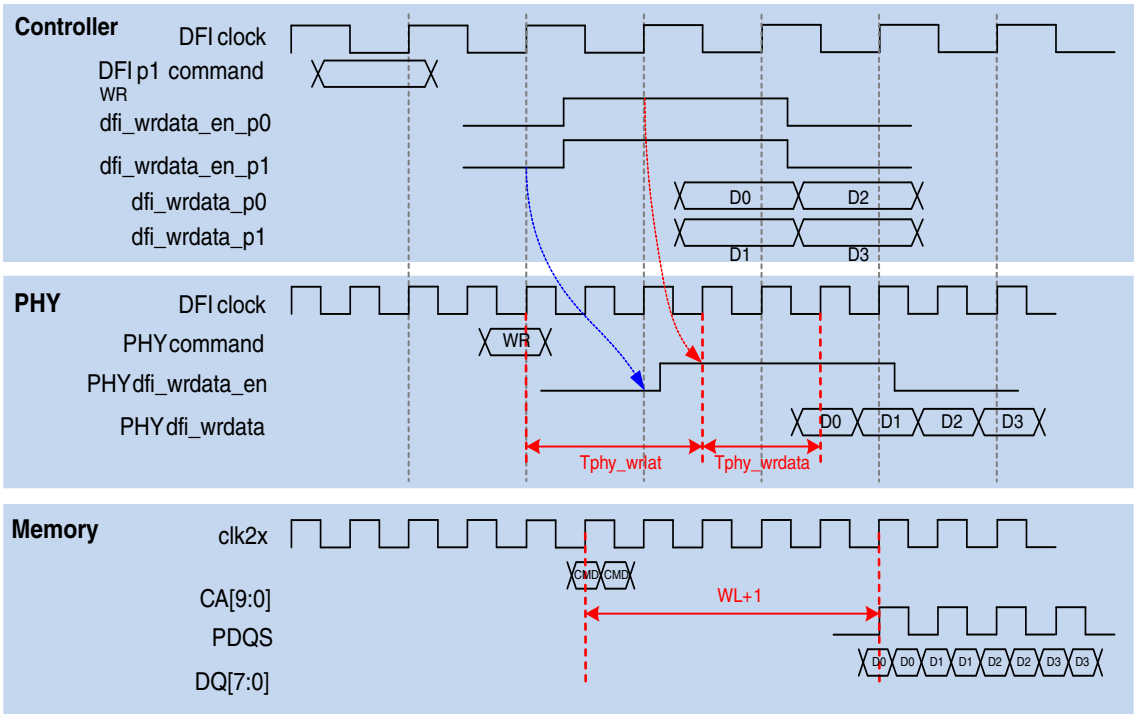

Figure 9-16. Data write Timing Diagram with phase 1 command (1:2 frequency ratio, LPDDR3)

The timing parameters trddata_en and tphy_rdlat define the delay from the read command to the dfi_rddata_en_pN signal, and from the dfi_rddata_en_pN signal to when data will be returned on the dfi_rddata_wN bus, respectively. These timing parameters are defined in terms of DFI PHY clocks and are measured relative to how the PHY interprets the data.

Signal interface timing for data read is shown in the following figure . After read command is issued, DQ and PDQS/NDQS are driven by the memory and DQ is stored in FIFO in read data path. After read data is stored in FIFO, when dfi_rddate_en_p0/p1 is issued from controller, the valid read data is driven during HIGH dfi_rddata_valid_w0/w1 signal at the rising edge of the clk signal.

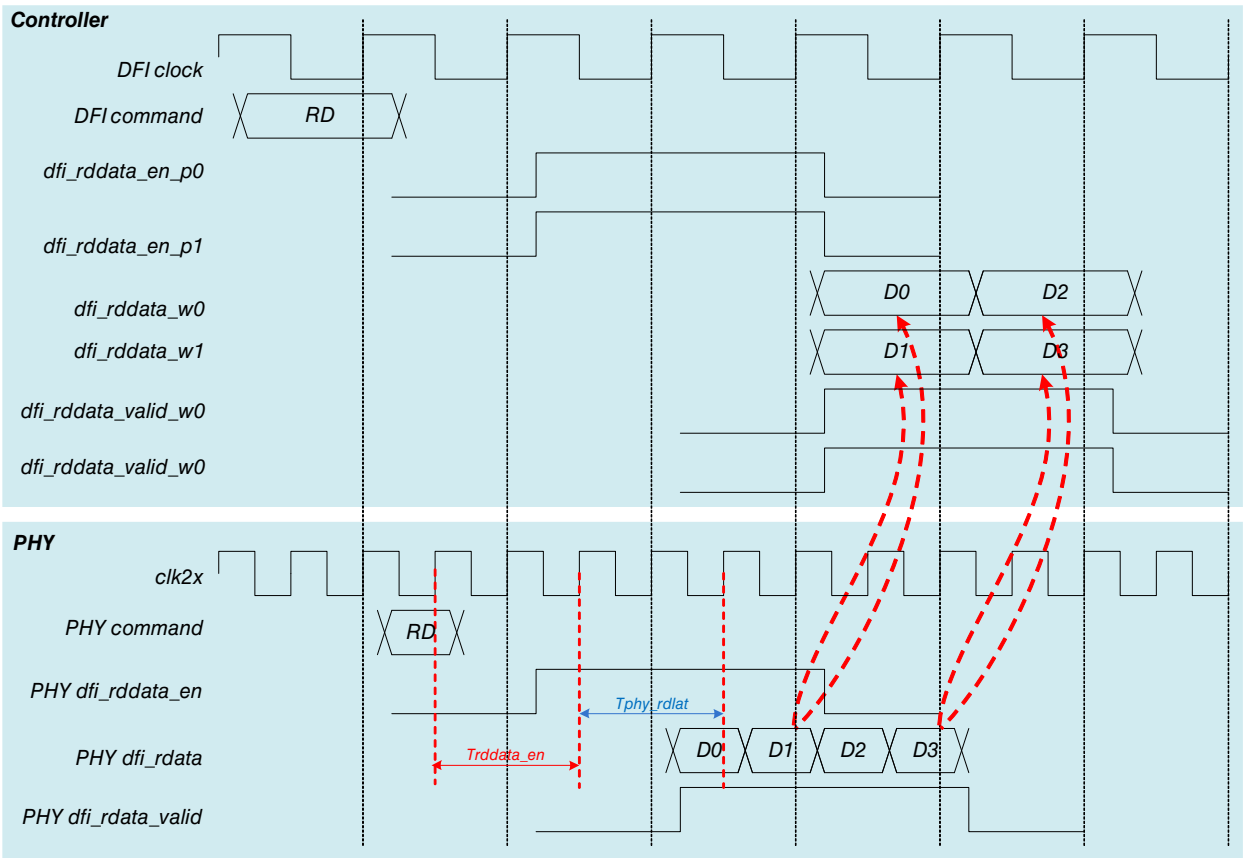

Figure 9-17. Data Read Timing Diagram (1:2 frequency ratio)

The following figure illustrates control signal and data read path. At the read path, DQS clean block is used to clean DQS signal and Delay line is used for 90° phase shift of DQS. If read command is issued at A point, read command is driven and memory drives DQ and DQS after CL(CAS Latency) at B point. DQ and DQS experience board and IO input delay and arrive at C point. Delay line execute 90° phase shift of DQS and shifted DQS is used as a clock signal to capture DQ in FIFO. After that dfi_rddata_en_p0/p1 is driven HIGH by the controller, the FIFO outputs valid read data at E point.

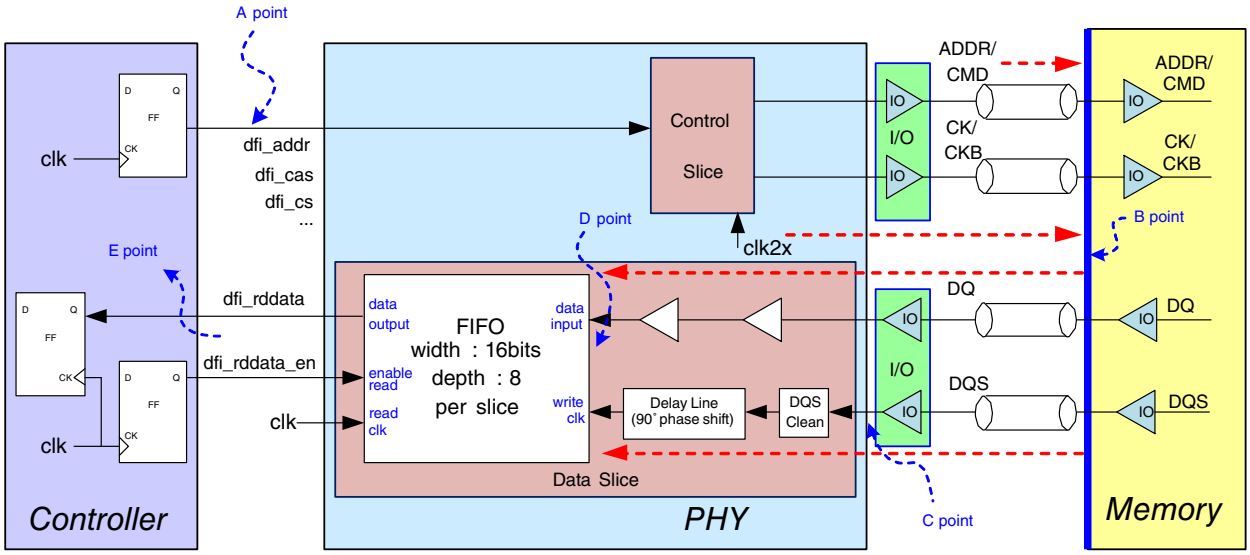

Figure 9-18. Read Data Path

The following figure illustrates the full timing diagram of command and data path for memory read. The deterministic timing values for the read path are latency to generate command (1 clock cycle), CL (CAS Latency) and data write time in FIFO (1 clock cycle). But the propagation delay of command (from PHY to memory) and DQ / DQS (from memory to PHY) varies according to the board designs and operating condition. And also internal logic delay in the following figure. is also different according to operating condition. For this reason, read data arrival time is quite different according to designs and environment and deterministic read timing calculation is difficult. To overcome this issue, FIFO of 8-depth is used in read path and data read timing can be programmed.

DQS cleaning is needed to remove high-Z state of DQS during read, but there is a lot of variation in DQS. We recommended that the pull-down mode in DQS (LP_CON0[NS-1:0]) should be used to remove high-Z state of DQS.

When it is in the pull-down mode, the duration of HIGH in "ctrl_gate_p0 /p1" should be extended to compensate the variation of DQS with ctrl_shgate = 0

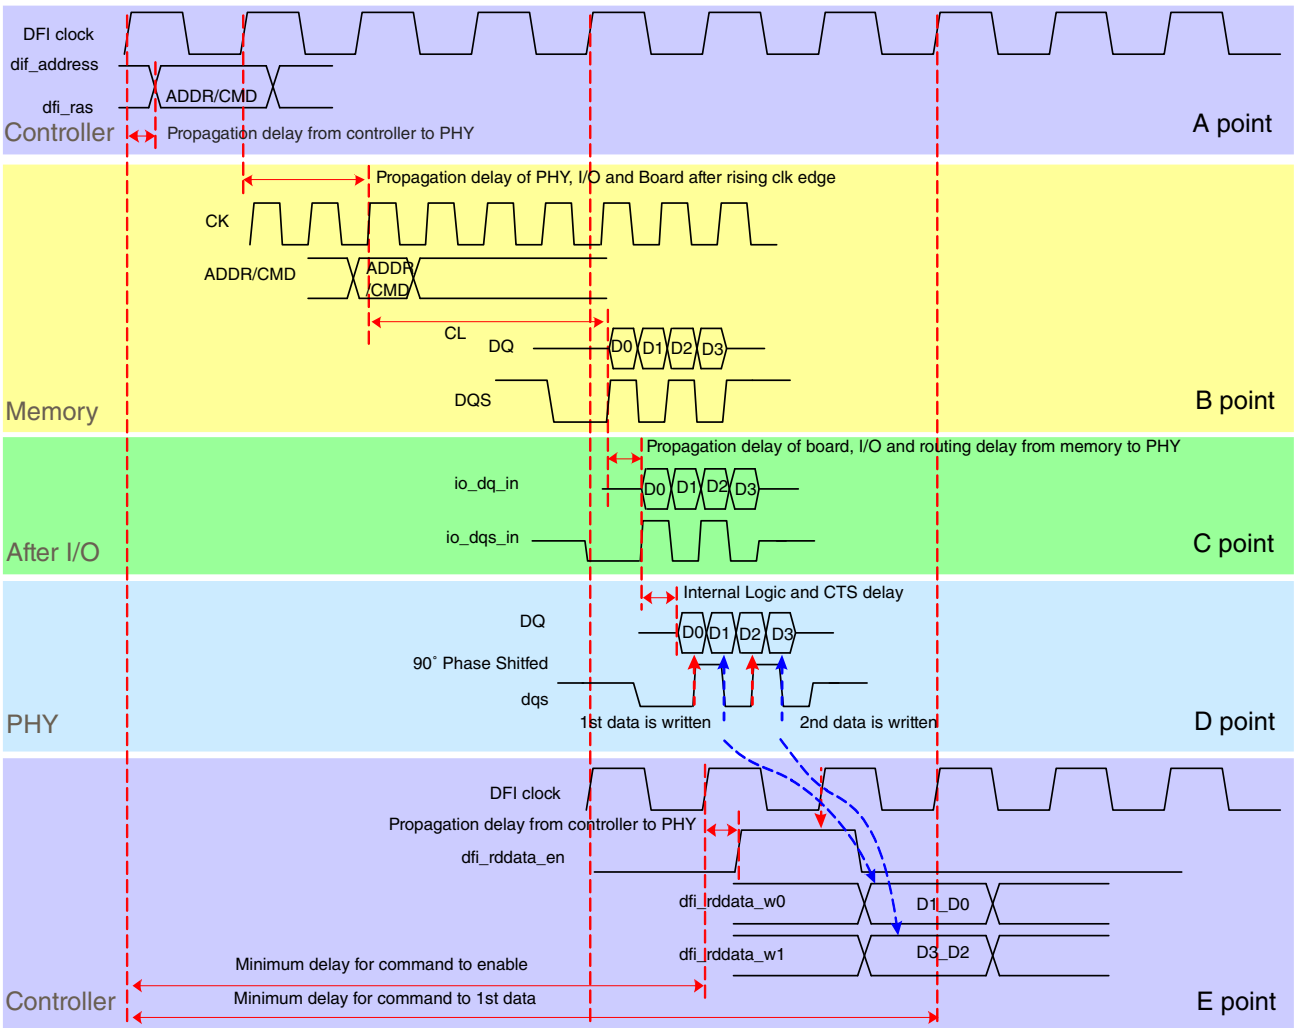

Figure 9-19. Full Read Path Timing Diagram

9.3.3.2 Package and board guide

In the following table, Skew in picoseconds is translated to physical length on the PCB.

Table 9-14. Skew Including Package and Board

Group	Signals	Skew	From	To
G0_1	CK / CKB	±10ps	Pad	Memory Pin
G0_2	PDQS[N] / NDQS[N]	±10ps	Pad	Memory Pin

Table continues on the next page...

Table 9-14. Skew Including Package and Board (continued)

Group	Signals	Skew	From	To
G1	PDQS[N] / NDQS[N] DQ[(N + 1) * 8 - 1:N * 8] DM[N]	±25ps from PDQS[N] / NDQS[N]	Pad	Memory Pin
G2	CK / CKB, RESET, ADCT[15:0], CS, RAS, CAS, BANK, CKE, WEN, ODT	±25ps from CK / CKB	Pad	Memory Pin
G3 (LPDDR2/LPDDR3)	CK / CKB, ADCT[9:0]	±25ps from CK / CKB	Pad	Memory Pin
G4	CK / CKB, P / NDQS[NS-1:0]	-100ps from CK / CKB	Pad	Memory Pin

NOTE

- Recommend that CK / CKB should be delayed than P/ NDQS[NS-1:0] (G4)
- When CK / CKB is connected to two rank, the skew of CK / CKB between two ranks should follow "G0_1" in.
- If using Write Leveling to support DIMM, The skew of "-100ps" for G4 can be changed by "-2500ps" which came from 2 cycles at 800 MHz.
- N means 0,1… NS-1.

9.3.3.3 Initialization

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Select Memory Type (= PHY_CON0[12:11]).
  - ctrl_ddr_mode = 2'b11 (LPDDR3)
  - ctrl_ddr_mode = 2'b10 (LDDR2)
  - ctrl_ddr_mode = 2'b01 (DDR3)
- GATE default settings for DQS Cleaning
  - Set "ctrl_gateadj = 1, ctrl_gateduradj = 2, ctrl_shgate = 0, ctrl_pulld_dqs = 0xF, ctrl_shiftc = 0x0" (ctrl_atgate = 1)
- Set Read Latency (RL), Burst Length (BL) and Write Latency (WL)
  - SetRL (= PHY_CON4[4:0]), BL (= PHY_CON4[12:8]),WL (= PHY_CON4[20:16])
- ZQ Calibration (Please refer to ZQ I/O control procedure for more details)
  - Enable and Disable "zq_clk_div_en" in ZQ_CON0[18]
  - Enable "zq_manual_str" in ZQ_CON0[1]
  - Wait until "zq_cal_done" (ZQ_CON1[0]) is enabled.
  - Disable "zq_manual_str" in ZQ_CON0[1]

- Memory Controller should assert "dfi_init_start" from LOW to HIGH.
- Memory Controller should wait until "dfi_init_complete" is set to finish DLL lock.
- Enable DQS pull down mode
  - Please be careful that DQS pull down can be disabled only after Gate Leveling is done.
- Memory Controller should assert "dfi_ctrlupd_req" after "dfi_init_complete" is set.
- Start Memory Initialization by memory controller.

NOTE

Recommend to set "upd_mode = 0" (= OFFSETD_CON0[28])
for PHY-Initiated Update

Caution: Please do not change the frequency of "clkm" or voltage during operation. Those conditions should be changed without memory access. After changing, "ctrl_start" should be clear and set to lock again.

9.3.3.4 Training Procedure

9.3.3.4.1 WRITE LEVELING

Write Leveling compensates for the additional flight time skew delay introduced by the package, board and on- chip with respect to strobe(= DQS) and clock.Write Leveling can support 1 rank only (CS[0] or CS[1]), so CK and DQS delay at each rank should be same as possibe to support two ranks. For example, CK delay at rank0 and rank1 should be designed to be same on package / board.

9.3.3.4.1.1 H/W write leveling

- Memory Controller should configure Memory (DDR3, LPDDR3) in Write Level mode.
  - Set "cmd_default[8:7] = 2'b11" (LPDDR_CON4[8:7]) to enable "ODT[1:0]" signals during Write Leveling.
- Configure PHY in Write Level mode.
  - Enable "wrlvl_mode" in PHY_CON0[16].
- Start Write Leveling by setting "wrlvl_start = 1'b1" (= PHY_CON3[16])
- Wait until "wrlvl_resp = 1'b1" (= PHY_CON3[24])
- Finish Write Leveling by setting "wrlvl_start = 1'b0" (= PHY_CON3[16])
- Configure PHY in normal mode.

    - Disable "wrlvl_mode" in PHY_CON0[16].
- Set "cmd_default[8:7] = 2'b00" (LPDDR_CON4[8:7]) to disable "ODT[1:0]" signals.
- Set"reg_mode[0] = 1'b1" (= PHY_CON3[0]).
- Memory Controller should configure Memory (DDR3, LPDDR3) in normal mode.
- Enable and Disable "ctrl_resync" (= OFFSETD_CON0[24])" to make sure All SDLL is updated.
- Recommend to set "ctrl_readduradj = 1"

9.3.3.4.1.2 Write leveling dll manual setting

After knowing the board and package delay exactly, you can use the following manual setting instead ofWrite Leveling.

- Set WR_LVL_CON0 for Data Slices 0-3.
    - For example, suppose the following conditions
        - "ctrl_lock_value[8:0] = 0x7F(= 127)"
        - The delay of CK is about 118ps, 295ps, 512ns, and 704ps for Data Slices 0-3.
    - Fine step delay will be about 9.84ps by calculating "1250 / 127" at 800 MHz.
    - The delay of CK can be represented by 0x0C, 0x1E, 0x34, and 0x47 with Fine step delay unit.
        - If the delay of CK at DRAM is greater than 1 or 2 cycle, please ignore that cycle delay when setting "WR_LVL_CON0". For example, the delay of CK for Data Slice0 is 1329ns and the fine step delay should be 0x85, but after ignoring 0x7F (= 1250ns), the setting value will be 0x08.
    - Please set "WR_LVL_CON0 = 0x47341E0C"
- Set "wrlvl_mode = 1" (= PHY_CON0[16])
- • Set "wrlvl_mode = 0" (= PHY_CON0[16])
- • Enable and Disable "ctrl_resync" (= OFFSETD_CON0[24])" to make sure All SDLL is updated.

9.3.3.4.2 GATE LEVELING

NOTE

Gate Leveling is a feature used for DDR3 mode only. Do not use Gate Leveling for LPDDR2/LPDDR3.

The goal of gate training is to locate the delay at which the initial read DQS rising edge aligns with the rising edge of the read DQS gate (= ctrl_gate_p0 / p1). Once this point is identified, the read DQS gate can be adjusted prior to the DQS, to the approximate midpoint of the read DQS preamble.

- Controller should configure Memory (DDR3) in MPR mode.
- Set Gate Leveling Mode.(1)
  - Enable "gate_cal_mode" (= PHY_CON2[24])
  - Enable "ctrl_shgate" (= PHY_CON0[8])
  - Set "ctrl_gateduradj[3:0]" (= PHY_CON1[23:20]) in the following way.
    - Set " 4'b0000" (DDR3)
    - Set " 4'b1011" (LPDDR3)
    - Set " 4'b1001" (LPDDR2)
- Enable "gate_lvl_start (= PHY_CON3[18])" to do read leveling.(2)
- Wait until "rd_wr_cal_resp" (= PHY_CON3[26]) is set.(3)
  - The maximum waiting time will be 20μs. If the any command (the refresh or pre-charge command) is required within 20μs, please issue those commands before "(1)".
- Disable "gate_lvl_start (= PHY_CON3[18])" after "rd_wr_cal_resp"(= PHY_CON3[26]) is disabled.
- Disable DQS pull down mode.(4)
- Memory Controller should configure Memory (DDR3) in normal mode.

9.3.3.5 Low frequency operation

Even if the operation frequency of "clk2x" is out of the range of MDLL Input frequency (400 ~ 800 MHz), DDR PHY can operate at the low frequency because MDLL Input clock is separated from PHY Input clock. It is recommended that Read Leveling should be done in the normal operation. The following sequence is how to operate PHY at low frequency with the different MDLL clock.

- If "dfi_init_start" = 0, Controller should assert "dfi_init_start" from LOW to HIGH.
- After "dfi_init_complete" is checked by controller, read the value of "ctrl_lock_value".
- Enter Self-Refresh (CKE = 0)
- Go to the low frequency.
  - Change "clk2x" to the low frequency, but do not change the frequency of "clkm"(400 ~ 800 MHz).
- Write the multiplied value of ctrl_lock_value[8:0] to ctrl_force[8:0].
  - Enter DLL OFF mode before Leveling.
    - Set "ctrl_dll_on = 0" (= MDLL_CON0[5])
    - Read "ctrl_lock_value[8:0]" (= MDLL_CON1[16:8]) after setting "ctrl_dll_on = 0"
  - For example, if the operation frequency will be the half of MDLL clock, two multiplied value of ctrl_lock_value should be written to "ctrl_force".
  - If "the multiplied value" is more than 0x1FF, "ctrl_force" will be "0x1FF".

- The low frequency is under 100 MHz,
  - Enter DLL OFF mode by setting "ctrl_dll_on = 0".
  - Set "ctrl_force" = 0x1FF, "ctrl_offsetd" = 0x7F, ctrl_offsetr* = 0x7F, ctrl_offsetw* = 0x7F (*means 0 ~ 3)
  - Set CA0DeSkewCode = 0x60, CA1DeSkewCode = 0x60, ~ CA9DeSkewCode = 0x60.
- "dfi_ctrlupd_req" should be issued more than 10 cycles after ctrl_dll_on is disabled.
- Exit Self-Refresh (CKE = 1).
- Operate in the low frequency.

Caution: If using RL = 3 or 4, "ctrl_atgate" (= PHY_CON0[6]) should be set as "0", and "ctrl_gate_p0 / p1" and "ctrl_read_p0 / p1" should be generated from controller.

If it goes back to the original high frequency again, please refer to the following procedures.

- Enter Self-Refresh (CKE = 0)
- If "ctrl_dll_on = 0", turn on "ctrl_dll_on".
- "ctrl_offsetd" = 0x08, ctrl_offsetr* = 0x08, ctrl_offsetw* = 0x08 (*means 0 ~ 3)
- CA0DeSkewCode ~ CA9DeSkewCode = 0x8.
- Wait until "ctrl_clock = 1".
- Controller should assert "dfi_ctrlupd_req" to apply the new "ctrl_lock_value" after "ctrl_clock = 1".
- Exit Self-Refresh (CKE = 1)

9.3.3.6 Offset control

ctrl_offset0 ~ 3 control the offset of 90° phase shift of DQS or 270° clock.

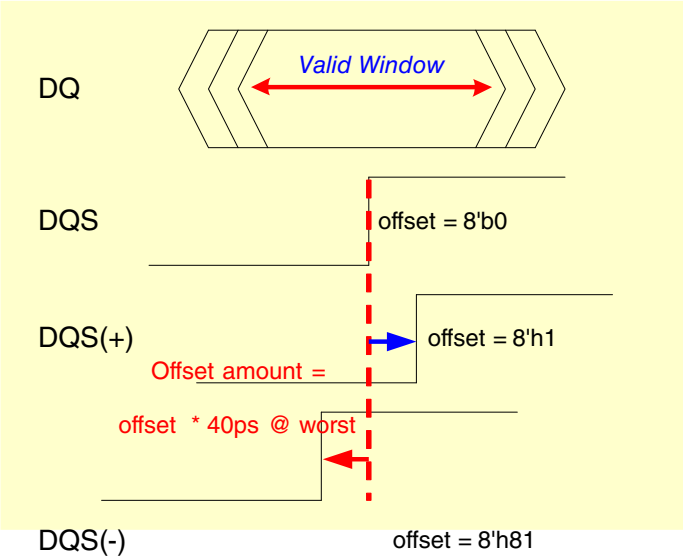

Figure 9-20. Offset Control Example for ctrl_offset0 ~ ctrl_offset3

9.3.3.7 DLL lock procedure

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Assert "dfi_init_start" from LOW to HIGH.
- When DLL lock is finished, "dfi_init_complete" is set.
- Before memory access, "dfi_ctrlupd_req" should be applied. It is recommended that "dfi_ctrlupd_req" should be set and clear at the start of refresh cycle automatically by the memory controller to update DLL lock information periodically.

DLL is used to compensate PVT condition. Therefore DLL should not be turned-off for reliable operation except for the case of frequency scaling.(only to lower frequency scaling is permitted).

To turn-off the DLL, follow the next steps.

- After DLL locking, Enter DLL OFF mode by clearing ctrl_dll_on.
- CPU reads ctrl_lock_value and write ctrl_lock_value[8:0] to ctrl_force.
- "dfi_ctrlupd_req" should be issued 6 cycles after ctrl_dll_on was set and cleared.

9.3.3.8 ZQ I/O control procedure

ZQ I/O calibrates the I/Os to match the driving and termination impedance by referencing resistor value of resistor (RZQ) connected externally from ZQ pin to ground. For DDR3, RZQ should be 240ohm. One-time calibration is provided for ZQ I/O control procedure. There are two modes for one-time calibration. One is “Long calibration mode” and the other is “Short calibration mode”.

9.3.3.8.1 One-time calibration

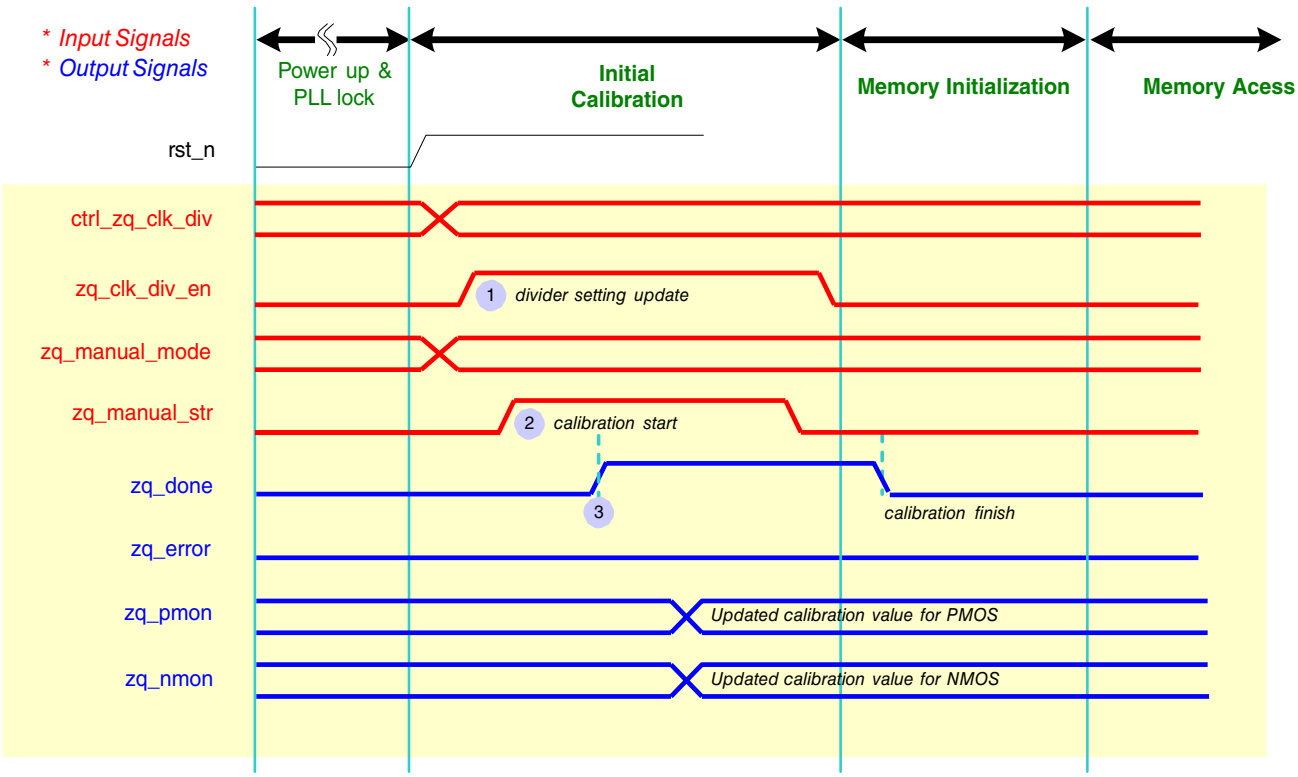

Figure 9-21. One-time Calibration Procedure

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Set ctrl_zq_clk_div[31:0] to proper value (= 0x7)
- Set zq_clk_div_en from 1’b0 to 1’b1 to update divider settings (ctrl_zq_clk_div[31:0] = 0x7).
- Set zq_manual_mode
  - Long calibration mode: 2’b01
  - Short calibration mode: 2’b10
- Start ZQ I/O calibration by setting zq_manual_str from 1’b0 to 1’b1
- When calibration is done, zq_done (= PHY_CON17[0]) will be set.

- After zq_done (= PHY_CON17[0]) is asserted, clear zq_manual_str
- Clear zq_clk_div_en

9.3.3.8.2 Manual setting

- After power-up and system PLL locking time, system reset (rst_n) is released.
- Set ctrl_zq_clk_div[31:0] to proper value (= 0x7)
- Set zq_clk_div_en from 1’b0 to 1’b1 to update divider settings (ctrl_zq_clk_div[31:0] = 0x7).
- Set zq_manual_mode=2'b00 (= Force calibration mode).
- Start ZQ I/O calibration by setting zq_manual_str from 1’b0 to 1’b1
- After zq_done (= PHY_CON17[0]) is asserted, clear zq_manual_str.

9.3.3.9 DLL code update

Assertion of the "dfi_ctrlupd_ack" or "dfi_phyupd_ack" signal indicates the control, read and write interfaces on the DFI should be idle. While the "dfi_ctrlupd_ack" or "dfi_phyupd_ack" signal is asserted, the DFI bus may only be used for commands related to the update process.

The MC guarantees that dfi_ctrlupd_req signal will be asserted for at least tctrlupd_min cycles, allowing the PHY time to respond. To acknowledge the request, the dfi_ctrlupd_ack signal must be asserted while the dfi_ctrlupd_req signal is asserted. The dfi_ctrlupd_ack signal must de-assert at least one cycle before tctrlupd_max expires (Tctrlupd_min = 2, Tctrlupd_max = 21). Please use "MC-Initiated Update" until initialization including all calibrations is finished.

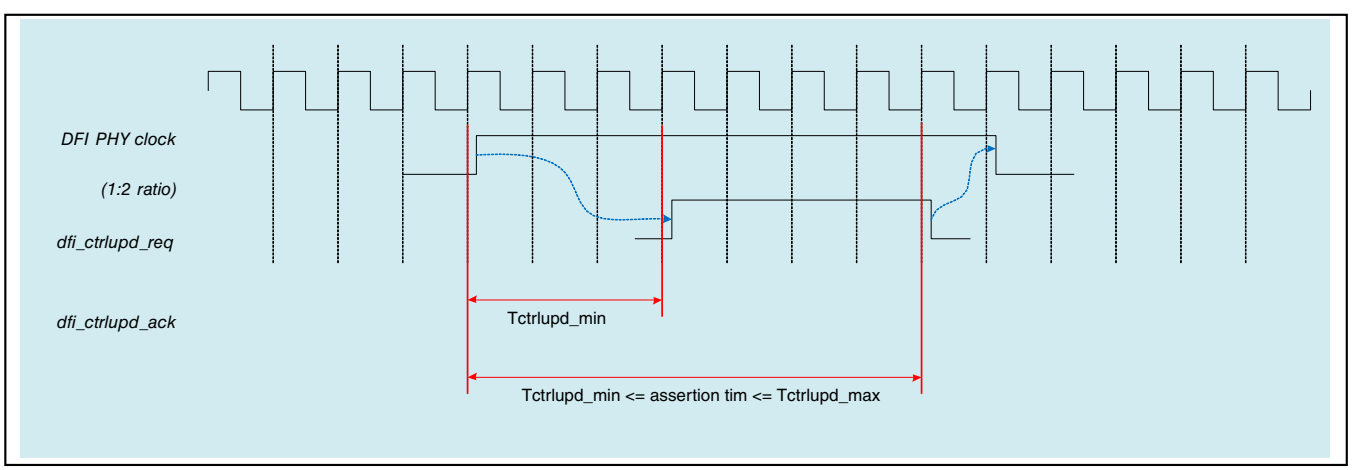

Figure 9-22. MC-Initiated Update Timing Diagram

Assertion of the dfi_phyupd_req signal indicates the control, read and write interfaces on the DFI are required. While the dfi_phyupd_ack signal is asserted, the DFI bus should be idle.

The Tphyupd_typeX parameters indicate the number of cycles of idle time on the DFI control, read and write data interfaces being requested. The dfi_phyupd_ack signal must assert within Tphyupd_resp cycles after the assertion of the dfi_phyupd_req signal (Tphyupd_resp = 64, Tphyupd_typeX = 4).

If MC (Memory Controller) does not assert dfi_phyupd_ack within Tphyupd_resp, PHY will keep dfi_phyupd_req asserting until dfi_phyupd_ack is asserted and Tphyupd_typeX will be changed up to "21".

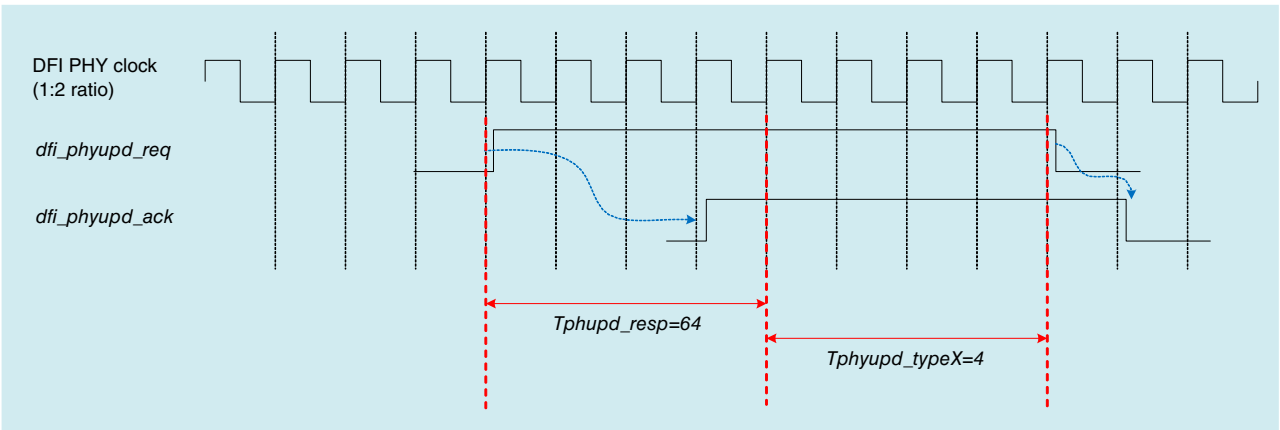

Figure 9-23. PHY-Initiated Update Timing Diagram

In case of LPDDR2 / LPDDR3, The PHY is expected to drive values on dfi_address[9:0] to ADCT[9:0] on the rising edge of clock and value on dfi_address[19:10] to ADCT[9:0] on falling edge of memory clock. But PHY will drive value on dfi_address[19:10] of controller to ADCT[9:0] during 4 clock cycles after "dfi_phyupd_ack" is issued.

When CPU or MC change the code value in SDLL or De-skew DLL by using APB Interface, "ctrl_resync" (PHY_CON[24]) or "wrlvl_resync" (= WR_LVL_CON3[0]) should be high and then low to apply the updated code values. And the following conditions should be met during the assertion of "dfi_ctrlupd_req", "ctrl_resync" or "wrlvl_resync".

- CS = 1 or CKE = 0 if any CA SDLL (LP_DDR_CON2) or DeSkew (WR_LVL_CON*) Code is changed.
- Any Write operation should not be permitted if Write SDLL (OFFSETW_CON*) Code is changed.

Caution: If the DeSkew Code for CKE[1:0], CS[1:0], CK, RESET is changed, CKE should be always "LOW" during the assertion of "dfi_ctrlupd_req", "ctrl_resync" or "wrlvl_resync".

9.3.3.10 Clock control

dfi_dram_clk_disable controls CK / CKB signals.

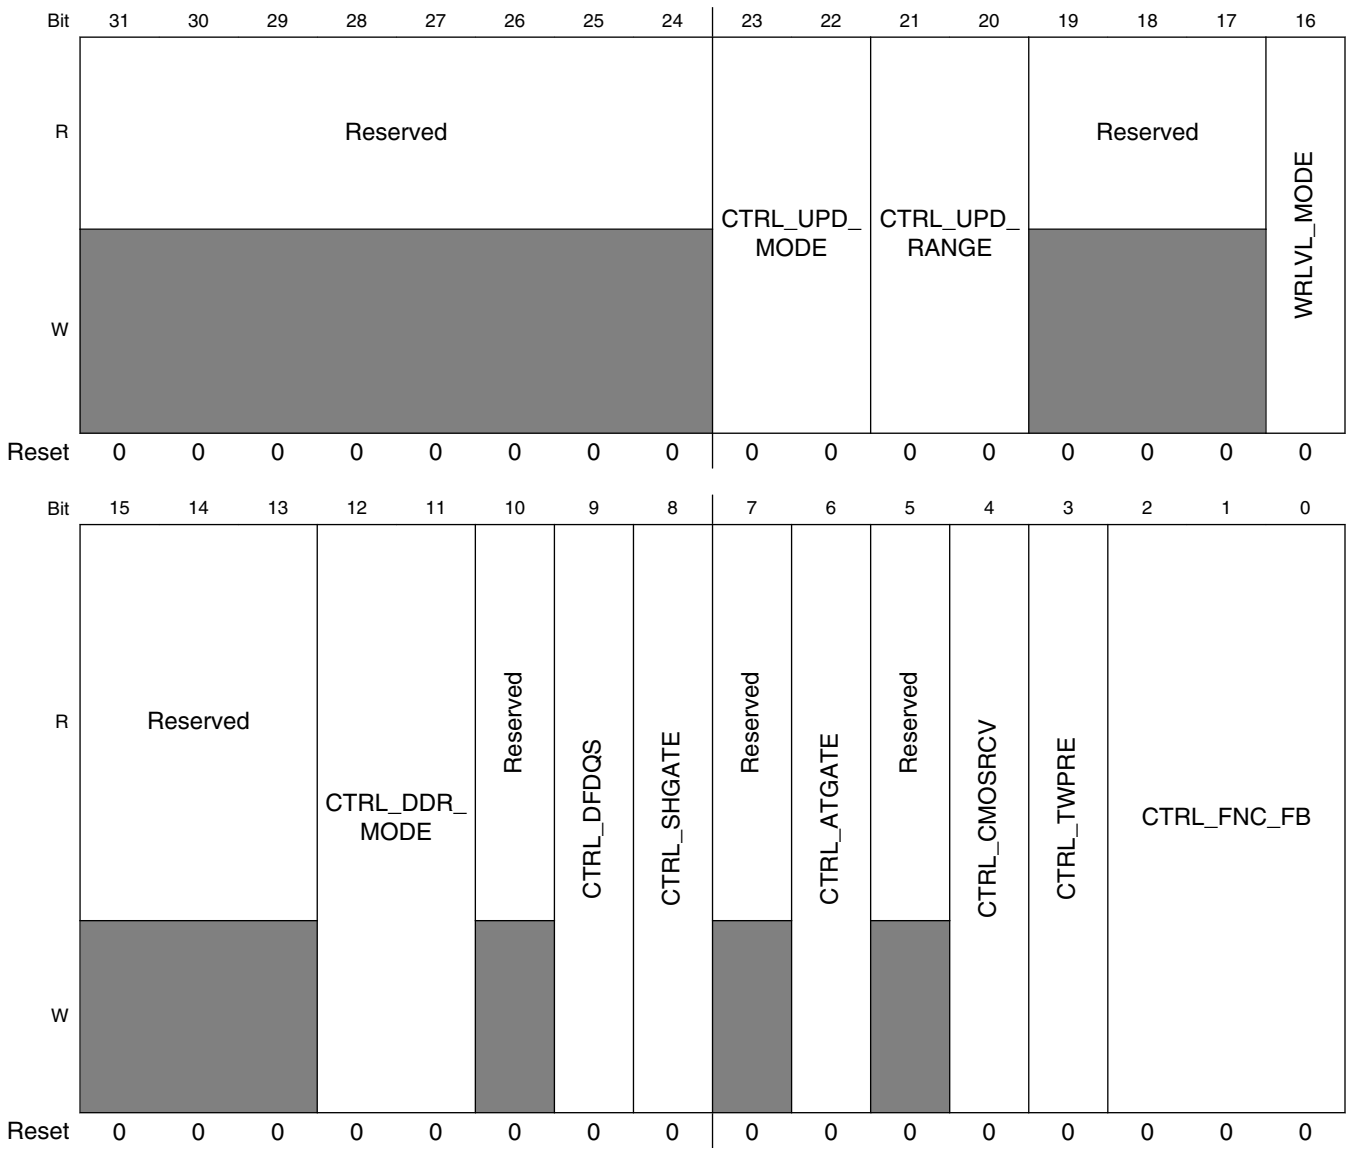
PHY Control Register

Address: 3079_0000h base + 0h offset = 3079_0000h



DDR_PHY_PHY_CON0 field descriptions

Field	Description
31–24 Reserved	This field is reserved. Initial Value = 8'h17
23–22 CTRL_UPD_ MODE	It controls when DLL is updated. Initial Value = 2'b01 2'b00 Update always

Table continues on the next page...

DDR_PHY_PHY_CON0 field descriptions (continued)

Field	Description
	2'b01 To update depending on "ctrl_flock" 2'b10 To update depending on "ctrl_flock" 2'b11 Do not update DLL
21–20 CTRL_UPD_ RANGE	It decides how many differences between the new lock value and the current lock value which is used in Slave-DLL is needed for updating lock value. Initial Value = 2'b00 2'b00 Update when difference is greater than 0 2'b01 Update when difference is greater than 1 2'b10 Update when difference is greater than 7 2'b11 Update when difference is greater than 15
19–17 Reserved	This field is reserved. Initial Value = 3'b001
16 WRLVL_MODE	Write Leveling Mode Enable Initial Value = 1'b0
15–13 Reserved	This field is reserved. Initial Value = 1'b0
12–11 CTRL_DDR_ MODE	Initial Value = 2'b11 2’b00 Reserved 2’b01 DDR3 2’b10 LPDDR2 2’b11 LPDDR3
10 Reserved	This field is reserved. Initial Value = 1'b1
9 CTRL_DFDQS	Initial Value = 1'b1 1’b0 Single-ended DQS — 1’b1 Differential DQS
8 CTRL_SHGATE	This field controls the gate control signal Initial Value = 1'b0 1’b0 Gate signal length = (burst length / 2) + N (DQS Pull-Down mode, ctrl_pulld_dqs[3:0] == 4'b1111, N = 0,1,2…) 1'b1 Gate signal length = (burst length / 2) – 1
7 Reserved	This field is reserved. Initial Value = 1'b0
6 CTRL_ATGATE	This bit should be set to 1’b1. Initial Value = 1'b1
5 Reserved	This field is reserved. Initial Value = 1'b0
4 CTRL_ CMOSRCV	This field controls the input mode of I/O. Initial Value = 1'b0

Table continues on the next page...

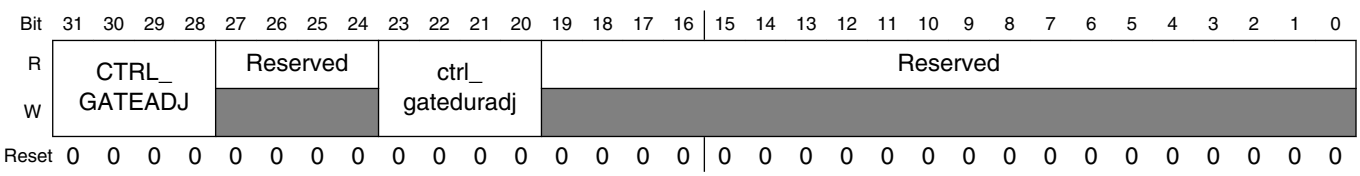
DDR_PHY_PHY_CON0 field descriptions (continued)

Field	Description
3 CTRL_TWPRE	Write preamble setting Initial Value = 1'b0
CTRL_FNC_FB	Valid only when {mode_phy, mode_nand, mode_scan, mode_mux} is 4'b00000. Initial Value = 3'b000 For normal operation • 3'b000: Normal operation mode. For ATE test purpose • 3'b010: External FNC read feedback test mode. • 3'b011: Internal FNC read feedback test mode. For Board test purpose • 3’b100: External PHY read feedback test mode. When memory is not attached on the board • 3’b101: Internal PHY read feedback test mode. mode_highz should be set. • 3’b110: Internal PHY write feedback test mode. mode_highz should be set.

9.3.4.2 DDR_PHY_PHY_CON1

PHY Control Register

Address: 3079_0000h base + 4h offset = 3079_0004h



DDR_PHY_PHY_CON1 field descriptions

Field	Description
31–28 CTRL_GATEADJ	It adjusts the enable time of "ctrl_gate" on a clock cycle base. MSB (bit3) controls direction: 1'b1 (subtract delay), 1'b0 (add delay), Bit[2:0] set delay value. Initial Value = 4'h2
27–24 Reserved	This field is reserved. Initial Value = 4’h0
23–20 ctrl_gateduradj	It adjusts the duration cycle of "ctrl_gate" on a clock cycle base. MSB (bit3) controls direction: 1'b1 (subtract delay), 1'b0 (add delay), Bit[2:0] set delay value. Initial Value = 4’h2
Reserved	This field is reserved. Initial Value = 32'h10100

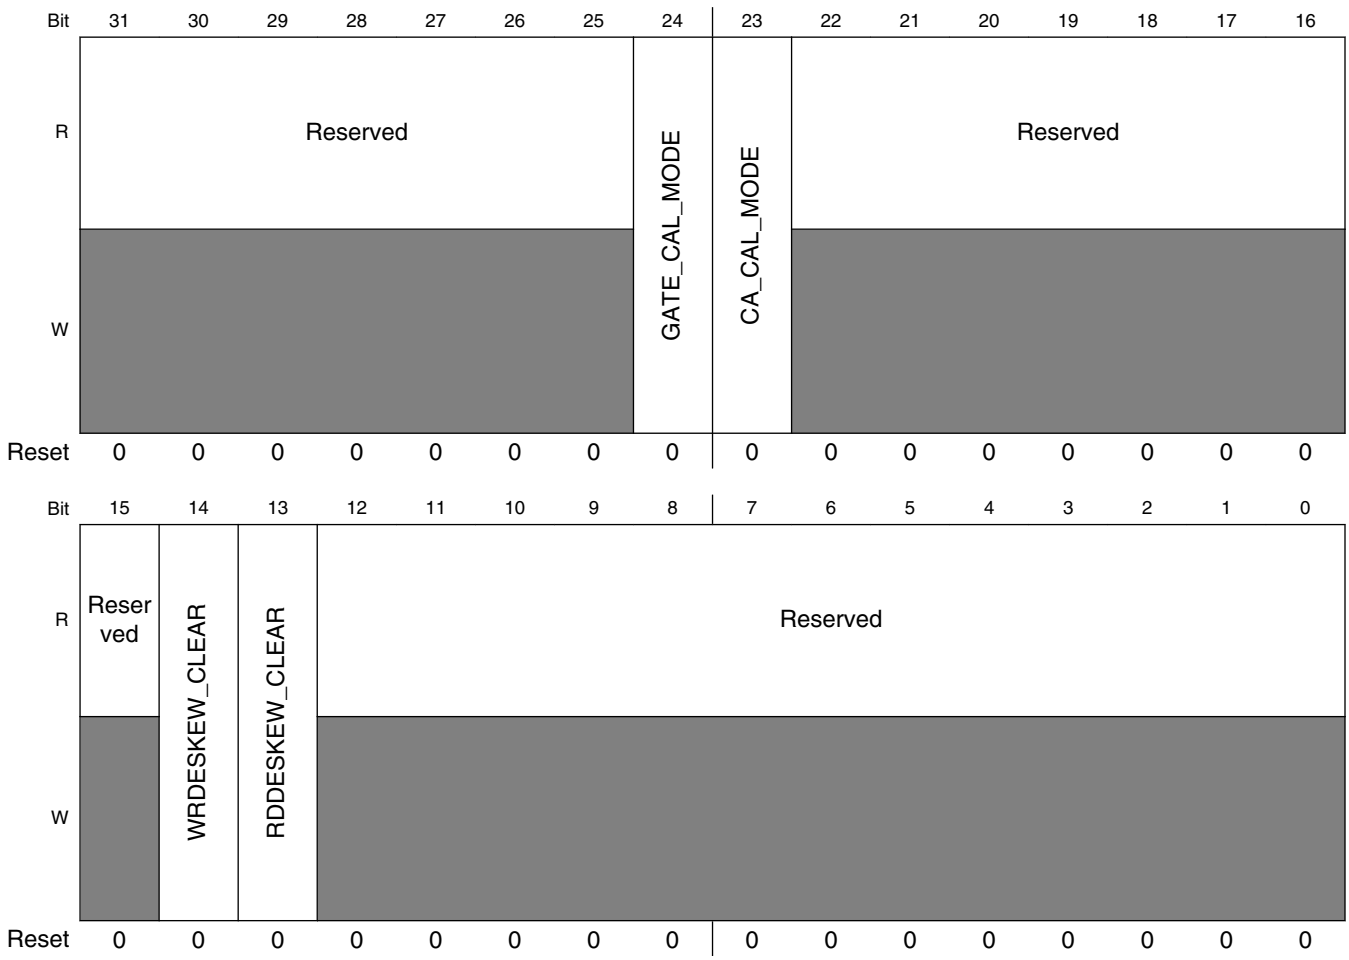
PHY Control Register

Address: 3079_0000h base + 8h offset = 3079_0008h



DDR_PHY_PHY_CON2 field descriptions

Field	Description
31–25 Reserved	This field is reserved. Initial Value = 7'b0
24 GATE_CAL_MODE	When gate_cal_mode = 1, Gate leveling offset value will be used instead of ctrl_shiftc*. If gate leveling is used, this value should be high during operation. Initial Value = 1'b0
23 CA_CAL_MODE	Not used Initial Value = 1'b0
22–15 Reserved	This field is reserved. Initial Value = 8'b02

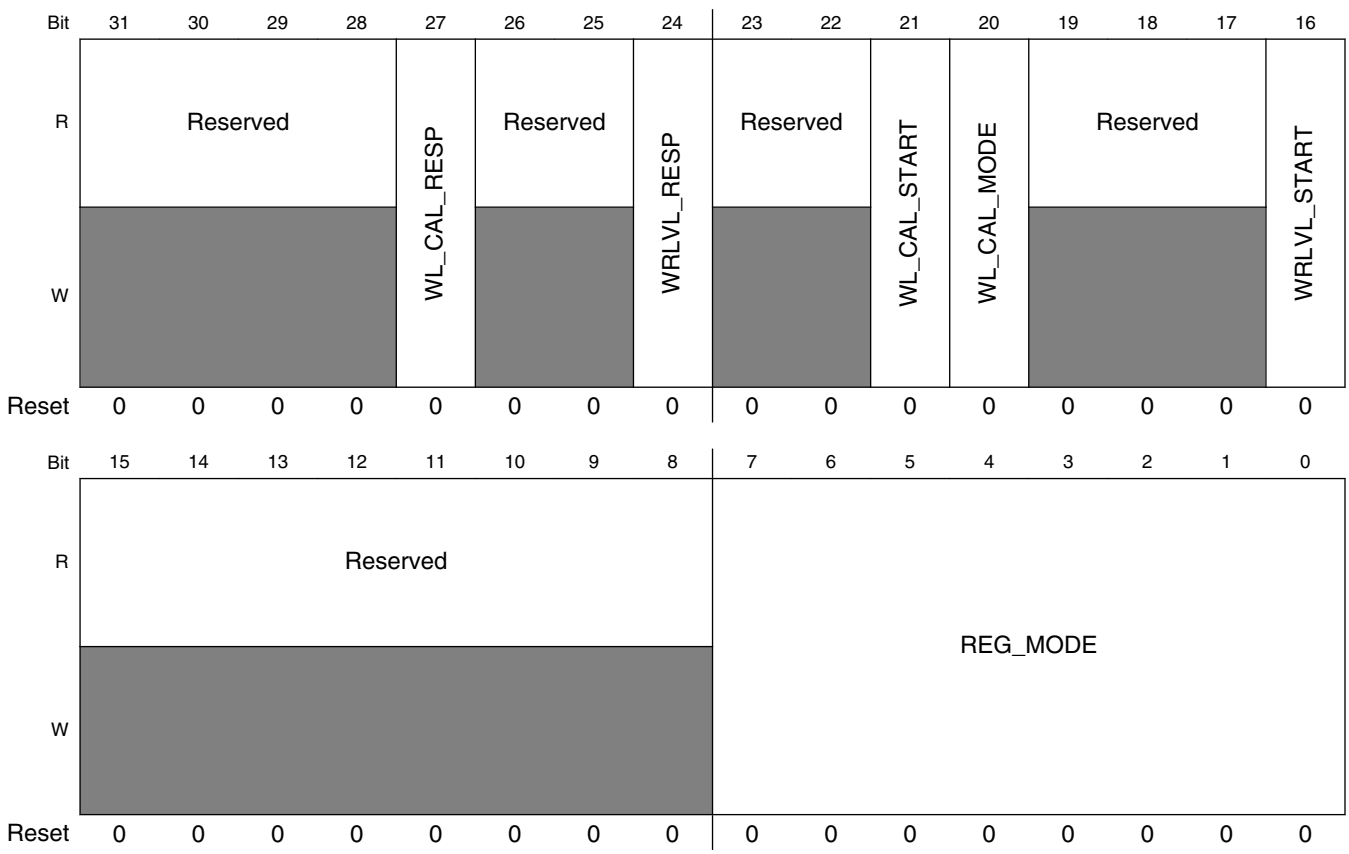
Table continues on the next page...

DDR_PHY_PHY_CON2 field descriptions (continued)

Field	Description
14 WRDESKEW_CLEAR	Write "ctrl_offsetw*" toWrDeSkewCode Initial Value = 1'b0
13 RDDESKEW_CLEAR	Clear "ctrl_offsetr*" to RdDeSkewCode Initial Value = 1'b0
Reserved	This field is reserved. Initial Value = 13'h4

9.3.4.4 DDR_PHY_PHY_CON3

Address: 3079_0000h base + Ch offset = 3079_000Ch



DDR_PHY_PHY_CON3 field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27 WL_CAL_RESP	Response after Write Leveling Calibration Initial Value = 0x0

Table continues on the next page...

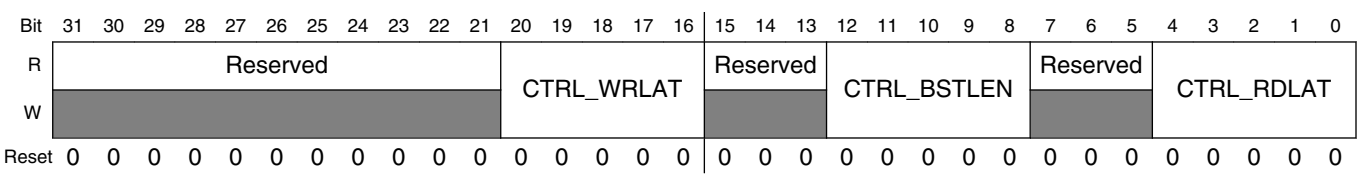
DDR_PHY_PHY_CON3 field descriptions (continued)

Field	Description
26–25 Reserved	This field is reserved.
24 WRLVL_RESP	Response after Write Leveling Initial Value = 0x0
23–22 Reserved	This field is reserved.
21 WL_CAL_START	Start Write Leveling Calibration Initial Value = 0x0
20 WL_CAL_MODE	Write Leveling Calibration mode Enable Initial Value = 0x0
19–17 Reserved	This field is reserved.
16 WRLVL_START	Start Write Leveling signal. It can be enabled when wrlvl_mode = 1. It should be disabled after Write Leveling Response is asserted. Initial Value = 0x0
15–8 Reserved	This field is reserved.
REG_MODE	Register mode control to write the information at each data Initial Value = 0x0

9.3.4.5 DDR_PHY_PHY_CON4

PHY Control Register

Address: 3079_0000h base + 10h offset = 3079_0010h



DDR_PHY_PHY_CON4 field descriptions

Field	Description
31–21 Reserved	This field is reserved.
20–16 CTRL_WRLAT	Clock cycles between write command and the first edge of DQS which can capture the first valid DQ. For example, if WL is 6, It should be set as 7(= WL + 1) in LPDDR3, 6(= WL) in DDR3. Initial Value = 5'h8
15–13 Reserved	This field is reserved.

Table continues on the next page...

DDR_PHY_PHY_CON4 field descriptions (continued)

Field	Description
12–8 CTRL_BSTLEN	Burst Length (BL) Initial Value = 5'h0
7–5 Reserved	This field is reserved.
CTRL_RDLAT	Read Latency (RL) Initial Value = 5'h0

9.3.4.6 DDR_PHY_PHY_CON5

NOTE

When "wl_cal_mode" = 1'b1, "PHY_CON5" will show the results of HW Write Latency Calibration. Please do not change "PHY_CON5" during "wl_cal_mode" = 1'b1.

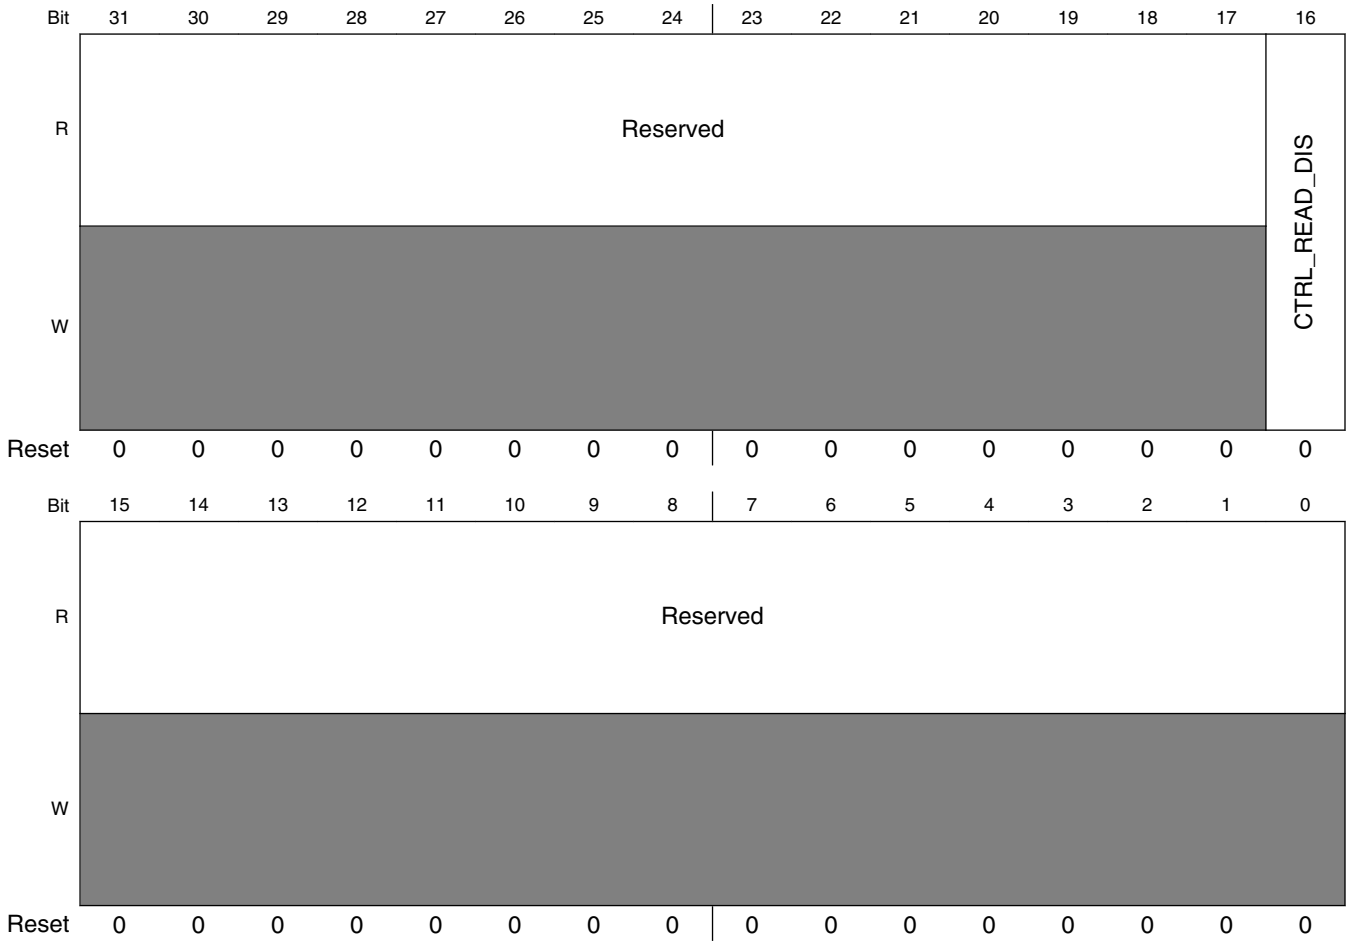
DDR_PHY_LP_CON0 field descriptions

Field	Description
31–25 Reserved	This field is reserved.
24–16 CTRL_PULLD_DQ	Active HIGH signal to down DQ signals. For normal operation this field should be zero. When bus is idle, it can be set to pull-down or up the bus not to make bus high-z state. Initial Value = 4'h0
15–9 Reserved	This field is reserved.
CTRL_PULLD_DQS	Active HIGH signal to pull-up or down PDQS / NDQS signals. When using Gate Leveling in DDR3, this field can be zero. When bus is idle, it can be set to pull-down or up the bus not to make bus high-z state (PDQS / NDQS is pulled-down / up). For LPDDR2 / LPDDR3 mode, this field should be always set for normal operation to make P / NDQS signals pull-down / up. Initial Value = 4'h0

9.3.4.8 DDR_PHY_RODT_CON0

Address: 3079_0000h base + 1Ch offset = 3079_001Ch



DDR_PHY_RODT_CON0 field descriptions

Field	Description
31–17 Reserved	This field is reserved. Initial Value = 15'h8
16 CTRL_READ_DIS	Read ODT (On-Die-Termination) Disable Signal. This signal should be one in LPDDR2 or LPDDR3 mode. Initial Value = 4'h0 1'b1 Drive ctrl_read_p* to 0 (If using LPDDR2 or LPDDR3, ctrl_read_p* will be always 0 by enabling this field). 1'b0 Drive ctrl_read_p* normally.
Reserved	This field is reserved. Initial Value = 16'h0

9.3.4.9 DDR_PHY_OFFSET_RD_CON0

To capture the DQs with DQS in read operation, DQS is shifted by 90° and this makes rising edge of DQS be located in the center of valid window of DQs. But according to the channel condition, i.e. PCB or SSN, rising edge of DQS could be biased from the center of valid window of DQs. ctrl_offset* is used to compensate the biased DQS and make it be placed in the center of DQs. If ctrl_offset*[7] is 0, ctrl_offset*[6:0] x tFS (tFS: fine step delay) is added to the 90° delay amount and if ctrl_offset*[7] is 1, ctrl_offset*[6:0] x tFS is subtracted from the 90° delay amount. ctrl_offset*[6:0] means the number of delay cells of the "delay line". Generally, ctrl_offset*[6:0] would be zero.

dfi_ctrlupd_req signal is required to update delay line control signals before the first normal operation after checking whether dfi_init_complete is set and at every memory refresh cycle. Before set and clear this signal during initialization, dfi_init_complete signal should be checked whether it's HIGH to confirm that DLL is locked.

Be careful that "ctrl_offsetr*" can be used for the other purpose (= Read Deskew Code Register). Please refer to mode (= PHY_CON3[7:0]).

Address: 3079_0000h base + 20h offset = 3079_0020h

Field	Description
31 Reserved	This field is reserved. Initial Value = 1'b0
30–24 CTRL_START_POINT	Initial DLL lock start point. This is the number of delay cells and is the start point where "DLL" start tracing to be locked. Initial delay time is calculated by multiplying the unit delay of delay cell and this value. Initial Value = 7'h10
23 Reserved	This field is reserved. Initial Value = 1'b0
22–16 CTRL_INC	Increase amount of start point Initial Value = 7'h10
15–7 CTRL_FORCE	This field is used instead of ctrl_lock_value[8:0] found by the DLL only when ctrl_dll_on is LOW, i.e. If the DLL is off, this field is used to generate 270° clock and shift DQS by 90°. Initial Value = 9'h00
6 CTRL_START	This field is used to start DLL locking. Initial Value = 1'b1
5 CTRL_DLL_ON	HIGH active start signal to turn on the DLL. This signal should be kept HIGH for normal operation. If this signal becomes LOW, DLL is turned off. This bit should be kept set before ctrl_start is set to turn on the DLL.HIGH active start signal to turn on the DLL. This signal should be kept HIGH for normal operation. If this signal becomes LOW, DLL is turned off. This bit should be kept set before ctrl_start is set to turn on the DLL. Initial Value = 1'b1
4–1 CTRL_REF	This field determines the period of time when ctrl_locked is cleared. Initial Value = 4'h8 4'b0000 Do not use. 4'b0001 ctrl_flock is de-asserted during 16 clock cycles, ctrl_locked is deasserted. 4'b0010 ctrl_flock is de-asserted during 24 clock cycles, ctrl_locked is deasserted. 4'b1110 ctrl_flock is de-asserted during 120 clock cycles, ctrl_locked is deasserted. 4'b1111 Once ctrl_locked and dfi_init_complete are asserted, those won't be deasserted until rst_n is asserted.
0 Reserved	This field is reserved. Initial Value = 1'b0

9.3.4.23 DDR_PHY_MDLL_CON1

"DLL" is used to get how many delay cells should be passed through the "delay line" to delay a signal to an amount of one clock period and is controlled by ctrl_start, ctrl_start_point and ctrl_inc.

ctrl_start should be set and kept high to make "DLL" keep tracing one clock period after clock(PHY clock) becomes stable. If ctrl_start becomes LOW, "DLL" stops tracing one clock period.

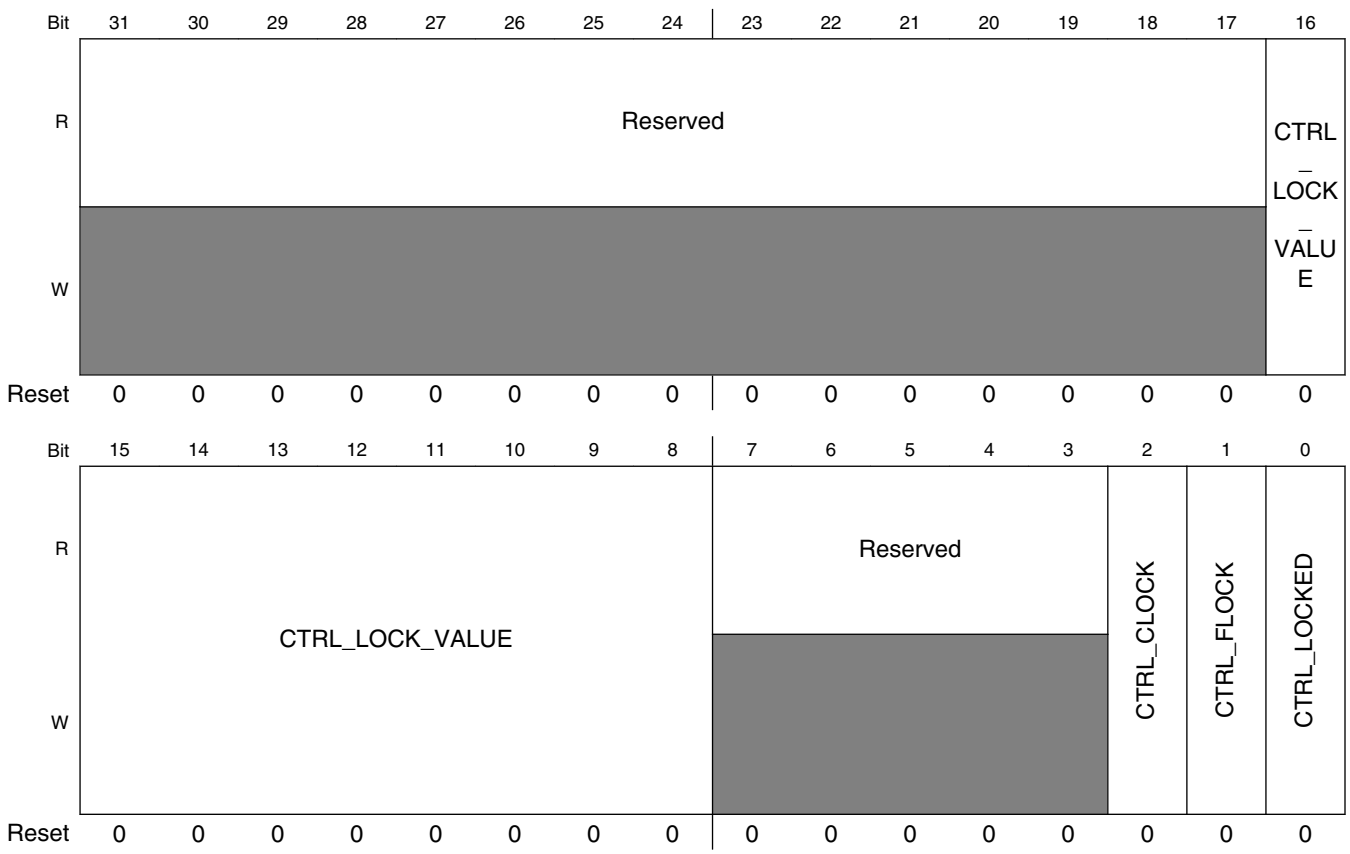
ctrl_clock and ctrl_flock are status fields indicating whether "DLL" is locked. After ctrl_start becomes HIGH, DLL starts tracing one clock period and controls (increases or decreases) the number of delay cells for the clock to pass through. And if ctrl_clock is set("DLL" is locked), "DLL" changes step delays of the "delay line" and controls the "delay line" in fine resolution to reduce the "phase offset error".When ctrl_flock is set, "DLL" is locked with fine resolution. ctrl_lock_value is information field to indicate the number of delay cells to delay a signal to one clock period through the "delay line".

- {ctrl_clock, ctrl_flock = 2'b00} : DLL is not locked.
- {ctrl_clock, ctrl_flock = 2'b01} : Impossible value.
- {ctrl_clock, ctrl_flock = 2'b10} : Locked.
- {ctrl_clock, ctrl_flock = 2'b11} : Locked.

NOTE

Recommended value for ctrl_start_point[7:0] and ctrl_inc[7:0] are 8'h10.

Address: 3079_0000h base + B4h offset = 3079_00B4h



DDR_PHY_MDLL_CON1 field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16–8 CTRL_LOCK_VALUE	Locked delay line encoding value. Defines the number of Fine Steps to be used for one clock period. From ctrl_lock_value[8:0], tFS (fine step delay) can be calculated. tFS = tCK / ctrl_lock_value[8:0].
7–3 Reserved	This field is reserved.
2 CTRL_CLOCK	Coarse lock information. According to clock jitter, ctrl_clock can be de-asserted.
1 CTRL_FLOCK	Fine lock information. According to clock jitter, ctrl_flock can be de-asserted.
0 CTRL_LOCKED	DLL stable lock information. This field is set after ctrl_flock is set. This field is cleared when ctrl_flock is de-asserted for some period of time specified by ctrl_ref[3:0] value. This field is required for stable lock status check.

9.3.4.24 DDR_PHY_ZQ_CON0

NOTE

"zq_manual_str" (= ZQ_CON0[1]) should be toggled after ZQ_CON0[17:2] or ZQ_CON0[26:19] is changed. For example, if zq_mode_dds is written by 3'b111, "zq_manual_str" should be set and cleared to apply this new strength value (3'b111).

VERSION_INFO	Version Information

9.4 AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

9.4.1 Overview

The AHB-to-APBH bridge provides the chip with an inexpensive peripheral attachment bus running on the AHB's HCLK. (The H in APBH denotes that the APB*H* is synchronous to HCLK , as compared to APB*X*, which runs on the crystal-derived XCLK.)

As shown in the figure below, the AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for a memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the ARM Cortex-A8 core. Each one of the APB peripherals, including the vectored interrupt controller, is documented in their respective chapters.

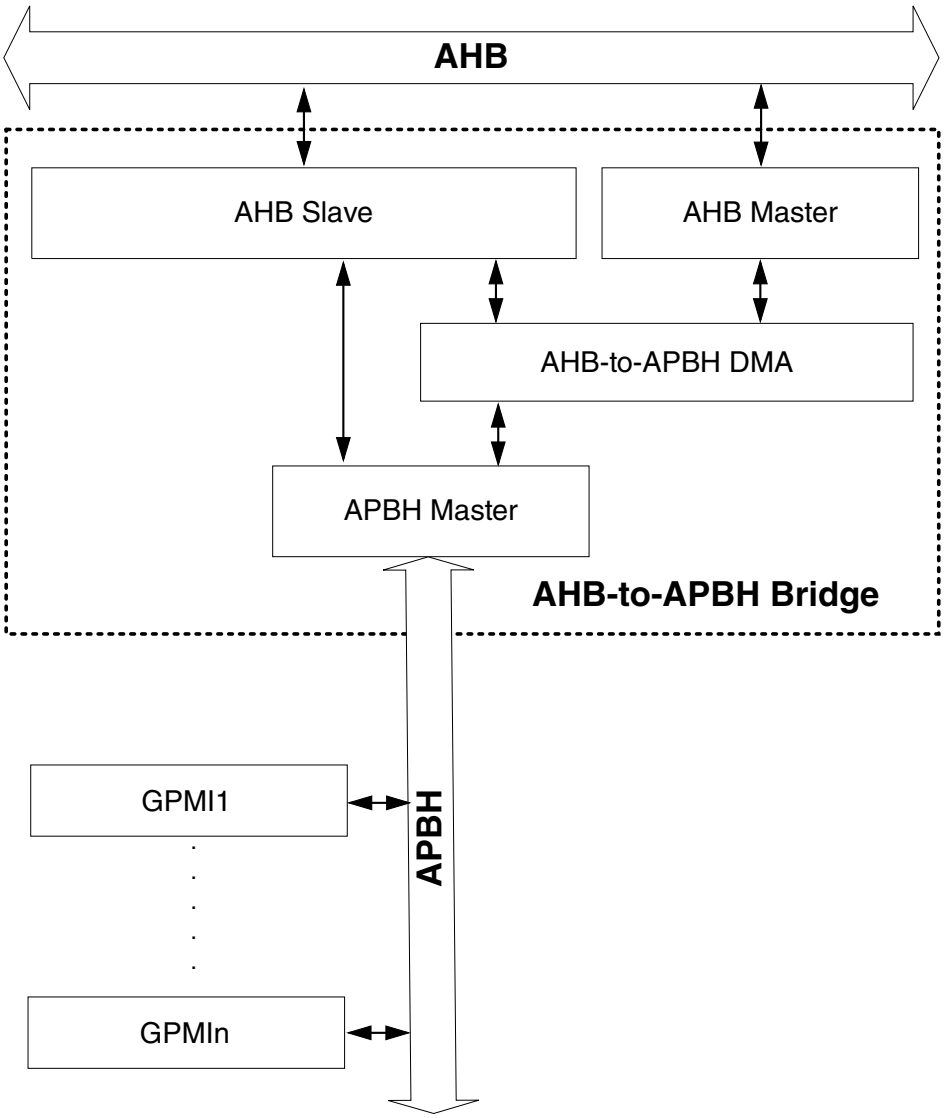

Figure 9-25. AHB-to-APBH Bridge DMA Block Diagram

The DMA controller uses the APBH bus to transfer read and write data to and from each peripheral. There is no separate DMA bus for these devices. Contention between the DMA's use of the APBH bus and the AHB-to-APB bridge functions' use of the APBH is mediated by an internal arbitration logic. For contention between these two units, the DMA is favored and the AHB slave will report "not ready" through its HREADY output until the bridge transfer can complete. The arbiter tracks repeated lockouts and inverts the priority, guaranteeing the ARM platform every fourth transfer on the APB.

9.4.2 Clocks

The table found here describes the clock sources for APBH. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 9-15. APBH Clocks

Clock name	Clock Root	Description
hclk	usdhc_clk_root	Module clock

9.4.3 APBH DMA

The DMA supports four sixteen channels of DMA services, as shown in the following table. The shared DMA resource allows each independent channel to follow a simple chained command list. Command chains are built up using the general structure, as shown in Figure 9-26.

Table 9-16. APBH DMA channel assignments

APBH DMA Channel #	Usage
0	SSP0GPMI0
1	SSP1GPMI1
2	SSP2GPMI2
3	SSP3GPMI3
4	GPMI0GPMI4
5	GPMI1GPMI5
6	GPMI2GPMI6
7	GPMI3GPMI7
8	GPMI4Reserved
9	GPMI5Unused
10	GPMI6Unused
11	GPMI7Unused
12	HSADCUnused
13	LCDIFUnused
14	Unused
15	Unused

A single command structure or channel command word specifies a number of operations to be performed by the DMA in support of a given device. Thus, the ARM platform can set up large units of work, chaining together many DMA channel command words, pass them off to the DMA, and have no further concern for the device until the DMA completion interrupt occurs. The goal is to have enough intelligence in the DMA and the devices to keep the interrupt frequency from any device below 1 KHz (arrival intervals longer than 1 ms).

A single command structure can issue 32-bit PIO write operations to key registers in the associated device using the same APB bus and controls that it uses to write DMA data bytes to the device. For example, this allows a chain of operations to be issued to the GPMI controller to send NAND command bytes, address bytes, and data transfers where the command and the address structure is completely under software control, but the administration of that transfer is handled autonomously by the DMA. Each DMA structure can have 0–15 PIO words appended to it. The CMDPIOWORDS field, if non-zero, instructs the DMA engine to copy these words to the APB, beginning at the first register address offset for the peripheral and and incrementing the register offset each cycle.

The DMA master generates only normal read/write transfers to the APBH. It does *not* generate set, clear, or toggle (SCT) transfers.

After any requested PIO words have been transferred to the peripheral, the DMA examines the two-bit command field in the channel command structure. Table 9-17 shows the four commands implemented by the DMA.

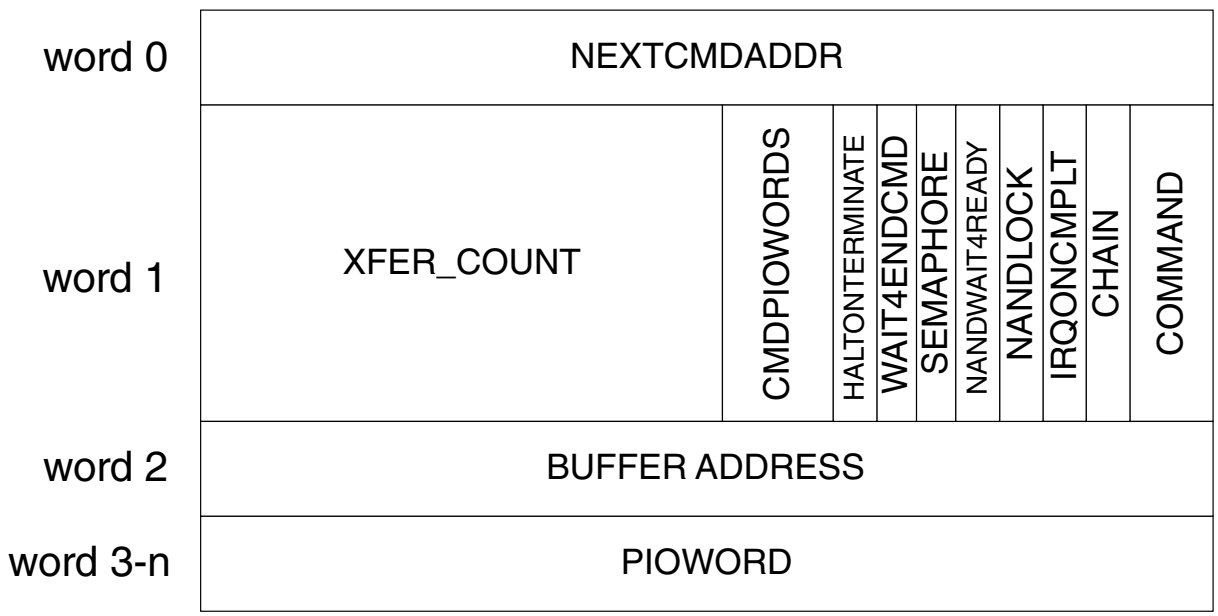

Figure 9-26. AHB-to-APBH Bridge DMA channel command structure

Table 9-17. APBH DMA commands

DMA Command	Usage
00	NO_DMA_XFER. Perform any requested PIO word transfers, but terminate the command before any DMA transfer.
01	DMA_WRITE. Perform any requested PIO word transfers, then perform a DMA transfer from the peripheral for the specified number of bytes.
10	DMA_READ. Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes.

Table continues on the next page...

Table 9-17. APBH DMA commands (continued)

DMA Command	Usage
11	DMA_SENSE. Perform any requested PIO word transfers, then perform a conditional branch to the next chained device. Follow the NEXTCMD_ADDR pointer if the peripheral sense is false. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is true. This command becomes a no-operation for any channel other than a GPMI channel.

DMA_WRITE operations copy data bytes to the system memory (on-chip RAM or SDRAM) from the associated peripheral. The DMA_WRITE transfer uses the BUFFER_ADDRESS word in the command structure to point to the beginning byte to write data from the peripheral.

DMA_READ operations copy data bytes to the APB peripheral from the system memory. The DMA engine contains a shared byte aligner that aligns bytes from system memory to or from the peripherals. Peripherals always assume little-endian-aligned data arrives or departs on their 32-bit APB. The DMA_READ transfer uses the BUFFER_ADDRESS word in the command structure to point to the DMA data buffer to be read by the DMA_READ command.

The NO_DMA_XFER command is used to write PIO words to a device without performing any DMA data byte transfers. This command is useful in such applications as activating the NAND devices CHECKSTATUS operation. The check status command reads a status byte from the NAND device, performs an XOR and MASK against an expected value supplied as part of the PIO transfer. Once the read check completes (see NAND Read Status Polling Example), the NO_DMA_XFER command completes. The result in the peripheral is that its sense line is driven by the results of the comparison. The sense flip-flop is only updated by CHECKSTATUS for the device that is executed. At some future point, the chain contains a DMA command structure with the fourth and final command value, that is, the DMA_SENSE command.

As each DMA command completes, it triggers the DMA to load the next DMA command structure in the chain. The normal flow list of DMA commands is found by following the NEXTCMD_ADDR pointer in the DMA command structure. The DMA_SENSE command uses the DMA buffer pointer word of the command structure to point to an alternate DMA command structure chain or list. The DMA_SENSE command examines the sense line of the associated peripheral. If the sense line is false, then the DMA follows the standard list found whose next command is found from the pointer in the NEXTCMD_ADDR word of the command structure. If the sense line is true, then the DMA follows the alternate list whose next command is found from the pointer in the DMA Buffer Pointer word of the DMA_SENSE command structure (see Figure 9-26). The sense command ignores the CHAIN bit, so that both pointers must be valid when the DMA comes to a sense command.

If the wait-for-end-command bit (WAIT4ENDCMD) is set in a command structure, the DMA channel waits for the device to signal completion of a command by toggling the endcmd signal before proceeding to load and execute the next command structure. Then, if DECREMENT_SEMAPHORE is set, the semaphore is decremented after the end command is seen.

A detailed bit-field view of the DMA command structure is shown in the following table, which shows a field that specifies the number of bytes to be transferred by this DMA command. The transfer-count mechanism is duplicated in the associated peripheral, either as an implied or as a specified count in the peripheral.

Table 9-18. DMA channel command word in system memory

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															
Number DMA Bytes to Transfer																Number PIO Words to Write							HALTONTERMINATE	WAIT4ENDCMD	DECREMENT SEMAPHORE	NANDwAIT4READY	NANDLOCK	IRQ_COMPLETE	CHAIN	COMMAND	
DMA Buffer or Alternate CCW																															
Zero or More PIO Words to Write to the Associated Peripheral Starting at its Base Address on the APBH Bus																															

Figure 9-26 also shows the CHAIN bit in bit 2 of the second word of the command structure. This bit is set to 1, if the NEXT_COMMAND_ADDRESS contains a pointer to another DMA command structure. If a null pointer (0) is loaded into the NEXT_COMMAND_ADDRESS, it is not detected by the DMA hardware. Only the CHAIN bit indicates whether a valid list exists beyond the current structure.

If the IRQ_COMPLETE bit is set in the command structure, then the last act of the DMA before loading the next command is to set the interrupt-status bit corresponding to the current channel. The sticky interrupt request bit in the DMA CSR remains set until cleared by the software. It can be used to interrupt the ARM platform.

The NAND_LOCK bit is monitored by the DMA channel arbiter. After a NAND channel (from channel 4 to channel 11) Once a NAND channel (from channel 0 to channel 3) succeeds in the arbiter with its NAND_LOCK bit set, then the arbiter ignores the other NAND channels until a command is completed in which the NAND_LOCK is not set. Notice that the semantic here is that the NAND_LOCK state is to limit scheduling of a non-locked DMA. A DMA channel can go from unlocked to locked in the arbiter at the beginning of a command when the NAND_LOCK bit is set. When the last DMA

command of an atomic sequence is completed, the lock should be removed. To accomplish this, the last command does not have the NAND_LOCK bit. It is still locked in the atomic state within the arbiter when the command starts, so that it is the only NAND command that can be executed. At the end, it drops from the atomic state within the arbiter.

The NAND_WAIT4READY bit also has a special use for GPMI channels (from channel 4 0 to channel 11 3), i.e., the NAND device channels. The GPMI peripheral supplies a sample of the ready line from the NAND device. This ready value is used to hold off of a command with this bit set until the ready line is asserted to 1. Once the arbiter sees a command with a wait-for-ready set, it holds off that channel until ready is asserted.

Receiving an IRQ for HALTONTERMINATE (HOT) is a feature in the APBH DMA descriptor that allows GPMI (as well as SSP and I2C) to signal to the DMA engine that an error has occurred. If a commmand is stalled due to an error, a HOT signal is sent from the peripheral to the DMA engine and causes an IRQ after terminating the DMA descriptor being executed.

Therefore, it is recommended that software use this signal as follows:

- Always set HALTONTERMINATE to 1 in a DMA descriptor. That way, if a peripheral signals HOT, the transfer will end, leaving the peripheral block and the DMA engine synchronized (but at the end of a command).
- When an IRQ from an APBH channel is received, and the IRQ is determined to be due to an error (as opposed to an IRQONCOMPLETE interrupt) the software should:
    - Reset the channel.
    - Determine the error from error reporting in the peripheral block, then manage the error in the peripheral that is attached to that channel in whatever appropriate way exists for that device (software recovery, device reset, block reset, etc).

Each channel has an eight-bit counting semaphore that controls whether it is in the idle state. When the semaphore is non-zero, the channel is ready to run, process commands and perform DMA transfers. Whenever a command finishes its DMA transfer, it checks the DECREMENT_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the idle state and remains there until the semaphore is incremented by the software. When the semaphore goes to non-zero and the channel is in its idle state, then it uses the value in the APBH_CHn_NXTCMDAR register (next command address register) to fetch a pointer to the next command to process.

NOTE

This is a double indirect case. This method allows the software to append to a running command list under the protection of the counting semaphore.

To start processing the first time, software creates the command list to be processed. It writes the address of the first command into the APBH_CHn_NXTCMDAR register, and then writes 1 to the counting semaphore in APBH_CHn_SEMA. The DMA channel loads APBH_CHn_CURCMDAR register and then enters the normal state machine processing for the next command. When the software writes a value to the counting semaphore, it is added to the semaphore count by hardware, protecting the case where both hardware and software are trying to change the semaphore on the same clock edge.

Software can examine the value of APBH_CHn_CURCMDAR at any time to determine the location of the command structure currently being processed.

9.4.4 NAND Read Status Polling Example

The following figure shows a more complicated scenario.

This subset of a NAND device workload shows that the first two command structures are used during the data-write phase of an NAND device write operation (CLE and ALE transfers omitted for clarity).

- After writing the data, one must wait until the NAND device status register indicates that the write charge has been transferred. This is built into the workload using a check status command in the NAND in a loop created from the next two DMA command structures.
- The NO_DMA_TRANSFER command is shown here performing the read check, followed by a DMA_SENSE command to branch the DMA command structure list, based on the status of a bit in the external NAND device.

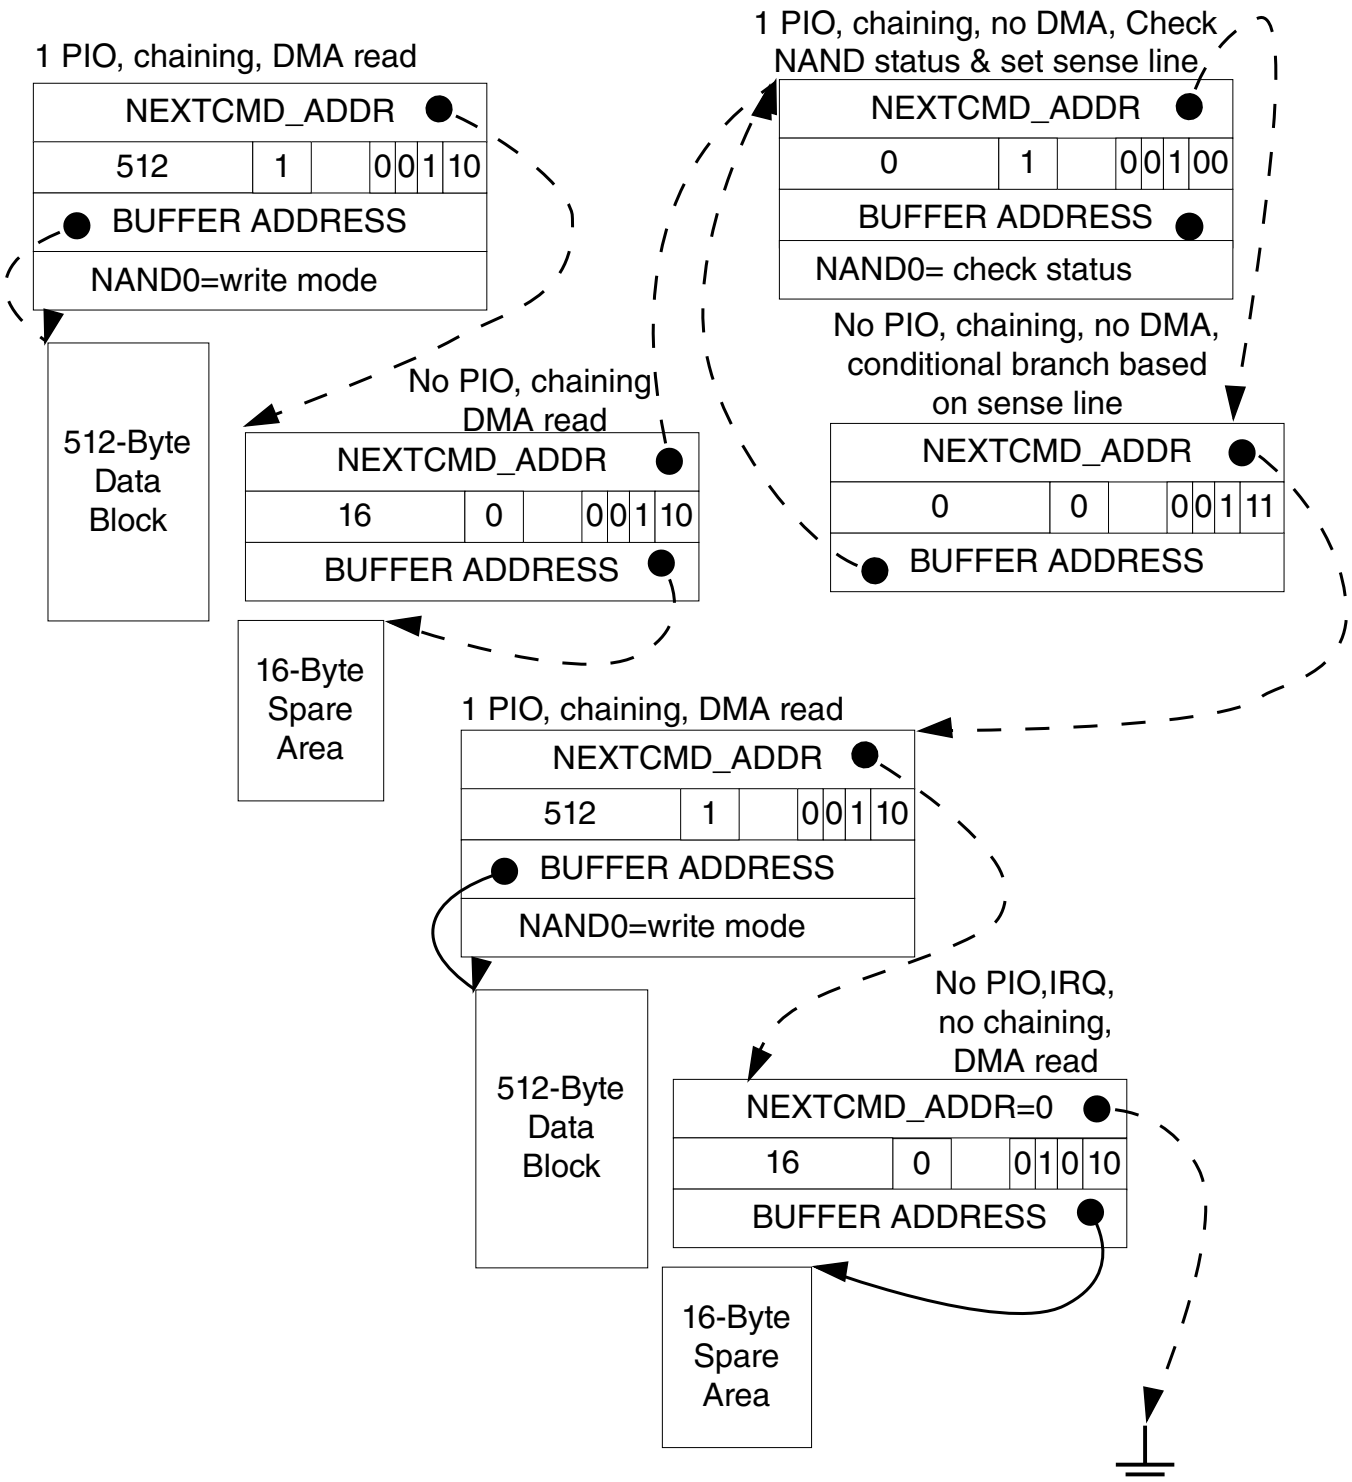

Figure 9-27. AHB-to-APBH Bridge DMA NAND Read Status Polling with DMA Sense Command

The example in the above figure shows the workload continuing immediately to the next NAND page transfer. However, one could perform a second sense operation to see if an error has occurred after the write. One could then point the sense command alternate branch at a NO_DMA_XFER command with the interrupt bit set. If the CHAIN bit is not

set on this failure branch, then the ARM platform is interrupted immediately, and the channel process is also immediately terminated in the presence of a workload-detected NAND error bit.

Note that each word of the three-word DMA command structure corresponds to a PIO register of the DMA that is accessible on the APBH bus. Normally, the DMA copies the next command structure onto these registers for processing at the start of each command by following the value of the pointer previously loaded into the NEXTCMD_ADDR register.

To start DMA processing for the first command, initialize the PIO registers of the desired channel, as follows:

- First, load the next command address register with a pointer to the first command to be loaded.
- Then, write 1 to the counting semaphore register. This causes the DMA to schedule the targeted channel for the DMA command structure load, just as if it had finished its previous command.

9.4.5 APBH Memory Map/Register Definition

APBH Hardware Register Format Summary

APBH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3300_0000	AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0)	32	R/W	E000_0000h	9.4.5.1/ 2360

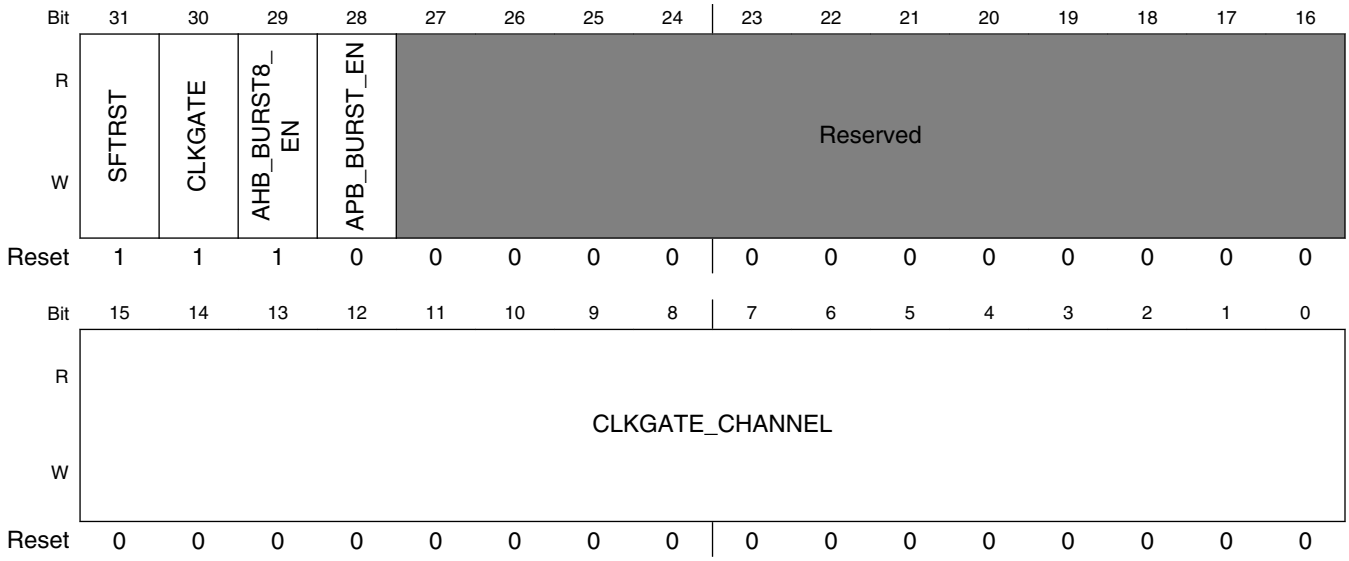
9.4.5.1 AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0*n*)

The APBH CTRL 0 provides overall control of the AHB to APBH bridge and DMA.

This register contains module softreset, clock gating, channel clock gating/freeze bits.

Address: 3300_0000h base + 0h offset + (4d × i), where i=0d to 3d



APBH_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal APBH DMA operation. Set this bit to one (default) to disable clocking with the APBH DMA and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the APBH DMA block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 AHB_BURST8_EN	Set this bit to one (default) to enable AHB 8-beat burst. Set to zero to disable 8-beat burst on AHB interface.
28 APB_BURST_EN	Set this bit to one to enable apb master do a continous transfers when a device request a burst dma. Set to zero will treat a burst dma request as 4/8 individual requests.
27–16 RSVD0	This field is reserved. Reserved, always set to zero.
CLKGATE_CHANNEL	These bits must be set to zero for normal operation of each channel. When set to one they gate off the individual clocks to the channels. 0x0001 **NAND0** — 0x0002 **NAND1** — 0x0004 **NAND2** — 0x0008 **NAND3** — 0x0010 **NAND4** — 0x0020 **NAND5** — 0x0040 **NAND6** — 0x0080 **NAND7** — 0x0100 **SSP** —

9.4.5.2 AHB to APBH Bridge Control and Status Register 1 (APBH_CTRL1*n*)

The APBH CTRL one provides overall control of the interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

Address: 3300_0000h base + 10h offset + (4d × i), where i=0d to 3d

Field	Description
29 CH13_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 13.
28 CH12_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 12.
27 CH11_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 11.
26 CH10_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 10.
25 CH9_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 9.
24 CH8_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 8.
23 CH7_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 7.
22 CH6_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 6.
21 CH5_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 5.
20 CH4_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 4.
19 CH3_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 3.
18 CH2_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 2.

Table continues on the next page...

APBH_CTRL1*n* field descriptions (continued)

Field	Description
17 CH1_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 1.
16 CH0_ CMDCMPLT_ IRQ_EN	Setting this bit enables the generation of an interrupt request for APBH DMA channel 0.
15 CH15_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
14 CH14_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
13 CH13_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
12 CH12_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
11 CH11_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
10 CH10_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
9 CH9_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
8 CH8_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
7 CH7_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 7. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
6 CH6_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 6. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

Table continues on the next page...

APBH_CTRL1*n* field descriptions (continued)

Field	Description
5 CH5_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 5. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
4 CH4_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 4. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
3 CH3_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 3. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
2 CH2_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 2. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
1 CH1_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 1. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
0 CH0_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 0. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

9.4.5.3 AHB to APBH Bridge Control and Status Register 2 (APBH_CTRL2*n*)

The APBH CTRL 2 provides channel error interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

Field	Description
16 CH0_ERROR_STATUS	Error status bit for APBX DMA Channel 0. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0x0 **TERMINATION** — An early termination from the device causes error IRQ. 0x1 **BUS_ERROR** — An AHB bus error causes error IRQ.
15 CH15_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
14 CH14_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
13 CH13_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
12 CH12_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
11 CH11_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
10 CH10_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
9 CH9_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
8 CH8_ERROR_IRQ	Error interrupt status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
7 CH7_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 7. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
6 CH6_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 6. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
5 CH5_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 5. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
4 CH4_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 4. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
3 CH3_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 3. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
2 CH2_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 2. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.

Table continues on the next page...

APBH_CTRL2*n* field descriptions (continued)

Field	Description
1 CH1_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 1. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
0 CH0_ERROR_IRQ	Error interrupt status bit for APBX DMA Channel 0. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.

9.4.5.4 AHB to APBH Bridge Channel Register (APBH_CHANNEL_CTRL*n*)

The APBH CHANNEL CTRL provides reset/freeze control of each DMA channel. This register contains individual channel reset/freeze bits.

Address: 3300_0000h base + 30h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
	0x0080 **NAND7** — 0x0100 **SSP** —

9.4.5.5 AHB to APBH DMA Device Assignment Register (APBH_DEVSEL)

This register allows reassignment of the APBH device connected to the DMA Channels.

In this chip, APBH DMA channel resource is enough for high speed peripherals, so this register is of no use and reserved.

Address: 3300_0000h base + 40h offset = 3300_0040h

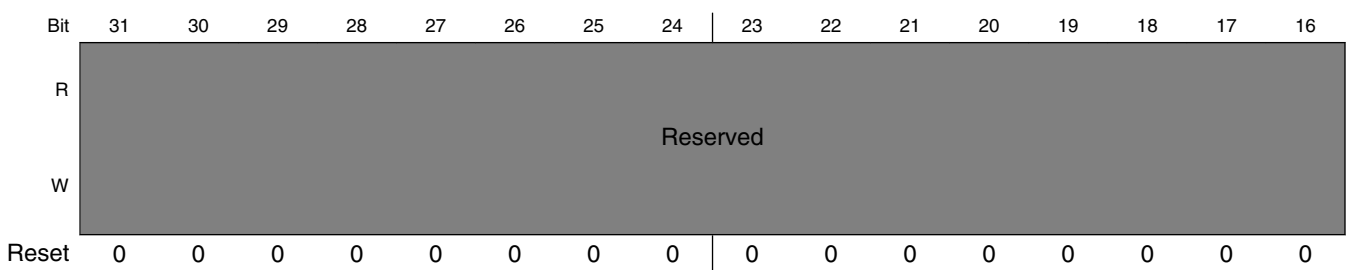
9–8 CH4	DMA burst size for GPMI channel 4. Do not change. GPMI only support burst size 4.
7–6 CH3	DMA burst size for GPMI channel 3. Do not change. GPMI only support burst size 4.
5–4 CH2	DMA burst size for GPMI channel 2. Do not change. GPMI only support burst size 4.
3–2 CH1	DMA burst size for GPMI channel 1. Do not change. GPMI only support burst size 4.
CH0	DMA burst size for GPMI channel 0. Do not change. GPMI only support burst size 4.

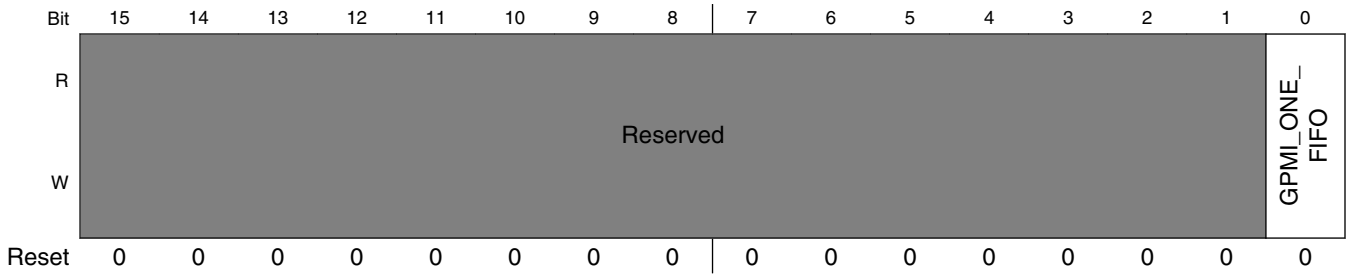
9.4.5.7 AHB to APBH DMA Debug Register (APBH_DEBUG)

This register is for debug purpose.

The debug register is for internal use only. Not recommend for customer useage.

Address: 3300_0000h base + 60h offset = 3300_0060h





APBH_DEBUG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved, always set to zero.
0 GPMI_ONE_FIFO	Set to 0ne and the 8 GPMI channels will share the DMA FIFO, and when set to zero, the 8 GPMI channels will use its own DMA FIFO.

9.4.5.8 APBH DMA Channel n Current Command Address Register (APBH_CH*n*_CURCMDAR)

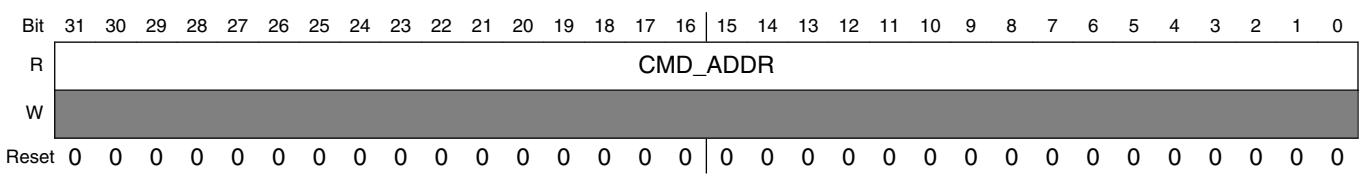
The APBH DMA channel n current command address register points to the multiword command that is currently being executed. Commands are threaded on the command address.

APBH DMA Channel n is controlled by a variable sized command structure. This register points to the command structure currently being executed.

EXAMPLE

```
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR_RD(0);              // read the whole
register, since there is only one field
pCurCmd = (apbh_chn_cmd_t *) BF_RDn(APBH_CHn_CURCMDAR, 0, CMD_ADDR);  // or, use multi-
register bitfield read macro
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR(0).CMD_ADDR;        // or, assign from
bitfield of indexed register's struct
```

Address: 3300_0000h base + 100h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_CURCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to command structure currently being processed for channel n.

9.4.5.9 APBH DMA Channel n Next Command Address Register (APBH_CH*n*_NXTCMDAR)

The APBH DMA Channel n Next Command Address register contains the address of the next multiword command to be executed. Commands are threaded on the command address. Set CHAIN to 1 in the DMA command word to process command lists.

APBH DMA Channel n is controlled by a variable sized command structure. Software loads this register with the address of the first command structure to process and increments the Channel n semaphore to start processing. This register points to the next command structure to be executed when the current command is completed.

EXAMPLE

```
APBH_CHn_NXTCMDAR_WR(0, (reg32_t) pCommandTwoStructure);         // write the entire
register, since there is only one field
BF_WRn(APBH_CHn_NXTCMDAR, 0, (reg32_t) pCommandTwoStructure);       // or, use multi-
register bitfield write macro
APBH_CHn_NXTCMDAR(0).CMD_ADDR = (reg32_t) pCommandTwoStructure;  // or, assign to bitfield
of indexed register's struct
```

Address: 3300_0000h base + 110h offset + (112d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMD_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

APBH_CH*n*_NXTCMDAR field descriptions

Field	Description
CMD_ADDR	Pointer to next command structure for channel n.

9.4.5.10 APBH DMA Channel n Command Register (APBH_CH*n*_CMD)

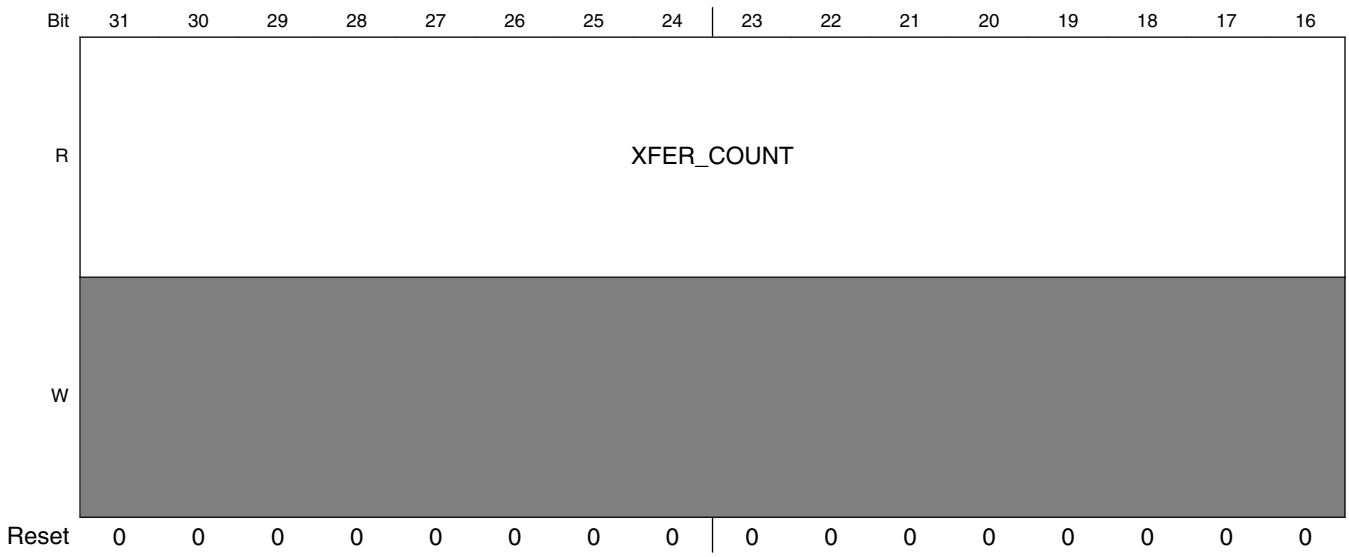
The APBH DMA Channel n command register specifies the DMA transaction to perform for the current command chain item.

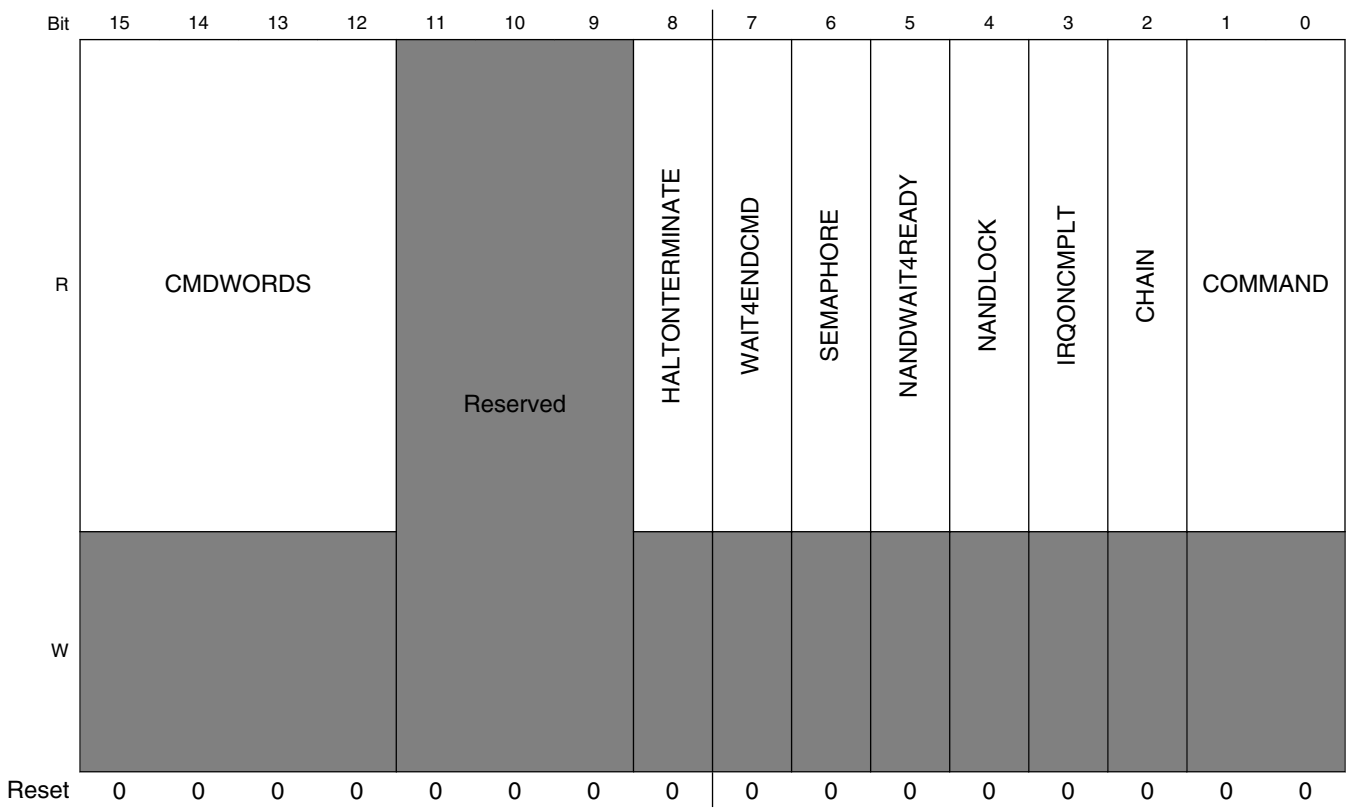
The command register controls the overall operation of each DMA command for this channel. It includes the number of bytes to transfer to or from the device, the number of APB PIO command words included with this command structure, whether to interrupt at command completion, whether to chain an additional command to the end of this one and whether this transfer is a read or write DMA transfer.

EXAMPLE

```
apbh_chn_cmd_t  dma_cmd;
dma_cmd.XFER_COUNT = 512;                                    // transfer 512 bytes
dma_cmd.COMMAND = BV_APBH_CHn_CMD_COMMAND__DMA_WRITE;  // transfer to system memory from
peripheral device
dma_cmd.CHAIN = 1;                                           // chain an additional command
structure on to the list
dma_cmd.IRQONCMPLT = 1;                                      // generate an interrupt on
completion of this command structure
```

Address: 3300_0000h base + 120h offset + (112d × i), where i=0d to 15d





APBH_CH*n*_CMD field descriptions

Field	Description
31–16 XFER_COUNT	This field indicates the number of bytes to transfer to or from the appropriate PIO register in the GPMI0 device. A value of 0 indicates a 64 KBytes transfer.
15–12 CMDWORDS	This field indicates the number of command words to send to the GPMI0, starting with the base PIO address of the GPMI0 control register and incrementing from there. Zero means transfer NO command words
11–9 -	This field is reserved. Reserved, always set to zero.
8 HALTONTERMINATE	A value of one indicates that the channel will immeditately terminate the current descriptor and halt the DMA channel if a terminate signal is set. A value of 0 will still cause an immediate terminate of the channel if the terminate signal is set, but the channel will continue as if the count had been exhausted, meaning it will honor IRQONCMPLT, CHAIN, SEMAPHORE, and WAIT4ENDCMD.
7 WAIT4ENDCMD	A value of one indicates that the channel will wait for the end of command signal to be sent from the APBH device to the DMA before starting the next DMA command.
6 SEMAPHORE	A value of one indicates that the channel will decrement its semaphore at the completion of the current command structure. If the semaphore decrements to zero, then this channel stalls until software increments it again.
5 NANDWAIT4READY	A value of one indicates that the NAND DMA channel will will wait until the NAND device reports "ready" before executing the command. It is ignored for non-NAND DMA channels.
4 NANDLOCK	A value of one indicates that the NAND DMA channel will remain "locked" in the arbiter at the expense of other NAND DMA channels. It is ignored for non-NAND DMA channels.
3 IRQONCMPLT	A value of one indicates that the channel will cause the interrupt status bit to be set upon completion of the current command, i.e. after the DMA transfer is complete.
2 CHAIN	A value of one indicates that another command is chained onto the end of the current command structure. At the completion of the current command, this channel will follow the pointer in APBH_CHn_CMDAR to find the next command.
COMMAND	This bitfield indicates the type of current command: 0x0 **NO_DMA_XFER** — Perform any requested PIO word transfers but terminate command before any DMA transfer. 0x1 **DMA_WRITE** — Perform any requested PIO word transfers and then perform a DMA transfer from the peripheral for the specified number of bytes. 0x2 **DMA_READ** — Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes. 0x3 **DMA_SENSE** — Perform any requested PIO word transfers and then perform a conditional branch to the next chained device. Follow the NEXCMD_ADDR pointer if the perpheral sense is true. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is false.

9.4.5.11 APBH DMA Channel n Buffer Address Register (APBH_CH*n*_BAR)

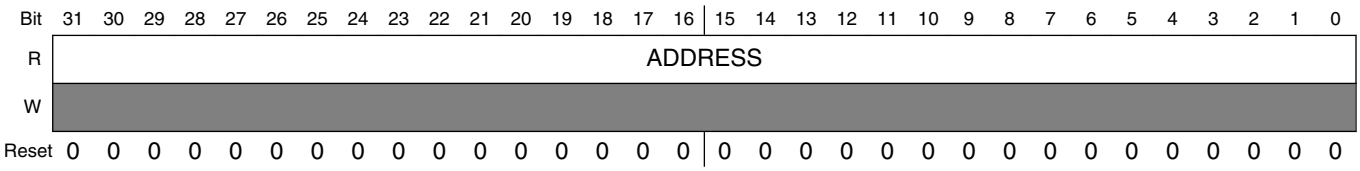
The APBH DMA Channel n buffer address register contains a pointer to the data buffer for the transfer. For immediate forms, the data is taken from this register. This is a byte address which means transfers can start on any byte boundary.

This register holds a pointer to the data buffer in system memory. After the command values have been read into the DMA controller and the device controlled by this channel, then the DMA transfer will begin, to or from the buffer pointed to by this register.

EXAMPLE

```
apbh_chn_bar_t  dma_data;
dma_data.ADDRESS = (reg32_t) pDataBuffer;
```

Address: 3300_0000h base + 130h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_BAR field descriptions

Field	Description
ADDRESS	Address of system memory buffer to be read or written over the AHB bus.

9.4.5.12 APBH DMA Channel n Semaphore Register (APBH_CH*n*_SEMA)

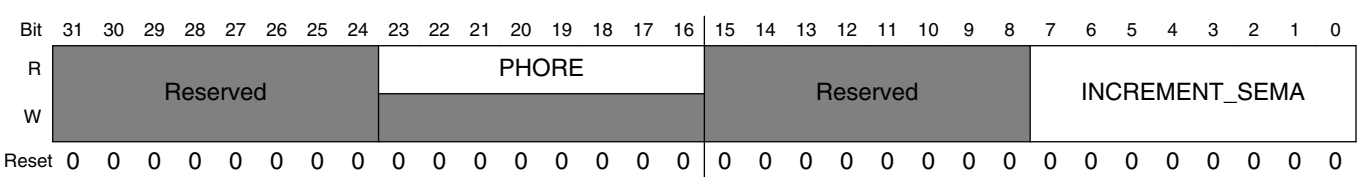
The APBH DMA Channel n semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state.

Each DMA channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DMA chain processing. DMA processing continues until the DMA attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DMA channel is stalled until software increments the semaphore count.

EXAMPLE

```
BF_WR(APBH_CHn_SEMA, 0, INCREMENT_SEMA, 2);     // increment semaphore by two
current_sema = BF_RD(APBH_CHn_SEMA, 0, PHORE);  // get instantaneous value
```

Address: 3300_0000h base + 140h offset + (112d × i), where i=0d to 15d



APBH_CH*n*_SEMA field descriptions

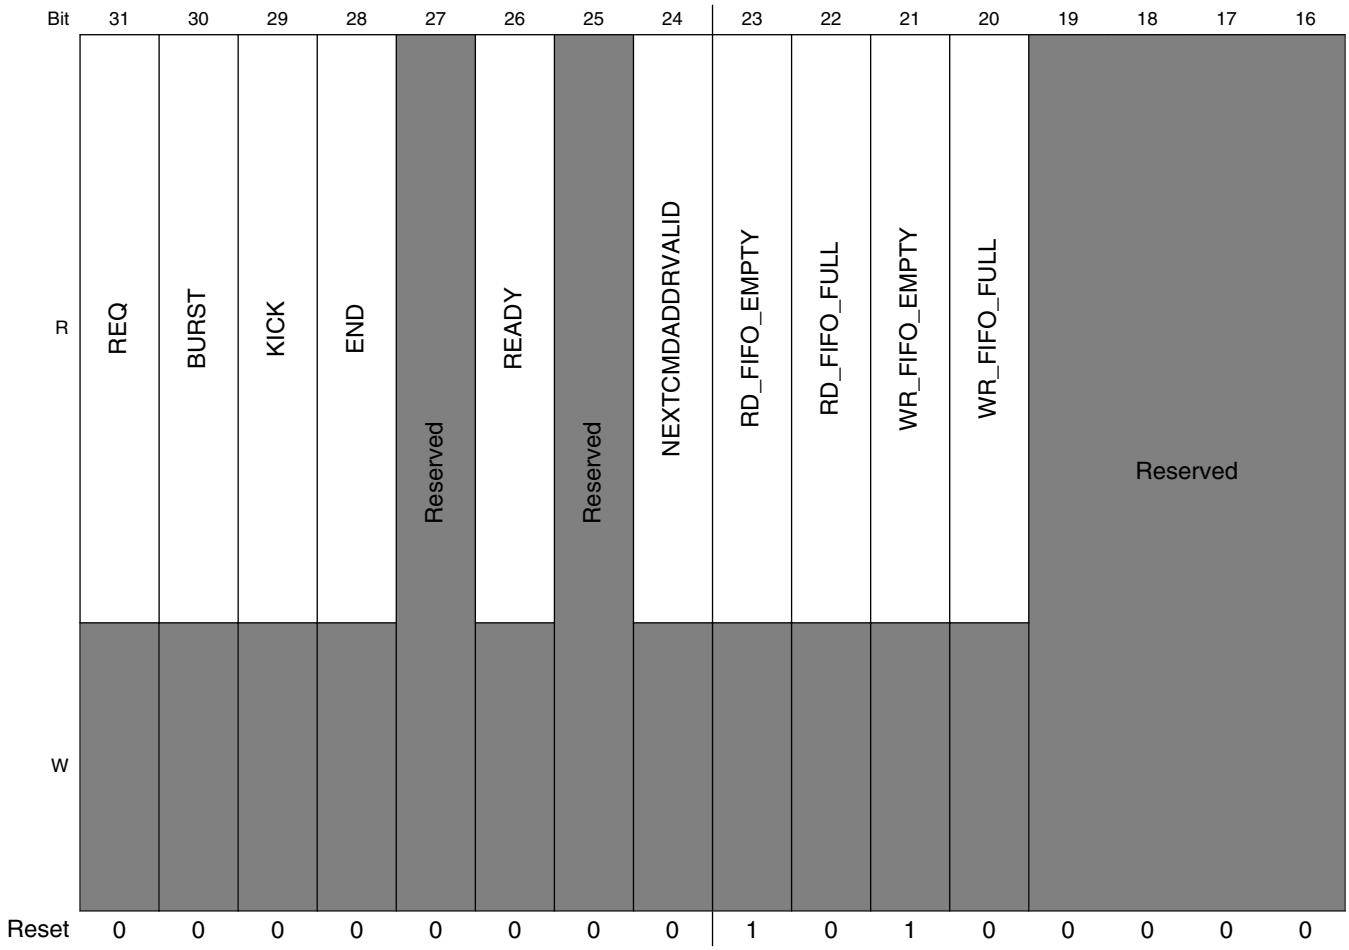
Field	Description
31–24 -	This field is reserved. Reserved, always set to zero.
23–16 PHORE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	This field is reserved. Reserved, always set to zero.
INCREMENT_ SEMA	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DMA hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DMA channel decrements the count on the same clock, then the count is incremented by a net one.

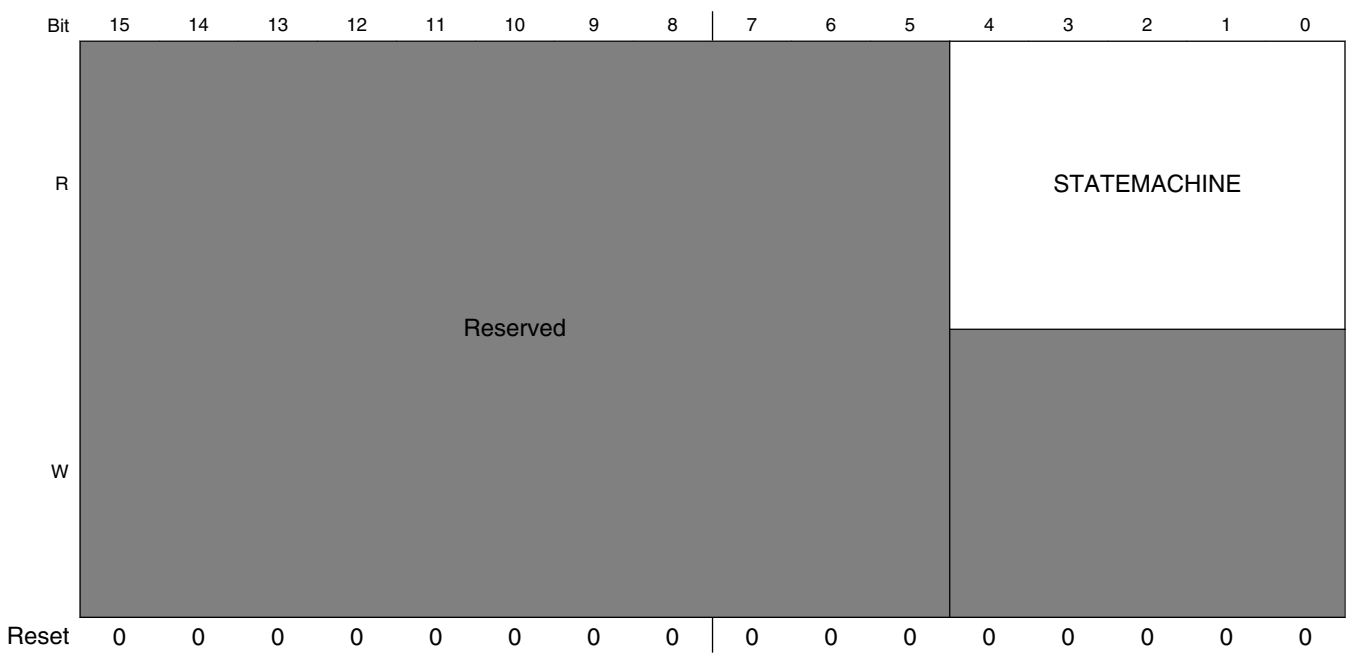
9.4.5.13 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG1)

This register gives debug visibility into the APBH DMA Channel n state machine and controls.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 150h offset + (112d × i), where i=0d to 15d





APBH_CH*n*_DEBUG1 field descriptions

Field	Description
31 REQ	This bit reflects the current state of the DMA Request Signal from the APB device
30 BURST	This bit reflects the current state of the DMA Burst Signal from the APB device
29 KICK	This bit reflects the current state of the DMA Kick Signal sent to the APB Device
28 END	This bit reflects the current state of the DMA End Command Signal sent from the APB Device
27 SENSE	This field is reserved. This bit is reserved for this DMA Channel and always reads 0.
26 READY	This bit is reserved for this DMA Channel and always reads 0.
25 LOCK	This field is reserved. This bit is reserved for this Channel and always reads 0.
24 NEXTCMDADDRVALID	This bit reflects the internal bit which indicates whether the channel's next command address is valid.
23 RD_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Read FIFO Empty signal.
22 RD_FIFO_FULL	This bit reflects the current state of the DMA Channel's Read FIFO Full signal.
21 WR_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Write FIFO Empty signal.
20 WR_FIFO_FULL	This bit reflects the current state of the DMA Channel's Write FIFO Full signal.
19–5 RSVD1	This field is reserved. Reserved
STATEMACHINE	PIO Display of the DMA Channel n state machine state. 0x00 **IDLE** — This is the idle state of the DMA state machine. 0x01 **REQ_CMD1** — State in which the DMA is waiting to receive the first word of a command. 0x02 **REQ_CMD3** — State in which the DMA is waiting to receive the third word of a command. 0x03 **REQ_CMD2** — State in which the DMA is waiting to receive the second word of a command. 0x04 **XFER_DECODE** — The state machine processes the descriptor command field in this state and branches accordingly. 0x05 **REQ_WAIT** — The state machine waits in this state for the PIO APB cycles to complete. 0x06 **REQ_CMD4** — State in which the DMA is waiting to receive the fourth word of a command, or waiting to receive the PIO words when PIO count is greater than 1. 0x07 **PIO_REQ** — This state determines whether another PIO cycle needs to occur before starting DMA transfers. 0x08 **READ_FLUSH** — During a read transfers, the state machine enters this state waiting for the last bytes to be pushed out on the APB. 0x09 **READ_WAIT** — When an AHB read request occurs, the state machine waits in this state for the AHB transfer to complete. 0x0C **WRITE** — During DMA Write transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 0x0D **READ_REQ** — During DMA Read transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel.

Table continues on the next page...

APBH_CH*n*_DEBUG1 field descriptions (continued)

Field	Description
	0x0E **CHECK_CHAIN** — Upon completion of the DMA transfers, this state checks the value of the Chain bit and branches accordingly. 0x0F **XFER_COMPLETE** — The state machine goes to this state after the DMA transfers are complete, and determines what step to take next. 0x14 **TERMINATE** — When a terminate signal is set, the state machine enters this state until the current AHB transfer is completed. 0x15 **WAIT_END** — When the Wait for Command End bit is set, the state machine enters this state until the DMA device indicates that the command is complete. 0x1C **WRITE_WAIT** — During DMA Write transfers, the state machine waits in this state until the AHB master completes the write to the AHB memory space. 0x1D **HALT_AFTER_TERM** — If HALTONTERMINATE is set and a terminate signal is set, the state machine enters this state and effectively halts. A channel reset is required to exit this state 0x1E **CHECK_WAIT** — If the Chain bit is a 0, the state machine enters this state and effectively halts. 0x1F **WAIT_READY** — When the NAND Wait for Ready bit is set, the state machine enters this state until the GPMI device indicates that the external device is ready.

9.4.5.14 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG2)

This register gives debug visibility for the APB and AHB byte counts for DMA Channel n.

This register allows debug visibility of the APBH DMA Channel n.

Address: 3300_0000h base + 160h offset + (112d × i), where i=0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_CH*n*_DEBUG2 field descriptions

Field	Description
31–16 APB_BYTES	This value reflects the current number of APB bytes remaining to be transfered in the current transfer.
AHB_BYTES	This value reflects the current number of AHB bytes remaining to be transfered in the current transfer.

9.4.5.15 APBH Bridge Version Register (APBH_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (APBH_VERSION.B.MAJOR != 3)
   Error();
```

Address: 3300_0000h base + 800h offset = 3300_0800h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

9.5 62BIT Correcting ECC Accelerator (BCH)

9.5.1 Overview

The hardware ECC accelerator provides a forward error-correction function for improving the reliability of various storage media that may be attached to the device.

For example, NAND flash devices use a spare area to store ecc codes to correct some hard bit errors in data stored within the device, allowing higher device yields and, therefore, lower NAND device costs.

The Bose, Ray-Chaudhuri, Hocquenghem (BCH) Encoder and Decoder module is capable of correcting from 2 to 62 single bit errors within a block of data no larger than about 1900 bytes (512 bytes or 1024 bytes are typical) in applications such as protecting data and resources stored on modern NAND flash devices. The correction level in the BCH block is programmable to provide flexibility for varying applications and configurations of flash page size. The design can be programmed to encode protection of 2 to 62 bit errors when writing flash and to correct the corresponding number of errors on decode. The correction level when decoding MUST be programmed to the same correction level as was used during the encode phase.

BCH-codes are a type of block-code, which implies that all error-correction is performed over a block of N-symbols. The BCH operation will be performed over GF(2^{13} = 8192) or GF(2^{14} = 16384), which is the Galois Field consisting of 8191 or 16383 one-bit symbols. BCH-encoding (or encode for any block-code) can be performed by two algorithms: systematic encoding or multiplicative encoding. Systematic encoding is the process of reading all the symbols which constitute a block, dividing continuously these symbols by the generator polynomial for the GF(8192) or GF(16384) and appending the resulting ***t*** parity symbols to the block to create a BCH codeword (where ***t*** is the number of correctable bits).

The BCH encode process creates *t**13 (or *t**14)-bit parity symbols for each data block when the data is written to the flash device. The parity symbols are written to the flash device after the corresponding data block, and together these are collectively called the codeword. The codeword can be used during the decode process to correct errors that occur in either the data or parity blocks.

The BCH decoder processes code words in a 4-step fashion:

1. Syndrome Calculation (SC): This is the process of reading in all of the symbols of the codeword and continuously dividing by the generator polynomial for the field. 2**t* syndromes must be calculated for each codeword and inspection of the syndromes determines if there are errors: a non-zero set of syndromes indicates one or more errors. This process is implemented parallel hardware to minimize processing time since it must be done every time the decode is performed.
2. Key Equation Solver (KES): The syndromes represent 2t-linear equations with 2t-unknown variables. The process of solving these equations and selecting from the numerous solutions constitutes the KES module. When the KES block completes its operations, it generates an error locator polynomial (sigma) that is used in the proceeding block to determine the locations and values of the errors.
3. Chien Search (CS): This block takes input from the KES block and uses the Chien Algorithm for finding the locations of the errors based on the error locator polynomial. The method basically involves substituting all 8191 symbols from the GF(8192) or 16383 symbols from the GF(16383) into the locator polynomial. All evaluations that produce a zero solution indicate locations of the various errors. Since each located error corresponds to a single bit, the bit in the original data may be corrected by simply flipping the polarity of the incorrect location.
4. Correction: this block has to convert the symbol index and mask information to memory byte indexes and masks.

The BCH block, shown in the figure, was designed to operate in a pipelined fashion to maximize throughput. Aside from the initial latency to fill the pipeline stages, the BCH throughput is about 7/4 cycles/byte. Thus, the bottleneck in performing NAND reads and error corrections is the BCH rate. Current GPMI read rates are approximately 1/2 cycles/byte maximally for the current generation of NAND flash. Fortunately, BCH has a different master clock from GPMI, this gives some flexibility to match the throughput rate. The CPU is not directly involved in generating parity symbols, checking for errors, or correcting them.

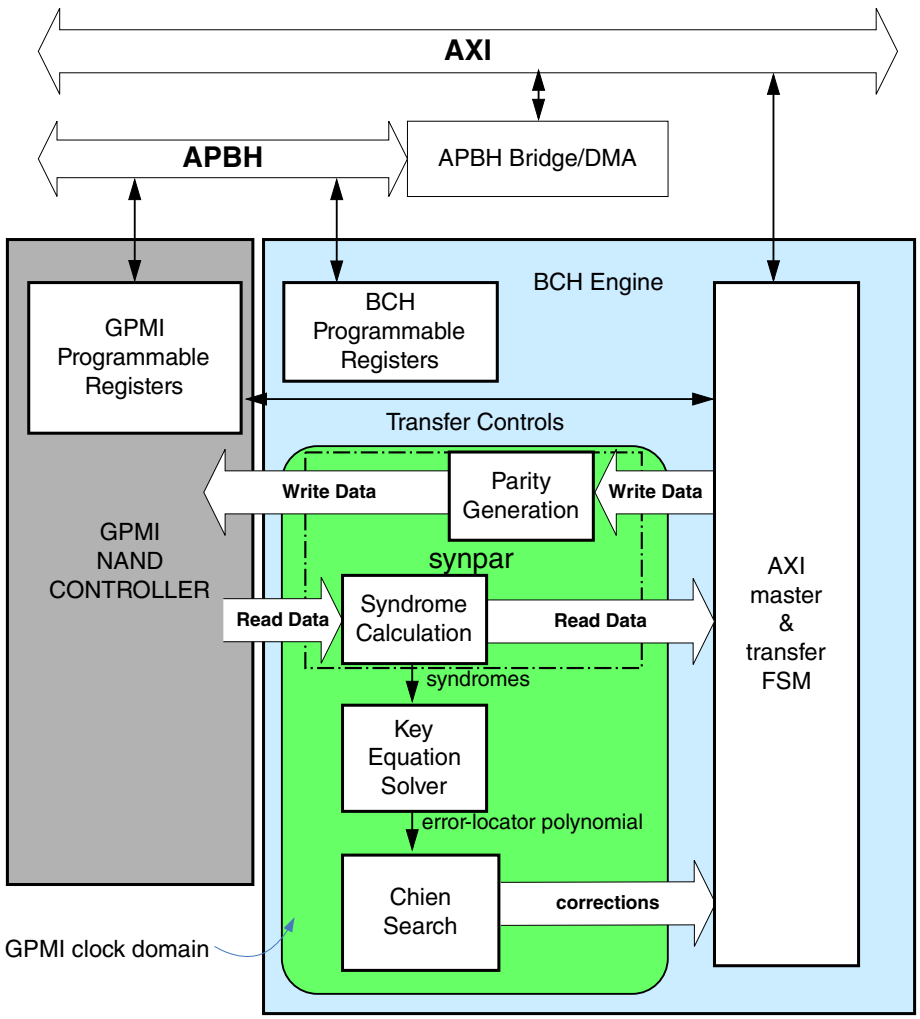

Figure 9-28. Hardware BCH Accelerator

9.5.2 Operation

Before performing any NAND flash read or write operations, software should first program the BCH's flash layout registers (see Flash Page Layout) to specify how data is to be formatted on the flash device.

The BCH hardware allows full programmability over the flash page layout to enable users flexibility in balancing ECC correction levels and ever-changing flash page sizes.

To initiate a NAND Flash write, software will program a GPMI DMA operation. The DMA need only program the GPMI control registers (and handle the requisite flash addressing handshakes) since the BCH will handle all data operations using its AXI bus interface. The BCH will then send the data to the GPMI controller to be written to flash as it computes the parity symbols. At the end of each data block the BCH will insert the parity symbols into the data stream so that the GPMI sees only a continuous stream of data to be written.

NAND Flash read operations operate in a similar manner. As the GPMI controller reads the device, all data is sent to the BCH hardware for error detection/correction. The BCH controller writes all incoming read data to system memory and in parallel computes the syndromes used to detect bit errors. If errors are detected within a block, the BCH hardware activates the error correction logic to determine where bit errors have occurred and ultimately correct them in the data buffer in system memory. After an entire flash page has been read and corrected, the BCH will signal an interrupt to the CPU.

The figure below indicates how data read from the GPMI is operated on within the BCH hardware. As the BCH receives data from the GPMI (top row), it is written to memory by the BCH's Bus Interface Unit (BIU) (second row). For blocks requiring correction, the KES logic will be activated after the entire block has been received. Once the error locator polynomial has been computed, the corrections are determined by the Chien Search and fed back to the BIU, which performs a read, modify, write operation on the buffer in memory to correct the data.

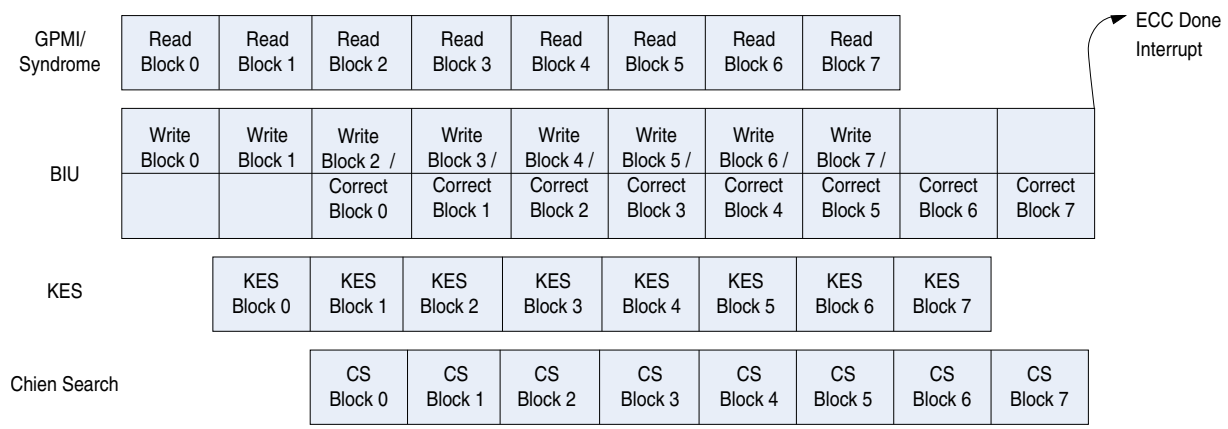

Figure 9-29. Block Pipeline while Reading Flash

9.5.2.1 BCH Limitations and Assumptions

- The BCH is programmable to support 2 to 62 bit error correction. ECC0 is supported as a pass-through, non-correcting mode.
- Data block sizes must be a multiple of 4 bytes and be aligned in system memory.
- The BCH supports a programmable number of metadata/auxiliary data bytes, from 0 to 255.
- Metadata will be written at the beginning of the flash page to facilitate fast access for filesystem operations.
- Metadata may be treated as an independent block for ECC purposes or combined with the first data block to conserve bits in the flash.
- The BCH does not support a partial page write (this can be accomplished by programming the BCH layout registers such that the BCH only sees a portion of the page).
- Flash read operations can read the entire page or the first block on the page.
- The BCH also supports a memory-to-memory mode of operation that does not require the use of DMA or the GPMI.

9.5.2.2 Flash Page Layout

The BCH supports a fully programmable flash page layout. The BCH maintains four independent layout registers that can describe four completely different NAND devices or layouts.

When the BCH initiates an operation, it selects one of the layouts by using the chip select as an index into the BCH_LAYOUTSELECT register that determines which layout should be used for the operation.

Three possible (generic) flash layout schemes are supported, as indicated in the figure below. (In each case, the metadata size may also be programmed to 0 bytes). Metadata may either be combined with the first block of data or the size of the first data block can be programmed to 0 to allow the metadata to be protected by its own ECC parity bits.

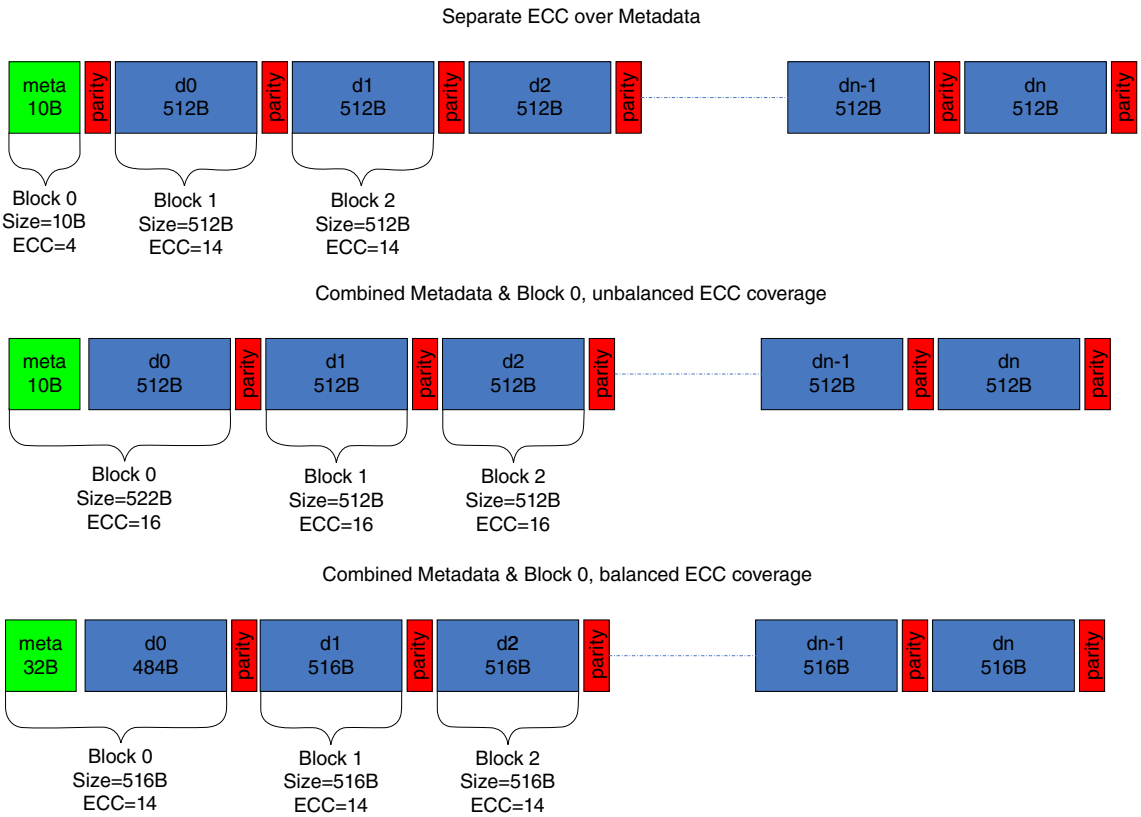

Figure 9-30. FLASH Page Layout Options

Each layout is determined by a pair of registers that define the following parameters:

- DATA0_SIZE: Indicates the number of data bytes in the first block on the page (this should not include parity or metadata bytes). This should be set to 0 when the metadata is to be covered separately with its own ECC. This must be a multiple of 4 bytes.
- ECC0: Indicates the ECC level to be used for the first block on the flash (data0+metadata).
- META_SIZE: Indicates the number of bytes (from 0-255) that are stored as metadata.
- NBLOCKS: Indicates the number of subsequent DATAN blocks on the flash, or the number of blocks following the DATA0 block.
- DATAN_SIZE: Indicates the number of data bytes in all subsequent data blocks. This MUST be a multiple of 4 bytes.
- ECCN: Indicates the ECC level to be used for the subsequent data blocks.

- GF0 or GFN: Indicates the Galois field the meta / data blocks are using
- PAGE_SIZE: Indicates the total number of bytes available per page on the physical flash device. This includes the spare area and is typically 4096+128, 4096+218, or 2048+64 bytes.

9.5.2.3 Determining the ECC layout for a device

Since the BCH is programmable, a system can trade off ECC levels for flash size and layout configurations.

The following examples indicate how to determine a valid layout based on the required storage space and flash size. For all cases, the size of the parity will be 13 (or 14 for GF(2^{14}))*ECC level ***bits***-- so for ECC8, 13 (or 14) bytes are required (per block).

9.5.2.3.1 4K+218 flash, 10 bytes metadata, 512 byte data blocks, separate metadata, Assuming GF(2^{13})

In this case, we have 8 data blocks each consisting of 512 bytes. Since the flash has 218 spare bytes (1744 bits), first estimate an ECC level for the data blocks by first subtracting the number of metadata bytes from the spare bytes (218 – 10 = 208 bytes = 1664 bits) then dividing the number of bits by 8 (number of blocks) and then by 13 (bits per ECC level).

(218 - 10) x 8 = 1664/13(8) = 16

Therefore all the data blocks could be covered by ECC16 if the metadata had no parity. This isn't acceptable, so assume ECC14 for all the data blocks. Now calculate the number of free bits for the metadata parity as

1664 - (14) x 13 x 8 = 208

Therefore, 208 bits remain for metadata parity. Dividing by 13 (bits/ECC) gives 16, so the metadata can be covered with ECC16. The settings for this device would then be

Table 9-19. Settings for 4K+218 FLASH

Setting	Value
PAGE_SIZE	4096+218=4314=0x10DA
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	16=0x10
GF0	GF(2^{13})

Table continues on the next page...

Table 9-19. Settings for 4K+218 FLASH (continued)

Setting	Value
DATAN_SIZE	512=0x200 (in register interface, assigned as 0x80)
ECCN	14=0x0E
GFN	GF(2^{13})
NBLOCKS	8

9.5.2.3.2 4K+128 flash, 10 bytes metadata, 1024 byte data blocks, separate metadata, assuming GF(2^{13}) for data and GF(2^{14}) for metadata

This flash will have 118 bytes available for ECC (after subtracting the metadata size), therefore, 994 bits.

Dividing by 4*14 (number of blocks * ECC level) we get 17.75, therefore we can support ECC16 on the data blocks. The number of free spare bits becomes 944 - 16 * 4 * 14 = 944 - 896 = 48, divided by 13 = 3.69, therefore the metadata can be also covered by ECC2.

Table 9-20. Settings for 4K+128 FLASH

Setting	Value
PAGE_SIZE	4096+128=4224=0x1080
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	2
GF0	GF(2^{13})
DATAN_SIZE	1024=0x400 (in register interface, assigned as 0x100)
ECCN	16
GFN	GF(2^{14})
NBLOCKS	4

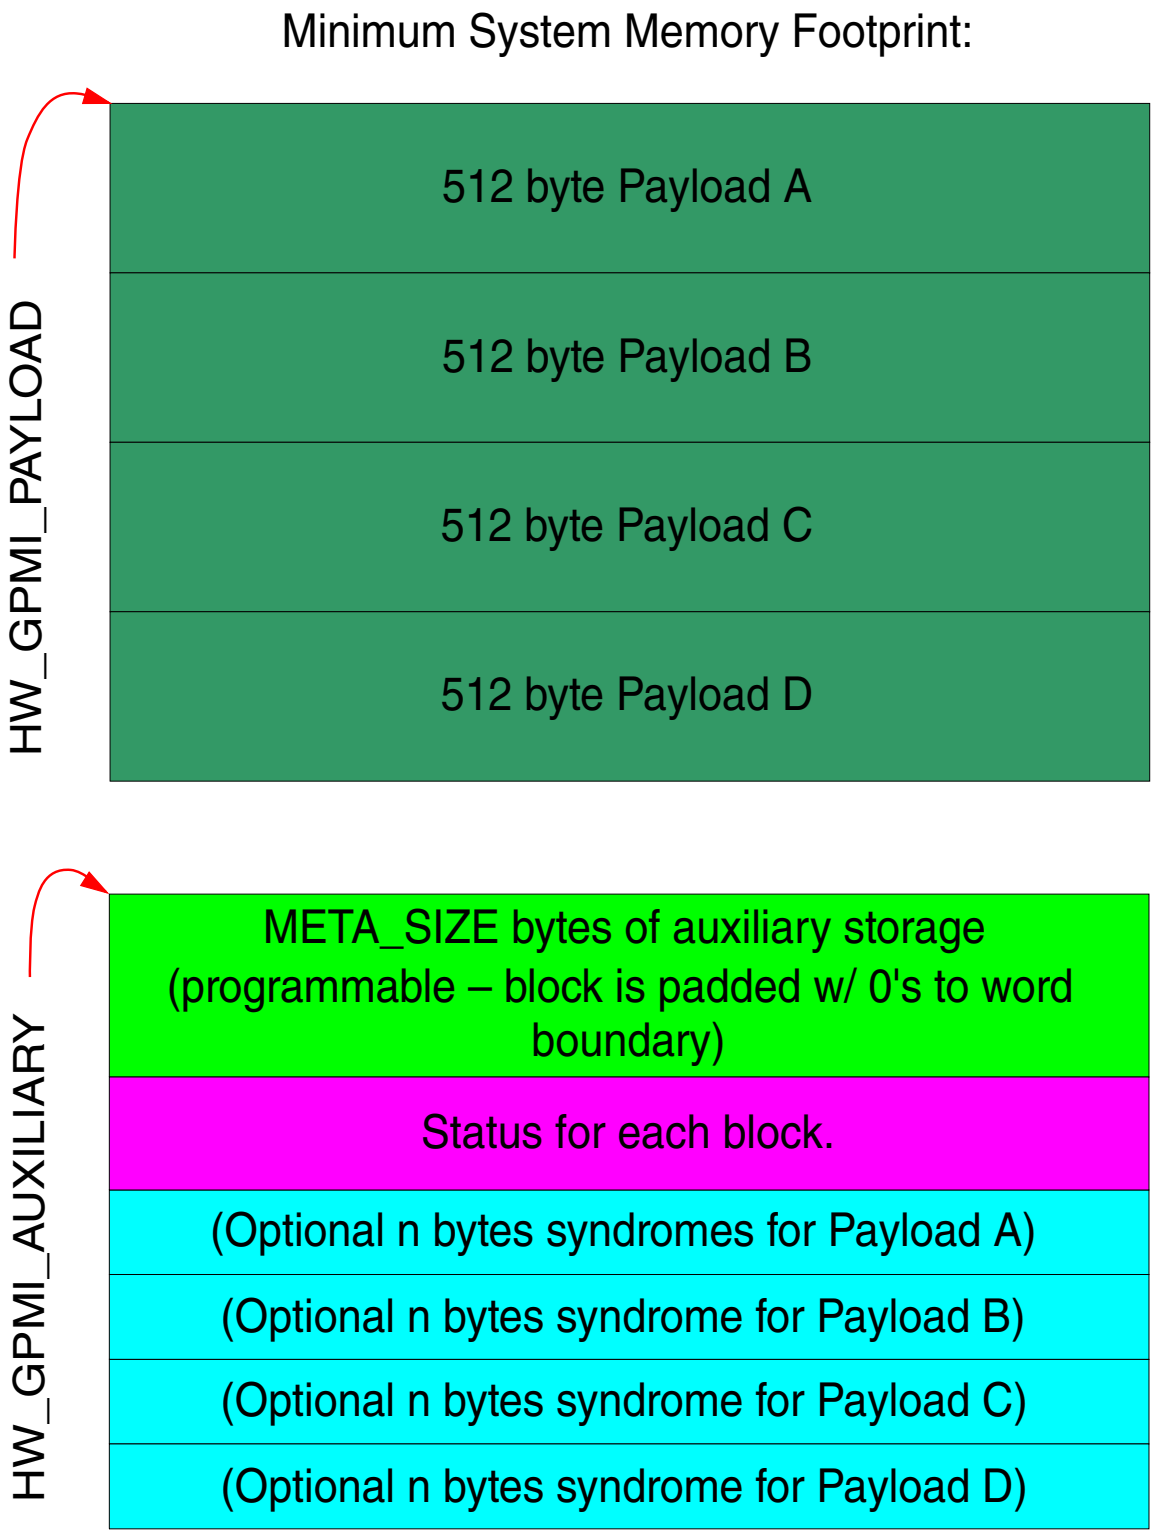
In this case, there will be additional unused spare bits, with the BCH will pad out with zeros.

9.5.2.4 Data Buffers in System Memory

While the data on the flash is interleaved with parity symbols, the BCH assumes that the data buffers in memory are contiguous.

Metadata read from the flash will be stored to the location pointed to by the GPMI_AUXILIARY register and data will be written to the address specified in the GPMI_PAYLOAD register as is shown in the following figure where the block length is 512 bytes for example. Since the number of blocks on a flash page is programmable, the BCH also writes individual block correction status to the auxiliary pointer at the word-aligned address following the end of the metadata. Optionally, the computed syndromes may also be written to the auxiliary area if the DEBUGSYNDROME bit is set in the control register.

As blocks complete processing, the bus master will accumulate the status for each block and write it to the auxiliary data buffer following the metadata. The metadata area will be padded with 0's until the next word boundary and the status for blocks 0-3 will be written to the next word. The status for subsequent blocks will then be written to the buffer. The status for the first block (metadata block) is also stored in the STATUS_BLK0 register in the BCH_STATUS register. The completion codes for the blocks are indicated in the Table 9-21. Note that the definition of the bytes and their ordering in the auxiliary and payload storage areas are user defined. When this data is read back from the flash and put into memory, it will resemble the original buffer that was written out to the flash.



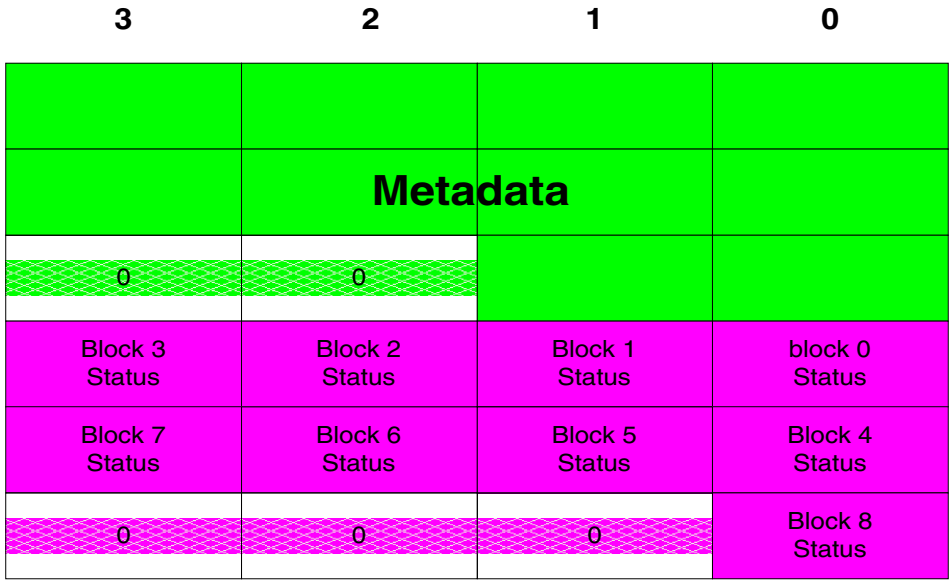
*Computed syndrome area consists of 2*t 13 (or 14)-bit symbols written as 16-bit half word.*

Figure 9-31. BCH Data Buffers in Memory

Table 9-21. Status Block Completion Codes

Code	Description
0xFF	Block is erased
0xFE	Block is uncorrectable
0x00	No errors found
0x01-0x3E	Number of errors corrected

The following figure shows the layout of the bytes within the status field.



Status bytes are allocated based on the NBLOCKS programmed into the flash format register. The number of status bytes will be computed by the NBLOCKS+1. The status area will be padded with zeros to the next word boundary.

Syndrome data written for debug purposes will follow the end of the status block.

Figure 9-32. Memory-to-Memory Operations

9.5.3 Memory to Memory (Loopback) Operation

The BCH supports a memory-to-memory mode of operation where both the encoded and decoded buffers reside in system memory.

This can be useful for applications where data must be protected by ECC, but the storage device does not reside on the GPMI bus.

The BCH operation in memory to memory mode is much simpler than in GPMI mode since DMAs are not required to manage the operation. Instead, software simply writes the BCH_DATAPTR and BCH_METAPTR with the addresses of the data and metadata

(auxiliary) buffers and the BCH_ENCODEPTR with the address of the buffer for encoded data. To initiate the operation, software simply sets the M2M_ENCODE and M2M_ENABLE bits in the control register. The BCH can be programmed to either issue an interrupt at the end of the operation or software may poll the status bits for completion.

Memory to memory decode operations work in a similar manner. The encoded data address is written to the BCH_ENCODEPTR and the data and meta pointers are written to buffers that correspond to the desired decoded data addresses. To initiate a decode, software must set the M2M_ENCODE bit to 0 while writing the M2M_ENABLE bit. Note that the addresses written to the BCH_DATAPTR, BCH_METAPTR and BCH_ENCODEPTR registers should always be aligned on a 4 byte boundary. In other words, the 2 lower bits of the address should always be written with zeros.

9.5.4 Programming the BCH/GPMI Interfaces

Programming the BCH for NAND operations consists largely of disabling the soft reset and clock bits (SFTRST and CLKGATE) from the BCH_CTRL register and then programming the flash layout registers to correspond to the format of the attached NAND device(s).

The BCH_LAYOUTSELECT register should also be programmed to map the chip select of each attached device into one of the four layout registers.

The bulk of the programming is actually applied to the GPMI through PIO operations embedded in DMA command structures. The DMA will perform all the requisite handshaking with the GPMI interface to negotiate the address portion of the transfer, then the BCH will handle all the movement of data from memory to the GPMI (writes) or the GPMI to memory (reads). The BCH will direct all data blocks to the buffer pointed to by the PAYLOAD_BUFFER and the metadata will be written to the AUXILIARY_BUFFER. Both of these registers are located in the GPMI PIO data space and are communicated to the BCH hardware at the beginning of the transfer. Thus, the normal multi-NAND DMA based device interleaving is preserved, that is, four NANDs on four separate chip selects can be scheduled for read or write operations using the BCH. Whichever channel finishes its ready wait first and enters the DMA arbiter with its lock bit set owns the GPMI command interface and through it owns the BCH resources for the duration of its processing.

9.5.4.1 BCH Encoding for NAND Writes

The BCH encoder flowchart in Figure 9-33 shows the detailed steps involved in programming and using the BCH encoder. This flowchart shows how to use the BCH block with the GPMI.

To use the BCH encoder with the GPMI's DMA, create a DMA command chain containing ten descriptor structures, as shown in Figure 9-35 and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The ten descriptors perform the following tasks:

1. Disable the BCH block (in case it was enabled) and issue NAND write setup command byte (under CLE) and address bytes (under ALE).
2. Configure and enable the BCH and GPMI blocks to perform the NAND write.
3. Disable the BCH block and issue NAND write execute command byte (under CLE).
4. Wait for the NAND device to finish writing the data by watching the ready signal.
5. Check for NAND timeout through PSENSE.
6. Issue NAND status command byte (under CLE).
7. Read the status and compare against expected.
8. If status is incorrect or incomplete, branch to error handling descriptor chain.
9. Otherwise, write is complete and emit GPMI interrupt.

```

9.5.4.1.2 Using the BCH Encoder

To use the BCH encoder, first turn off the module-wide soft reset bit in both the GPMI and BCH blocks before starting any DMA activity.

Turning off the soft reset must take place by itself, prior to programming the rest of the control registers. Turn off the BCH bus master soft reset bit. Turn off the clock gate bits.

Program the remainder of the GPMI, BCH and APBH DMA as follows:

```
// bring APBH out of reset
APBH_CTRL0_CLR(BM_APBH_CTRL0_SFRST);
APBH_CTRL0_CLR(BM_APBH_CTRL0_CLKGATE);

// bring BCH out of reset
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);

// bring gpmi out of reset
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_SFTRST);
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_CLKGATE);
GPMI_CTRL1_SET(BM_GPMI_CTRL1_DEV_RESET | // deassert reset
                   BM_GPMI_CTRL1_BCH_MODE  );    // enable BCH mode

// enable pinctrl
PINCTRL_CTRL_WR(0x00000000);

// enable gpmi pins
PINCTRL_MUXSEL0_CLR(0x0000ffff);    // data bits
PINCTRL_MUXSEL1_CLR(0x03ffffff);    // control bits
PINCTRL_MUXSEL8_CLR(0x0003f3ff);    // control bits
PINCTRL_MUXSEL8_SET(0x00015155);    // control bits
```

Note that for writing NANDs (ECC encoding), only GPMI DMA command complete interrupts are used. The BCH engine is used for writing to the NAND but may optionally produces an interrupt. From the sample code in DMA Structure Code Example:

- DMA descriptor 1 prepares the NAND for data write by using the GPMI to issue a write setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is disabled and not used for these commands.
- DMA descriptor 2 enables the BCH engine for encoding to begin the initial writing of the NAND data by specifying where the data and auxiliary payload are coming from in system memory.

- DMA descriptor 3 issues the write commit command byte under CLE to the NAND.
- DMA descriptor 4 waits for the NAND to complete the write commit/transfer by watching the NAND's ready line status. This descriptor relinquishes the NANDLOCK on the GPMI to enable the other DMA channels to initiate NAND transactions on different NAND CS lines.
- DMA descriptor 6 issues a NAND status command byte under "CLE" to check the status of the NAND device following the page write.
- DMA descriptor 7 reads back the NAND status and compares the status with an expected value. If there are differences, then the DMA processing engine follows an error-handling DMA descriptor path.
- DMA descriptor 8 disables the BCH engine and emits a GPMI interrupt to indicate that the NAND write has been completed.

9.5.4.2 BCH Decoding for NAND Reads

When a page is read from NAND flash, BCH syndromes will be computed and, if correctable errors are found, they will be corrected on a per block basis within the NAND page.

This decoding process is fully overlapped with other NAND data reads and with CPU execution. The BCH decoder flowchart in the figure below shows the steps involved in programming the decoder. The hardware flow of reading and decoding a 4096-byte page is shown in Figure 9-37.

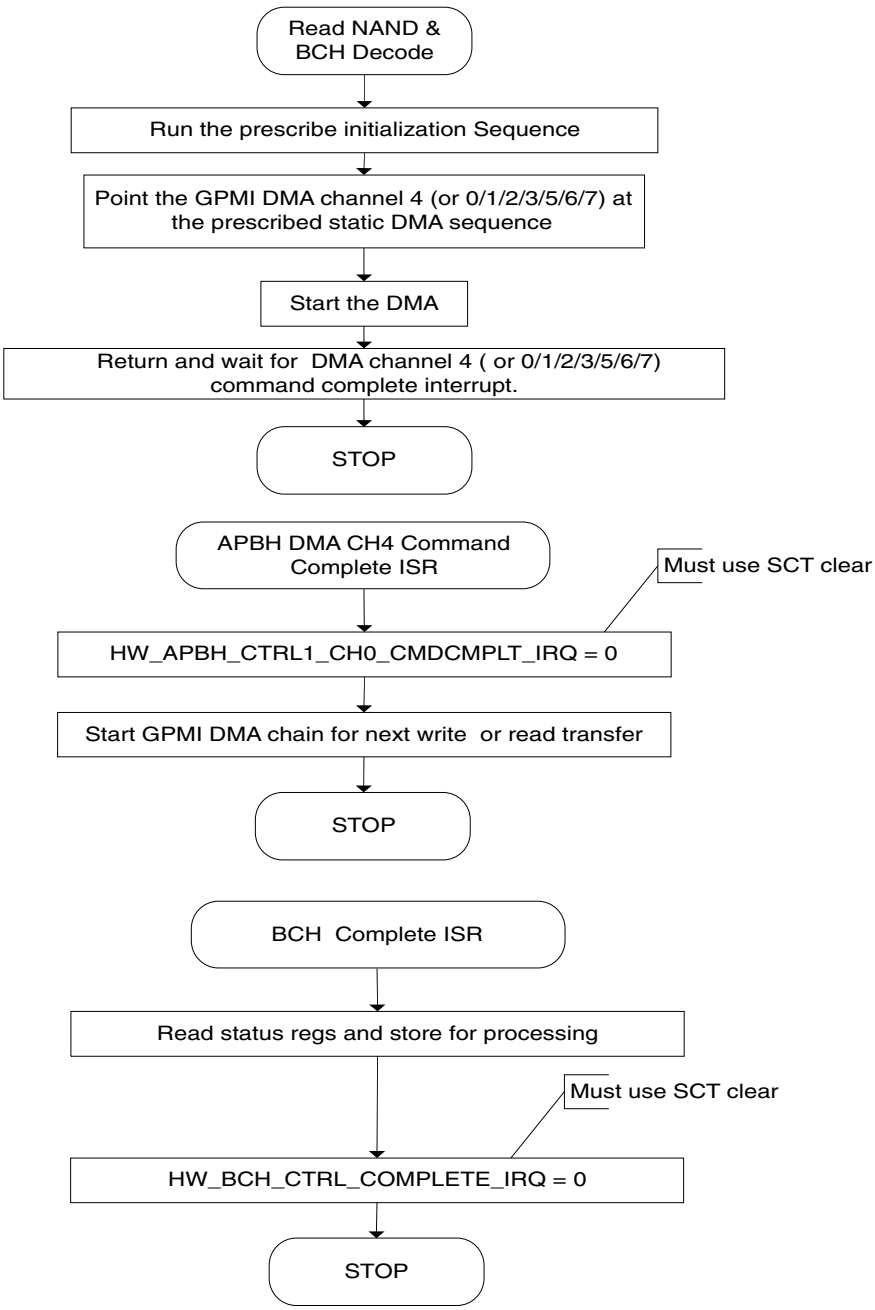

Figure 9-36. BCH Decode Flowchart

Conceptually, an APHB DMA Channel command chain with seven command structures linked together is used to perform the BCH decode operation (as shown in Figure 9-37).

Note

The GPMI's DMA command structures controls the BCH decode operation.

To use the BCH decoder with the GPMI's DMA, create a DMA command chain containing seven descriptor structures, as shown in the figure below and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The seven DMA descriptors perform the following tasks:

1. Issue NAND read setup command byte (under "CLE") and address bytes (under "ALE").
2. Issue NAND read execute command byte (under "CLE").
3. Wait for the NAND device to complete accessing the block data by watching the ready signal.
4. Check for NAND timeout through "PSENSE".
5. Configure and enable the BCH block and read the NAND block data.
6. Disable the BCH block.
7. Descriptor NOP to allow NANDLOCK in the previous descriptor to the thread-safe.

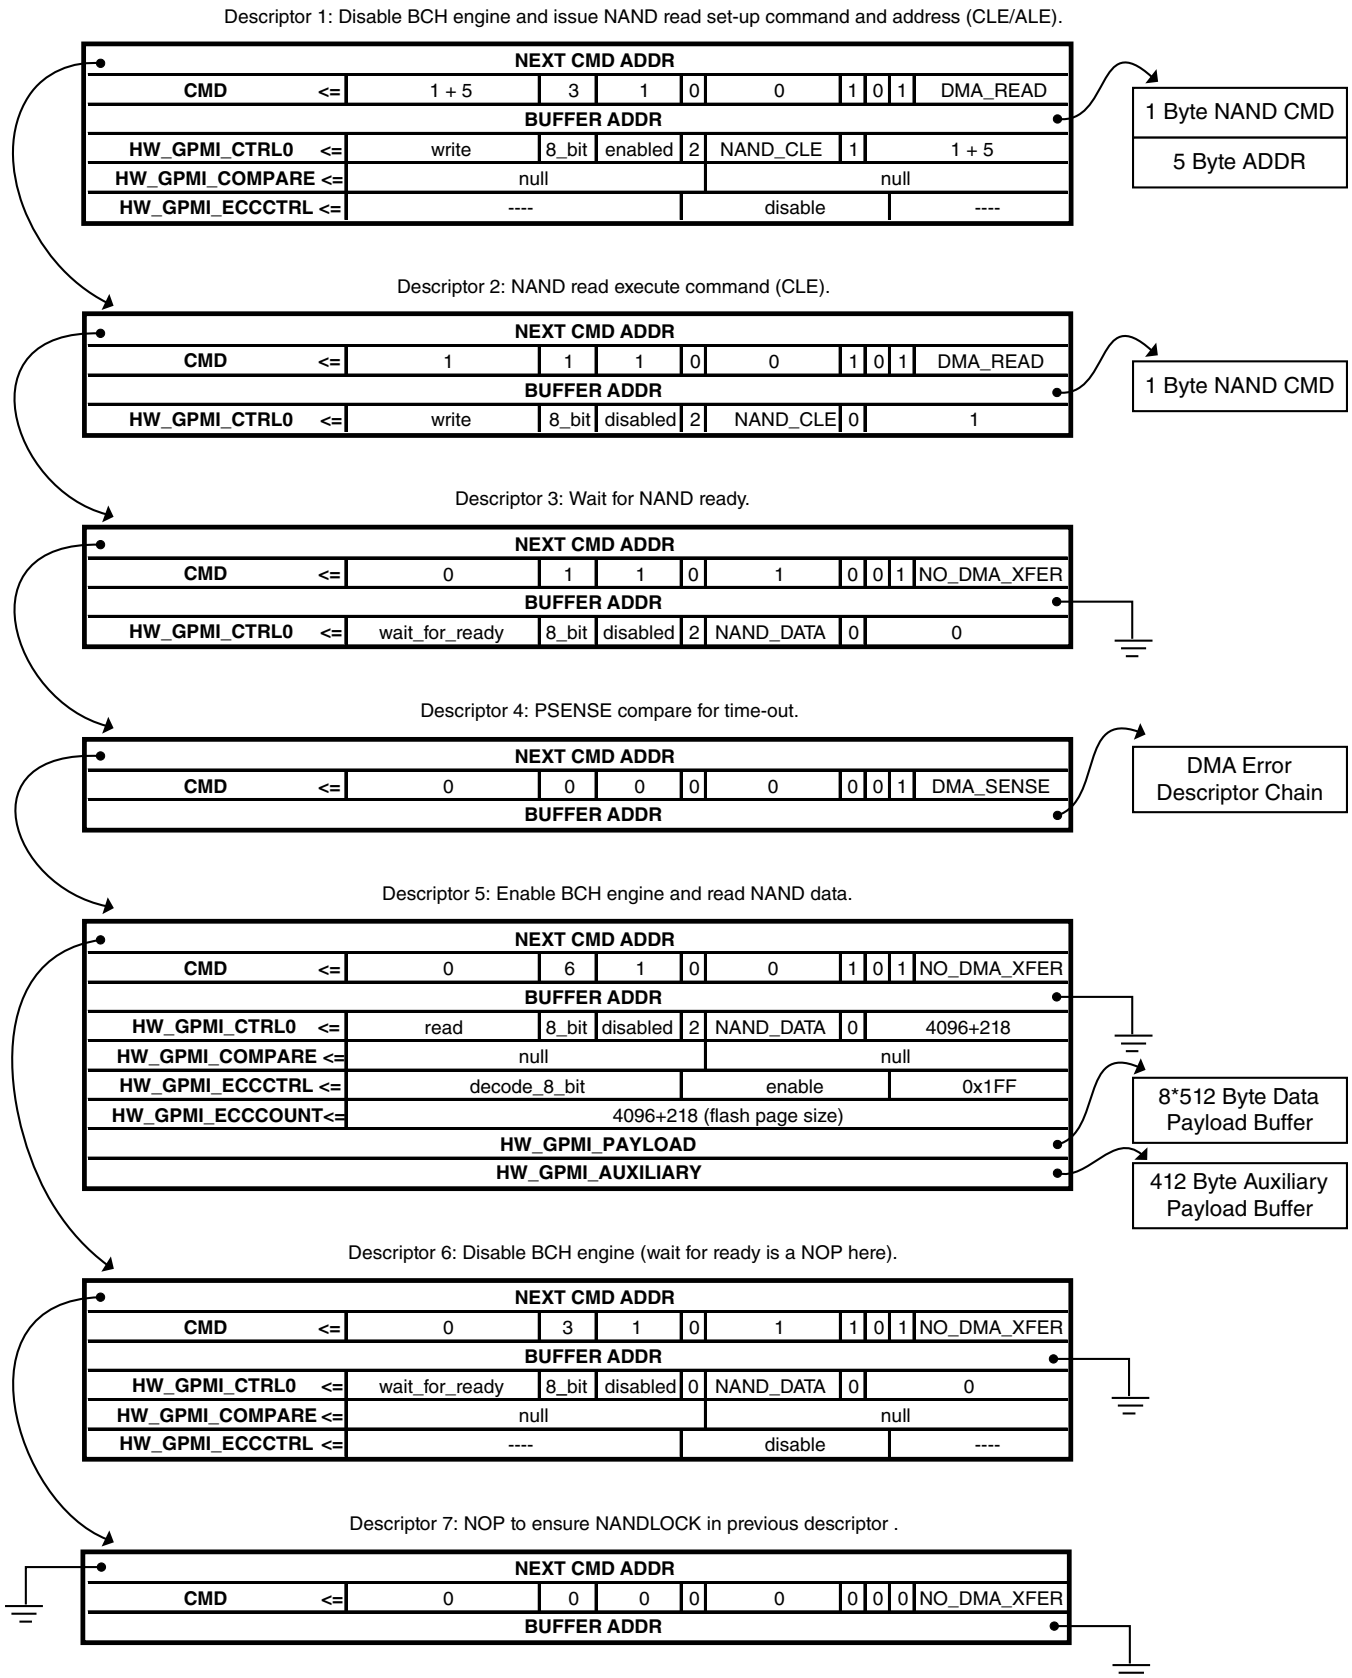

Figure 9-37. BCH Decode DMA Descriptor Chain

9.5.4.2.1 DMA Structure Code Example

The following sample code illustrates the coding for one read transaction, consisting of a seven DMA command structure chain for reading all 4096 bytes of payload data (eight 512-byte blocks) and 65 bytes of metadata with the associative parity bytes (8 * (18) + 9) from a 4K NAND page sitting on GPMI CS2.

```

9.5.4.2.2 Using the Decoder

As illustrated in Figure 9-37 and the sample code in DMA Structure Code Example :

- DMA descriptor 1 prepares the NAND for data read by using the GPMI to issue a NAND read setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is not used for these commands.
- DMA descriptor 2 issues a one-byte read execute command to the NAND device that triggers its read access. The NAND then goes not ready.
- DMA descriptor 3 performs a wait for ready operation allowing the DMA chain to remain dormant until the NAND device completes its read access time.

- DMA descriptor 5 handles the reading and error correction of the NAND data. This command's PIOs activate the BCH engine to write the read NAND data to system memory and to process it for any errors that need to be corrected. This DMA descriptor contains two PIO values that are system memory addresses pointing to the PAYLOAD data area and to the AUXILIARY data area. These addresses are used by the BCH engine's AHB master to move data into system memory and to correct it. While this example is reading an entire 4K page—payload plus metadata—it is equally possible to read just one 512-byte payload block or just the uniquely protected metadata block in a single 7 DMA structure transfer.
- DMA descriptor 6 disables the BCH engine with the NANDLOCK asserted. This is necessary to ensure that the GPMI resource is not arbitrated to another DMA channel when multiple DMA channels are active concurrently.
- DMA descriptor 7 deasserts the NANDLOCK to free up the GPMI resource to another channel.

As the BCH block receives data from the GPMI:

- The decoder transforms the read NAND data block into a BCH code word and computes the codeword syndrome.
- If no errors are present, then the BCH block can immediately report back to firmware. This report is passed as the BCH_CTRL_COMPLETE_IRQ interrupt status bit and the associated status registers in BCH_STATUS0/1 registers.
- If an error is present, then the BCH block corrects the necessary data block or parity block bytes, if possible (not all errors are correctable).

As the BCH decoder reads the data and parity blocks, it records a special condition, i.e., that all of the bits of a payload data block or metadata block are one, including any associated parity bytes. The all-ones case for both parity and data indicates an erased block in the NAND device.

The BCH_STATUS0 register contains a 4-bit field that indicates the final status of the auxiliary block. A value of 0x0 indicates no errors found for a block.

- A value of 1 to 20 inclusive indicates that many correctable errors were found and fixed.
- A value of 0xFE indicates uncorrectable errors detected on the block.

- A value of 0xFF indicates that the block was in the special ALL ONES state and is therefore considered to be an ERASED block.
- All other values are disallowed by the hardware design.

Recall that up to eight NAND devices can have DMA chains in-flight at once, i.e. they can all be contending for access to the GPMI data bus. It is impossible to predict which NAND device will enter the BCH engine with a transfer first, because each chain includes a wait4ready command structure. As a result, firmware should look at the BCH_STATUS0_COMPLETED_CE bit field to determine which block is being reported in the status register. There is also a 16-bit HANDLE field in the GPMI_ECCCTRL register that is passed down the pipeline with each transaction. This handle field can be used to speed firmware's detection of which transaction is being reported.

These examples of reading and writing have focused on full page transfers of 4K page NAND devices. Other device configurations can be specified by changing the ECCOUNT field in the GPMI registers and reprogramming the BCH's FLASHnLAYOUTm registers.

The BCH and GPMI blocks are designed to be very efficient at reading single 512 (or 1024)-byte pages in one transaction. With no errors, the transaction takes less than 20 HCLKs longer than the time to read the raw data from the NAND.

To summarize, the APBH DMA command chain for a BCH decode operation is shown in Figure 9-37. Seven DMA command structures must be present for each NAND read transaction decoded by the BCH. The seven DMA command structures for multiple NAND read transaction blocks can be chained together to make larger units of work for the BCH, and each will produce an appropriate error report in the BCH PIO space. Multiple NAND devices can have such multiple chains scheduled. The results can come back out of order with respect to the multiple chains.

9.5.4.3 Interrupts

There are two interrupt sources used in processing BCH protected NAND read and write transfers.

Since all BCH operations are initiated by GPMI DMA command structures, the DMA completion interrupt for the GPMI is an important ISR. Both of the flow charts of Figure 9-33 and Figure 9-36 show the GPMI DMA complete ISR skeleton. In both reads and writes, the GPMI DMA completion interrupt is used to schedule work ***INTO*** the error correction pipeline. As the front end processing completes, the DMA interrupt is

generated and additional work, such as DMA chains, are passed to the GPMI DMA to keep it *fed*. For write operations, this is the only interrupt that is generated for processing the NAND write transfer.

For reads, however, two interrupts are needed. Every read is started by a GPMI DMA command chain and the front end queue is fed as described above. The back end of the read pipeline is drained by monitoring the BCH completion interrupt found int HW_BCH_CTRL_COMPLETE_IRQ.

An BCH transaction consists of reading or writing all of the blocks requested in the HW_GPMI_ECCCTRL_BUFFER_MASK bit field. As every read transaction completes, it posts the status of all of the blocks to the HW_BCH_STATUS0 and HW_BCH_STATUS1 registers and sets the completion interrupt. The five stages of the BCH read pipeline completes, one in the GPMI and four in the BCH, are independently stalled as they complete and try to deliver to the next stage in the data flow. Several of these stages can be skipped if no-errors are found or once an uncorrectable error is found in a block.

In any case, the final stage will stall if the status register is busy waiting for the CPU to take status register results. The hardware monitors the state of the HW_BCH_CTRL_COMPLETE_IRQ bit. If it is still set when the last pipeline stage is ready to post data, then the stage will stall. It follows that the next previous stage will stall when it is ready to hand off work to the final stage, and so on up the pipeline.

CAUTION

It is important that firmware read the STATUS0/1 results and save them before clearing the interrupt request bit. Otherwise, a transaction and its results could be completely lost.

9.5.4.4 Randomizer

BCH ECC has a Randomizer module that is interfaced through the GPMI APBHDMA chain. The Randomizer can generate random data based on BCH ECC encoded/decoded data. It can be employed to reduce the disturbances caused by a neighboring cell in the NAND chip, thus reducing bit errors.

To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled,

GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

9.5.5 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically. The exemplary code is shown below.

```
// A soft reset can take multiple clocks to complete, so do NOT gate the
// clock when setting soft reset. The reset process will gate the clock
// automatically. Poll until this has happened before subsequently
// preparing soft-reset and clock gate
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// asserting soft-reset
  BCH_CTRL_SET(BM_BCH_CTRL_SFTRST);
// waiting for confirmation of soft-reset
  while (!BCH_CTRL.B.CLKGATE)
  {
// busy wait
  }
// Done.
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
```

9.5.6 BCH Memory Map/Register Definition

BCH Hardware Register Format Summary

BCH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3300_4000	Hardware BCH ECC Accelerator Control Register (BCH_CTRL)	32	R/W	C000_0000h	9.5.6.1/ 2419
3300_4004	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_SET)	32	R/W	C000_0000h	9.5.6.1/ 2419
3300_4008	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_CLR)	32	R/W	C000_0000h	9.5.6.1/ 2419

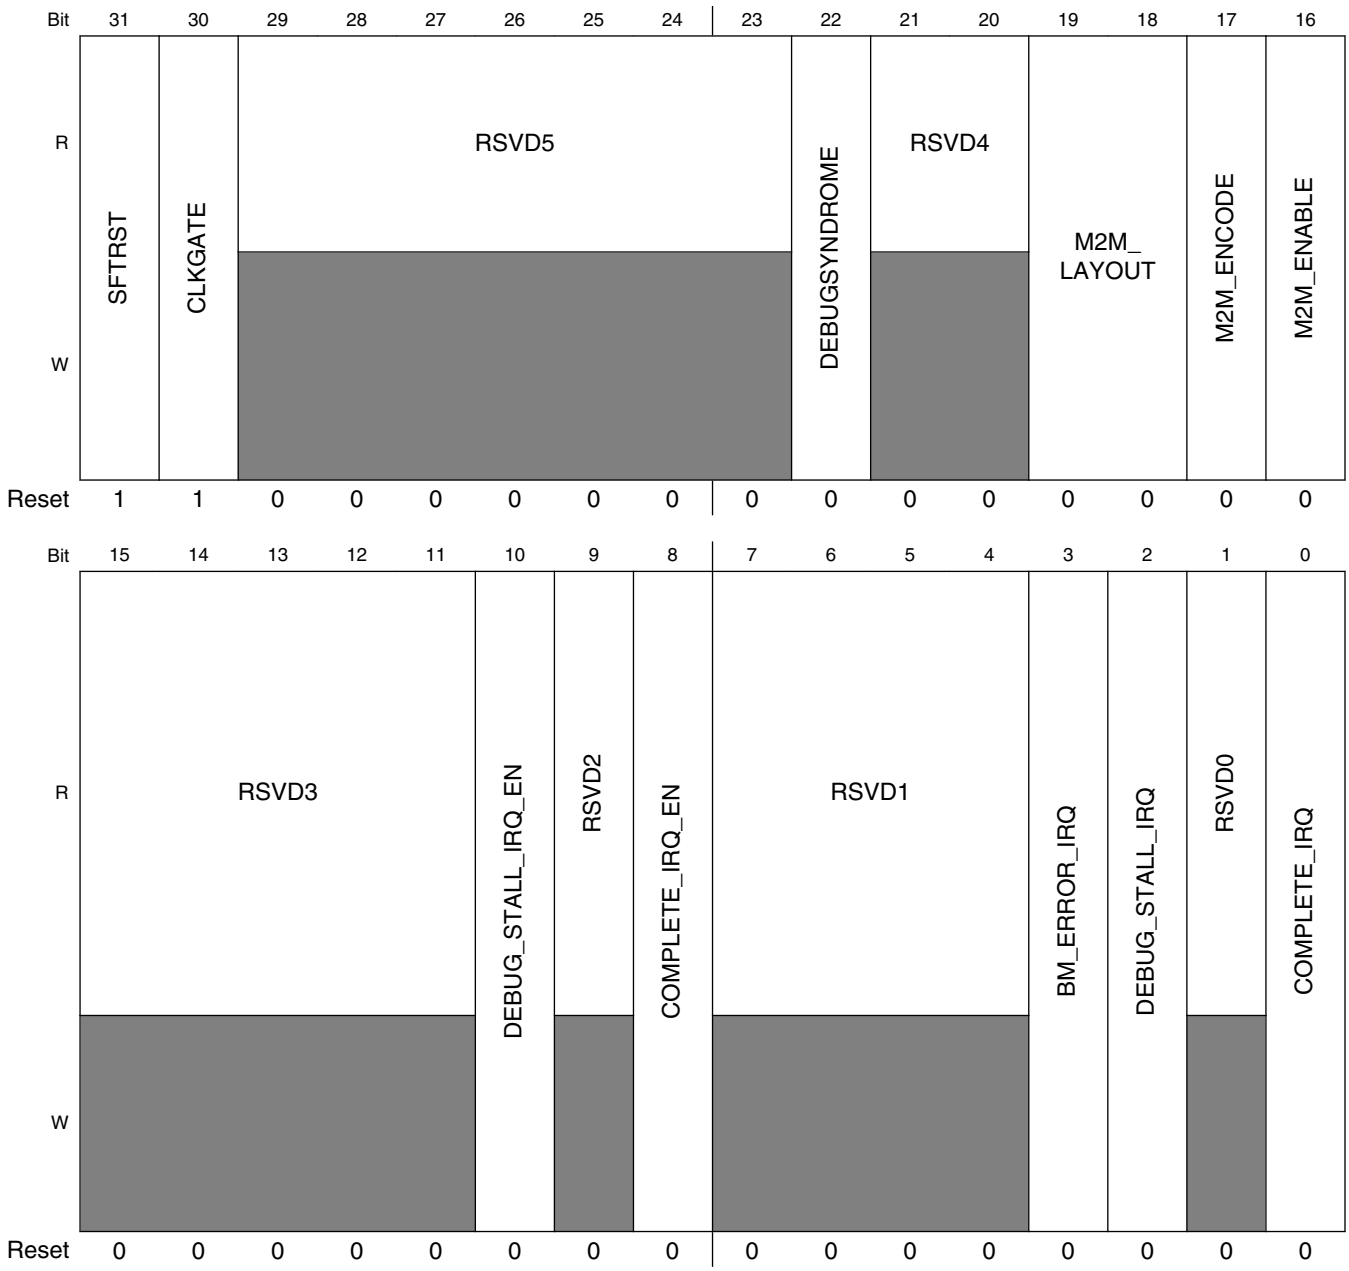
9.5.6.1 Hardware BCH ECC Accelerator Control Register (BCH_CTRL*n*)

The BCH CTRL provides overall control of the hardware ECC accelerator

Address: 3300_4000h base + 0h offset + (4d × i), where i=0d to 3d



BCH_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to 0 to enable normal BCH operation. Set this bit to 1 (default) to disable clocking with the BCH and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the BCH block to its default state. This bit resets all state machines except for the AHB master state machine 0x0 **RUN** — Allow BCH to operate normally. 0x1 **RESET** — Hold BCH in reset.
30 CLKGATE	This bit must be set to 0 for normal operation. When set to 1 it gates off the clocks to the block. 0x0 **RUN** — Allow BCH to operate normally. 0x1 **NO_CLKS** — Do not clock BCH gates in order to minimize power consumption.
29–23 RSVD5	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUGSYNDROME	(For debug purposes only). Enable write of computed syndromes to memory on BCH decode operations. Computed syndromes will be written to the auxiliary buffer after the status block. Syndromes will be written as padded 16-bit values.
21–20 RSVD4	This field is reserved. This read-only field is reserved and always has the value 0
19–18 M2M_LAYOUT	Selects the flash page format for memory-to-memory operations.
17 M2M_ENCODE	Selects encode (parity generation) or decode (correction) mode for memory-to-memory operations.
16 M2M_ENABLE	NOTE! WRITING THIS BIT INITIATES A MEMORY-TO-MEMORY OPERATION. The BCH module must be inactive (not processing data from the GPMI) when this bit is set. The M2M_ENCODE and M2M_LAYOUT bits as well as the ENCODEPTR, DATAPTR, and METAPTR registers are used for memory-to-memory operations and must be correctly programmed before writing this bit.
15–11 RSVD3	This field is reserved. This read-only field is reserved and always has the value 0
10 DEBUG_STALL_ IRQ_EN	1 = interrupt on debug stall mode is enabled. The IRQ is raised on every block
9 RSVD2	This field is reserved. This read-only field is reserved and always has the value 0.
8 COMPLETE_IRQ_ EN	1 = interrupt on completion of correction is enabled.
7–4 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
3 BM_ERROR_IRQ	AHB Bus interface Error Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
2 DEBUG_STALL_IRQ	DEBUG STALL Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
1 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

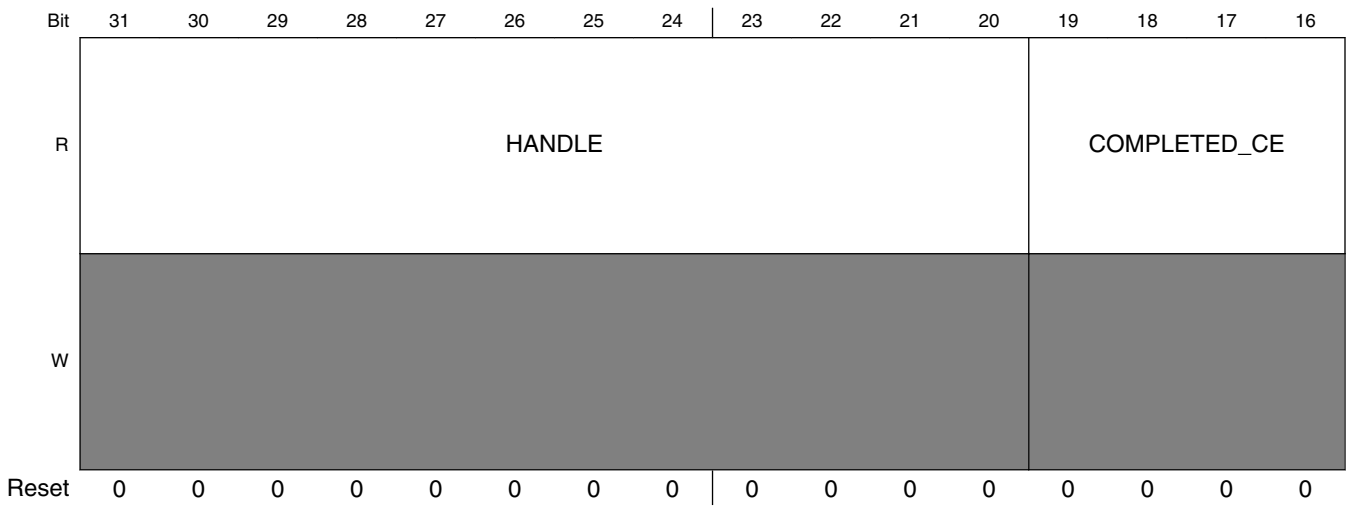
BCH_CTRL*n* field descriptions (continued)

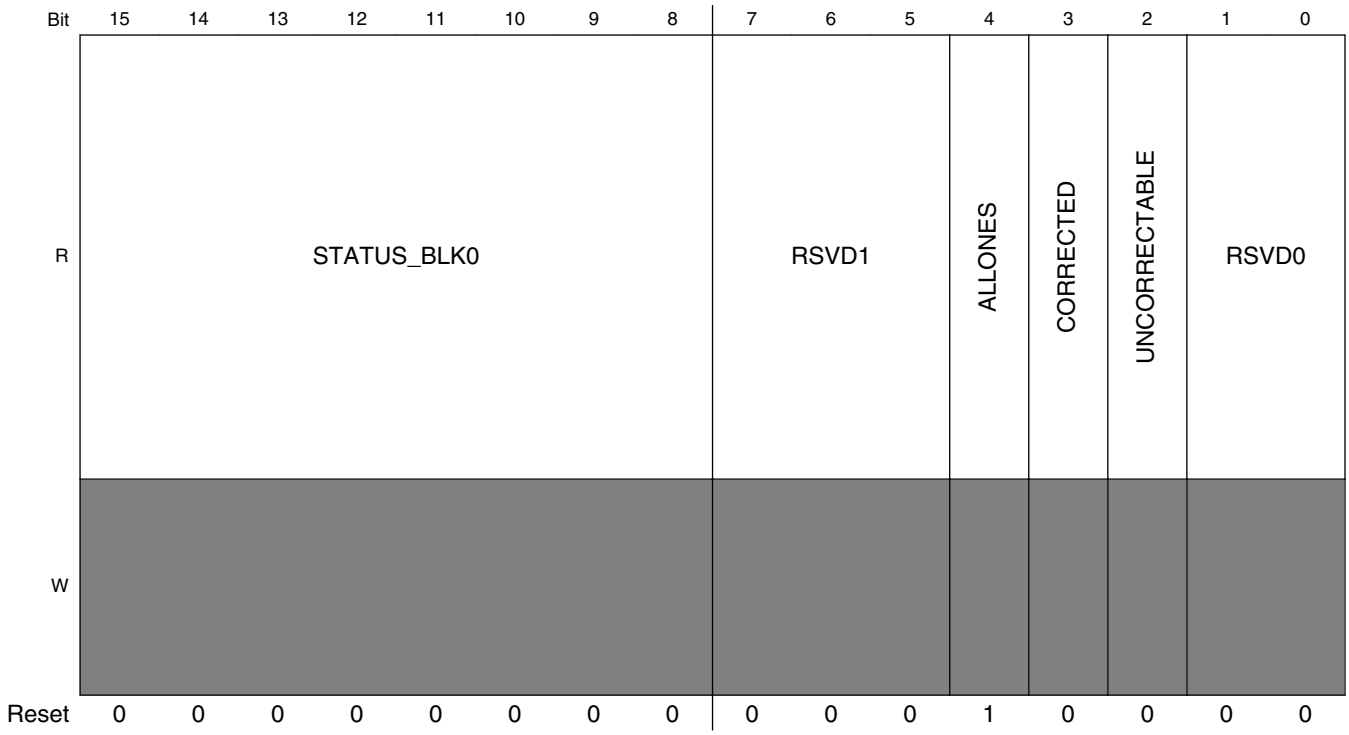
Field	Description
0 COMPLETE_IRQ	This bit indicates the state of the external interrupt line. Write a 1 to the SCT clear address to clear the interrupt status bit. NOTE: subsequent ECC completions will be held off as long as this bit is set. Be sure to read the data from BCH_STATUS0, 1 before clearing this interrupt bit.

9.5.6.2 Hardware ECC Accelerator Status Register 0 (BCH_STATUS0*n*)

The BCH STAT register provides visibility into the run-time status of the BCH and status information when processing is complete. It provides overall status of the hardware ECC accelerator.

Address: 3300_4000h base + 10h offset + (4d × i), where i=0d to 3d





BCH_STATUS0*n* field descriptions

Field	Description
31–20 HANDLE	Software supplies a 12 bit handle for this transfer as part of the GPMI DMA PIO operation that started the transaction. That handle passes down the pipeline and ends up here at the time the BCH interrupt is signaled.
19–16 COMPLETED_CE	This is the chip enable number corresponding to the NAND device from which this data came.
15–8 STATUS_BLK0	Count of symbols in error during processing of first block of flash (metadata block). The number of errors reported will be in the range of 0 to the ECC correction level for block 0. 0x00 **ZERO** — No errors found on block. 0x01 **ERROR1** — One error found on block. 0x02 **ERROR2** — One errors found on block. 0x03 **ERROR3** — One errors found on block. 0x04 **ERROR4** — One errors found on block. 0xFE **UNCORRECTABLE** — Block exhibited uncorrectable errors. 0xFF **ERASED** — Page is erased.
7–5 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
4 ALLONES	1 = All data bits of this transaction are ONE.
3 CORRECTED	1 = At least one correctable error encountered during last processing cycle.
2 UNCORRECTABLE	1 = Uncorrectable error encountered during last processing cycle.
RSVD0	This field is reserved.

Table continues on the next page...

BCH_STATUS0*n* field descriptions (continued)

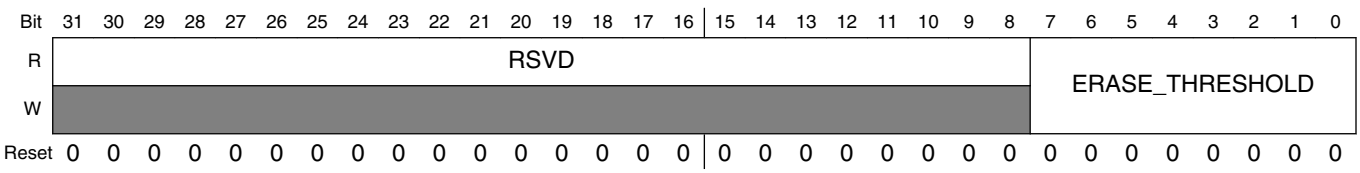
Field	Description
	This read-only field is reserved and always has the value 0.

9.5.6.3 Hardware ECC Accelerator Mode Register (BCH_MODE*n*)

The BCH MODE register provides additional mode controls.

Contains additional global mode controls for the BCH engine.

Address: 3300_4000h base + 20h offset + (4d × i), where i=0d to 3d



BCH_MODE*n* field descriptions

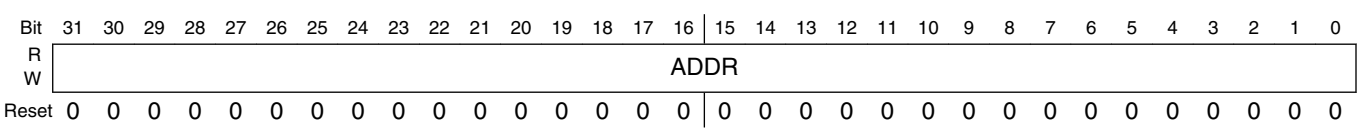
Field	Description
31–8 RSVD	This field is reserved. This read-only field is reserved and always has the value 0.
ERASE_ THRESHOLD	This value indicates the maximum number of zero bits on a flash subpage for it to be considered erased. For SLC NAND devices, this value should be programmed to 0 (meaning that the entire page should consist of bytes of 0xFF. For MLC NAND devices, bit errors may occur on reads (even on blank pages), so this threshold can be used to tune the erased page checking algorithm.

9.5.6.4 Hardware BCH ECC Loopback Encode Buffer Register (BCH_ENCODEPTR*n*)

When performing memory to memory operations, indicates the address of the encode buffer. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register.

For memory to memory operations, this register is used as the pointer to the encoded data, which is an output when encoding and an input while decoding.

Address: 3300_4000h base + 30h offset + (4d × i), where i=0d to 3d



BCH_ENCODEPTR*n* field descriptions

Field	Description
ADDR	Address pointer to encode buffer. This is the source for decode operations and the destination for encode operations. This value must be aligned on a 4 bytes boundary.

9.5.6.5 Hardware BCH ECC Loopback Data Buffer Register (BCH_DATAPTR*n*)

When performing memory to memory operations, indicates the address of the data buffer.

For memory to memory operations, this register is used as the pointer to the data to encode or the destination buffer for decode operations.

Address: 3300_4000h base + 40h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_DATAPTR*n* field descriptions

Field	Description
ADDR	Address pointer to data buffer. This is the source for encode operations and the destination for decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

9.5.6.6 Hardware BCH ECC Loopback Metadata Buffer Register (BCH_METAPTR*n*)

When performing memory to memory operations, indicates the address of the metadata buffer.

For memory to memory operations, this register is used as the pointer to the metadata to encode or the extracted metadata for decode operations.

Address: 3300_4000h base + 50h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_METAPTR*n* field descriptions

Field	Description
ADDR	Address pointer to metadata buffer. This is the source for encode metadata read operations and the destination for metadata decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 bytes boundary.

9.5.6.7 Hardware ECC Accelerator Layout Select Register (BCH_LAYOUTSELECT*n*)

The BCH LAYOUTSELECT register provides a mapping of chip selects to layout registers.

When the BCH engine receives a request to process a data block from the GPMI interface, it will use this register to map the incoming chip select to one of the four possible flash layout registers

Address: 3300_4000h base + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BCH_LAYOUTSELECT*n* field descriptions

Field	Description
31–30 CS15_SELECT	Selects which layout is used for chip select 15.
29–28 CS14_SELECT	Selects which layout is used for chip select 14.
27–26 CS13_SELECT	Selects which layout is used for chip select 13.
25–24 CS12_SELECT	Selects which layout is used for chip select 12.
23–22 CS11_SELECT	Selects which layout is used for chip select 11.
21–20 CS10_SELECT	Selects which layout is used for chip select 10.
19–18 CS9_SELECT	Selects which layout is used for chip select 9.

Table continues on the next page...

BCH_LAYOUTSELECT*n* field descriptions (continued)

Field	Description
17–16 CS8_SELECT	Selects which layout is used for chip select 8.
15–14 CS7_SELECT	Selects which layout is used for chip select 7.
13–12 CS6_SELECT	Selects which layout is used for chip select 6.
11–10 CS5_SELECT	Selects which layout is used for chip select 5.
9–8 CS4_SELECT	Selects which layout is used for chip select 4.
7–6 CS3_SELECT	Selects which layout is used for chip select 3.
5–4 CS2_SELECT	Selects which layout is used for chip select 2.
3–2 CS1_SELECT	Selects which layout is used for chip select 1.
CS0_SELECT	Selects which layout is used for chip select 0.

9.5.6.8 Hardware BCH ECC Flash 0 Layout 0 Register (BCH_FLASH0LAYOUT0*n*)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT1 register to control the format for the devices selecting layout 0 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections *Flash Page Layout* and *Determining the ECC layout for a device* for more detail information on setting up the flash layout registers.

Address: 3300_4000h base + 80h offset + (4d × i), where i=0d to 3d

Reset	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0

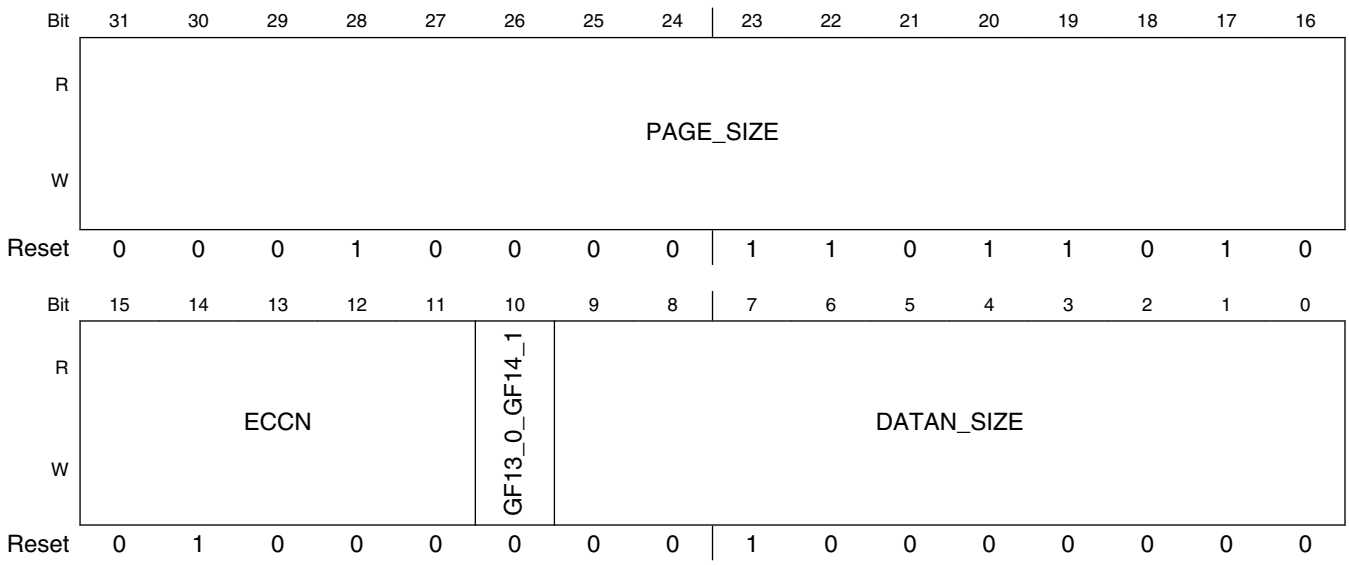
BCH_FLASH0LAYOUT0*n* field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block only contains metadata.

9.5.6.9 Hardware BCH ECC Flash 0 Layout 1 Register (BCH_FLASH0LAYOUT1*n*)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT0 register to control the format for the device selecting layout 0 in the LAYOUTSELECT register.

Address: 3300_4000h base + 90h offset + (4d × i), where i=0d to 3d



BCH_FLASH0LAYOUT1*n* field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.5.6.10 Hardware BCH ECC Flash 1 Layout 0 Register (BCH_FLASH1LAYOUT0*n*)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT1 register to control the format for the devices selecting layout 1 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections *Flash Page Layout* and *Determining the ECC layout for a device* for more detail information on setting up the flash layout registers.

15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed : — 0x1E **ECC60** — ECC 60 to be performed 0x1F **ECC62** — ECC 62 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

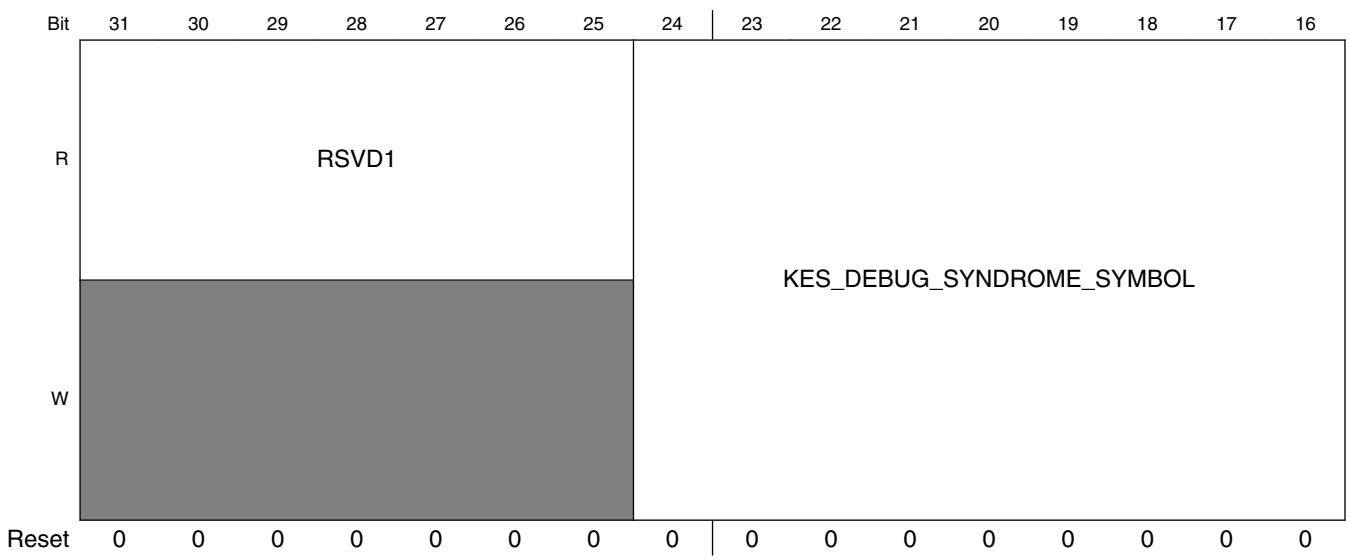
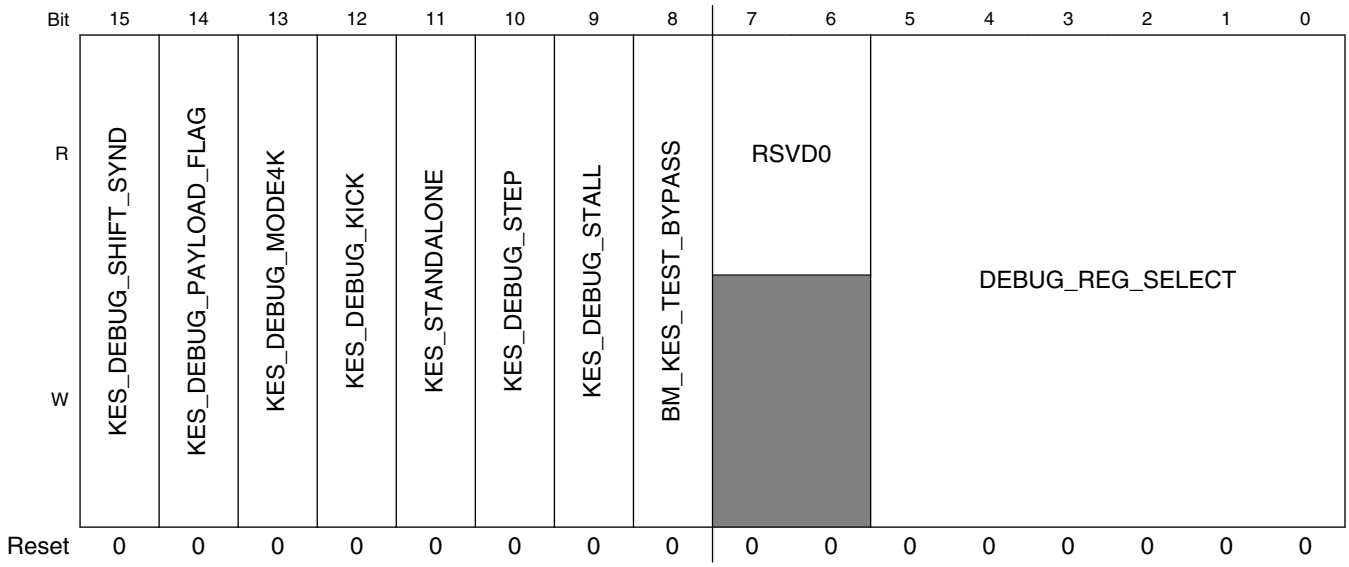
9.5.6.16 Hardware BCH ECC Debug Register0 (BCH_DEBUG0*n*)

The hardware BCH accelerator internal state machines and signals can be seen in the ECC debug register.

The BCH_DEBUG0 register provides access to various internal state information which might prove useful during hardware debug and validation.

Address: 3300_4000h base + 100h offset + (4d × i), where i=0d to 3d





BCH_DEBUG0*n* field descriptions

Field	Description
31–25 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
24–16 KES_DEBUG_ SYNDROME_ SYMBOL	The 9 bit value in this bit field shifts into the syndrome register array at the input of the KES engine whenever BCH_DEBUG0_KES_DEBUG_SHIFT_SYND is toggled. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.
15 KES_DEBUG_ SHIFT_SYND	Toggling this bit causes the value in BCH_DEBUG0_KES_SYNDROME_SYMBOL to be shift into the syndrome register array at the input to the KES engine. After shifting in 16 symbols, one can kick off both KES and CF cycles by toggling BCH_DEBUG0_KES_DEBUG_KICK. Make sure that set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
14 KES_DEBUG_ PAYLOAD_FLAG	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input payload flag. 0x1 **DATA** — Payload is set for 512 bytes data block. 0x1 **AUX** — Payload is set for 65 or 19 bytes auxiliary block.
13 KES_DEBUG_ MODE4K	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input mode (4K or 2K pages). 0x1 **4k** — Mode is set for 4K NAND pages. 0x1 **2k** — Mode is set for 2K NAND pages.
12 KES_DEBUG_ KICK	Toggling causes KES engine FSM to start as if kick by the Bus Master. This allows stand alone testing of the KES and Chien Search engines. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
11 KES_ STANDALONE	Set to one, cause the KES engine to suppress toggling the KES_BM_DONE signal to the bus master and suppress toggling the CF_BM_DONE signal by the CF engine. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.

Table continues on the next page...

BCH_DEBUG0*n* field descriptions (continued)

Field	Description
10 KES_DEBUG_STEP	Toggling this bit causes the KES FSM to skip passed the stall state if it is in DEBUG_STALL mode and completed processing a block.
9 KES_DEBUG_STALL	Set to one to cause KES FSM to stall after notifying Chien search engine to start processing its block but before notifying the bus master that the KES computation is complete. This allows a diagnostic to stall the FSM after each blocks key equations are solved. This also has the effect of stalling the CSFE search engine so it's state can be examined after it finishes processing the KES stalled block. 0x0 **NORMAL** — KES FSM proceeds to next block supplied by bus master. 0x1 **WAIT** — KES FSM waits after current equations are solved and the search engine is started.
8 BM_KES_TEST_BYPASS	1 = Point all SYND_GEN writes to dummy area at the end of the AUXILLIARY block so that diagnostics can preload all payload, parity bytes and computed syndrome bytes for test the KES engine. 0x0 **NORMAL** — Bus master address generator for SYND_GEN writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxiliary block.
7–6 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
DEBUG_REG_SELECT	The value loaded in this bit field is used to select the internal register state view of KES engine or the Chien search engine.

9.5.6.17 KES Debug Read Register (BCH_DBGKESREAD*n*)

The hardware BCH ECC accelerator key equation solver internal state machines and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 110h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

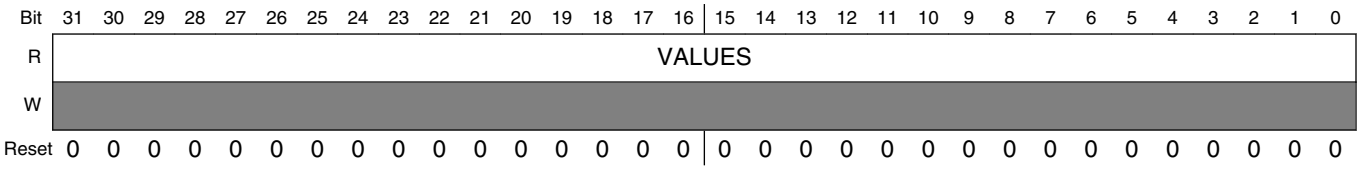
BCH_DBGKESREAD*n* field descriptions

Field	Description
VALUES	This register returns the ROM BIST CRC value after a BIST test.

9.5.6.18 Chien Search Debug Read Register (BCH_DBGCSFEREAD*n*)

The hardware BCH ECC accelerator Chien Search internal state machines and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 120h offset + (4d × i), where i=0d to 3d



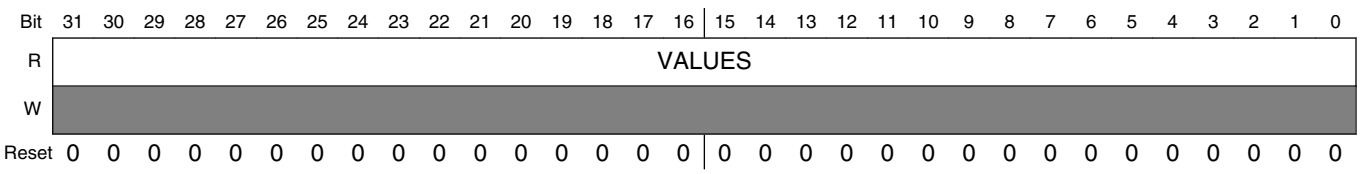
BCH_DBGCSFEREAD*n* field descriptions

Field	Description
VALUES	Reserved

9.5.6.19 Syndrome Generator Debug Read Register (BCH_DBGSYNDGENREAD*n*)

The hardware BCH ECC accelerator syndrome generator internal state machines and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 130h offset + (4d × i), where i=0d to 3d



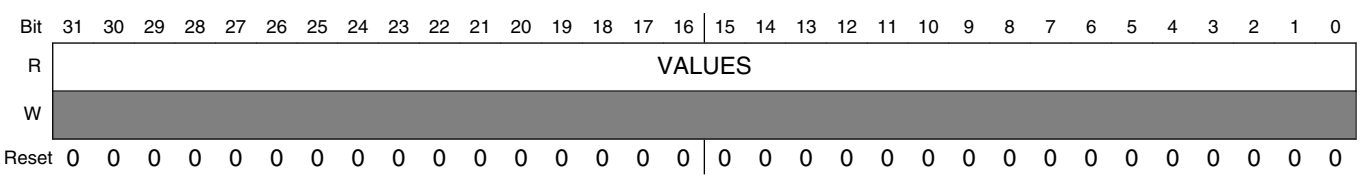
BCH_DBGSYNDGENREAD*n* field descriptions

Field	Description
VALUES	Reserved

9.5.6.20 Bus Master and ECC Controller Debug Read Register (BCH_DBGAHBMREAD*n*)

The hardware BCH ECC accelerator bus master, ECC controller internal state machines, and signals can be seen in the ECC debug registers.

Address: 3300_4000h base + 140h offset + (4d × i), where i=0d to 3d



BCH_DBGAHBMREAD*n* field descriptions

Field	Description
VALUES	Reserved

9.5.6.21 Block Name Register (BCH_BLOCKNAME*n*)

Read only view of the block name string BCH.

Fixed pattern read only value is for test purposes. It can be read as an ASCII string with the zero termination coming from the first byte of the BLOCKVERSION register.

Address: 3300_4000h base + 150h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description

9.6 General Purpose Media Interface (GPMI)

9.6.1 Overview

The GPMI controller is a flexible interface to supporting up to four NAND flash chip selects.

- ONFI3.2, DDR Mode, Samsung / Toshiba Toggle NAND protocol compatible.
- Fully configurable address and command behavior, providing support for future devices not yet specified.

The GPMI resides on the APBH. The GPMI also provides an interface to the BCH module to allow direct parity processing.

Registers are clocked on the HCLK domain. The I/O and pin timing are clocked on a dedicated GPMICLK domain. GPMICLK can be set to maximize I/O performance.

The following figure shows a block diagram of the GPMI controller.

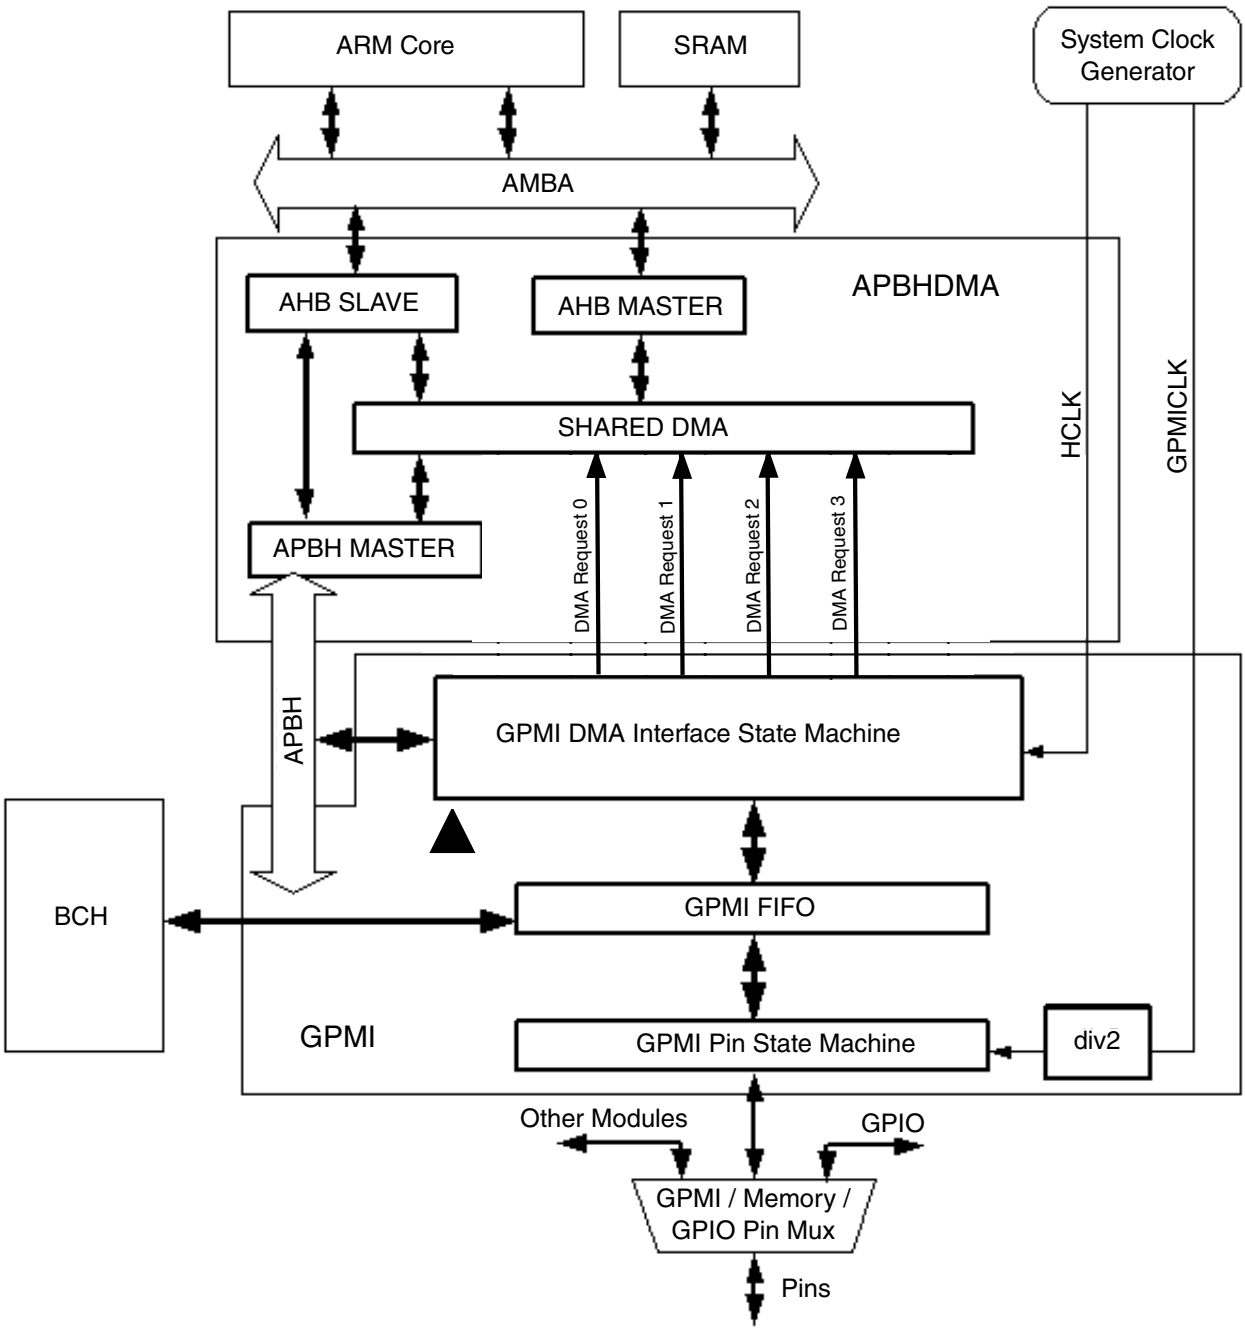

Figure 9-38. General-Purpose Media Interface Controller Block Diagram

9.6.2 External Signals

The table found here describes the external signals of GPMI.

Table 9-22. GPMI External Signals

Signal	Description	Pad	Mode	Direction
NAND_ALE	Address latch enable signal	SD3_CMD	ALT1	O
NAND_CE0_B	Chip enable signal	SAI1_TXC	ALT1	O
NAND_CE1_B	Chip enable signal	SAI1_RXD	ALT1	O
NAND_CE2_B	Chip enable signal	SAI1_RXFS	ALT1	O
NAND_CE3_B	Chip enable signal	SAI1_RXC	ALT1	O
NAND_CLE	Command latch enable signal	SD3_CLK	ALT1	O
NAND_DATA00	Data signal	SD3_DATA0	ALT1	IO
NAND_DATA01	Data signal	SD3_DATA1	ALT1	IO
NAND_DATA02	Data signal	SD3_DATA2	ALT1	IO
NAND_DATA03	Data signal	SD3_DATA3	ALT1	IO
NAND_DATA04	Data signal	SD3_DATA4	ALT1	IO
NAND_DATA05	Data signal	SD3_DATA5	ALT1	IO
NAND_DATA06	Data signal	SD3_DATA6	ALT1	IO
NAND_DATA07	Data signal	SD3_DATA7	ALT1	IO
NAND_DQS	DQS signal	SAI1_TXFS	ALT1	IO
NAND_RE_B	Read enable signal	SD3_STROBE	ALT1	O
NAND_READY	Ready signal	SAI1_TXD	ALT1	IO
NAND_WE_B	Write enable signal	SD3_RESET_B	ALT1	O
NAND_WP_B	Wait polarity signal	SAI1_MCLK	ALT1	O

9.6.3 Clocks

The table found here describes the clock sources for GPMI.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 9-23. GPMI Clocks

Clock name	Clock Root	Description
bch_input_apb_clk	nand_usdhc_bus_clk_root	BCH to APBH input clock
gpmi_bch_input_bch_clk	nand_usdhc_bus_clk_root	BCH input clock

Table continues on the next page...

Table 9-23. GPMI Clocks (continued)

Clock name	Clock Root	Description
gpmi_bch_input_gpmi_io_clk	nand_clk_root	GPMI IO input clock
gpmi_input_apb_clk	nand_usdhc_bus_clk_root	GPMI to APBH clock

9.6.4 GPMI NAND Mode

The general-purpose media interface has several features to efficiently support NAND:

- Individual chip select pins and ganged ready/busy pin for up to four NANDs.
- Individual state machine and DMA channel for each chip select.
- Special command modes work with DMA controller to perform all normal NAND functions without CPU intervention.
- Configurable timing based on a dedicated clock allows optimal balance of high NAND performance and low system power.

GPMI and DMA have been designed to handle complex multi-page operations without CPU intervention. The DMA uses a linked descriptor function with branching capability to automatically handle all of the operations needed to read/write multiple pages:

- **Data/Register Read/Write**-The GPMI can be programmed to read or write multiple cycles to the NAND address, command or data registers.
- **Wait for NAND Ready**-The GPMI's Wait-for-Ready mode can monitor the ready/busy signal of a single NAND flash and signal the DMA when the device has become ready. It also has a time-out counter and can indicate to the DMA that a time-out error has occurred. The DMAs can conditionally branch to a different descriptor in the case of an error.
- **Check Status**-The Read-and-Compare mode allows the GPMI to check NAND status against a reference. If an error is found, the GPMI can instruct the DMA to branch to an alternate descriptor, which attempts to fix the problem or asserts a CPU IRQ.

9.6.4.1 Multiple NAND Support

The GPMI supports up to four NAND chip selects, with ganged ready/busy pins.

Since they share a data bus and control lines, the GPMI can only actively communicate with a single NAND at a time. However, all NANDs can concurrently perform internal read, write, or erase operations. With fast NAND flash and software support for

concurrent NAND operations, this architecture allows the total throughput to approach the data bus speed, which can be as high as 50 MB/s (8-bit bus running at 50 MHz single clock edge) in asynchronous mode and 200MB/s (8-bit bus running at 100MHz both clock edges) in Source Synchronous mode.

There are two options for controlling the four NAND chip selects via the DMA interface. The first option is the one to one mapping, where the each DMA channel is tied to its own NAND chip select. For example DMA channel 'n' accesses only NAND attached to chip select 'n'. The second option is the decoupled mode where a DMA channel can access any or all NAND chip selects connected to the GPMI. A DMA channel will signify the NAND chip select it wants to access by writing its chip select value in the GPMI_CTRL0[CS] field and setting the GPMI_CTRL1[DECOUPLE_CS] to 1. This option is useful if software chooses to use only one DMA channel to access all the attached NAND devices.

9.6.4.2 GPMI NAND Timing and Clocking

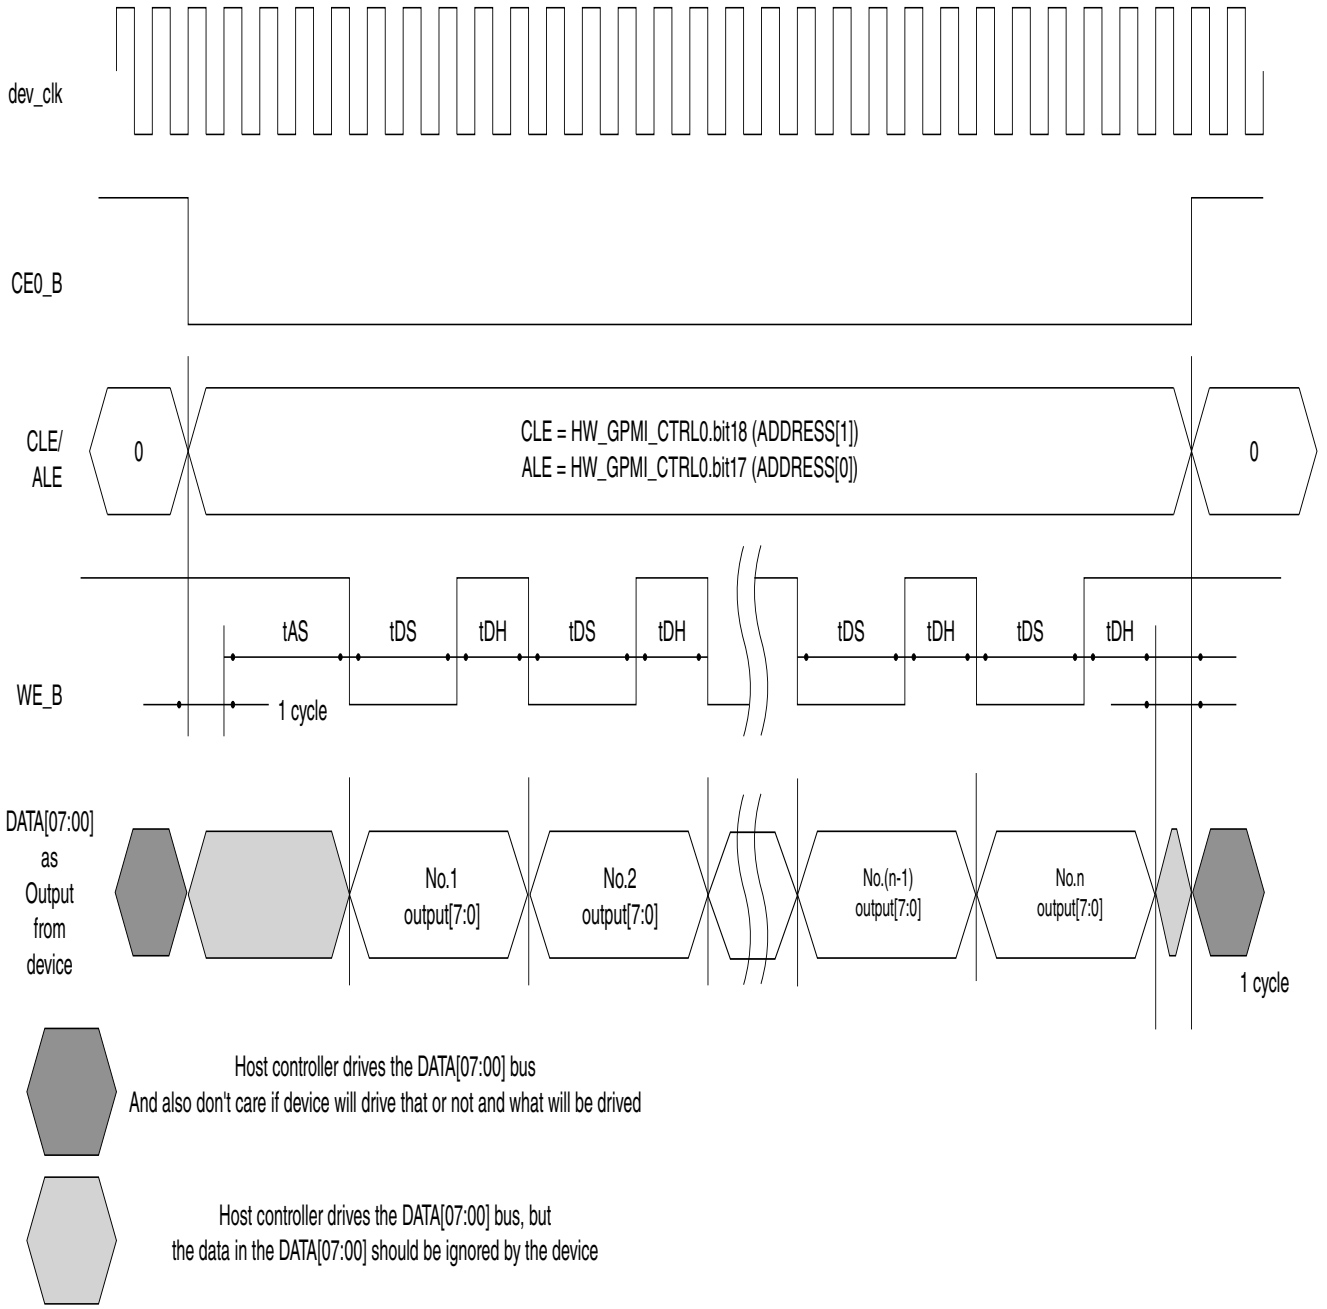
The dedicated clock, GPMICLK, is used as a timing reference for NAND flash I/O. Since various NANDs have different timing requirements, GPMICLK may need to be adjusted for each application.

While the actual pin timings are limited by the NAND chips used and the I/O pad configuration, the GPMI can support data bus speeds of up to 200 MHz x 8 bits. The actual read/write strobe timing parameters are adjusted as indicated in the register descriptions in Memory Map.

9.6.4.3 Basic NAND Timing

9.6.4.3.1 NAND Asynchronous Timing

Figure 9-40 and illustrates the operation of the output (from host to device) timing parameters in NAND ONFI asynchronous mode.



- tAS is configurable by programming HW_GPMI_TIMING0 Address_Setup: in this example, Address_Setup = 4, tAS is equal to 4 dev_clk cycles.
- tDS is configurable by programming HW_GPMI_TIMING0 Data_Setup; in this example, Data_Setup = 3, tDS is equal to 3 dev_clk cycles
- tDH is configuarble by programming HW_GPMI_TIMING0 Data_Hold: in this example, Data_Hold = 2, tDH is equal to 2 dev_clk cycles
- tAS/tDS/tDH will extend, if the output data is not ready in device fifo.

Figure 9-39. Asynchronous Mode Basic Write Timing Diagram (command write, address write, or data write

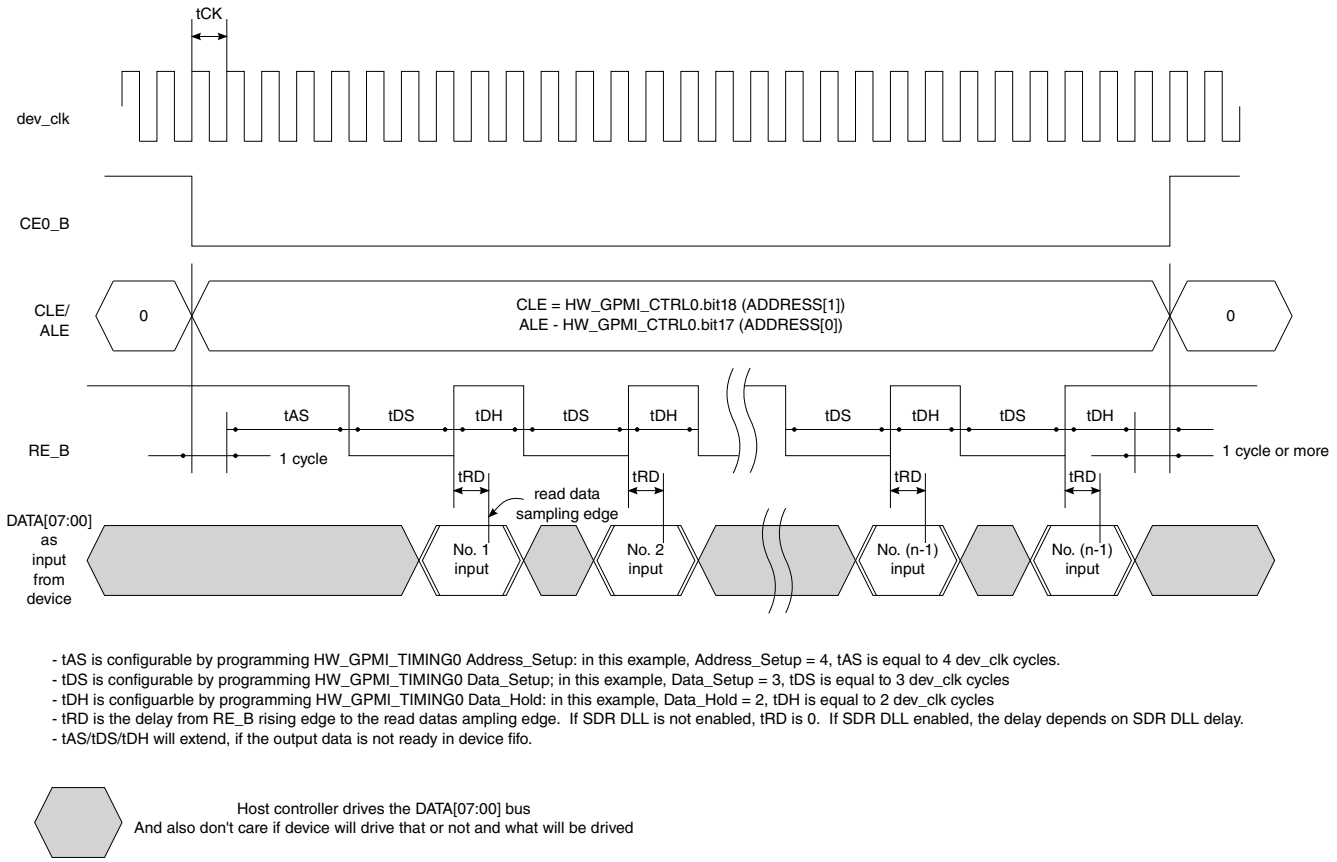


Figure 9-40. ONFI Asynchronous Mode Basic Read Timing Diagram (data read)

9.6.4.3.2 NAND Asynchronous EDO Mode Timing

In high-speed NANDS, the read data may not be valid until after the read strobe (NAND_RE_B) deasserts. This is the case when the minimum tDS is programmed to achieve higher bandwidth.

The GPMI implements a feedback read strobe to sample the read data. The feedback read strobe can be delayed to support fast nand EDO (Extended Data Out) timing where the read strobe may deassert before the read data is valid, and read data is valid for some time after read strobe.

Nand EDO timings is applied typically for read cycle frequency above 33 MHz. See Figure 9-41.

The GPMI provides control over the amount of delay applied to the feedback read strobe. This delay depends on the maximum read access time (tREA) of the nand and the read pulse width (tRP) used to access the nand. tRP is specified by GPMI_TIMING0[DATA_SETUP] register. When (tREA + 4ns) is less than tRP, no

delay is required to sample to nand read data. (The 4ns provides adequate data setup time for the GPMI.) In this case set GPMI_CTRL1[HALF_PERIOD] = 0; GPMI_CTRL1[RDN_DELAY] = 0; GPMI_CTRL1[DLL_ENABLE] = 0.

When (tREA + 4ns) is greater than or equal to tRP, a delay of the feedback read strobe is required to sample to nand read data. This delay is equal to the difference between these two timings:

DELAY = tREA + 4ns - tRP.

Since the GPMI delay chain is limited to ns maximum, if DELAY > ns then increase tRP by increasing the value of GPMI_TIMING0[DATA_SETUP] until DELAY is less than or equal to ns.

The GPMI programming for this DELAY depends on the GPMICLK period. The GPMI DLL will not function properly if the GPMICLK period is greater than ns: disable the DLL if this is the case. If the GPMICLK period is greater than ns (and not greater than ns), set the GPMI_CTRL1[HALF_PERIOD]=1; This will cause the DLL reference period (RP) to be one-half of the GPMICLK period. If the GPMICLK period is ns or less then set the GPMI_CTRL1[HALF_PERIOD]=0; This will cause the DLL reference period (RP) to be equal to the GPMICLK period. DELAY is a multiple (0 to 1.875) of RP.

The GPMI_CTRL1[RDN_DELAY] is encoded as a 1-bit integer and 3-bit fraction delay factor. DELAY is a multiple of the delay factor and the reference period. See table below for details.

Table 9-24. RDN DELAY

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
0	0.000
1	0.125
2	0.250
3	0.375
4	0.500
5	0.625
6	0.750
7	0.875
8	1.000
9	1.125
10	1.250
11	1.375
12	1.500
13	1.625

Table continues on the next page...

Table 9-24. RDN DELAY (continued)

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
14	1.750
15	1.875

DELAY = DelayFactor x RP or DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP.

Use this equation to calculate the value for GPMI_CTRL1[RDN_DELAY]. Then set GPMI_CTRL1[DLL_ENABLE]=1.

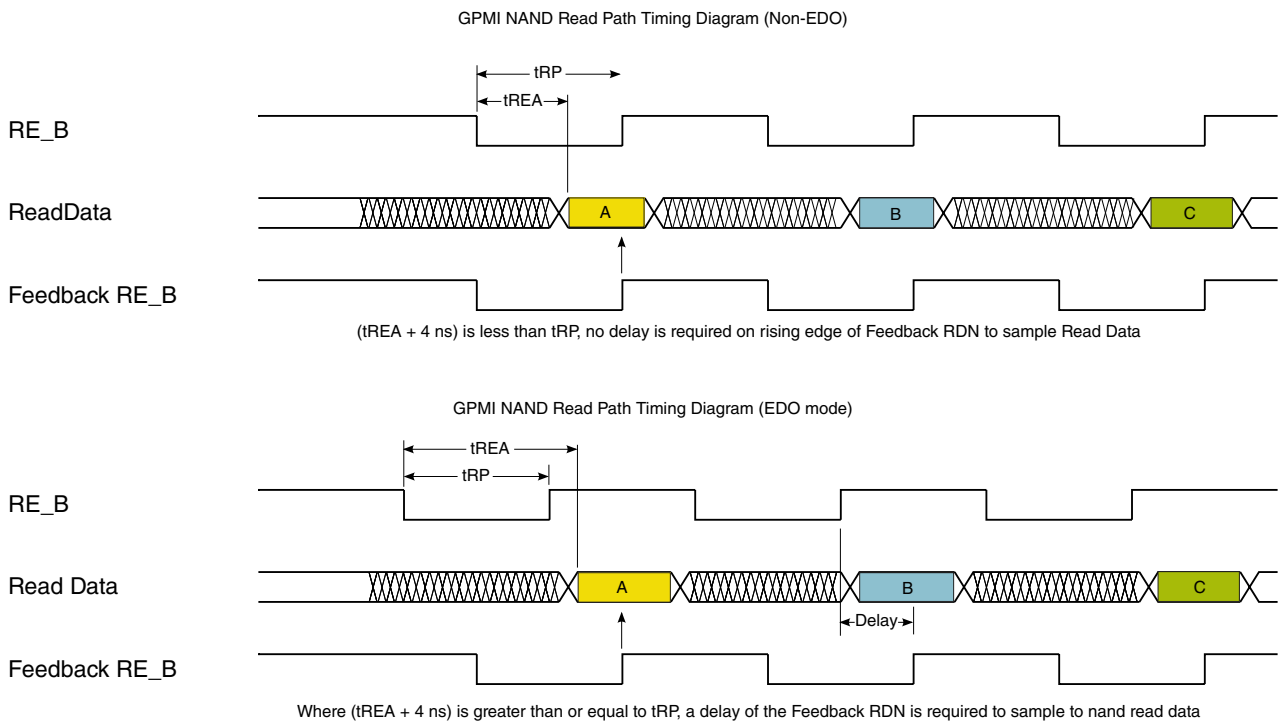

Figure 9-41. NAND Read Path Timing

For example, a NAND with tREAmax = 20 ns, tRPmin = 12 ns, and tRCmin = 25 ns (read cycle time) may be programmed as follows:

- GPMICLK clock frequency: Consider 480/6 = 80 MHz which is 12.5 ns clock period. This is too close to the minimum NAND spec if we program the data setup and hold to 1 GPMICLK cycle. Consider 480/7=68.57 MHz which is 14.58 ns clock period. With data setup and hold set to 1, we have a tRP of 14.58ns and a tRC of 29.16 ns (good margins).
- Since (tREA +4ns) is greater than tRP, required DELAY = tREA + 4ns - tRP = 20 + 4 - 14.58ns = 9.42 ns.

- GPMI_CTRL1[HALF_PERIOD] =, since GPMICLK period is ns. So RP=GPMICLK period = ns.
- DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP. 9.42 ns = GPMI_CTRL1[RDN_DELAY] x 0.125 x ns. GPMI_CTRL1[RDN_DELAY] =

NOTE

It is recommended that the drive strength of NAND_RE_B and NAND_WE_B output pins be set to 8 mA. This will reduce the transition time under heavy loads. Low transition times will be important when NAND interface read and write cycle times are below 30 ns. The other GPMI pins may remain at 4 mA, since their frequency is only up to half that of NAND_RE_B and NAND_WE_B.

9.6.4.3.3 NAND ONFI Source Synchronous Mode Timing

NOTE

In the following figures, CLK shares the same pin as WE_B in Async Mode. And W/R# shares the same pin as RE_B in Async Mode.

9.6.4.4 Hardware BCH Interface

The GPMI provides an interface to the BCH module. This reduces the SOC bus traffic and the software involvement.

The GPMI also provides an interface to the Randomizer module. The Randomizer can generate random data based on BCH ECC encoded / decoded data. It can be employed to reduce the disturbances caused by neighboring cells in the NAND chip, thus reducing bit errors. To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed

to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled, GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

When BCH ECC is enable, parity information is inserted on-the-fly during writes to 8-bit NAND devices. The BCH will supply payload and parity to the GPMI to write to the NAND. During NAND reads, parity is checked and ECC processing is performed after each read block. In this case the GPMI reads the NAND device and redirects the data and parity to the BCH module for ECC processing.

To program the BCH for NAND writes, remove the soft reset and clock gates from BCH_CTRL[SFTRST] and BCH_CTRL[CLKGATE]. The bulk of BCH programming is actually applied to the GPMI via PIO operations embedded in its DMA command structures. This has a subtle implication when writing to the GPMI ECC registers: access to the these registers must be written in progressive register order. Thus, to write to the GPMI_ECCCOUNT register, write first (in order) to registers GPMI_CTRL0, GPMI_COMPARE, and GPMI_ECCCTRL before writing to GPMI_ECCCOUNT. These additional register writes need to be accounted for in the CMDWORDS field of the respective DMA channel command register.

Note that the GPMI_PAYLOAD and GPMI_AUXILIARY pointers need to be word-aligned for proper ECC operation. If those pointers are non-word-aligned, then the BCH engine will not operate properly and could possibly corrupt system memory in the adjoining memory regions.

9.6.5 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

9.6.6 GPMI Memory Map/Register Definition

The following registers provide control for programmable elements of the GPMI module.

NOTE

All ATA or UDMA features are not supported for the chip.

NOTE

GPMI does not support the Set feature command in Toggle mode. The NANDF_DQS output is only enabled in program operation for Toggle mode, but the Set feature command also needs to use the NANDF_DQS signal to write data to Toggle NAND flash. So the Set feature command in Toggle mode is not supported.

9.6.6.1 GPMI Control Register 0 Description (GPMI_CTRL0*n*)

The GPMI control register 0 specifies the GPMI transaction to perform for the current command chain item.

Address: 3300_2000h base + 0h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SFTRST	CLKGATE	RUN	DEV_IRQ_EN	LOCK_CS	UDMA	COMMAND_MODE		WORD_LENGTH	CS			ADDRESS			ADDRESS_INCREMENT
Reset	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	XFER_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. This will not work if the CLKGATE bit is already set to '1'. CLKGATE must be cleared to '0' before issuing a soft reset. Also the GPMICLK must be running for this to work properly. RUN = 0x0 Allow GPMI to operate normally. RESET = 0x1 Hold GPMI in reset.
30 CLKGATE	Set this bit zero for normal operation. Setting this bit to one (default), gates all of the block level clocks off for miniminizing AC energy consumption. RUN = 0x0 Allow GPMI to operate normally. NO_CLKS = 0x1 Do not clock GPMI gates in order to minimize power consumption.
29 RUN	The GPMI is busy running a command whenever this bit is set to '1'. The GPMI is idle whenever this bit set to zero. This can be set to one by a CPU write. In addition, the DMA sets this bit each time a DMA command has finished its PIO transfer phase. IDLE = 0x0 The GPMI is idle. BUSY = 0x1 The GPMI is busy running a command.

Table continues on the next page...

GPMI_CTRL0*n* field descriptions (continued)

Field	Description
28 DEV_IRQ_EN	When set to '1' and ATA_IRQ pin is asserted, the GPMI_IRQ output will assert.
27 LOCK_CS	For ATA/NAND mode: 0= Deassert chip select (CS) after RUN is complete. 1= Continue to assert chip select (CS) after RUN is complete. For Camera Mode: 0= Dont wait for VSYNC rising edge before capturing data. 1= Wait for VSYNC rising edge before capturing data (Camera mode only). DISABLED = 0x0 Deassert chip select (CS) after RUN is complete. ENABLED = 0x1 Continue to assert chip select (CS) after RUN is complete.
26 UDMA	DISABLED = 0x0 Use ATA-PIO mode on the external bus. ENABLED = 0x1 Use ATA-Ultra DMA mode on the external bus. 0 Use ATA-PIO mode on the external bus. 1 Use ATA-Ultra DMA mode on the external bus.
25–24 COMMAND_ MODE	WRITE = 0x0 Write mode. READ = 0x1 Read mode. READ_AND_COMPARE = 0x2 Read and Compare mode (setting sense flop). WAIT_FOR_READY = 0x3 Wait for Ready mode. For ATA WAIT_FOR_READY command set CS=01. 00 Write mode. 01 Read Mode. 10 Read and Compare Mode (setting sense flop). 11 Wait for Ready.
23 WORD_LENGTH	This bit should only be changed when RUN==0. Reserve = 0x0 Reserved. 8_BIT = 0x1 8-bit Data Bus mode. 0 Reserved. 1 8-bit Data Bus mode.
22–20 CS	Selects which chip select is active for this command. For ATA WAIT_FOR_READY command, this must be set to b01.
19–17 ADDRESS	Specifies the three address lines for ATA mode. In NAND mode, use A0 for CLE and A1 for ALE. NAND_DATA = 0x0 In NAND mode, this address is used to read and write data bytes. NAND_CLE = 0x1 In NAND mode, this address is used to write command bytes. NAND_ALE = 0x2 In NAND mode, this address is used to write address bytes.
16 ADDRESS_ INCREMENT	In ATA mode, the address will increment with each cycle. In NAND mode, the address will increment once, after the first cycle (going from CLE to ALE). DISABLED = 0x0 Address does not increment. ENABLED = 0x1 Increment address. 0 Address does not increment. 1 Increment address.
XFER_COUNT	Number of bytes to transfer for this command. A value of zero will transfer 64K bytes.

9.6.6.2 GPMI Compare Register Description (GPMI_COMPARE)

The GPMI compare register specifies the expect data and the xor mask for comparing to the status values read from the device. This register is used by the Read and Compare command.

GPMI_COMPARE 0x010

Address: 3300_2000h base + 10h offset = 3300_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MASK																REFERENCE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

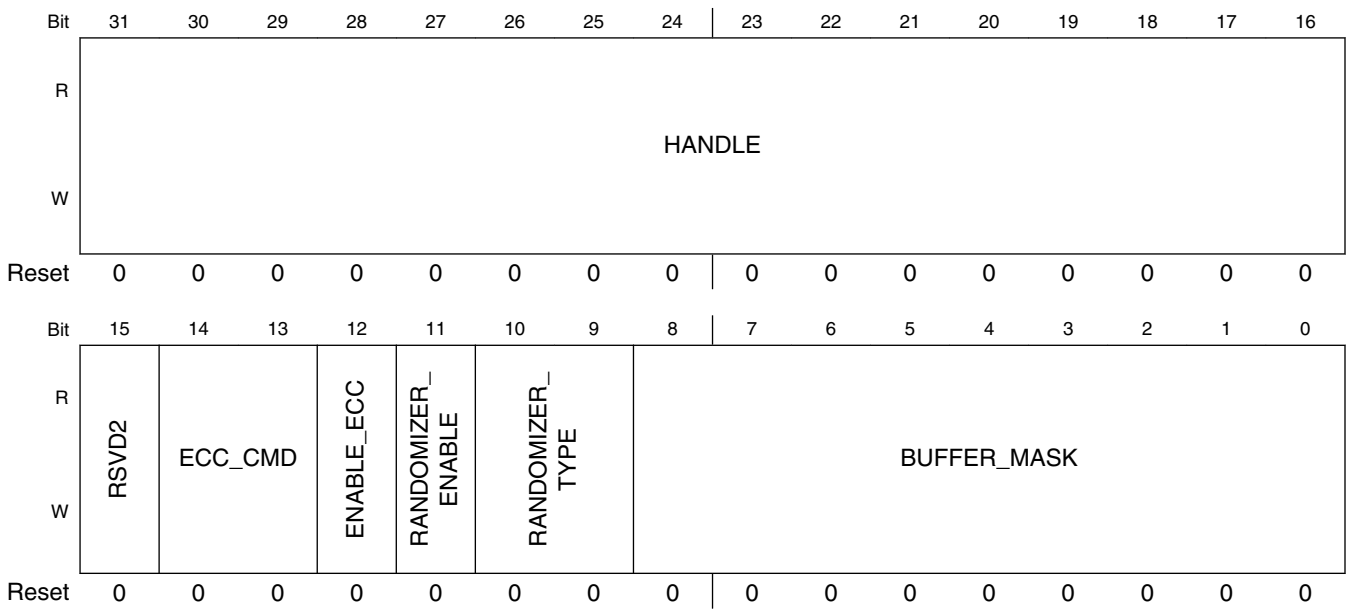
GPMI_COMPARE field descriptions

Field	Description
31–16 MASK	16-bit mask which is applied after the read data is XORed with the REFERENCE bit field.
REFERENCE	16-bit value which is XORed with data read from the NAND device.

9.6.6.3 GPMI Integrated ECC Control Register Description (GPMI_ECCCTRL*n*)

The GPMI ECC control register handles configuration of the integrated ECC / Randomizer accelerator.

Address: 3300_2000h base + 20h offset + (4d × i), where i=0d to 3d



GPMI_ECCCTRL*n* field descriptions

Field	Description
31–16 HANDLE	This is a register available to software to attach an identifier to a transaction in progress. This handle will be available from the ECC register space when the completion interrupt occurs.
15 RSVD2	Always write zeroes to this bit field.
14–13 ECC_CMD	ECC Command information. DECODE = 0x0 Decode. ENCODE = 0x1 Encode. RESERVE2 = 0x2 Reserved. RESERVE3 = 0x3 Reserved.
12 ENABLE_ECC	Enable ECC processing of GPMI transfers. ENABLE = 0x1 Use integrated ECC for read and write transfers. DISABLE = 0x0 Integrated ECC remains in idle.
11 RANDOMIZER_ ENABLE	Enable randomizer function. If this bit is set to enable, ENABLE_ECC should be also enable.

Table continues on the next page...

GPMI_ECCCTRL*n* field descriptions (continued)

Field	Description
	0x0 disable 0x1 enable
10–9 RANDOMIZER_ TYPE	Set randomizer type 0x00 Type 0 0x01 Type 1 0x10 Type 2
BUFFER_MASK	ECC buffer information. The BCH error correction only allows two configurations of the buffer mask - software may either read just the first block on the flash page or the entire flash page. Write operations must be for the entire flash page. Invalid buffer mask values will cause the DMA descriptor command to be terminated. BCH_AUXONLY = 0x100 Set to request transfer from only the auxiliary buffer (block 0 on flash). BCH_PAGE = 0x1FF Set to request transfer to/from the entire page.

9.6.6.4 GPMI Integrated ECC Transfer Count Register Description (GPMI_ECCCOUNT)

The GPMI ECC Transfer Count Register contains the count of bytes that flow through the ECC / Randomizer subsystem.

GPMI_ECCCOUNT 0x030

Address: 3300_2000h base + 30h offset = 3300_2030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								RANDOMIZER_PAGE								COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_ECCCOUNT field descriptions

Field	Description
31–24 -	Always write zeroes to this bit field.
23–16 RANDOMIZER_ PAGE	Set NAND page number needed to be randomized. The value is between 0-255
COUNT	Number of bytes to pass through ECC. This is the GPMI transfer count plus the syndrome count that will be inserted into the stream by the ECC. In DMA2ECC_MODE this count must match the GPMI_CTRL0_XFER_COUNT. A value of zero will transfer 64K words.

9.6.6.5 GPMI Payload Address Register Description (GPMI_PAYLOAD)

The GPMI payload address register specifies the location of the data buffers in system memory. This value must be word aligned.

GPMI_PAYLOAD 0x040

Address: 3300_2000h base + 40h offset = 3300_2040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS														RSVD0	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_PAYLOAD field descriptions

Field	Description
31–2 ADDRESS	Pointer to an array of one or more 512 byte payload buffers.
RSVD0	Always write zeroes to this bit field.

9.6.6.6 GPMI Auxiliary Address Register Description (GPMI_AUXILIARY)

The GPMI auxiliary address register specifies the location of the auxiliary buffers in system memory. This value must be word aligned.

GPMI_AUXILIARY 0x050

Address: 3300_2000h base + 50h offset = 3300_2050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_AUXILIARY field descriptions

Field	Description
31–2 ADDRESS	Pointer to ECC control structure and meta-data storage.
RSVD0	Always write zeroes to this bit field.

9.6.6.7 GPMI Control Register 1 Description (GPMI_CTRL1*n*)

The GPMI control register 1 specifies additional control fields that are not used on a per-transaction basis.

Address: 3300_2000h base + 60h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DEV_CLK_STOP	SSYNC_CLK_STOP	WRITE_CLK_STOP	TOGGLE_MODE	GPMI_CLK_DIV2_EN	UPDATE_CS	SSYNCMODE	DECOUPLE_CS	WRN_DLY_SEL		TEST_TRIGGER	TIMEOUT_IRQ_EN	GANGED_RDYBUSY	BCH_MODE	DLL_ENABLE	HALF_PERIOD
W

R	RDN_DELAY				DMA2ECC_MODE	DEV_IRQ	TIMEOUT_IRQ	BURST_EN	ABORT_WAIT_REQUEST	ABORT_WAIT_FOR_READY_CHANNEL			DEV_RESET	ATA_IRQRDY_POLARITY	CAMERA_MODE	GPMI_MODE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

GPMI_CTRL1*n* field descriptions

Field	Description
31 DEV_CLK_STOP	set this bit to 1 will stop gpmi io working clk.
30 SSYNC_CLK_STOP	set this bit to 1 will stop the source synchronous mode clk.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
29 WRITE_CLK_STOP	In onfi source synchronous mode, host may save power during the data write cycles by holding the CLK signal high (i.e. stopping the CLK). The host may only stop the CLK during data write, by setting this bit to 1, if the device supports this feature as indicated in the parameter page.
28 TOGGLE_MODE	enable samsung toggle mode.
27 GPMI_CLK_DIV2_EN	This bit should be reset to 0 in asynchronous mode. The frequence ratio of (device clock : ccm gpmi clock) will be (1 : 1). This bit should be set to 1, in source synchronous mode or toggle mode. The frequence raito of (device clock : ccm gpmi clock) will be (1 : 2). enable the gpmi clk divider. 0x0 internal factor-2 clock divider is disabled 0x1 internal factor-2 clock divider is enabled.
26 UPDATE_CS	force the CS value is be updated to external chip select pin, even GPMI is idle.
25 SSYNCMODE	source synchronouse mode 1 or asynchrous mode 0. ASYNC = 0x0 Asynchronous mode. SSYNC = 0x1 Source Synchronous mode.
24 DECOUPLE_CS	Decouple Chip Select from DMA Channel. Setting this bit to 1 will allow a DMA channel to specify any value in the CTRL0_CS register field. Software can use one DMA channel to access all 8 Nand devices.
23–22 WRN_DLY_SEL	Since the GPMI write strobe (WRN) is a fast clock pin, the delay on this signal can be programmed to match the load on this pin. 0 = ~2ns; 1 = ~4ns; 2 = ~6ns; 3 = no delay.
21 TEST_TRIGGER	Test Trigger Enable 0 Disable 1 Enable
20 TIMEOUT_IRQ_EN	Setting this bit to '1' will enable timeout IRQ for transfers in ATA mode only, and for WAIT_FOR_READY commands in both ATA and Nand mode. The Device_Busy_Timeout value is used for this timeout.
19 GANGED_RDYBUSY	Set this bit to 1 will force all Nand RDY_BUSY inputs to be sourced from (tied to) RDY_BUSY0. This will free up all, except one, RDY_BUSY input pins.
18 BCH_MODE	This bit selects which error correction unit will access GPMI. This bit must always be set to '1', since only the BCH unit is available in this design.
17 DLL_ENABLE	Set this bit to 1 to enable the GPMI DLL. This is required for fast NAND reads (above 30 MHz read strobe). After setting this bit, wait 64 GPMI clock cycles for the DLL to lock before performing a NAND read.
16 HALF_PERIOD	Set this bit to 1 if the GPMI clock period is greater than 16ns for proper DLL operation. DLL_ENABLE must be zero while changing this field.
15–12 RDN_DELAY	This variable is a factor in the calculated delay to apply to the internal read strobe for correct read data sampling. The applied delay (AD) is between 0 and 1.875 times the reference period (RP). RP is one half of the GPMI clock period if HALF_PERIOD=1 otherwise it is the full GPMI clock period. The equation is: AD = RDN_DELAY x 0.125 x RP. This value must not exceed 16ns.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
	This variable is used to achieve faster NAND access. For example if the Read Strobe is asserted from time 0 to 13ns but the read access time is 20ns, then choose AD=12ns will cause the data to be sampled at time 25ns (13+12) giving a 5ns data setup time. If RP=13ns then RDN_DELAY = 12/(0.125 x 13ns) = 7.38 (0111b). DLL_ENABLE must be zero while changing this field.
11 DMA2ECC_ MODE	This is mainly for testing HWECC without involving the Nand device. Setting this bit will cause DMA write data to redirected to HWECC module (instead of Nand Device) for encoding or decoding.
10 DEV_IRQ	This bit is set when an Interrupt is received from the ATA device. Write 0 to clear.
9 TIMEOUT_IRQ	This bit is set when a timeout occurs using the Device_Busy_Timeout value. Write 0 to clear.
8 BURST_EN	When set to 1 each DMA request will generate a 4-transfer burst on the APB bus.
7 ABORT_WAIT_ REQUEST	Request to abort "wait for ready" command on channel indicated by ABORT_WAIT_FOR_READY_CHANNEL. Hardware will clear this bit when abort is done.
6–4 ABORT_WAIT_ FOR_READY_ CHANNEL	Abort a wait for ready command on selected channel. Set the ABORT_WAIT_REQUEST to kick of operation.
3 DEV_RESET	ENABLED = 0x0 NANDF_WP_B(WPN) pin is held low (asserted). DISABLED = 0x1 NANDF_WP_B(WPN) pin is held high (de-asserted). 0 NANDF_WP_B pin is held low (asserted). 1 NANDF_WP_B pin is held high (de-asserted).
2 ATA_IRQRDY_ POLARITY	For ATA MODE: Note NAND_RDY_BUSY[3:2] are not affected by this bit. ACTIVELOW = 0x0 ATA IORDY and IRQ are active low, or NAND_RDY_BUSY[1:0] are active low ready. ACTIVEHIGH = 0x1 ATA IORDY and IRQ are active high, or NAND_RDY_BUSY[1:0] are active high ready. 0 External ATA IORDY and IRQ are active low. 1 External ATA IORDY and IRQ are active high. For NAND MODE: 0 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when low and busy when high. 1 External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when high and busy when low.
1 CAMERA_MODE	When set to 1 and ATA UDMA is enabled the UDMA interface becomes a camera interface.
0 GPMI_MODE	ATA mode is only supported on channel zero. If ATA mode is selected, then only channel three is available for NAND use. NAND = 0x0 NAND mode. ATA = 0x1 ATA mode.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
	0 NAND mode. 1 ATA mode.

9.6.6.8 GPMI Timing Register 0 Description (GPMI_TIMING0)

The GPMI timing register 0 specifies the timing parameters that are used by the cycle state machine to guarantee the various setup, hold and cycle times for the external media type.

GPMI_TIMING0 0x070

Address: 3300_2000h base + 70h offset = 3300_2070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R									ADDRESS_SETUP								DATA_HOLD								DATA_SETUP							
W	0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	1

GPMI_TIMING0 field descriptions

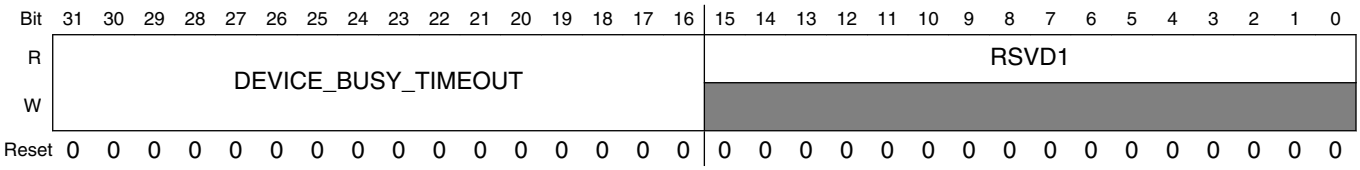
Field	Description
31–24 RSVD1	Always write zeroes to this bit field.
23–16 ADDRESS_ SETUP	Number of GPMICLK cycles that the CE/ADDR signals are active before a strobe is asserted. A value of zero is interpreted as 0. For ATA PIO modes this is known in the ATA7 specification as "Address valid to DIOR-/DIOW- setup"
15–8 DATA_HOLD	Data bus hold time in GPMICLK cycles. Also the time that the data strobe is de-asserted in a cycle. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as "DIOR-/DIOW- recovery time"
DATA_SETUP	Data bus setup time in GPMICLK cycles. Also the time that the data strobe is asserted in a cycle. This value must be greater than 2 for ATA devices that use IORDY to extend transfer cycles. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as ""DIOR-/DIOW-"

9.6.6.9 GPMI Timing Register 1 Description (GPMI_TIMING1)

The GPMI timing register 1 specifies the timeouts used when monitoring the NAND READY pin or the ATA IRQ and IOWAIT signals.

GPMI_TIMING1 0x080

Address: 3300_2000h base + 80h offset = 3300_2080h



GPMI_TIMING1 field descriptions

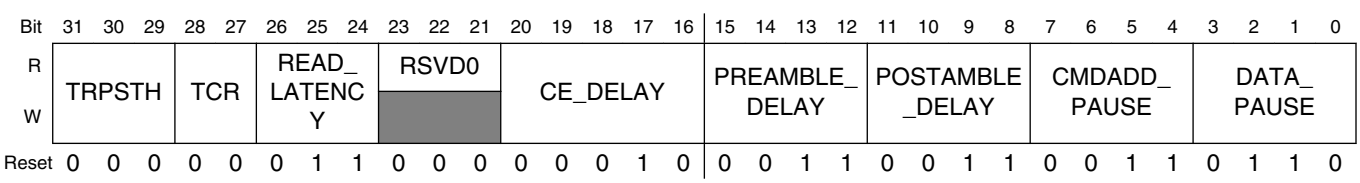
Field	Description
31–16 DEVICE_BUSY_ TIMEOUT	Timeout waiting for NAND Ready/Busy or ATA IRQ. Used in WAIT_FOR_READY mode. This value is the number of GPMI_CLK cycles multiplied by 4096.
RSVD1	Always write zeroes to this bit field.

9.6.6.10 GPMI Timing Register 2 Description (GPMI_TIMING2)

The GPMI timing register 2 specifies the double data rate timing parameters that are used by the cycle state machine to guarantee the various cs delay, pre-amble delay, post-amble delay, command/address delay, data delay, TCR, TRPSTH, and read latency cycle times for the external media type.

GPMI_TIMING2 0x090

Address: 3300_2000h base + 90h offset = 3300_2090h



GPMI_TIMING2 field descriptions

Field	Description
31–29 TRPSTH	Only for Toggle NAND timing control delay TRPSTH GPMICLK cycles for CEn_B high to RE_B high, A value of zero is interpreted as 8
28–27 TCR	Only for Toggle NAND timing control delay (TCR+1) GPMICLK cycles for CEn_B low to RE_B low, 0 is less than or equal to TCR, which is less than the PREAMBLE_DELAY
26–24 READ_ LATENCY	This field is for double data rate read latency configuration. others READ LATENCY is 3 000 READ LATENCY is 0 001 READ LATENCY is 1 010 READ LATENCY is 2 011 READ LATENCY is 3 100 READ LATENCY is 4 101 READ LATENCY is 5

Table continues on the next page...

GPMI_TIMING2 field descriptions (continued)

Field	Description
23–21 RSVD0	Always write zeroes to this bit field.
20–16 CE_DELAY	GPMI dealy from CEn assert to W/Rn changing edge. value of zero is interpreted as 32.
15–12 PREAMBLE_ DELAY	GPMI pre-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
11–8 POSTAMBLE_ DELAY	GPMI post-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
7–4 CMDADD_ PAUSE	GPMI delay time from command or addres pause to command or address resume in GPMICLK cycles. A value of zero is interpreted as 16.
DATA_PAUSE	GPMI delay time from data pause to data resume in GPMICLK cycles. A value of zero is interpreted as 16.

9.6.6.11 GPMI DMA Data Transfer Register Description (GPMI_DATA)

The GPMI DMA data transfer register is used by the DMA to read or write data to or from the ATA/NAND control state machine.

GPMI_DATA 0x0A0

Address: 3300_2000h base + A0h offset = 3300_20A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DATA field descriptions

Field	Description
DATA	In 8-bit mode, one, two, three or four bytes can can be accessed to send the same number of bus cycles.

9.6.6.12 GPMI Status Register Description (GPMI_STAT)

The GPMI control and status register provides a read back path for various operational states of the GPMI controller.

GPMI_STAT 0x0B0

Address: 3300_2000h base + B0h offset = 3300_20B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	READY_BUSY								RDY_TIMEOUT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DEV7_ERROR	DEV6_ERROR	DEV5_ERROR	DEV4_ERROR	DEV3_ERROR	DEV2_ERROR	DEV1_ERROR	DEV0_ERROR	RSVD1			ATA_IRQ	INVALID_BUFFER_MASK	FIFO_EMPTY	FIFO_FULL	PRESENT
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

GPMI_STAT field descriptions

Field	Description
31–24 READY_BUSY	Read-only view of NAND Ready_Busy Input pins.
23–16 RDY_TIMEOUT	State of the RDY/BUSY Timeout Flags. When any bit is set to '1' in this field, it indicates that a time out has occurred while waiting for the ready state of the requested NAND device. Multiple bits may be set simultaneously. When GPMI_CTRL1_DECOUPLE_CS = 0, RDY_TIMEOUT[n] is associated with the NAND device on chip_select[n]. When GPMI_CTRL1_DECOUPLE_CS = 1, these flags become associated to a DMA channel instead of a NAND device. For example if DMA channel 6 sends a WAIT_FOR_READY command for NAND Device 2, and a timeout occured on READY_BUSY2, then READY_TIMEOUT[6] will be set instead of READY_TIMEOUT[2].
15 DEV7_ERROR	DMA channel 7 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 7. 1 An Error has occurred on ATA/NAND Device accessed by
14 DEV6_ERROR	DMA channel 6 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 6. 1 An Error has occurred on ATA/NAND Device accessed by
13 DEV5_ERROR	DMA channel 5 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 5. 1 An Error has occurred on ATA/NAND Device accessed by
12 DEV4_ERROR	DMA channel 4 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 4. 1 An Error has occurred on ATA/NAND Device accessed by
11 DEV3_ERROR	DMA channel 3 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 3. 1 An Error has occurred on ATA/NAND Device accessed by
10 DEV2_ERROR	DMA channel 2 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 2. 1 An Error has occurred on ATA/NAND Device accessed by
9 DEV1_ERROR	DMA channel 1 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 1. 1 An Error has occurred on ATA/NAND Device accessed by
8 DEV0_ERROR	DMA channel 0 (Timeout or compare failure, depending on COMMAND_MODE). 0 No error condition present on ATA/NAND Device accessed by DMA channel 0. 1 An Error has occurred on ATA/NAND Device accessed by
7–5 RSVD1	Always write zeroes to this bit field.

Table continues on the next page...

GPMI_STAT field descriptions (continued)

Field	Description
4 ATA_IRQ	Status of the ATA_IRQ input pin.
3 INVALID_ BUFFER_MASK	Buffer Mask Validity bit. 0 ECC Buffer Mask is not invalid. 1 ECC Buffer Mask is invalid.
2 FIFO_EMPTY	NOT_EMPTY = 0x0 FIFO is not empty. EMPTY = 0x1 FIFO is empty. 0 FIFO is not empty. 1 FIFO is empty.
1 FIFO_FULL	NOT_FULL = 0x0 FIFO is not full. FULL = 0x1 FIFO is full. 0 FIFO is not full. 1 FIFO is full.
0 PRESENT	UNAVAILABLE = 0x0 GPMI is not present in this product. AVAILABLE = 0x1 GPMI is present in this product. 0 GPMI is not present in this product. 1 GPMI is present is in this product.

9.6.6.13 GPMI Debug Information Register Description (GPMI_DEBUG)

The GPMI debug information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG 0x0C0

Address: 3300_2000h base + C0h offset = 3300_20C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WAIT_FOR_READY_END								DMA_SENSE								DMAREQ								CMD_END							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DEBUG field descriptions

Field	Description
31–24 WAIT_FOR_ READY_END	Read Only view of the Wait_For_Ready End toggle signals to DMA. One per channel

Table continues on the next page...

GPMI_DEBUG field descriptions (continued)

Field	Description
23–16 DMA_SENSE	Read-only view of sense state of the 8 DMA channels. A value of "1" in any bit position indicates that a read and compare command failed or a timeout occured for the corresponding channel.
15–8 DMAREQ	Read-only view of DMA request line for 8 DMA channels. A toggle on any bit position indicates a DMA request for the corresponding channel.
CMD_END	Read Only view of the Command End toggle signals to DMA. One per channel

9.6.6.14 GPMI Version Register Description (GPMI_VERSION)

This register reflects the version number for the GPMI.

GPMI_VERSION 0x0D0

Address: 3300_2000h base + D0h offset = 3300_20D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	1	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_VERSION field descriptions

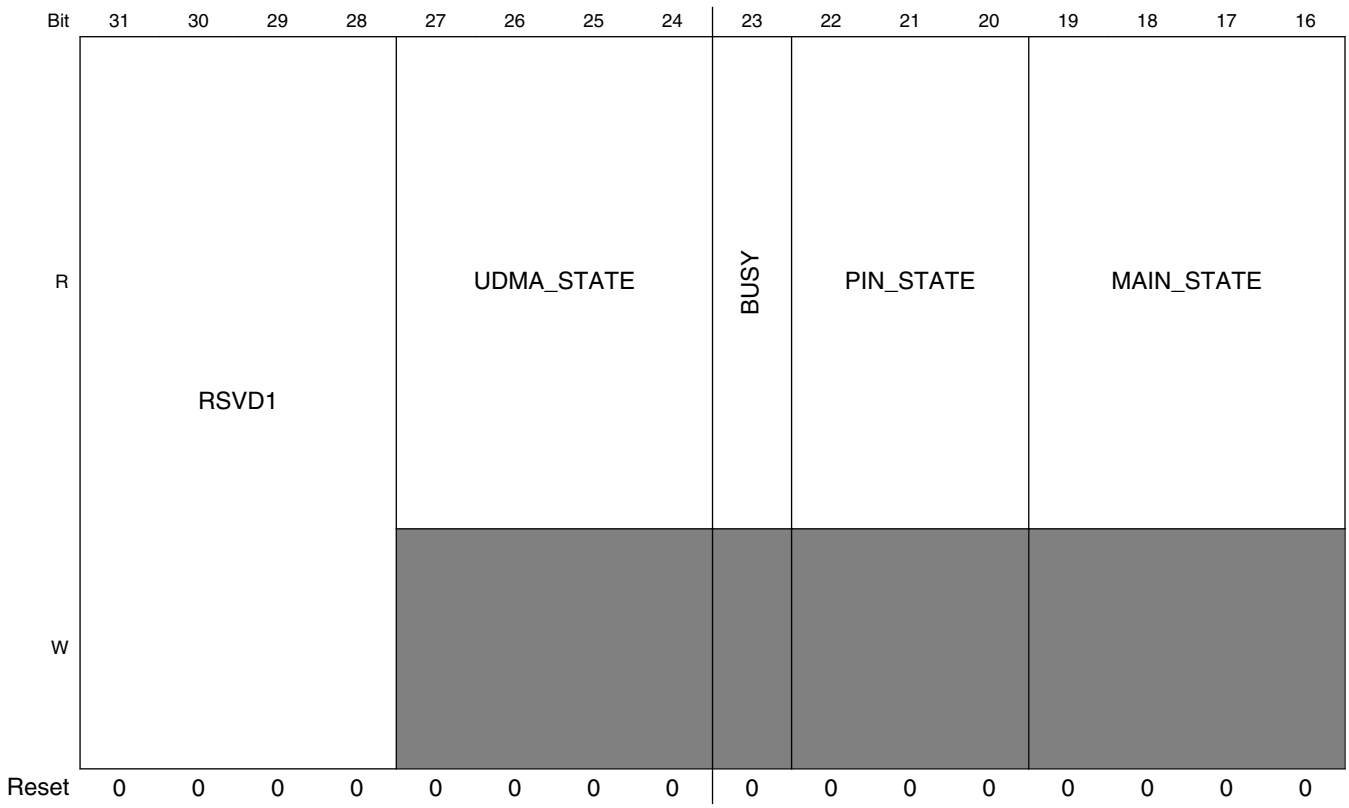
Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
STEP	Fixed read-only value reflecting the stepping of the RTL version.

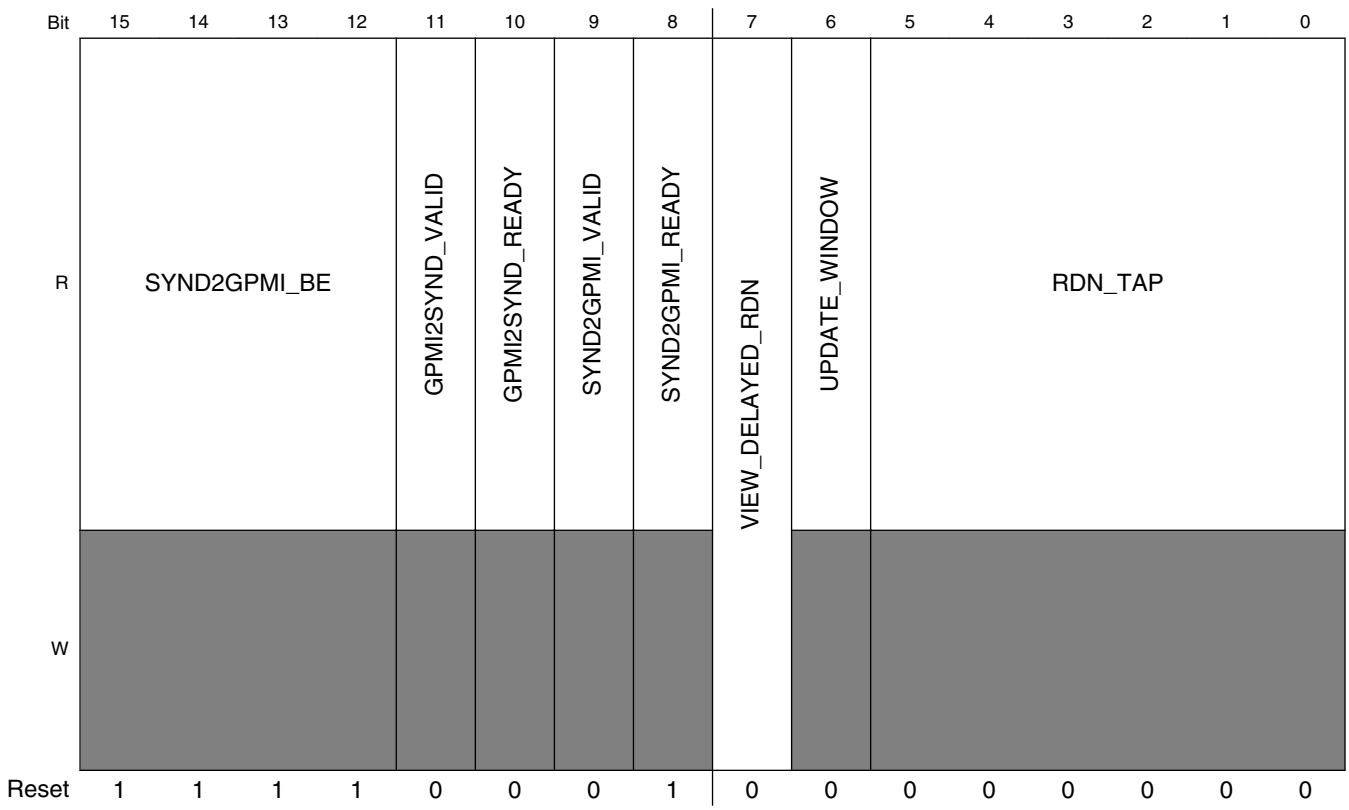
9.6.6.15 GPMI Debug2 Information Register Description (GPMI_DEBUG2)

The GPMI Debug2 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG2 0x0E0

Address: 3300_2000h base + E0h offset = 3300_20E0h





GPMI_DEBUG2 field descriptions

Field	Description
31–28 RSVD1	Always write zeroes to this bit field.
27–24 UDMA_STATE	USM_IDLE = 4'h0, idle USM_DMARQ = 4'h1, DMA req USM_ACK = 4'h2, DMA ACK USM_FIFO_E = 4'h3, Fifo empty USM_WPAUSE = 4'h4, WR DMA Paused by device USM_TSTRB = 4'h5, Toggle HSTROBE USM_CAPTUR = 4'h6, Capture Stage, (data sampled with DSTROBE is valid) USM_DATOUT = 4'h7, Change Burst DATAOUT USM_CRC = 4'h8, Source CRC to Device USM_WAIT_R = 4'h9, Waiting for DDMARDY- USM_END = 4'ha; Negate DMAACK (end of DMA) USM_WAIT_S = 4'hb, Waiting for DSTROBE USM_RPAUSE = 4'hc, Rd DMA Paused by Host USM_RSTOP = 4'hd, Rd DMA Stopped by Host USM_WTERM = 4'he, Wr DMA Termination State USM_RTERM = 4'hf, Rd DMA Termination state
23 BUSY	When asserted the GPMI is busy. Undefined results may occur if any registers are written when BUSY is asserted. DISABLED = 0x0 The GPMI is not busy. ENABLED = 0x1 The GPMI is busy.
22–20 PIN_STATE	parameter PSM_IDLE = 3'h0, PSM_BYTCNT = 3'h1, PSM_ADDR = 3'h2, PSM_STALL = 3'h3, PSM_STROBE = 3'h4, PSM_ATARDY = 3'h5, PSM_DHOLD = 3'h6, PSM_DONE = 3'h7. PSM_IDLE = 0x0 PSM_BYTCNT = 0x1 PSM_ADDR = 0x2 PSM_STALL = 0x3 PSM_STROBE = 0x4 PSM_ATARDY = 0x5 PSM_DHOLD = 0x6 PSM_DONE = 0x7
19–16 MAIN_STATE	parameter MSM_IDLE = 4'h0, MSM_BYTCNT = 4'h1, MSM_WAITFE = 4'h2, MSM_WAITFR = 4'h3, MSM_DMAREQ = 4'h4, MSM_DMAACK = 4'h5, MSM_WAITFF = 4'h6, MSM_LDFIFO = 4'h7, MSM_LDDMAR = 4'h8, MSM_RDCMP = 4'h9, MSM_DONE = 4'hA. MSM_IDLE = 0x0 MSM_BYTCNT = 0x1 MSM_WAITFE = 0x2 MSM_WAITFR = 0x3

Table continues on the next page...

GPMI_DEBUG2 field descriptions (continued)

Field	Description
	MSM_DMAREQ = 0x4 MSM_DMAACK = 0x5 MSM_WAITFF = 0x6 MSM_LDFIFO = 0x7 MSM_LDDMAR = 0x8 MSM_RDCMP = 0x9 MSM_DONE = 0xA
15–12 SYND2GPMI_BE	Data byte enable Input from BCH.
11 GPMI2SYND_VALID	Data handshake output to BCH.
10 GPMI2SYND_READY	Data handshake output to BCH.
9 SYND2GPMI_VALID	Data handshake Input from BCH.
8 SYND2GPMI_READY	Data handshake Input from BCH.
7 VIEW_DELAYED_RDN	Set to a 1 to select the delayed feedback RE_B to drive the GPMI_ADDR[0] (Nand CLE) pin. For debug purposes, this will allow you see if DLL is functioning properly.
6 UPDATE_WINDOW	A 1 indicates that the DLL is busy generating the required delay.
RDN_TAP	This is the DLL tap calculated by the DLL controller. The selects the amount of delay form the DLL chain.

9.6.6.16 GPMI Debug3 Information Register Description (GPMI_DEBUG3)

The GPMI Debug3 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

GPMI_DEBUG3 0x0F0

Address: 3300_2000h base + F0h offset = 3300_20F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	APB_WORD_CNTR																DEV_WORD_CNTR															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DEBUG3 field descriptions

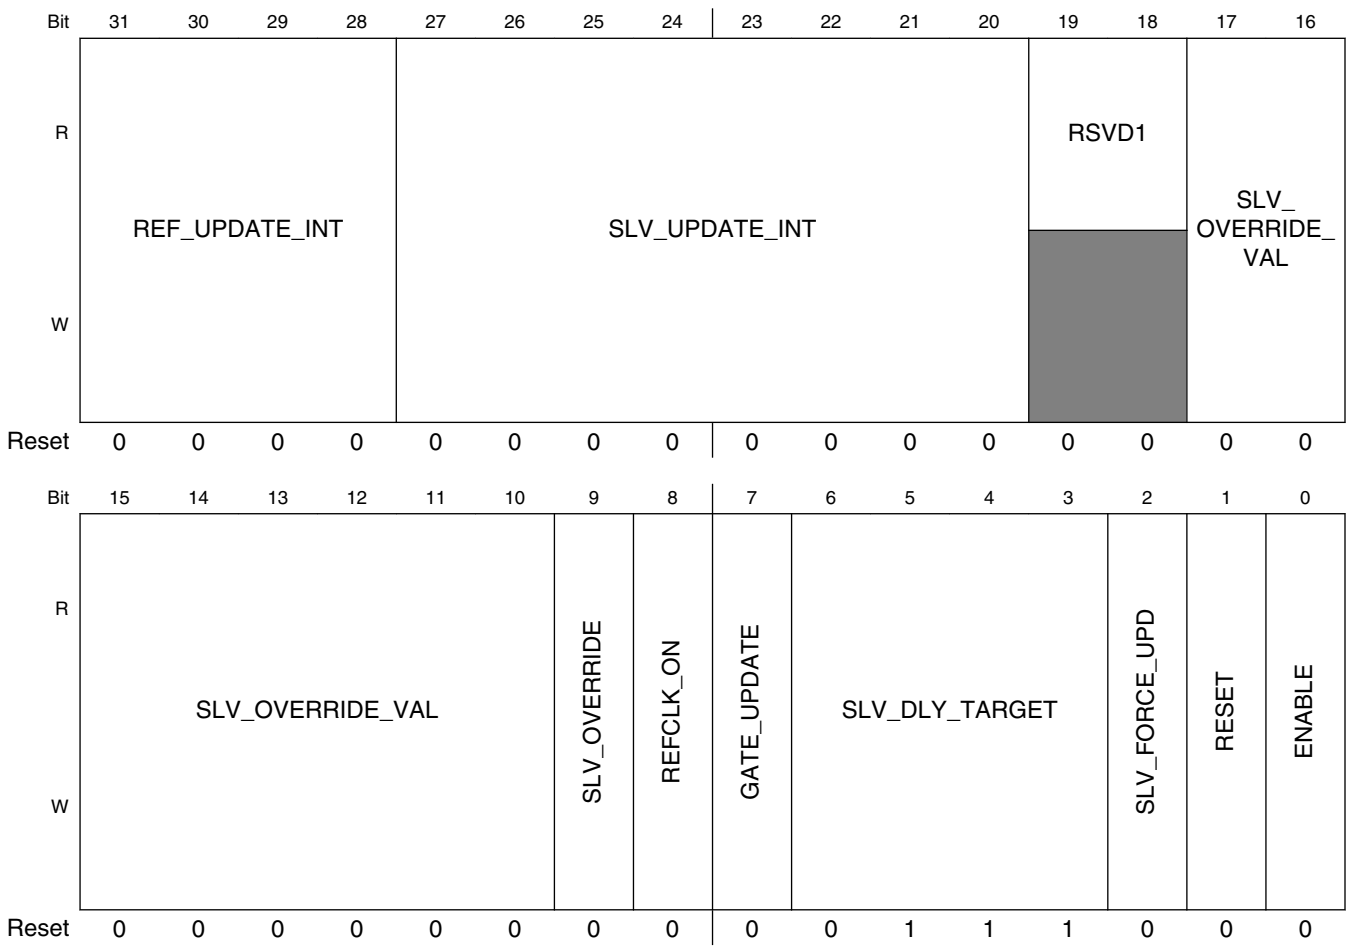
Field	Description
31–16 APB_WORD_ CNTR	Reflects the number of bytes remains to be transferred on the APB bus.
DEV_WORD_ CNTR	Reflects the number of bytes remains to be transferred on the ATA/Nand bus.

9.6.6.17 GPMI Double Rate Read DLL Control Register Description (GPMI_READ_DDR_DLL_CTRL)

GPMI DDR Read Delay Loop Lock Control Register. This register provides programmability in DDR mode for data input timing and data formats.

GPMI_READ_DDR_DLL_CTRL 0x100

Address: 3300_2000h base + 100h offset = 3300_2100h



GPMI_READ_DDR_DLL_CTRL field descriptions

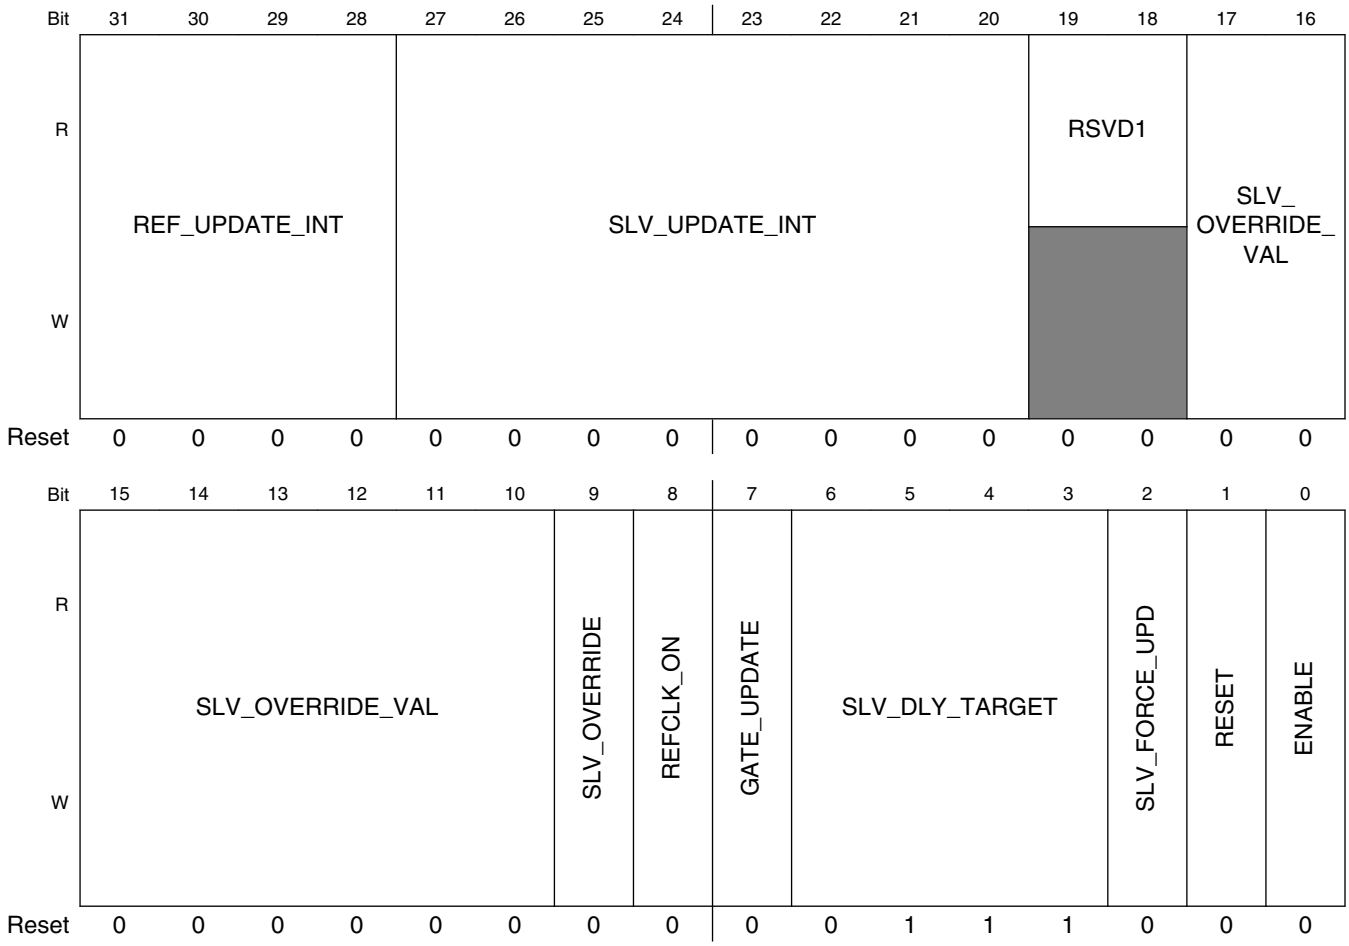
Field	Description
31–28 REF_UPDATE_INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * GPMICLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_TARGET	The delay target for the read clock is can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from (GPMICLK/2)/16 to GPMICLK/2.
2 SLV_FORCE_UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

9.6.6.18 GPMI Double Rate Write DLL Control Register Description (GPMI_WRITE_DDR_DLL_CTRL)

GPMI DDR Write Delay Loop Lock Control Register. This register provides programmability in DDR mode for data output timing and data formats.

GPMI_WRITE_DDR_DLL_CTRL 0x110

Address: 3300_2000h base + 110h offset = 3300_2110h



GPMI_WRITE_DDR_DLL_CTRL field descriptions

Field	Description
31–28 REF_UPDATE_ INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * GPMICLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_ INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_ OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0

Table continues on the next page...

GPMI_WRITE_DDR_DLL_CTRL field descriptions (continued)

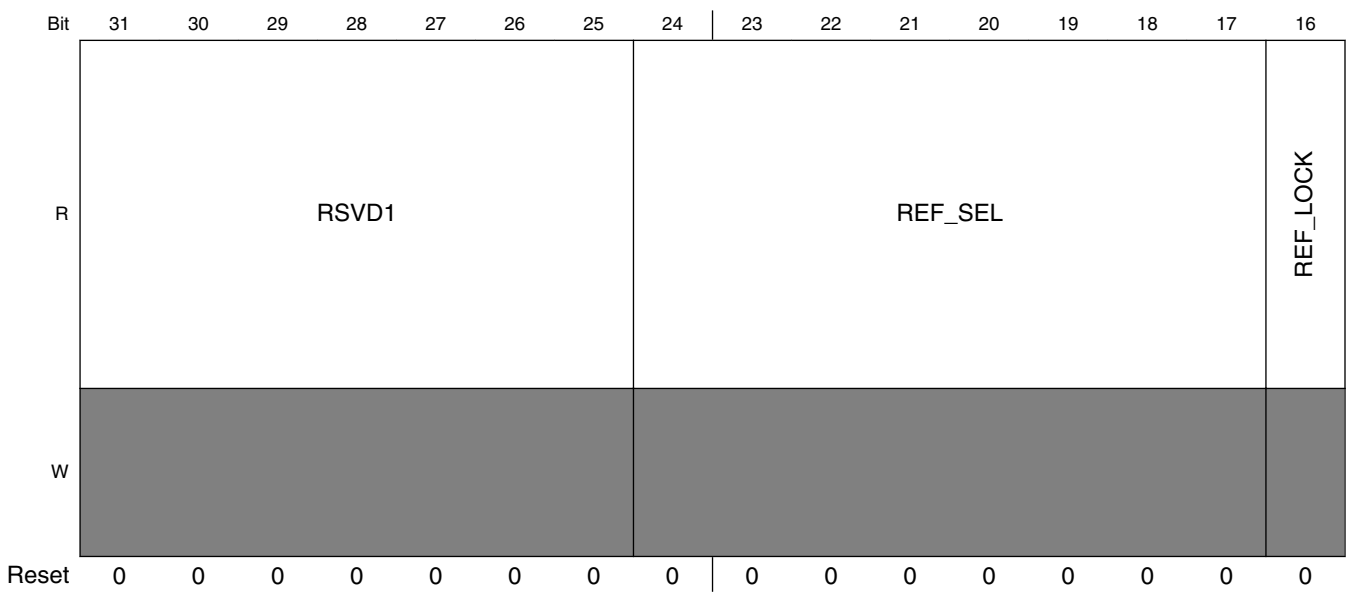
Field	Description
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_ TARGET	The delay target for the read clock can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from (GPMICLK/2)/16 to GPMICLK/2.
2 SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

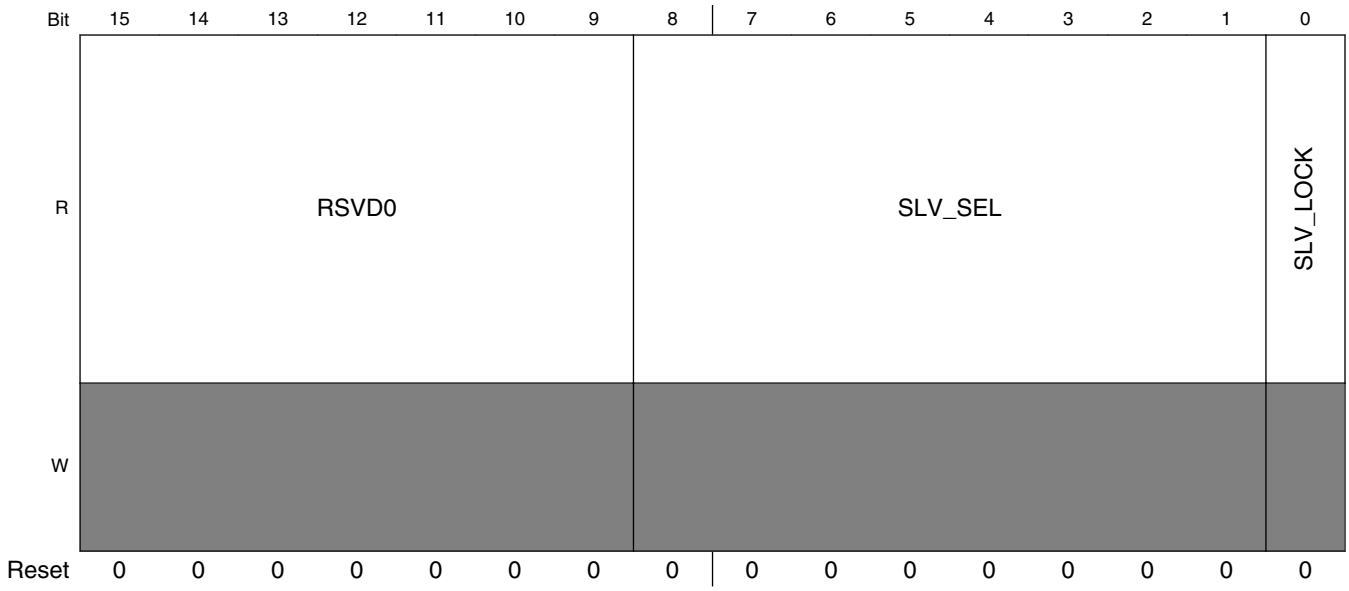
9.6.6.19 GPMI Double Rate Read DLL Status Register Description (GPMI_READ_DDR_DLL_STS)

GPMI Double Rate Read DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_READ_DDR_DLL_STS 0x120

Address: 3300_2000h base + 120h offset = 3300_2120h





GPMI_READ_DDR_DLL_STS field descriptions

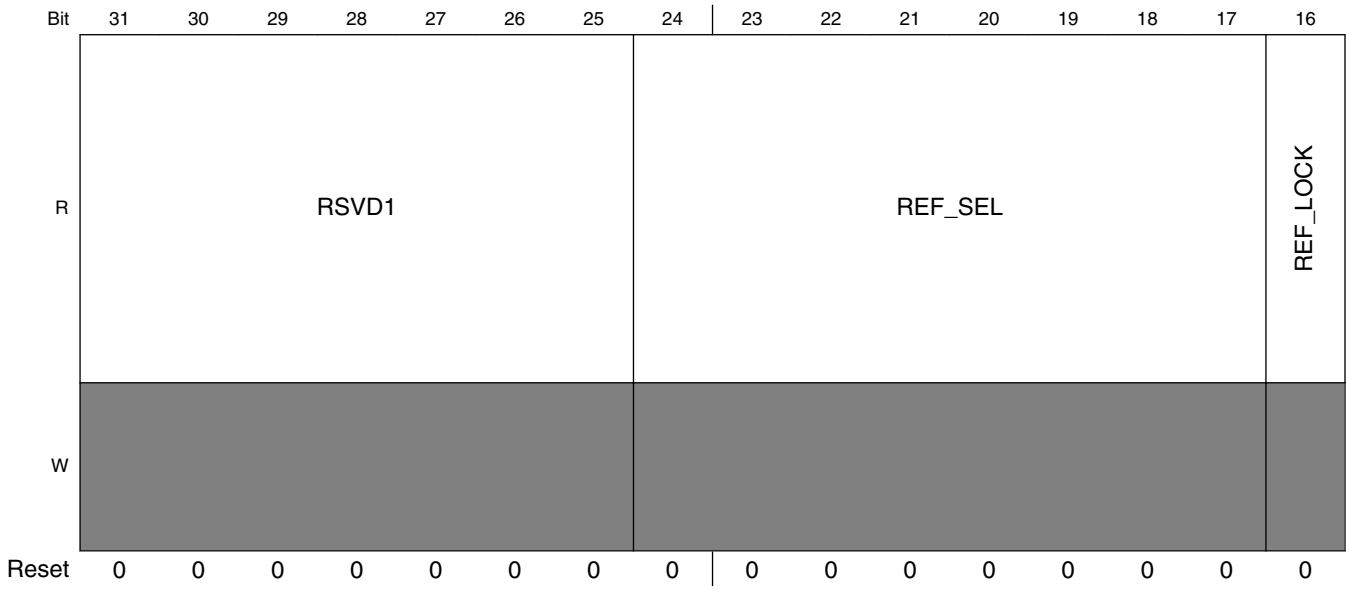
Field	Description
31–25 RSVD1	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 RSVD0	Reserved
8–1 SLV_SEL	Slave delay line select status
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

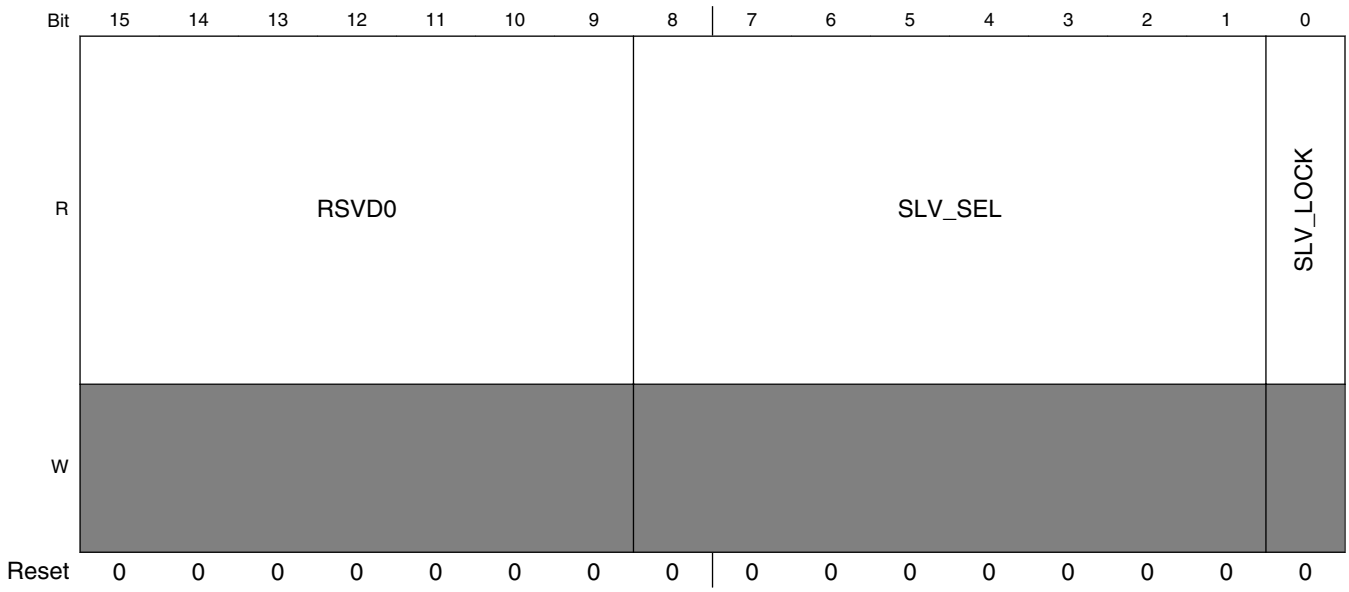
9.6.6.20 GPMI Double Rate Write DLL Status Register Description (GPMI_WRITE_DDR_DLL_STS)

GPMI Double Rate Write DLL Status Register, Read Only. GPMI DLL status fields are provided in this register.

GPMI_WRITE_DDR_DLL_STS 0x130

Address: 3300_2000h base + 130h offset = 3300_2130h





GPMI_WRITE_DDR_DLL_STS field descriptions

Field	Description
31–25 RSVD1	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 RSVD0	Reserved
8–1 SLV_SEL	Slave delay line select status

Table continues on the next page...

GPMI_WRITE_DDR_DLL_STS field descriptions (continued)

Field	Description
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

9.7 External Interface Module (EIM)

9.7.1 Overview

The EIM handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash-like or PSRAM-like interface.

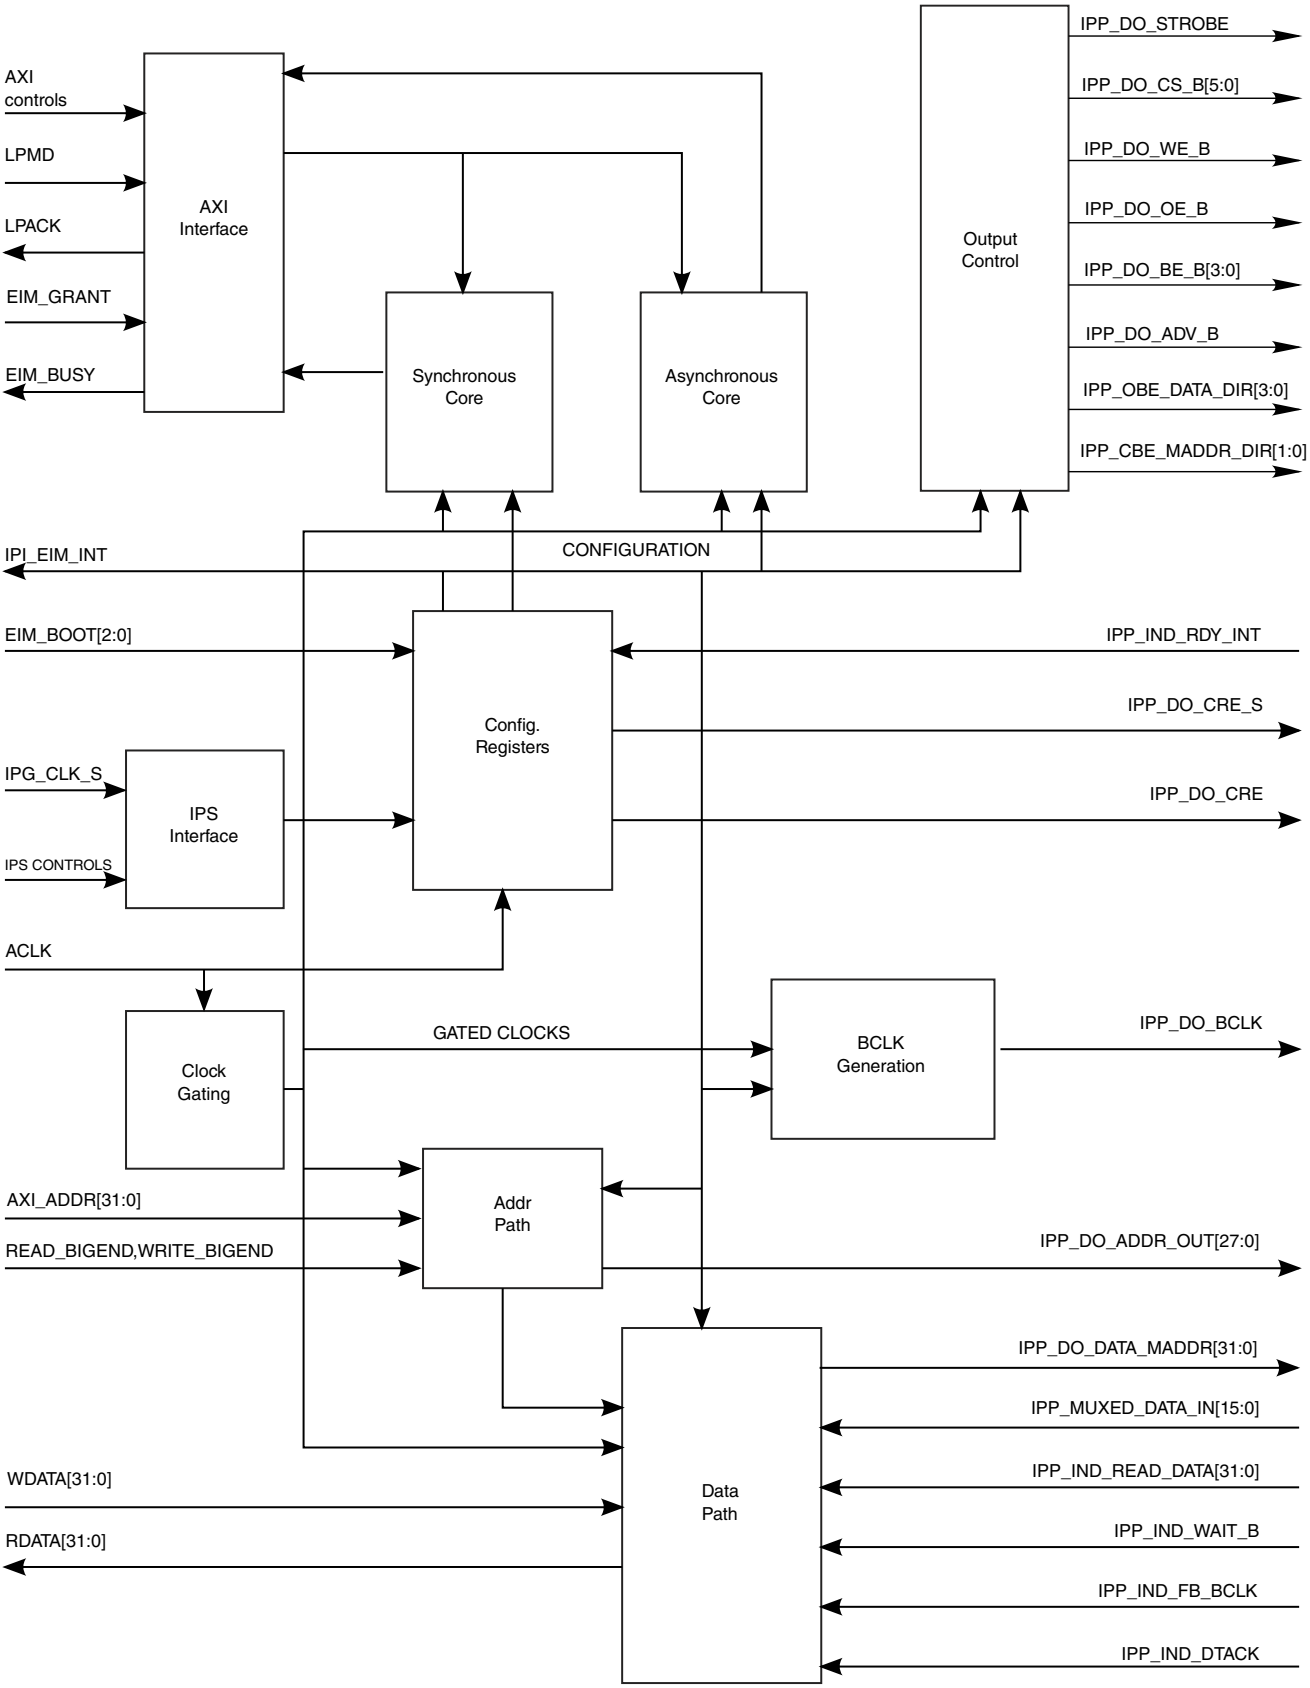


Figure 9-55. EIM Diagram

9.7.1.1 Features

- Six chip selects for external devices
  - Flexible address decoding. Each chip select memory space determined separately, according to VIA port configuration (see Chip Select Memory Map). Configurable Chip Select 0 base address (by VIA)
  - Individual select signal for each one of the memory space defined. Up to 6 memory spaces may be defined and programmed individually.
- Selectable Write Protection for each Chip Select
- Support for multiplexed address / data bus operation x16 port size
- Programmable Data Port Size for each Chip Select (x8, x16)
- Programmable Wait-State generator for each Chip Select, for write and read accesses separately
- Asynchronous accesses with programmable setup and hold times for control signals
- Support for Asynchronous page mode accesses (x16 port size)
- Independent synchronous Memory Burst Read Mode support for NOR-Flash and PSRAM memories (x16 port size)
- Independent synchronous Memory Burst Write Mode support for PSRAM and NOR-Flash like memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNAND™ and utRAM™ from Samsung, and COSMORAM™ from Toshiba)
- Support of NAND-Flash devices with NOR-Flash like interface - MDOC™ (M-Systems), OneNAND™ (Samsung)
- Independent programmable variable/fix Latency support for read and write synchronous (burst) mode
- Support for Big Endian and Little Endian operation modes per access
- ARM AXI slave interface. One ID at a time support.

9.7.1.2 Modes of Operation

The EIM has the following modes of operation:

- Asynchronous Mode
- Asynchronous Page Mode
- Multiplexed Address/Data mode
- Burst Clock Mode
- Low Power Modes
- Boot Mode

See details in the EIM Operational Modes.

9.7.1.2.1 Asynchronous Mode

This is a non-burst mode that is used for SRAM access. In this mode, a single data is read/written with each access (asserted address).

All controls' timings are controlled by preset values in Chip Select Configuration Registers.

9.7.1.2.2 Asynchronous Page Read Mode

Setting the APR bit causes the EIM to perform memory burst accesses by emulating page mode operation.

The external address asserts for each piece of data. The initial access timing is according to RWSC field, and the next address assertions timing is according to PAT field. When APR bit is set, RCSN OEN, RADVN and RBEN fields are ignored for burst access to the external device.

The page size can be set via the BL field to 2, 4, 8, or 16 words (the word size is determined by the DSZ field).

9.7.1.2.3 Multiplexed Address/Data Mode

In this mode, multiplexing addresses and data bits on the same pins is supported for synchronous/asynchronous accesses to x8/x16 data width memory devices.

For more information about the pins that drive data/address in 8/16 non-muxed mode and 16 muxed mode, see the following table.

9.7.1.2.4 Burst Clock Mode

The controller has the ability to support burst synchronous operations in various frequencies, depending on the frequency of the input clock supplied by the system (EIM clock).

The EIM clock can be divided by one, two, three or four, and its frequency can be changed according to the requirements. Variable and fix latency are supported for this mode, according to the external device requirements.

- Synchronous read mode. This is a burst mode, which is used for reading from Flash/ PSRAM memory devices. In this mode, after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK being generated

by EIM. An access is delayed according to external WAIT_B signal assertion (signal from the memory device).

- Synchronous write mode. A burst mode used for accessing external devices, which support synchronous write type of access (PSRAM protocol). In this mode, after address assertion a burst of sequential data can be written to the external device. Access may be delayed according to WAIT_B signal assertion (signal from the memory device) before first piece of data arrived to the external device.

NOTE

Maximum frequency of the EIM main clock is 133 Mhz. It may be reduced by the system for special cases of external devices, which demand a different frequency then integer division of the 133 MHz clock.

9.7.1.2.5 Low Power Modes

The input clock is gated by ACT_CS bits. When all the ACT_CS are negated (all CS disable) the internal clock is turned off; awready/wready & arready signal are de-asserted and the master can't access the EIM.

9.7.1.2.6 Boot Mode

It is possible to perform a boot operation from external device located on CS0. The configuration of the relevant bits are done with boot mode signals according to the external device parameters (for example, port size and protocol assertion).

See for more details.

9.7.2 External Signals

The following table describes the external signals of EIM:

Table 9-25. EIM External Signals

Signal	Description	Pad	Mode	Direction
EIM_ACLK_FREERUN	AXI clock signal	LCD1_DATA17	ALT4	I
EIM_AD00	LSB multiplexed Address/Data Bus signal	EPDC1_DATA00	ALT4	IO
EIM_AD01	LSB multiplexed Address/Data Bus signal	EPDC1_DATA01	ALT4	IO
EIM_AD02	LSB multiplexed Address/Data Bus signal	EPDC1_DATA02	ALT4	IO

Table continues on the next page...

Table 9-25. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
EIM_AD03	LSB multiplexed Address/Data Bus signal	EPDC1_DATA03	ALT4	IO
EIM_AD04	LSB multiplexed Address/Data Bus signal	EPDC1_DATA04	ALT4	IO
EIM_AD05	LSB multiplexed Address/Data Bus signal	EPDC1_DATA05	ALT4	IO
EIM_AD06	LSB multiplexed Address/Data Bus signal	EPDC1_DATA06	ALT4	IO
EIM_AD07	LSB multiplexed Address/Data Bus signal	EPDC1_DATA07	ALT4	IO
EIM_AD08	LSB multiplexed Address/Data Bus signal	EPDC1_BDR1	ALT4	IO
EIM_AD09	LSB multiplexed Address/Data Bus signal	EPDC1_PWRCOM	ALT4	IO
EIM_AD10	LSB multiplexed Address/Data Bus signal	EPDC1_SDCLK	ALT4	IO
EIM_AD11	LSB multiplexed Address/Data Bus signal	EPDC1_SDLE	ALT4	IO
EIM_AD12	LSB multiplexed Address/Data Bus signal	EPDC1_SDOE	ALT4	IO
EIM_AD13	LSB multiplexed Address/Data Bus signal	EPDC1_SDSHR	ALT4	IO
EIM_AD14	LSB multiplexed Address/Data Bus signal	EPDC1_SDCE0	ALT4	IO
EIM_AD15	LSB multiplexed Address/Data Bus signal	EPDC1_SDCE1	ALT4	IO
EIM_ADDR16	MSB Address Bus signal	EPDC1_SDCE2	ALT4	O
EIM_ADDR17	MSB Address Bus signal	EPDC1_SDCE3	ALT4	O
EIM_ADDR18	MSB Address Bus signal	EPDC1_GDCLK	ALT4	O
EIM_ADDR19	MSB Address Bus signal	EPDC1_GDOE	ALT4	O
EIM_ADDR20	MSB Address Bus signal	EPDC1_GDRL	ALT4	O
EIM_ADDR21	MSB Address Bus signal	EPDC1_GDSP	ALT4	O
EIM_ADDR22	MSB Address Bus signal	EPDC1_BDR0	ALT4	O
EIM_ADDR23	MSB Address Bus signal	LCD1_DATA20	ALT4	O

EIM_ADDR25	MSB Address Bus signal	LCD1_DATA22	ALT4	O
EIM_ADDR26	MSB Address Bus signal	LCD1_DATA23	ALT4	O
EIM_BCLK	Burst Clock (BCLK). This active-high output signal is used to clock external burstcapable devices to synchronize the loading and incrementing of addresses and delivery of burst read and write data to/from the EIM. Its behavior is affected by the BCM field in the	EPDC1_DATA11	ALT4	O

Table continues on the next page...

Table 9-25. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
	EIM_WCR and the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1.			
EIM_CRE	Used as CRE/PS for CellularRam memory. It is used for the Mode Register Set command. This signal can be configured as active low or active high. See CRE and CREP field descriptions of the EIM_CSxGCR1 registers.	LCD1_DATA16	ALT4	O
EIM_CS0	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.	EPDC1_DATA10	ALT4	O
EIM_CS1	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.	EPDC1_DATA15	ALT4	O
EIM_CS2	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.	LCD1_DATA18	ALT4	O
EIM_CS3	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.	LCD1_DATA19	ALT4	O
EIM_DATA00	MSB Data Bus signal	LCD1_DATA00	ALT4	IO
EIM_DATA01	MSB Data Bus signal	LCD1_DATA01	ALT4	IO
EIM_DATA02	MSB Data Bus signal	LCD1_DATA02	ALT4	IO
EIM_DATA03	MSB Data Bus signal	LCD1_DATA03	ALT4	IO
EIM_DATA04	MSB Data Bus signal	LCD1_DATA04	ALT4	IO
EIM_DATA05	MSB Data Bus signal	LCD1_DATA05	ALT4	IO
EIM_DATA06	MSB Data Bus signal	LCD1_DATA06	ALT4	IO
EIM_DATA07	MSB Data Bus signal	LCD1_DATA07	ALT4	IO
EIM_DATA08	MSB Data Bus signal	LCD1_DATA08	ALT4	IO
EIM_DATA09	MSB Data Bus signal	LCD1_DATA09	ALT4	IO
EIM_DATA10	MSB Data Bus signal	LCD1_DATA10	ALT4	IO
EIM_DATA11	MSB Data Bus signal	LCD1_DATA11	ALT4	IO
EIM_DATA12	MSB Data Bus signal	LCD1_DATA12	ALT4	IO
EIM_DATA13	MSB Data Bus signal	LCD1_DATA13	ALT4	IO

Table continues on the next page...

Table 9-25. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
EIM_DATA14	MSB Data Bus signal	LCD1_DATA14	ALT4	IO
EIM_DATA15	MSB Data Bus signal	LCD1_DATA15	ALT4	IO
EIM_DTACK_B	Data Acknowledge, asynchronous access. This input is used as a data acknowledge signal for single asynchronous accesses.	LCD1_RESET	ALT4	I
EIM_EB0	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[0] corresponds to DATA_OUT[7:0] For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.	EPDC1_DATA14	ALT4	O
EIM_EB1	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[1] corresponds to DATA_OUT[15:8] For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.	EPDC1_PWRSTAT	ALT4	O
EIM_LBA_B	Address Valid. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of LBA indicates that a valid address is present on the address bus. Its behavior is affected by the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1 registers, the RADVA and RADVN fields of the EIM_CSxRCR1 registers, and the WADVA and WADVN fields of the EIM_CSxWCR1 registers. In asynchronous mode, LBA length is affected by the RADVA, WADVA,	EPDC1_DATA12	ALT4	O

Table continues on the next page...

Table 9-25. EIM External Signals (continued)

Signal	Description	Pad	Mode	Direction
	RADVN, and WADVN fields. Minimum length of LBA signal in all modes is one EIM clock cycle.			
EIM_OE	Output Enable. This active-low output signal indicates the bus access is a read and enables external devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN bit fields in the Chip Select Configuration Registers.	EPDC1_DATA08	ALT4	O
EIM_RW	Memory Write Enable. This activelow output signal indicates the bus access is a write and enables external devices to sample the data bus. Its behavior is affected by the WEA and WEN bit fields in the Chip Select Configuration Registers.	EPDC1_DATA09	ALT4	O
EIM_WAIT	Ready/Busy/Wait signal. This activelow input signal is asserted by external burst capable devices which support fixed or variable latency of data. It is serviced in synchronous mode only (EIM_CSxGCR1[SWR, SRD] =1). WAIT will have a pull up resistor in pad. The signal indicates whether the External device is ready for data transaction or not. Busy cycles (or wait cycles) of the external device can occur at the start of a Burst access or at page boundary crossover. NOTE: For burst devices, WAIT output should be configured to change one cycle before data is ready (before delay). NOTE: Some External devices may not use this input signal for ready state indication (fix latency without WAIT signal monitoring). For these devices EIM should be configured accordingly (see RFL, WFL, and PSZ field descriptions). NOTE: This is same as what is shown in IP_IND_WAIT_B	EPDC1_DATA13	ALT4	I

9.7.2.1 Other Important Block I/O Signals Internal to the SoC

The following table provides a description of other signals which are internal to the i.MX 6UltraLite that are important to understand the function of EIM.

Name	I/O	Description
EIM_FB_BCLK	Input	Burst Clock Feedback. This block input is used to sample read data during high transfer speeds. The signal provides feedback from the I/O pad of the BCLK output pin and tends to align more closely with data from the external memory device.
EIM_BOOT	Input	EIM Boot Configuration. These block inputs determine the reset state of DSZ[1:0] and MUM.
ACLK	Input	AXI clock, maximum frequency 133 Mhz
IPG_CLK_S	Input	EIM module IPG clock
RST_B	Input	Active low HW reset
EIM_WARM_RESET	Input	Warm Reset. If this signal is asserted the rst_b will reset only the internal FF and state machine while S/W registers will keep their current state. This signal is active high signal.

9.7.3 Clocks

The following table describes the clock sources for EIM. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 9-26. EIM Clocks

Clock name	Clock Root	Description
aclk	aclk_eim_slow_clk_root	EIM clock (main)
aclk_slow	aclk_eim_slow_clk_root	EIM clock (slow)
ipg_clk_s	ipg_clk_root	Peripheral access clock
aclk_exsc	aclk_eim_slow_clk_root	EIM clock (external device)

- ACLK: EIM clock (main clock, AXI clock) with a Max frequency of 133 MHz. Can be gated externally when there is no active AXI access.
- ACLK_SLOW: EIM all time running ACLK. Used for flip-flops that must be active even when EIM is in low power down mode to provide clock for lpack/lpmd registers, IP registers and IP to AXI sync registers.
- IPG_CLK_S: IPG clock for IP accesses. IP registers are activated by ACLK_SLOW clock.
- ACLK_EXSC: Clock created from EIM clock for External device usage. Integer division by 1, 2, 3 and 4 of the clock can be use with BCD bit field configuration, according to external devices demands. EIM clock frequency may be reduced for lower frequency support which cannot be achieved via BCD bit field.

9.7.4 Chip Select Memory Map

The following four configurations are supported:

- CS0 (128 MB), CS1 (0 MB), CS2 (0 MB), CS3 (0 MB) [default configuration]
- CS0 (64 MB), CS1 (64 MB), CS2 (0 MB), CS3 (0 MB)
- CS0 (64 MB), CS1 (32 MB), CS2 (32 MB), CS3 (0 MB)
- CS0 (32 MB), CS1 (32 MB), CS2 (32 MB), CS3 (32 MB)

9.7.5 Functional Description

This section provides the functional description for the EIM.

9.7.5.1 Bus Sizing Configuration

The EIM supports byte, half word and word operands allowing access to x8, x16 ports. It can be address/data multiplexed in x16 ports. The port size is programmable via the DSZ bit field in the corresponding Chip Select Configuration Register. An 8-bit port can reside in each one of the bytes of the data bus.

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The EIM address bus is configured according to DSZ bit field and AUS bits.

The EIM has a data multiplexer which takes the four bytes of the AXI data bus and routes them to their required positions to properly interface to memory.

NOTE

A word access to or from a x16 port requires two external bus cycles to complete the transfer.

A word access to or from a x8 port requires four external bus cycles to complete the transfer.

9.7.5.1.1 8 BIT PORT SUPPORT

EIM has limited support for mot68000 & intel 386 protocols.

9.7.5.1.1.1 MOTOROLA 68000

EIM has limited support for mot68000 protocol. Only basic read or write asynchronous operations are supported.

The following operations are not supported:

- Read modify write

- Sync access
- All special accesses (ARM platform space, bus arbitration, bus control, bus error & reset operations)
- FC outputs

9.7.5.1.1.2 INTEL 386

EIM has limited support for intel 386 protocol. Only basic read or write async non-pipelined operations are supported.

The following operations are not supported:

- Other bus cycles (interrupt, halt & refresh)
- Bus lock
- M/IO, DC, LBA, NA, REFRESH & BS8 signals

9.7.5.2 EIM Operational Modes

Listed here are the main operational modes for EIM selected by control bit fields settings.

For details, see the bit field descriptions of SWR / SRD / MUM. All modes are supported in with 8-, 16- or 32-bit port configuration, according to DSZ bit field.

Table 9-27. EIM Operation Modes Field Settings

Control bit fields			Brief mode description
MUM	SRD	SWR	
0	0	0	Asynchronous write / Asynchronous read for APR=0 / Asynchronous page read for APR=1, none multiplexed
		1	Synchronous write/ Asynchronous read or APR=0 / Asynchronous page read for APR=1,none multiplexed
	1	0	Asynchronous write/Synchronous read none multiplexed
		1	Synchronous write/read none multiplexed
1	0	0	Asynchronous write/read multiplexed
		1	Synchronous write/ Asynchronous read multiplexed
	1	0	Asynchronous write/Synchronous read multiplexed
		1	Synchronous write/read multiplexed

9.7.5.3 Burst Mode (Synchronous) Memory Operation

This mode is enabled for read or write access. Bit SWR sets the burst mode for write operations at the corresponding chip select and bit SRD sets it for read operation.

When this mode is set, the controller attempts to translate the Master burst accesses to memory burst accesses, being limited by the memory burst length, predefined by BL value, or memory and Master WRAP/INCR boundary crossing non-matching. Only the first address accessed is put by the controller on the external address bus in a memory burst sequence.

EIM may translate from some Master sequential accesses to one or several memory bursts, but not from two Master individual accesses to one memory burst.

For the first access in a memory burst sequence, the EIM asserts $\overline{\text{ADV}}$, causing the external burst device to latch the starting burst address; then toggle the burst clock (BCLK) for a predefined number of cycles in order to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

NOTE

The BCLK signal toggles only when burst access is executed toward the external device (BCM=1'b0 for normal mode use). It runs with a 50% duty cycle until the end of access is reached. When access is terminated, BCLK stops toggling.

Memory burst accesses are terminated by the EIM whenever it detects the following:

- The specific burst length has executed completely (end of access)
- Write access - missing data in write buffer (Master is delaying the data transfer toward the EIM)
- Next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the Master and memory
- Current memory burst length reached

9.7.5.4 Burst Clock Divisor (BCD)

In some cases, it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency less than the operating frequency of the internal bus.

The internal bus frequency can be divided by one, two, three or four for presentation on the external bus in burst mode operation.

BCLK can only be set to integer divisions of the incoming clock frequency. To get a specific frequency on BCLK, configure the divider to change the incoming EIM clock accordingly.

By programming the BCD bit field to various values, two signals on the external bus are affected; $\overline{ADV}$ and BCLK. The $\overline{ADV}$ signal is asserted according to RADVA or WADVA bit fields programming, and is negated according to the formula mentioned in RADVN and WADVN bit fields description. The BCLK signal runs with a 50% duty cycle until the end of access is reached.

If BCM = 1, the BCLK runs at frequency according to GBCD bit field settings on every async memory access, regardless of the SWR and SRD bits configuration. Caution should be exercised when using BCM bit; GBCD bit field should be updated once and should not change when BCLK is toggling. The BCM bit is used mainly for system debug mode. It has no functional use of the EIM in normal mode.

9.7.5.5 Burst Clock Start (BCS)

In an effort to allow greater flexibility in achieving the minimum number of wait states on burst accesses, you can determine when you want the BCLK to start toggling after the start of access. This allows the BCLK to be skewed from point of data capture on the EIM clock by any number of EIM clock cycles.

Care must be exercised when setting BCS bit field in conjunction with the BCD and RWSC/WWSC bit fields. See the external timing diagrams in Burst (Synchronous Mode) Read Memory Accesses Timing Diagram - BCD=1 and Burst (Synchronous Mode) Read Memory Accesses Timing Diagram - BCD=0 for examples of how to use the BCS, BCD and RWSC/WWSC bit fields together.

9.7.5.6 Multiplexed Address/Data Mode Support

The control bit MUM allows support memory with multiplexed address/data bus both in asynchronous and in synchronous modes.

Caution should be exercised for using OEA/WEA & ADH bit fields. They should be configured according to the external device requirements, as it determines the time point of end of address phase and start of data phase.

9.7.5.7 Mixed Master/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different length, EIM interprets burst signal and generate additional $\overline{\text{ADV}}$ signals whenever there appear unequal address or burst boundary crossing condition.

BL bit field is used to notify EIM about current memory burst and wrap condition for properly external address generation. In case of non-matching boundaries in both the memory and Master access, EIM starts a new memory burst access by updating address from Master on address bus and generating $\overline{\text{ADV}}$ signal.

9.7.5.8 AXI (Master) Bus Cycles Support

The EIM uses an ARM AXI slave interface. It has a 32-bit bus and supports one access (one ID) at a time. No out of order or parallel accesses are supported.

The following AXI protocol signals are not supported:

- AWLOCK
- AWCACHE
- ARLOCK
- ARCACHE

ARID bus is sampled when:

- new read access is valid on the read address channel and is reflected on the RID bus output toward the master.

AWID bus is sampled when:

- new write access is valid on the write address channel and is reflected on the WID/BID bus output toward the master.

ARPROT and AWPROT signal are partially used. ARPROT[0] and AWPROT[0] bits are used for normal/privileged access detection. ARPROT[2:1] and AWPROT[2:1] are not used.

When sampling a valid access on both of the address channels, the read access will be performed first while write access is pending. After last data transfer completed, the pending write will be executed.

A new access may be executed one cycle after sampling a valid access on the read or write address channels, assuming there is no current access (back to back) which can cause a recovery or end of access penalty cycles, for write access, also assuming data is in write buffer for fast execution.

NOTE

- Only 32-bit word size accesses are supported for burst mode accesses.
- Only 8-bit (1 byte), 16-bit (2 byte) and 32-bit (4 byte) word size supported for single access.
- Maximum number of burst length is 16.
- According to AXI protocol, burst access should not cross 4 KB blocks. In case EIM gets an access that crosses the 4 KB, memory address calculation is invalid.

AXI transfers shown in the table below are also supported. These AXI cycles will be translated into the necessary cycles on the memory side. For example, for optimal operation in case ARM cache is configured to 8 beat burst with wrap, a synchronous flash and cellular RAM memory should be configured in 16 word wrap burst mode when using a 16-bit data port, and in 8 word wrap burst mode when using a 32-bit data port. EIM uses BL bit field to support different memory configurations. The controller splits the transaction when needed in some cases. See Table 9-29.

Table 9-28. AXI Burst Cycles Supported

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
1	1	INCR	Single transfer
1	2	INCR	Single transfer
1	4	INCR	Single transfer
2	4	WRAP	2-beat wrapping burst
4	4	WRAP	4-beat wrapping burst
8	4	WRAP	8-beat wrapping burst
16	4	WRAP	16-beat wrapping burst
2	4	INCR	2-beat incrementing burst
3	4	INCR	3-beat incrementing burst
4	4	INCR	4-beat incrementing burst
5	4	INCR	5-beat incrementing burst
6	4	INCR	6-beat incrementing burst
7	4	INCR	7-beat incrementing burst
8	4	INCR	8-beat incrementing burst
9	4	INCR	9-beat incrementing burst
10	4	INCR	10-beat incrementing burst
11	4	INCR	11-beat incrementing burst
12	4	INCR	12-beat incrementing burst
13	4	INCR	13-beat incrementing burst
14	4	INCR	14-beat incrementing burst

Table continues on the next page...

Table 9-28. AXI Burst Cycles Supported (continued)

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
15	4	INCR	15-beat incrementing burst
16	4	INCR	16-beat incrementing burst

Aligned Addr.	Cont.	1	1	1
WRAP8 Unaligned Addr.	WRAP16	2 or 3	1	2
	Cont.	2	2	2

9.7.5.9 WAIT_B Signal, RWSC and WWSC bit fields Usage

Most of the external devices supporting burst mode for write or read accesses provide a signal which indicates data is valid on the memory bus (a.k.a. handshake mode). For this mode, RFL and WFL bits should be cleared and RWSC/ WWSC bit fields indicate when the controller should start sampling this signal from the external device or, in other words, how many BCLK cycles should be masked.

For devices which do not use this signal or have a fixed latency ability, the RFL and WFL bits may be set for internal calculation regarding BCLK cycles penalty until data is valid (memory initial access time). For this mode, RWSC/ WWSC indicates when the data is ready for sampling by the controller (read access) or the external device (write

access). There is separation between read and write accesses wait-state control. For read access, RWSC bit field is valid and WWSC bit field is ignored; for write access, WWSC is valid and RWSC is ignored.

9.7.5.10 IPS Register Interface

Access to the registers of the EIM, read or write, is made with IPS protocol signals. The system should avoid changing the registers while master/memory transaction is valid, as this can cause an unknown behavior of the controller.

Register access size is 32-bit as the register size definition, other size of access (byte or half word) is not supported.

9.7.5.11 MRS Set for PSRAM

Memory registers of PSRAM devices can be configured according to external signal, which indicates whether the access is to a memory array or memory register domain.

When the CRE bit is set, the following transactions to the external device will assert the CRE signal. The polarity of this signal is determined by the CREP bit for active low or active high assertion of the signal.

9.7.5.12 EIM Access Termination

EIM is monitoring the corresponding CSx control signal every time variable latency access or dtack access is performed toward the external device.

In variable latency accesses, the Watchdog Timer (WDOG-1) counts BCLK cycles. If it reaches the wdog_limit (according to the WDOG_LIMIT bit field in the WCR) before the device signals can drive/sample new data, the controller will terminate the access and generate an error response transfer toward the Master.

In dtack access, WDOG-1 counts ACLK cycles instead of BCLK and it reaches the wdog_limit before the device asserts the dtack signal, the controller will terminate the access and generate an error response transfer toward the Master.

WDOG-1 can by disabled by WDOG_EN bit in the WCR.

9.7.5.13 Error Conditions

The following conditions cause an error (AXI error or IPS error) response signal:

- AXI errors
  - Access to a disabled chip select - access to a mapped chip select address space where the CSEN bit in the corresponding chip select Configuration Register is clear
  - Access to a non mapped address - access to an address that is not mapped to any CS.
  - User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select Configuration Register is set)
  - User access in fixed mode access
  - User performs write access to write protected chip select
  - First write data ID and write address ID do not match. (No data is written to the memory.)
  - First Write Data ID and write address ID match but one or more of the other Write data IDs does not match the First Write data ID (data is written to memory according)
  - Access duration to external device from CSx signal assertion is 128/256/512/1024 cycles (access is terminated by the controller) - This error can be disabled be software.
- IPS errors
  - User read or write access to a reserved/non-valid address in the EIM Configuration Register

9.7.5.14 DTACK Mode

In DTACK mode, the EIM uses DTACK signal as an indication of when to end the access.

DTACK is an asynchronous edge/level sensitive signal. DTACK polarity is configurable by the DAP bit in CsxGCR2 (default value is 0).

In this case, EIM begins the access and after a few cycles (according DAPS field) and waits until DTACK (after synchronization) becomes asserted, then samples the data in read access and completes the current data access (see Figure 9-69, Figure 9-70 & Figure 9-71).

If more than one data is needed, CS will be negated between access (CSREC field is not zero) and the AXI burst access will be split into single accesses (see Figure 9-73).

9.7.5.15 EIM_GRANT / EIM_BUSY Handshake Description

Prior to executing command to one of the external device (chip select), EIM assert EIM_BUSY signal (1'b1) and checks the EIM_GRANT signal status.

If EIM_GRANT signal is high, it indicates external data bus is not used by other slaves (NAND Flash Controller) and EIM may start to execute the access. If EIM_GRANT is low, EIM waits until it is set (1'b1) before executing the access.

EIM keeps EIM_BUSY signal set until it completes the access toward the external device.

Once EIM_GRANT signal is set, it can not be reset until EIM_BUSY signal is cleared by EIM.

NOTE

In 16-bit Muxed EIM doesn't use the data bus, therefore there is no sharing of the data bus with NFC. EIM doesn't wait for EIM_GRANT signal from NFC and doesn't assert the EIM_BUSY signal.

9.7.5.16 LPMD / LPACK Handshake Description

These signals are used for frequency and/or voltage change, and for entering low power mode during normal operation of the EIM. Before any change can take place, the controller and all the relevant external devices should be in idle state, which means no access or data transfer is in process.

LPMD input signal is asserted once EIM detects the assertion of LPMD, all ready signals of the AXI channels are negated, and EIM is not sampling new accesses. It finishes all the ongoing accesses and already pending ones. When EIM is in idle state, the LPACK output signal is asserted. EIM will stay in idle state and the LPACK signal will stay asserted until the LPMD signal is negated.

9.7.5.17 Endianness

Big and Little endianness are supported by the controller according to the following table.

Table 9-30. EIM Out/in Data in Case AXI Out/in Data is 0xB3B2B1B0

Endian mode	AXI access	AXI address [1:0]	Port size and used bits

9.7.5.18 Strobe Signal Use

The strobe signal is toggling according to address/data valid condition on the external bus for read and write accesses, and for both synchronous and asynchronous modes.

At any time point when address/data is valid on the external bus, the strobe signal will generate a positive edge, which can be used to sample the external data and control signal.

NOTE

Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

9.7.6 Initialization Information

9.7.6.1 Booting from EIM

EIM is ready to work with CS0 after the hardware reset, but it has been configured for very slow access (for boot purposes), with additional setup and hold time.

Other CSs are disabled by hardware reset. Therefore, all CSs must be properly initialized before use in writing values to the corresponding chip select configuration registers.

DSZ[1:0] and MUM fields are set according to EIM_BOOT [2:0] block inputs.

9.7.7 Typical Application

Application note uses following functions to illustrate EIM and memory accesses:

- WR16(address, data) is a 16 bit write access
- WR32(address, data) is a 32 bit write access
- RD16(address, data) is a 16 bit read access
- RD32(address, data) is a 32 bit read access
- WR_I(address, data, delta, counter) is a write data sequence, there data(i+1) = data(i) + delta
- COMMAND_SEQUENCE
- CHECK_STATUS

NOTE

COMMAND_SEQUENCE and CHECK_STATUS are described in AMD Flash Utility, Intel Sibley Flash Utility, MDOC Device Utility, Samsung OneNAND Utility, and Spansion Flash Utility.

All addresses are byte addresses. "CS0" is a Chip Select 0 base address. "EIM_" is a prefix of EIM's registers. 'h is a prefix of hexadecimal constant. "//" is a comment beginning. csba[cs] is a dimension of CS base addresses. "addr" means an address offset in current CS address space. Examples use CS0 address space, but it may apply to any CS except for boot mode functionality.

Configuration examples were verfied with the memory models listed below and may require some adjustments for other family members.

9.7.7.1 Access to Intel Sibley Flash

The following configurations are intended to Sibley family muxed and non-muxed devices.

9.7.7.1.1 Intel Sibley Flash Asynchronous Mode Configuration

- WR32('EIM_CS0GCR1,'h00210081);
- WR32('EIM_CS0RCR1,'h0e020000);
- WR32('EIM_CS0RCR2,'h00000000);
- WR32('EIM_CS0WCR1,'h0704a040);

9.7.7.1.2 Intel Sibley Flash Synchronous Mode Configuration

Configuration used for 133 MHz synchronous access to flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h5903<<1),'h0060);
     WR16('CS0+('h5903<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h50214225);                    // 133 MHz
     WR32('EIM_CS0RCR1,'h0c000000);                    // 12 cycles on memory
```

Configuration used for 66 MHz synchronous access to muxed flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h3103<<1),'h0060);
     WR16('CS0+('h3103<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
//-------------------------------------------------------------------------
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h5021122d);                    // 66 MHz
     WR32('EIM_CS0RCR1,'h07000000);                    // 7cycles on memory
```

9.7.7.1.3 Intel Sibley Flash Utility

```
// Single data word programming to addr
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     WR16('CS0+addr, 'h0041);
     WR16('CS0+addr, data);
     WR16('CS0+caddr, 'h0070);                 // Read Status command
     while('CS0+data[7] == 0)                              // Wait / Polling
         RD16('CS0+addr, data);              // Read status
     RD16('CS0+addr, data);                  // Read status
     WR16('CS0+'h0000,'h00ff);
// Write buffer programming
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     data    = 0;
```

```
WR16('CS0+addr, 'h0070);                // Read Status command
while(data[7] == 0)                           // Wait
    RD16('CS0+addr, data);              // Read status
WR16('CS0+'h0000,'h00ff);
WR16('CS0+addr,'h00e9);             // Write Buffer command
WR16('CS0+addr,255);                // Word counter (<256)
for(i=0; i<'h200; i = i + 'h40)
   WR_I('CS0+addr+i, data+((i>2)*'h0010_0001), 'h0010_0001, 16); // Data
WR16('CS0+addr,'h00d0);             // Write Confirm command
data  = 0;
while(data[7] == 0)                          // Wait
   RD16('CS0+addr, data);           // Read status
RD16('CS0+addr, data);              // Read status
WR16('CS0+'h0000,'h00ff);
```

9.7.7.2 Access to MDOC Device

The following configurations are intended to MDOC H3 device.

9.7.7.2.1 MDOC Device Boot

To boot from the MDOC device the ERRST bit should be configured to 1, so that EIM will hold the first read access to CS0 until the MDOC asserts the RDY signal.

9.7.7.2.2 MDOC Device Asynchronous Mode Configuration

```
// Non-muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
// Muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
```

9.7.7.2.3 MDOC Device Utility

```
// Read Manufacturer ID and Device ID
    RE16('CS0+'h9400,'h4833);
    RE16('CS0+'h9422,'hb7cc);
```

9.7.7.3 Access to Micron PSRAM

The following configurations are intended to mt45w4mw16bfb_706.

9.7.7.3.1 Micron PSRAM Asynchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0RCR1,'h0b010000);
```

```
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0b040040);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h403304b1);
    WR32('EIM_CS0RCR1,'h0f010000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0f040040);
```

9.7.7.3.2 Micron PSRAM Synchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0WCR1,'h0b040000);
    WR16('CS0+('h85947<<1),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4021_5487);// fixed latency memory wrap 4
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h6003_04f1);
    WR32('EIM_CS0WCR1,'h0b04_0000);
    WR32('CS0+('h85947<<2),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4003_1487); // var latency memory inc. page size 128
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
```

9.7.7.4 Access to Samsung OneNAND

Mentioned below are the configurations intended for Samsung OneNAND muxed and non-muxed devices.

9.7.7.4.1 Samsung OneNAND Boot

There are two ways to boot from Samsung OneNAND. In the first way, the ERRST bit is set to 0 and the user has to poll the interrupt status in the OneNAND interrupt register (or set interrupt handler there). In the second way, the ERRST bit is set to 1 and the user should enable the device interrupt output before the first read from CS0 access is issued.

Load sectors 2,3 to DataRAM, page 0 done in the next example:

- WR16('CS0+('hF241<<1),'h0); // Clear interrupt status
- WR16('CS0+('hF100<<1),'h0); // block[8:0] address
- WR16('CS0+('hF107<<1),'h2); // sector[1:0] and page[7:2] addresses
- WR16('CS0+('hF200<<1),'h802); // buffer[11:8] address and counter[1:0]
- WR16('CS0+('hF101<<1),'h0); // DDP choose
- WR16('CS0+('hF220<<1),'h0); // Set command

9.7.7.4.2 Samsung OneNAND Asynchronous Mode Configuration

```
// Non-muxed memory
    WR32('EIM_CS0GCR1,'h00410081);
```

```
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
// Muxed memory
    WR32('EIM_CS0GCR1,'h00410089);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
```

9.7.7.4.3 Samsung OneNAND Synchronous Mode Configuration

Set memory and EIM to synchronous read mode is shown in the next example:

```
    WR16('CS0+('hF221<<1),'hc0e0); // Synchronous read, 4 clk latency
    WR32('EIM_CS0GCR1,'h50412405); // 44 MHz (non-muxed)
    WR32('EIM_CS0RCR1,'h05010000);
```

The muxed Samsung OneNAND supports synchronous write, too:

```
// Set memory & EIM to synchronous read and write mode
    WR16('CS0+('hF221<<1),'hc0f2); // Sync. read and write, 4 clk latency
    WR32('EIM_CS0GCR1,'h5041240f); // 44 MHz
    WR32('EIM_CS0RCR1,'h05010000);
    WR32('EIM_CS0WCR1,'h05040000);
```

9.7.7.4.4 Samsung OneNAND Utility

The following utility algorithms are used on the Samsung OneNAND:

```
// Unlock Block command
    WR16('CS0+('hF100<<1),'h0);        // DFS
    WR16('CS0+('hF100<<1),'h0);        // DBS
    WR16('CS0+('hF24c<<1),'h2);        // SBA - block number (2)
    WR16('CS0+('hF241<<1),'h0);        // Clear interrupt status
    WR16('CS0+('hF220<<1),'h23);       // Unlock command
    data ='h0;
    while(!(data &'h0004))             // Polling
       RD32('WIAR, data); // Read status
// Erase block command
    WR16('CS0+('hF100<<1),'h2);        // DFS and block ([8:0]) address
    WR16('CS0+('hF101<<1),'h0);        // DBS
    WR16('CS0+('hF241<<1),'h0);        // Clear interrupt status
            WR16('CS0+('hF220<<1),'h94);           // Erase command
    data ='h0;
    while(!(data &'h0004))                  // Wait
        RD32('WIAR, data); // Read status
// Program page command
    WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
    WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
    WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
    WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
    WR16('CS0+('hF220<<1),'h80);            // Program command
    data ='h0;
    while(!(data &'h0004))                  // Wait
        RD32('WIAR, data); // Read status
```

9.7.7.5 Access to Samsung UtRAM

Below mentioned configurations are intended for Samsung UtRAM.

9.7.7.5.1 Samsung UtRAM Asynchronous Mode Configuration

```
WR32('EIM_CS0GCR1,'h400104b1);
WR32('EIM_CS0RCR1,'h0a010000);
WR32('EIM_CS0RCR2,'h00000008);
WR32('EIM_CS0WCR1,'h0b040040);
```

9.7.7.5.2 Samsung UtRAM Synchronous Mode Configuration

```
RD16('CS0+('hff_ffff<<1),data);             // command sequence
RD16('CS0+('hff_ffff<<1),data);
RD16('CS0+('hff_ffff<<1),data);
RD16('CS0+('hff_feff<<1),data);
RD16('CS0+('h00_82a0<<1),data);             // memory sync. configuration
WR32('EIM_CS0GCR1,'h4021_53b7);            // fixed latency memory wrap 32
WR32('EIM_CS0RCR1,'h0500_0000);
WR32('EIM_CS0WCR1,'h0300_0000);
```

9.7.7.6 Access to Spansion Flash

Below mentioned configurations are intended for Spansion Flash.

9.7.7.6.1 Spansion Flash Asynchronous Mode Configuration

```
          WR32('EIM_CS0GCR1,'h00410081);
          WR32('EIM_CS0RCR1,'h0a018000);
          WR32('EIM_CS0RCR2,'h00000000);
          WR32('EIM_CS0WCR1,'h0704a240);
WR16('CS0+('hF220<<1),'h94);            // Erase command
          data ='h0;
          while(!(data &'h0004))                    // Wait
              RD32('WIAR, data); // Read status
     // Program page command
          WR16('CS0+('hF100<<1),'h2);               // DFS and block[8:0] address
          WR16('CS0+('hF107<<1),'h0);               // sector[1:0] and page[7:2] addresses
          WR16('CS0+('hF200<<1),'h800);             // buffer[11:8] address and counter[1:0]
          WR16('CS0+('hF241<<1),'h0);               // Clear interrupt status
          WR16('CS0+('hF220<<1),'h80);              // Program command
          data ='h0;
          while(!(data &'h0004))                    // Wait
              RD32('WIAR, data); // Read status
```

9.7.7.6.2 Spansion Flash Synchronous Mode Configuration

```
          WR16('CS0+('h0555<<1),'h00aa);   // command sequence
          WR16('CS0+('h02aa<<1),'h0055);
          WR16('CS0+('h0555<<1),'hd0);
          WR16('CS0+('h0000<<1),'h1ec4);   // memory sync. configuration
          WR32('EIM_CS0GCR1,'h50411325); // 66 MHz
          WR32('EIM_CS0RCR1,'h05000000); // 5 cycles on memory
```

9.7.7.6.3 Spansion Flash Utility

```
      // Single word programming
          COMMAND_SEQUENCE(cs,16,'ha0);           // single word programming
```

```
            WR16('CS0+addr, data);
            CHECK_STATUS('CS0+addr,data,16,1,errst);
        // Write buffer programming
            COMMAND_SEQUENCE(0,16,'h25);              // write buffer programming
            WR16('CS0+addr,'h001f);                     // counter-1
            WR_I('CS0+addr, data, 'h0010_0001, 16); // data
            WR16('CS0+addr,'h0029);                     // write buffer to flash
            CHECK_STATUS('CS0+addr+'h3e,data[31:16]+'h00f0,16,1,errst);
```

There COMMAND_SEQUENCE and CHECK_STATUS are next functions:

```
        task COMMAND_SEQUENCE;
            input[2:0]    cs;
            input[7:0]    port_size;
            input[31:0]   code;
        begin
            if(port_size == 16)
               begin
               WR16(csba[cs]+('h0555<<1),'h00aa);
               WR16(csba[cs]+('h02aa<<1),'h0055);
               WR16(csba[cs]+('h0555<<1),code);
               end
            else
               begin
               WR32(csba[cs]+('h0555<<2),'h00aa);
               WR32(csba[cs]+('h02aa<<2),'h0055);
               WR32(csba[cs]+('h0555<<2),code);
               end
        end
        endtask
        task     CHECK_STATUS;
            input[31:0] addr;
            input[31:0] edata;
            input[7:0]   port_size;
            input[7:0]   opcode;
            output[7:0] errst;
            reg[31:0]    data;
            reg[31:0]    data3;
        begin
            errst = 0;
            data  = 0;
            data3 = 0;
while(!(data == edata) && !errst) // Wait operation
          begin: BR_EN
          RD16(addr, data);             // Read status
          if(data[7] !== edata[7])
              begin
              if(data[5] == 1)
                   begin

9.7.7.7 8 bit support

This section details the pin connections for Intel mode and Motorola mode.

Intel Mode - For intel mode use the following connection:

Table 9-31. Intel Mode pin connections

ARM platform Pin	EIM Pin	Notes
ADS#	IPP_DO_ADV_B	WAL = 1,RAL = 1
W/R	IPP_DO_BE_B	WBED = 1
WR#	WE#	
RD#	OE#	

Mot. Mode - For intel mode use the following connection:

Table 9-32. Motorola Mode pin connections

ARM platform Pin	EIM Pin	Notes
AS#	IPP_DO_CS_B	
R/W#	WE#	
LDS#	BE#	

9.7.8 External Bus Timing Diagrams

The following timing diagrams show the timing of accesses to memory or a peripheral with different timing parameters. All examples done for CS0, but are valid for any others chip select. BE means one from current used BE[3:0].

9.7.9 EIM Memory Map/Register Definition

The EIM includes 33 user-accessible 32-bit registers. The the EIM Configuration Register (EIM_WCR) contains control bits that configure the EIM for certain operation modes.

The 160 bits used to control Individual Chip Select are divided into five registers:

- Chip Select n General Configuration Register 1 (EIM_CSnGCR1)
- Chip Select n General Configuration Register 2 (EIM_CSnGCR2)
- Chip Select n Read Configuration Register 1 (EIM_CSnRCR1)
- Chip Select n Read Configuration Register 2 (EIM_CSnRCR2)
- Chip Select n Write Configuration Register (EIM_CSnWCR)

In addition there are 3 general registers: EIM_WCR, EIM_WIAR & EIM_EAR.

NOTE

- All EIM registers are sampled by IPG_CLK_S, therefore IPG_CLK_S must be active when accessing through IP bus.
- Read access from all registers (except EIM_WIAR & EIM_EAR) will generate one IPG_XFR_WAIT cycle.
- Read access from EIM_WIAR & EIM_EAR will generate six IPG_XFR_WAIT cycles.
- Write access to all registers (except EIM_EAR) will generate three IPG_XFR_WAIT cycles.
- Write access to EIM_EAR will generate six IPG_XFR_WAIT cycles.

EIM_CS*n*GCR1 field descriptions

Field	Description
31–28 PSZ	Page Size. This bit field indicates memory page size in words (word is defined by the DSZ field). PSZ is used when fix latency mode is applied, WFL=1 for sync. write accesses, RFL=1 for sync. Read accesses. When working in fix latency mode WAIT signal from the external device is not being monitored, PSZ is used to determine if page boundary is reached and renewal of access is preformed. This bit field is ignored when sync. Mode is disabled or fix latency mode is not being used for write or read access separately. It can be valid for both access type, read or write, or only for one type, according to configuration. PSZ is cleared by a hardware reset. 0000 8 words page size 0001 16 words page size 0010 32 words page size 0011 64 words page size 0100 128 words page size 0101 256 words page size 0110 512 words page size 0111 1024 (1k) words page size 1000 2048 (2k) words page size 1001 - 1111 Reserved
27 WP	Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset. 0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response and no assertion of the chip select output.
26–24 GBC	Gap Between Chip Selects. This bit field, according to the settings shown below, determines the minimum time between end of access to the current chip select and start of access to different chip select. GBC is cleared by a hardware reset. Example settings: 000 minimum of 0 EIM clock cycles before next access from different chip select (async. mode only) 001 minimum of 1 EIM clock cycles before next access from different chip select 010 minimum of 2 EIM clock cycles before next access from different chip select 111 minimum of 7 EIM clock cycles before next access from different chip select
23 AUS	Address UnShifted. This bit indicates an unshifted mode for address assertion for the relevant chip select accesses. AUS bit is cleared by hardware reset. 0 Address shifted according to port size (DSZ config) (128 Mbyte maximum supported memory density). 1 Address unshifted (32 Mbyte maximum supported memory density).
22–20 CSREC	CS Recovery. This bit field, according to the settings shown below, determines the minimum pulse width of CS, OE, and WE control signals before executing a new back to back access to the same chip select. CSREC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0GCR1, CSREC[2:0] is 0b110. For EIM_CS1GCR1 - EIM_CS5GCR, the reset value is 0b000. Example settings: 000 0 EIM clock cycles minimum width of CS, OE and WE signals (read async. mode only) 001 1 EIM clock cycles minimum width of CS, OE and WE signals

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	010 2 EIM clock cycles minimum width of CS, OE and WE signals 111 7 EIM clock cycles minimum width of CS, OE and WE signals
19 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in an error response and no assertion of the chip select output.
18–16 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown below. **NOTE:** Only async. access supported for 8 bit port. **NOTE:** The reset value for EIM_CS0GCR1, DSZ[2] = 0, DSZ[1:0] = EIM_BOOT[1:0]. For EIM_CS1GCR1 - EIM_CS5GCR1, the reset value is 0b001. 000 Reserved. 001 16 bit port resides on DATA[15:0] 010 16 bit port resides on DATA[31:16] 011 32 bit port resides on DATA[31:0] 100 8 bit port resides on DATA[7:0] 101 8 bit port resides on DATA[15:8] 110 8 bit port resides on DATA[23:16] 111 8 bit port resides on DATA[31:24]
15–14 BCS	Burst Clock Start. When SRD=1 or SWR=1,this bit field determines the number of EIM clock cycles delay from start of access before the first rising edge of BCLK is generated. When BCD=0 value of BCS=0 results in a half clock delay after the start of access. For other values of BCD a one clock delay after the start of access is applied, not an immediate assertion. BCS is cleared by a hardware reset. 00 0 EIM clock cycle additional delay 01 1 EIM clock cycle additional delay 10 2 EIM clock cycle additional delay 11 3 EIM clock cycle additional delay
13–12 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal EIMbus frequency. BCD is cleared by a hardware reset. **NOTE:** For other then the mentioned below frequency such as 104 MHz, EIM clock (input clock) should be adjust accordingly. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
11 WC	Write Continuous. The WI bit indicates that write access to the memory are always continuous accesses regardless of the BL field value. WI is cleared by hardware reset. 0 Write access burst length occurs according to BL value. 1 Write access burst length is continuous.
10–8 BL	Burst Length. The BL bit field indicates memory burst length in words (word is defined by the DSZ field) and should be properly initialized for mixed wrap/increment accesses support. Continuous BL value corresponds to continuous burst length setting of the external memory device. For fix memory burst size,

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	type is always wrap. In case not matching wrap boundaries in both the memory (BL field) and Master access on the current address, EIM update address on the external device address bus and regenerates the access. BL is cleared by a hardware reset. When APR=1, Page Read Mode is applied, BL determine the number of words within the read page burst. BL is cleared by a hardware reset for EIM_CS0GCR1 - EIM_CS5GCR1. 000 4 words Memory wrap burst length (read page burst size when APR = 1) 001 8 words Memory wrap burst length (read page burst size when APR = 1) 010 16 words Memory wrap burst length (read page burst size when APR = 1) 011 32 words Memory wrap burst length (read page burst size when APR = 1) 100 Continuous burst length (2 words read page burst size when APR = 1) 101 Reserved 110 Reserved 111 Reserved
7 CREP	Configuration Register Enable Polarity. This bit indicates CRE memory pin assertion state, active-low or active-high, while executing a memory register set command to the external device (PSRAM memory type). CREP is set by a hardware reset. **NOTE:** Whenever PSRAM is connected the CREP value must be correct also for accesses where CRE is disabled. For Non-PSRAM memory CREP value should be 1. 0 CRE signal is active low 1 CRE signal is active high
6 CRE	Configuration Register Enable. This bit indicates CRE memory pin state while executing a memory register set command to PSRAM external device. CRE is cleared by a hardware reset. 0 CRE signal use is disable 1 CRE signal use is enable
5 RFL	Read Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start sampling data according to RWSC field, it only valid in synchronous mode. RFL is cleared by a hardware reset. When RFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device. 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
4 WFL	Write Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start data transfer according to WWSC field, it only valid in synchronous mode. WFL is cleared by a hardware reset. When WFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
3 MUM	Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses for 8 bit, 16 bit or 32 bit devices (DSZ config. dependent).

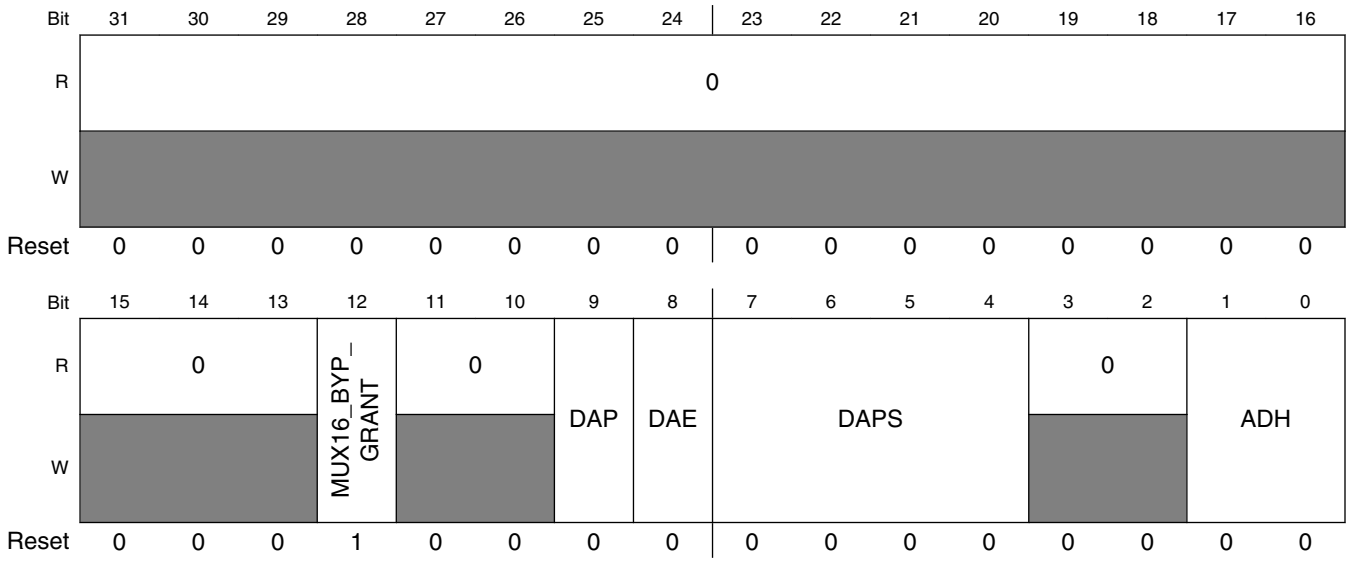
Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	NOTE: The reset value for EIM_CS0GCR1[MUM] = EIM_BOOT[2]. For EIM_CS1GCR1 - EIM_CS5GCR1 the reset value is 0. 0 Multiplexed Mode disable 1 Multiplexed Mode enable
2 SRD	Synchronous Read Data. This bit field determine the read accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SRD is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port. 0 read accesses are in Asynchronous mode 1 read accesses are in Synchronous mode
1 SWR	Synchronous Write Data. This bit field determine the write accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SWR is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port. 0 write accesses are in Asynchronous mode 1 write accesses are in Synchronous mode
0 CSEN	CS Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSGCR0 to allow external boot operation. CSEN is cleared by a hardware reset to CSGCR1-CSGCR5. **NOTE:** Reset value for EIM_CS0GCR1 for CSEN is 1. For EIM_CS1GCR1-CS1GCR5 reset value is 0. 0 Chip select function is disabled; attempts to access an address mapped by this chip select results in an error respond and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid access.

9.7.9.2 Chip Select n General Configuration Register 2 (EIM_CS*n*GCR2)

Address: 30BC_0000h base + 4h offset + (24d × i), where i=0d to 5d



EIM_CS*n*GCR2 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value 0.
12 MUX16_BYP_GRANT	Muxed 16 bypass grant. This bit when asserted causes EIM to bypass the grant/ack. arbitration with NFC (only for 16 bit muxed mode accesses). 0 EIM waits for grant before driving a 16 bit muxed mode access to the memory. 1 EIM ignores the grant signal and immediately drives a 16 bit muxed mode access to the memory.
11–10 Reserved	This read-only field is reserved and always has the value 0.
9 DAP	Data Acknowledge Polarity. This bit indicates DTACK memory pin assertion state, active-low or active-high, while executing an async access using DTACK signal from the external device. DAP is cleared by a hardware reset. 0 DTACK signal is active high 1 DTACK signal is active low
8 DAE	Data Acknowledge Enable. This bit indicates external device is using DTACK pin as strobe/terminator of an async. access. DTACK signal may be used only in asynchronous single read (APR=0) or write accesses. DTACK poling start point is set by DAPS bit field. polarity of DTACK is set by DAP bit field. DAE is cleared by a hardware reset. 0 DTACK signal use is disable 1 DTACK signal use is enable
7–4 DAPS	Data Acknowledge Poling Start. This bit field determine the starting point of DTACK input signal polling. DAPS is used only in asynchronous single read or write accesses.

Table continues on the next page...

EIM_CS*n*GCR2 field descriptions (continued)

Field	Description
	NOTE: Since DTACK is an async. signal the start point of DTACK signal polling is at least 3 cycles after the start of access. DAPS is cleared by a hardware reset. Example settings: 0000 3 EIM clk cycle between start of access and first $\overline{\text{DTACK}}$ check 0001 4 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0010 5 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0111 10 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 1011 14 EIM clk cycles between start of access and first DTACK check 1111 18 EIM clk cycles between start of access and first DTACK check
3–2 Reserved	This read-only field is reserved and always has the value 0.
ADH	Address hold time - This bit field determine the address hold time after ADV negation when mum = 1 (muxed mode). When mum = 0 this bit has no effect. For read accesses the field determines when the pads direction will be switched. **NOTE:** Reset value for EIM_CS0GCR2 for ADH is 10. For EIM_CS1GCR2-EIM_CS5GCR2 reset value is 00. 00 0 cycle after ADV negation 01 1 cycle after ADV negation 10 2 cycle after ADV negation 11 Reserved

9.7.9.3 Chip Select n Read Configuration Register 1 (EIM_CS*n*RCR1)

Address: 30BC_0000h base + 8h offset + (24d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EIM_CS*n*RCR1 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
29–24 RWSC	Read Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous read access to the external device connected to the chip select. When SRD=1 and RFL=0, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the controller can start sample data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SRD=1 and RFL=1, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SRD=0, RFL bit is ignored, RWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. RWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0RCR1, RWSC[5:0] = 0b011100. For CG1RCR1 - CS1RCR5 the reset value is 0b000000. Example settings: 000000 Reserved 000001 RWSC value is 1 000010 RWSC value is 2 111101 RWSC value is 61 111110 RWSC value is 62 111111 RWSC value is 63
23 Reserved	This read-only field is reserved and always has the value 0.
22–20 RADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous read modes according to the settings shown below. RADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
19 RAL	Read ADV Low. This bit field determine ADV signal negation time. When RAL=1, RADVN bit field is ignored and ADV signal will stay asserted until end of access. When RAL=0 negation of ADV signal is according to RADVN bit field configuration.
18–16 RADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during read accesses. When SRD=1 (synchronous read mode), ADV negation occurs according to the following formula: (RADVN + RADVA + BCD + BCS + 1) EIM clock cycles from start of access. When asynchronous read mode is applied (SRD=0) and RAL=0 ADV negation occurs according to the following formula: (RADVN + RADVA + 1) EIM clock cycles from start of access. RADVN is cleared by a hardware reset. **NOTE:** the reset value for EIM_CS0RCR1[RADVN] = 2. For EIM_CS1RCR1 - EIM_CS5RCR1, the reset value is 0b000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should RAL bit.

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
15 Reserved	This read-only field is reserved and always has the value 0.
14–12 OEA	OE Assertion. This bit field determines when OE signal are asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. OEA is cleared by a hardware reset. In muxed mode OE assertion occurs (OEA + RADVN + RADVA + ADH +1) EIM clock cycles from start of access. **NOTE:** The reset value for EIM_CS0RCR1[OEA] is 0b000 if EIM_BOOT[2] = 0. If EIM_BOOT[2] is 1, the reset value for EIM_CS0RCR1 is 0b010. The reset value of this field for EIM_CS1RCR1 - EIM_CS5RCR1 is 0b000. Example settings: 000 0 EIM clock cycles between beginning of access and OE assertion 001 1 EIM clock cycles between beginning of access and OE assertion 010 2 EIM clock cycles between beginning of access and OE assertion 111 7 EIM clock cycles between beginning of access and OE assertion
11 Reserved	This read-only field is reserved and always has the value 0.
10–8 OEN	OE Negation. This bit field determines when OE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. OEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of access and OE negation 001 1 EIM clock cycles between end of access and OE negation 010 2 EIM clock cycles between end of access and OE negation 111 7 EIM clock cycles between end of access and OE negation
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 RCSA	Read CS Assertion. This bit field determines when CS signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and CS assertion 001 1 EIM clock cycles between beginning of read access and CS assertion 010 2 EIM clock cycles between beginning of read access and CS assertion 111 7 EIM clock cycles between beginning of read access and CS assertion
3 Reserved	This read-only field is reserved and always has the value 0.
RCSN	Read CS Negation. This bit field determines when CS signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. RCSN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation

9.7.9.4 Chip Select n Read Configuration Register 2 (EIM_CS*n*RCR2)

Address: 30BC_0000h base + Ch offset + (24d × i), where i=0d to 5d

EIM_CS*n*RCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 APR	Asynchronous Page Read. This bit field determine the asynchronous read mode to the external device. When APR=0, the async. read access is done as single word (where word is defined by the DSZ field). when APR=1, the async. read access executed as page read. page size is according to BL field config., RCSN,RBEN,OEN and RADVN are being ignored. APR is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. **NOTE:** SRD=0 and MUM=0 must apply when APR=1
14–12 PAT	Page Access Time. This bit field is used in Asynchronous Page Read mode only (APR=1). the initial access is set by RWSC as in regular asynchronous mode. the consecutive address assertions width determine by PAT field according to the settings shown below. when APR=0 this field is ignored. PAT is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. 000 Address width is 2 EIM clock cycles 001 Address width is 3 EIM clock cycles 010 Address width is 4 EIM clock cycles 011 Address width is 5 EIM clock cycles 100 Address width is 6 EIM clock cycles 101 Address width is 7 EIM clock cycles 110 Address width is 8 EIM clock cycles 111 Address width is 9 EIM clock cycles
11–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 RL	Read Latency. This bit field indicates cycle latency when executing a synchronous read operation. The fields holds the feedback clock loop delay in aclk cycle units. This field is cleared by a hardware reset. 00 Feedback clock loop delay is up to 1 cycle for BCD = 0 or 1.5 cycles for BCD != 0 01 Feedback clock loop delay is up to 2 cycles for BCD = 0 or 2.5 cycles for BCD != 0 10 Feedback clock loop delay is up to 3 cycles for BCD = 0 or 3.5 cycles for BCD != 0 11 Feedback clock loop delay is up to 4 cycles for BCD = 0 or 4.5 cycles for BCD != 0

Table continues on the next page...

EIM_CS*n*RCR2 field descriptions (continued)

Field	Description
7 Reserved	This read-only field is reserved and always has the value 0.
6–4 RBEA	Read BE Assertion. This bit field determines when BE signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RBEA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and BE assertion 001 1 EIM clock cycles between beginning of read access and BE assertion 010 2 EIM clock cycles between beginning of read access and BE assertion 111 7 EIM clock cycles between beginning of read access and BE assertion
3 RBE	Read BE enable. This bit field determines if BE will be asserted during read access. 0 - BE are disabled during read access. 1- BE are enable during read access according to value of RBEA & RBEN bit fields.
RBEN	Read BE Negation. This bit field determines when BE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR=0), according to the settings shown below. This bit field is ignored when SRD=1. RBEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and BE negation 001 1 EIM clock cycles between end of read access and BE negation 010 2 EIM clock cycles between end of read access and BE negation 111 7 EIM clock cycles between end of read access and BE negation

9.7.9.5 Chip Select n Write Configuration Register 1 (EIM_CS*n*WCR1)

Address: 30BC_0000h base + 10h offset + (24d × i), where i=0d to 5d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	WAL	WBED	WWSC						WADVA			WADVN			WBEA	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WBEA	WBEN			WEA				WEN			WCSA			WCSN	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_CS*n*WCR1 field descriptions

Field	Description
31 WAL	Write ADV Low. This bit field determine ADV signal negation time in write accesses. When WAL=1, WADVN bit field is ignored and ADV signal will stay asserted until end of access. When WAL=0 negation of ADV signal is according to WADVN bit field configuration.
30 WBED	Write Byte Enable Disable. When asserted this bit prevent from IPP_DO_BE_B[x] to be asserted during write accesses.This bit is cleared by hardware reset.
29–24 WWSC	Write Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous write access to the external device connected to the chip select. When SWR=1 and WFL=0, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the memory can sample the first data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SWR=1 and WFL=1, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SWR=0, WFL bit is ignored, WWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. WWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0WCR1, WWSC[5:0] = 0b011100. For EIM_CS1WCR1 - EIM_CS5WCR1, the reset value of this field is 0b000000. Example settings: 000000 Reserved 000001 WWSC value is 1 000010 WWSC value is 2 000011 WWSC value is 3 111111 WWSC value is 63
23–21 WADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous write modes according to the settings shown below. WADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
20–18 WADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during write accesses. When SWR=1 (synchronous write mode), ADV negation occurs according to the following formula: (WADVN + WADVA + BCD + BCS + 1) EIM clock cycles. When asynchronous read mode is applied (SWR=0) ADV negation occurs according to the following formula: (WADVN + WADVA + 1) EIM clock cycles. **NOTE:** Reset value for EIM_CS0WCR for WADVN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time as the end of access, S/W should set the WAL bit.
17–15 WBEA	BE Assertion. This bit field determines when BE signal is asserted during write cycles in async. mode only (SWR=0), according to the settings shown below. BEA is cleared by a hardware reset.

Table continues on the next page...

EIM_CS*n*WCR1 field descriptions (continued)

Field	Description
	NOTE: Reset value for EIM_CS0WCR for WBEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and BE assertion 001 1 EIM clock cycles between beginning of access and BE assertion 010 2 EIM clock cycles between beginning of access and BE assertion 111 7 EIM clock cycles between beginning of access and BE assertion
14–12 WBEN	BE[3:0] Negation. This bit field determines when BE[3:0] bus signal is negated during write cycles in async. mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. BEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WBEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between end of access and WE negation 001 1 EIM clock cycles between end of access and WE negation 010 2 EIM clock cycles between end of access and WE negation 111 7 EIM clock cycles between end of access and WE negation
11–9 WEA	WE Assertion. This bit field determines when WE signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. This bit field is ignored when executing a read access to the external device. WEA is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIMclock cycles between beginning of access and WE assertion
8–6 WEN	WE Negation. This bit field determines when WE signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIM clock cycles between beginning of access and WE assertion
5–3 WCSA	Write CS Assertion. This bit field determines when CS signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below.this bit field is ignored when executing a read access to the external device. WCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of write access and CS assertion

Table continues on the next page...

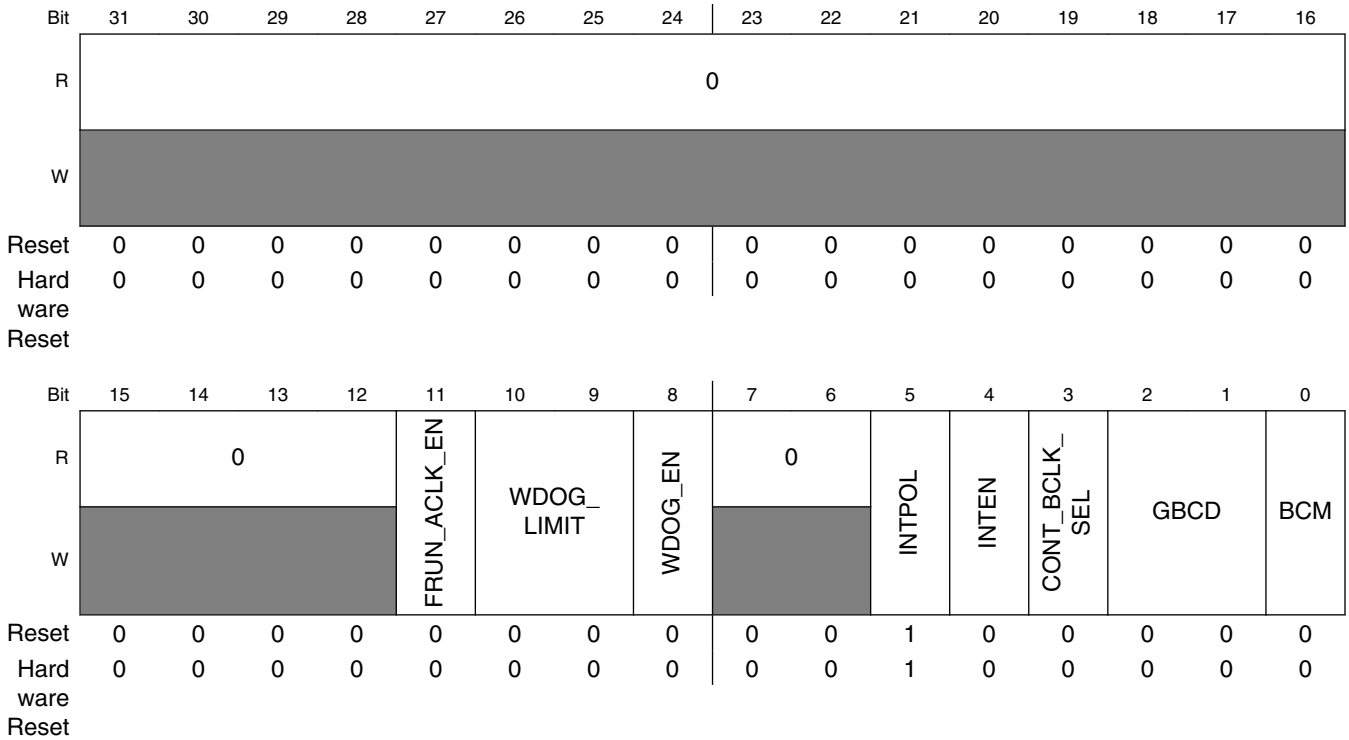
EIM_CS*n*WCR2 field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 WBCDD	Write Burst Clock Divisor Decrement. If this bit is asserted and BCD value is 0 sync. write access will be preformed as if BCD value is 1.When this bit is negated or BCD value is not 0 this bit has no affect. This bit is cleared by hardware reset.

9.7.9.7 EIM Configuration Register (EIM_WCR)

Address: 30BC_0000h base + 90h offset = 30BC_0090h



EIM_WCR field descriptions

Field	Description
31–12 Reserved	Reserved This read-only field is reserved and always has the value 0.
11 FRUN_ACLK_EN	Free run ACLK enable
10–9 WDOG_LIMIT	Memory Watchdog (WDOG) cycle limit. This bit field determines the number of BCLK cycles (ACLK cycles in dtack mode) before the WDOG counter terminates the access and send an error response to the master. 00 128 BCLK cycles 01 256 BCLK cycles 10 512 BCLK cycles 11 1024 BCLK cycles
8 WDOG_EN	Memory WDOG enable. This bit controls the operation of the wdog counter that terminates the EIM access. 0 Memory WDOG is Disabled 1 Memory WDOG is Enabled

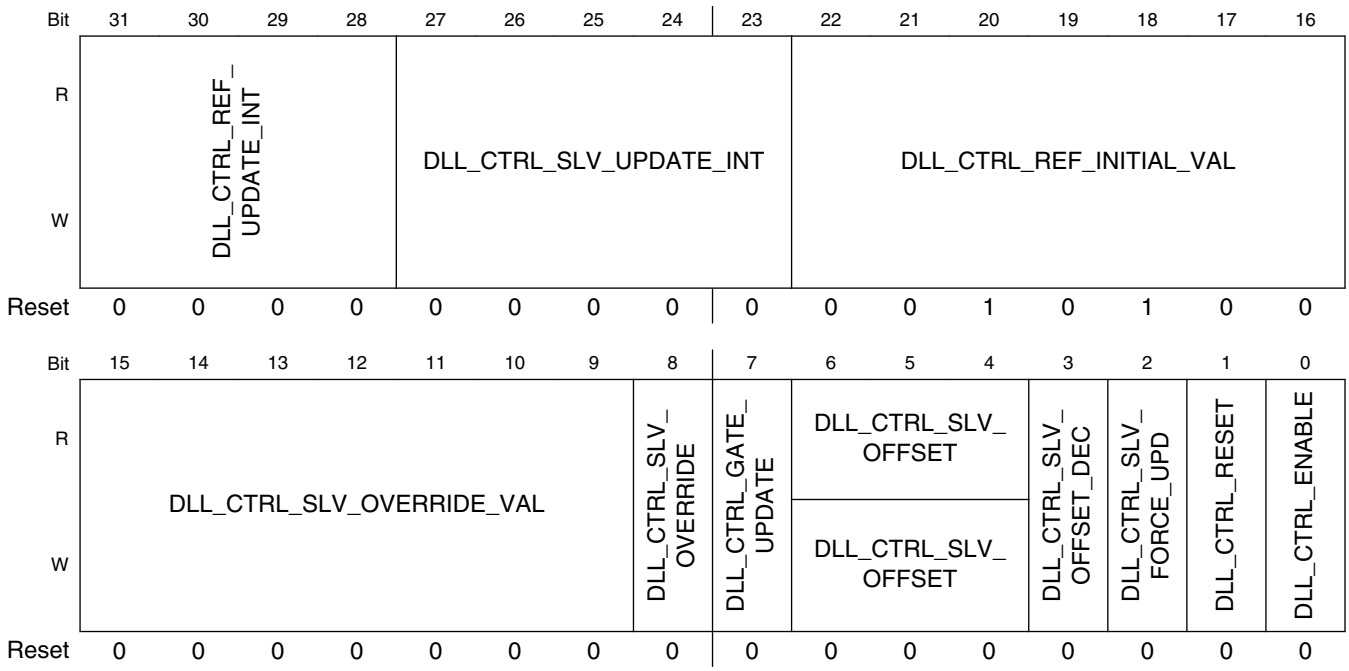
Table continues on the next page...

EIM_WCR field descriptions (continued)

Field	Description
7–6 Reserved	This read-only field is reserved and always has the value 0.
5 INTPOL	Interrupt Polarity. This bit field determines the polarity of the external device interrupt. 0 External interrupt polarity is active low 1 External interrupt polarity is active high
4 INTEN	Interrupt Enable. When this bit is set the External signal RDY_INT as active interrupt. When interrupt occurs, INT bit at the WCR will be set and t EIM_EXT_INT signal will be asserted correspondingly. This bit is cleared by a hardware reset. 0 External interrupt Disable 1 External interrupt Enable
3 CONT_BCLK_ SEL	Continuous BCLK select When this bit is set BCLK pin output continuous clock. Otherwize, BCLK will output clock only when nesserary. 0 BCLK When nesserary 1 BCLK Continuous
2–1 GBCD	General Burst Clock Divisor. When BCM bit is set, this bit field contains the value used to program the burst clock divisor for Continuous BCLK generation. The other BCD bit fields for each chip select are ignored. It is used to divide the internal AXI bus frequency. When BCM=0 GBCD bit field has no influence. GBCD is cleared by a hardware reset. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
0 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. BCM is cleared by a hardware reset. **NOTE:** The BCLK frequency in this mode is according to GBCD bit field. **NOTE:** The BCLK phase is opposite to the EIM clock in this mode if GBCD is 0. **NOTE:** This bit should be used only in async. accesses. No sync access can be executed if this bit is set. **NOTE:** When this bit is set bcd field shouldn't be configured to 0. 0 The burst clock runs only when accessing a chip select range with the SWR/SRD bits set. When the burst clock is not running it remains in a logic 0 state. When the burst clock is running it is configured by the BCD and BCS bit fields in the chip select Configuration Register. 1 The burst clock runs whenever ACLK is active (independent of chip select configuration)

9.7.9.8 DLL Control Register (EIM_DCR)

Address: 30BC_0000h base + 94h offset = 30BC_0094h



EIM_DCR field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT	Reference DLL Update Interval DLL control loop update interval. The interval cycle is (2 + REF_UPDATE_INT) * ref_clock. By default, the DLL control loop shall update every two ref_clock cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–23 DLL_CTRL_SLV_UPDATE_INT	Slave DLL Update Interval If default 0 is used, it means 256 cycles of ref_clock. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
22–16 DLL_CTRL_REF_INITIAL_VAL	This field is used to select the initial value of reference chain before DLL enabled. It's recommended to set the initial value close to the locked value to accelerate the locking.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0

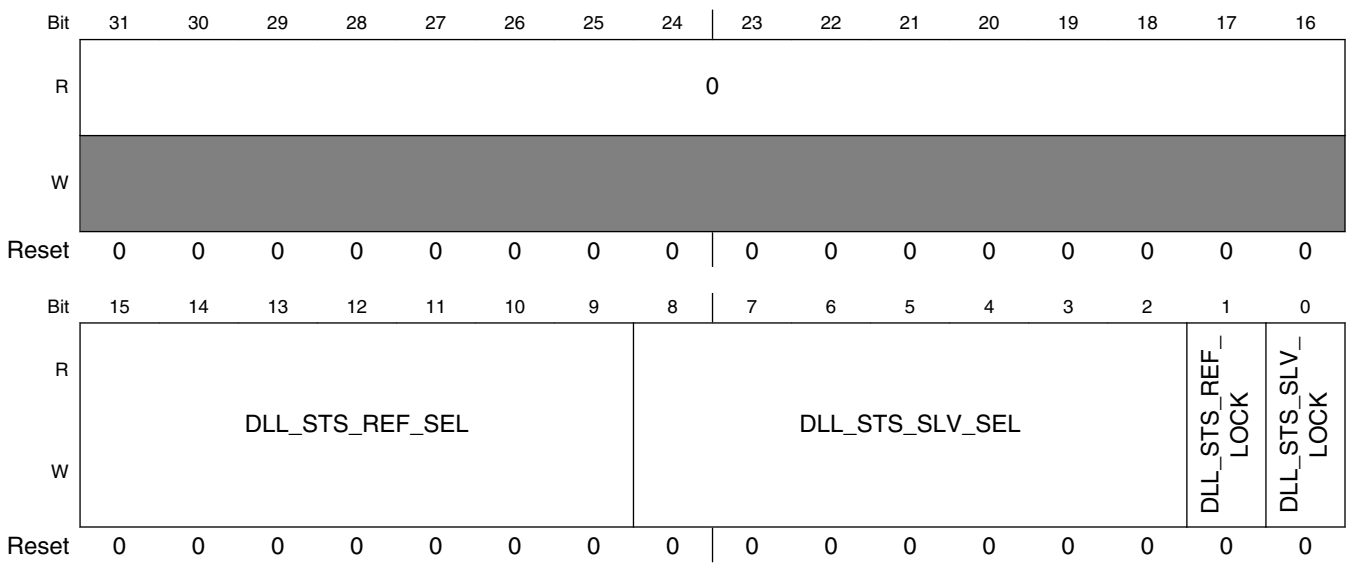
Table continues on the next page...

EIM_DCR field descriptions (continued)

Field	Description
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to force DLL not update from now on. Since when clock exists, glitches might appear during update. This bit is used by software if we met such kind of condition. Set it to 0 to let DLL update automatically
6–4 DLL_CTRL_ SLV_OFFSET	OFFSET value for DLL_CTRL_SLV_SEL
3 DLL_CTRL_ SLV_OFFSET_ DEC	Slave Chain Offset Decrease Decrease(or increase) the value defined by DLL_CTRL_SLV_OFFSET when calculating DLL_STS_SLV_SEL 0 DLL_STS_SLV_SEL = DLL_STS_REF_SEL + DLL_CTRL_SLV_OFFSET 1 DLL_STS_SLV_SEL = DLL_STS_REF_SEL - DLL_CTRL_SLV_OFFSET
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when EIM is idle.
1 DLL_CTRL_ RESET	DLL Reset Bit Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-lock. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled

9.7.9.9 DLL Status Register (EIM_DSR)

Address: 30BC_0000h base + 98h offset = 30BC_0098h

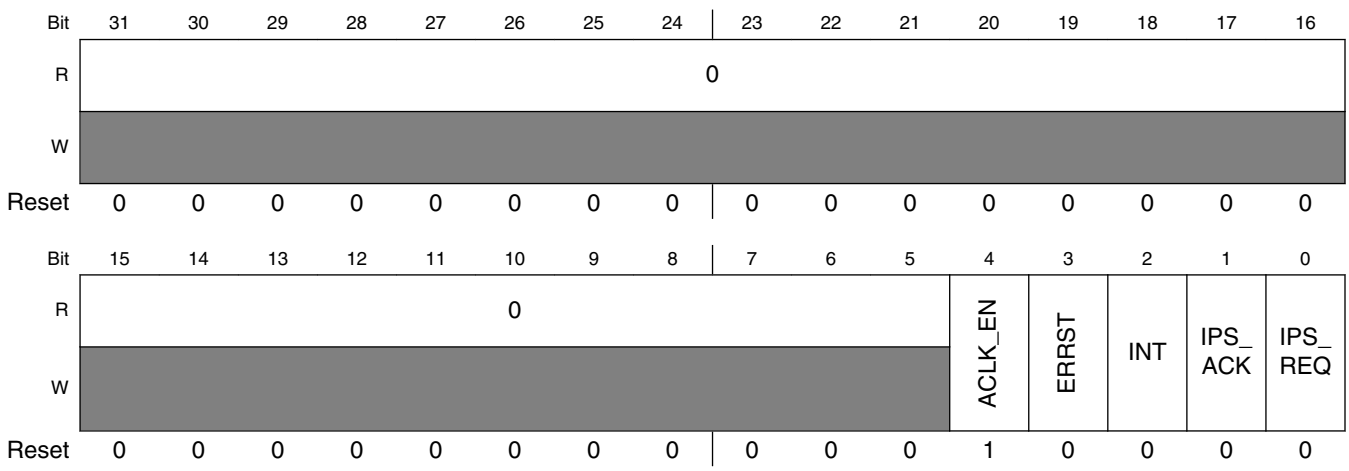


EIM_DSR field descriptions

Field	Description
31–16 Reserved	Reserved This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL	Reference delay line select taps. Be noted this is encoded by 7 bits for 127taps.
8–2 DLL_STS_SLV_SEL	Slave delay line select status. This is the instant value generated from reference chain. Since only when ref_lock is detected can the reference chain get updated, this value should be the right value next be update to the slave line when reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to feedback BCLK, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid delay has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

9.7.9.10 EIM IP Access Register (EIM_WIAR)

Address: 30BC_0000h base + 9Ch offset = 30BC_009Ch



EIM_WIAR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value 0.
4 ACLK_EN	ACLK enable. This bit gates the ACLK for the EIM except from FFs that get ipg_aclk_s. After reset ACLK is enabled. 0 ACLK is disabled 1 ACLK is enabled

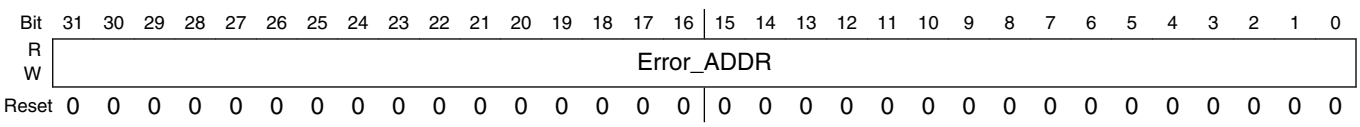
Table continues on the next page...

EIM_WIAR field descriptions (continued)

Field	Description
3 ERRST	READY After Reset. This bit controls the initial ready/busy status for external devices on CS0 immediately after hardware reset. This is a sticky bit which is cleared once the RDY_INT signal is asserted by the external device. When ERRST = 1 the first fetch access from EIM to the external device located on CS0 will be pending until RDY_INT signal indicates that the external device is ready, then EIM will execute the access. **NOTE:** Reset value for ERRST is EIM_BOOT[4]. 0 RDY_INT After Reset Disable 1 RDY_INT After Reset Enable
2 INT	Interrupt. This bit indicates interrupt assertion by an external device according to RDY_INT signal. When polling this bit, INT=0 indicates interrupt not occurred and INT=1 indicates assertion of the external device interrupt. This bit is cleared by a hardware reset.
1 IPS_ACK	IPS ACK. The EIM is ready for ips access. There is no active AXI access and no new AXI access is accepted till this bit is cleared. This bit is cleared by the master after it completes the ips accesses. 0 Master cannot access ips. 1 Master can access ips.
0 IPS_REQ	IPS request. The Master requests to access one of the IPS registers.Dutring such access the EIM should not preform any AXI/memory accesses. The EIM finishes the AXI accesses that already starts and asserts the IPS_ACK bit. 0 No Master requests ips access 1 Master requests ips access

9.7.9.11 Error Address Register (EIM_EAR)

Address: 30BC_0000h base + A0h offset = 30BC_00A0h



EIM_EAR field descriptions

Field	Description
Error_ADDR	Error Address. This bit field holds the AXI address of the last access that caused error. This register is read only register.

Chapter 10
Mass Storage

10.1 Enhanced Configurable SPI (ECSPI)

10.1.1 Overview

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block.

The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts. The figure below shows a block diagram of the ECSPI.

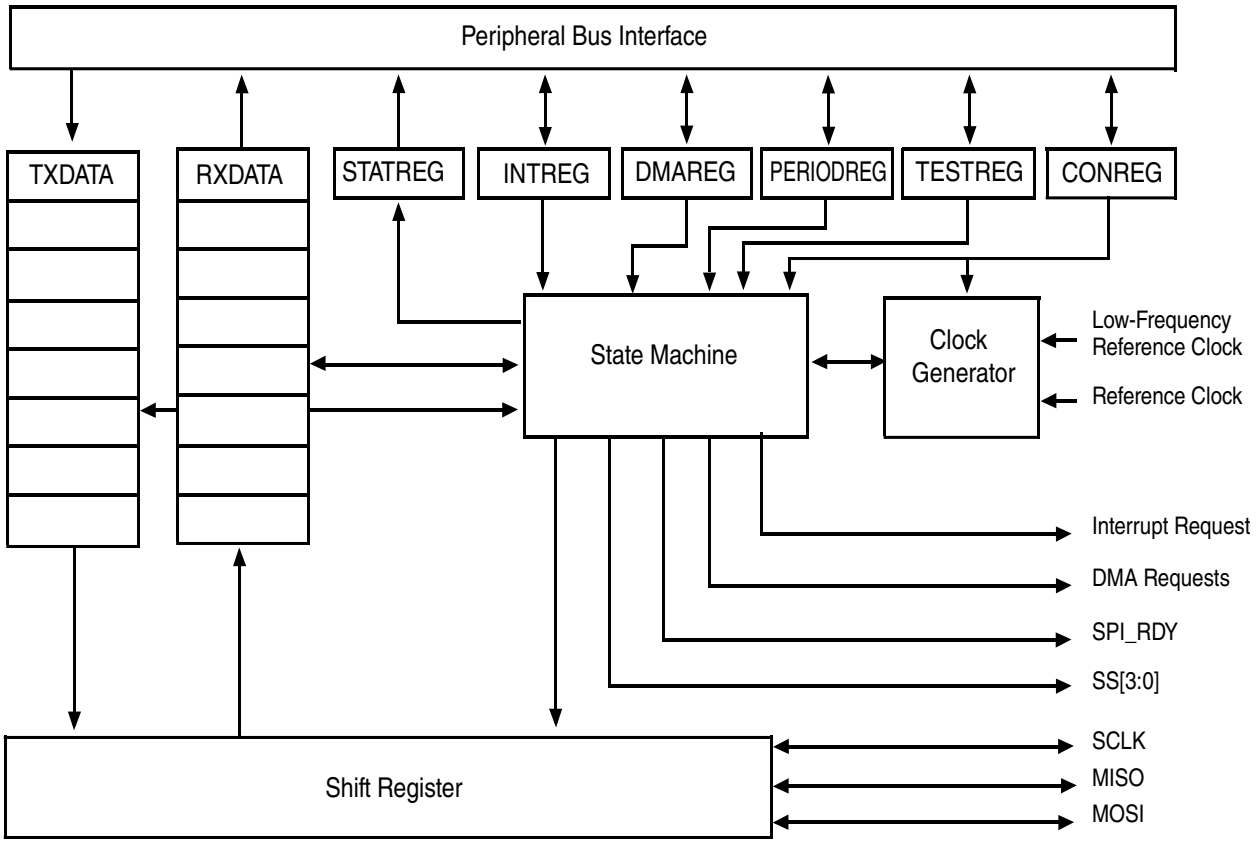


Figure 10-1. ECSPI Block Diagram

10.1.1.1 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to the reference clock frequency.

10.1.1.2 Modes and Operations

The ECSPI supports the modes described in the indicated sections:

- Master Mode
- Slave Mode
- Low Power Modes

As described in Operations, the ECSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SS_CTL[3:0] Control
  - Master Mode with Phase Control
- Typical Slave Mode

10.1.2 External Signals

Table 10-1. eCSPI External Signals

Signal	Description	Pad	Mode	Direction
ECSPI1_MISO	Master data in; slave data out	ECSPI1_MISO	ALT0	IO
		UART3_RXD	ALT3

ECSPI4_SS3	Chip select signal	SD1_DATA1	ALT3	IO

Figure 10-2 shows the ECSPI in master mode connected to four external devices in a one-way communication link.

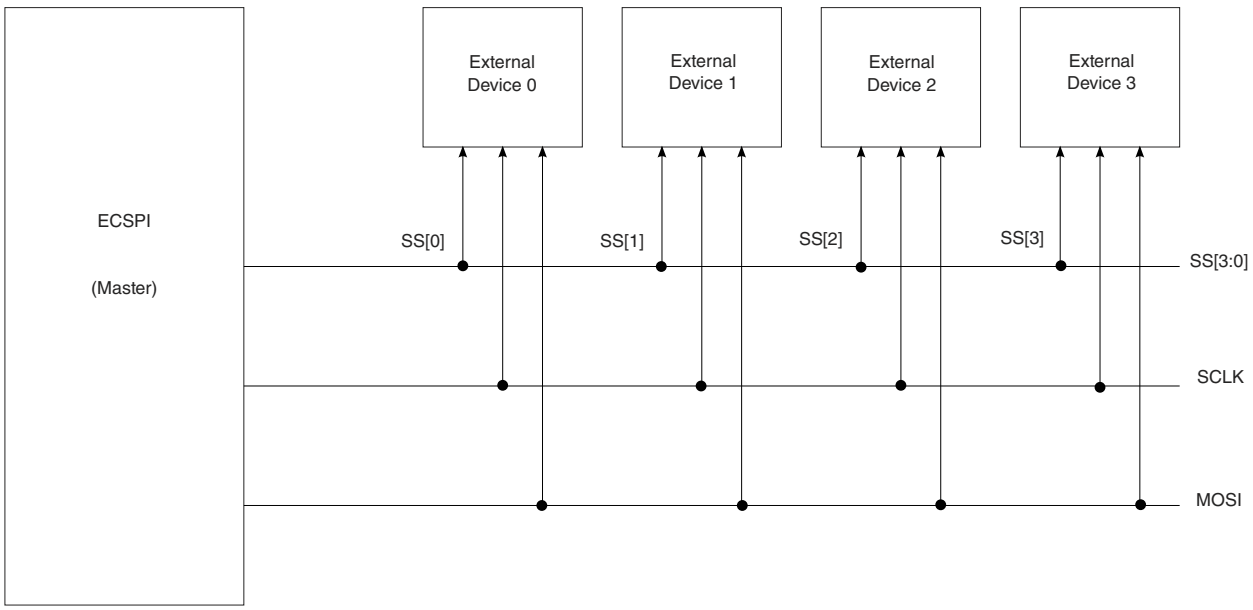

Figure 10-2. Example Connection Diagram

10.1.3 Clocks

The following table describes the clock sources for eCSPI. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 10-2. eCSPI Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32kHz)
ipg_clk_per	ecspi_clk_root	eCSPI module clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

10.1.4 Functional Description

This section provides a complete functional description of the ECSPI. The figure found here shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

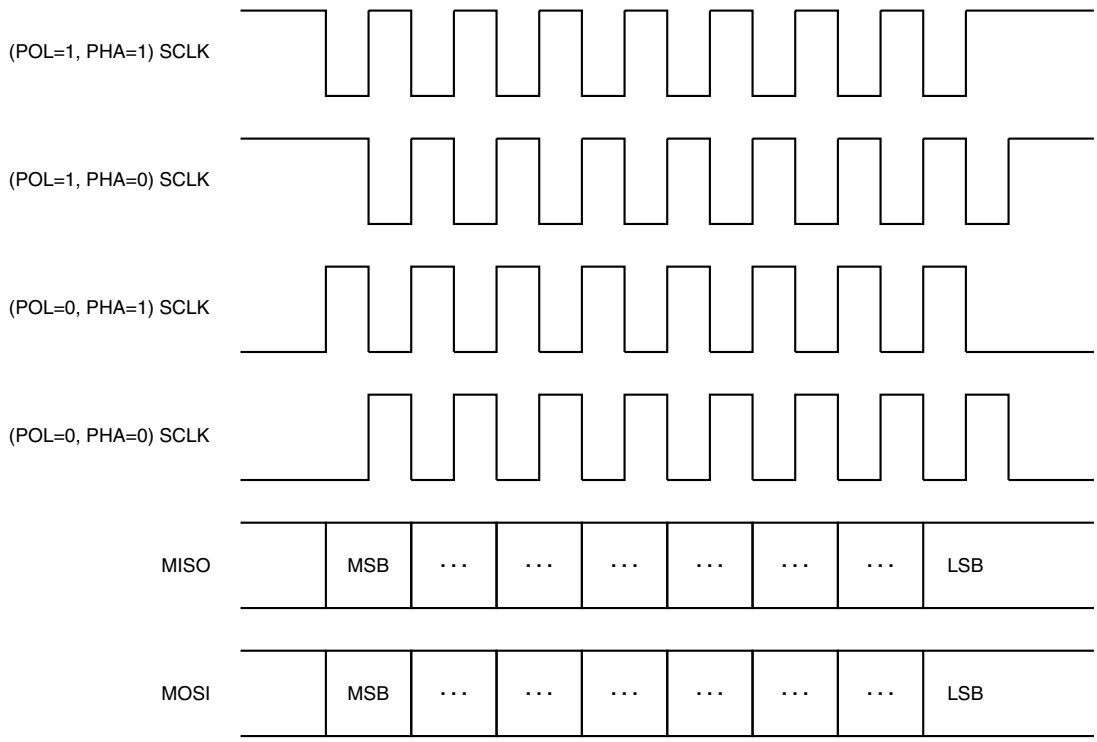

Figure 10-3. ECSPI SCLK, MISO, and MOSI Relationship

10.1.4.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device.

One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

10.1.4.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing.

In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

Slave mode only supports the case when ECSPIx_CONFIGREG[SS_CTL] is cleared. The accurate burst length should always be specified using the BURST_LENGTH parameter. ECSPIx_CONFIGREG[SS_CTL] set to 1 is not supported in slave mode.

10.1.4.3 Low Power Modes

The ECSPI does not operate under low power mode.

It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

10.1.4.4 Operations

The information found here describes the ECSPI's operations.

10.1.4.4.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register.

The SPI_RDY enables fast data communication with fewer software interrupts. By programming the ECSPI_PERIODREG register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

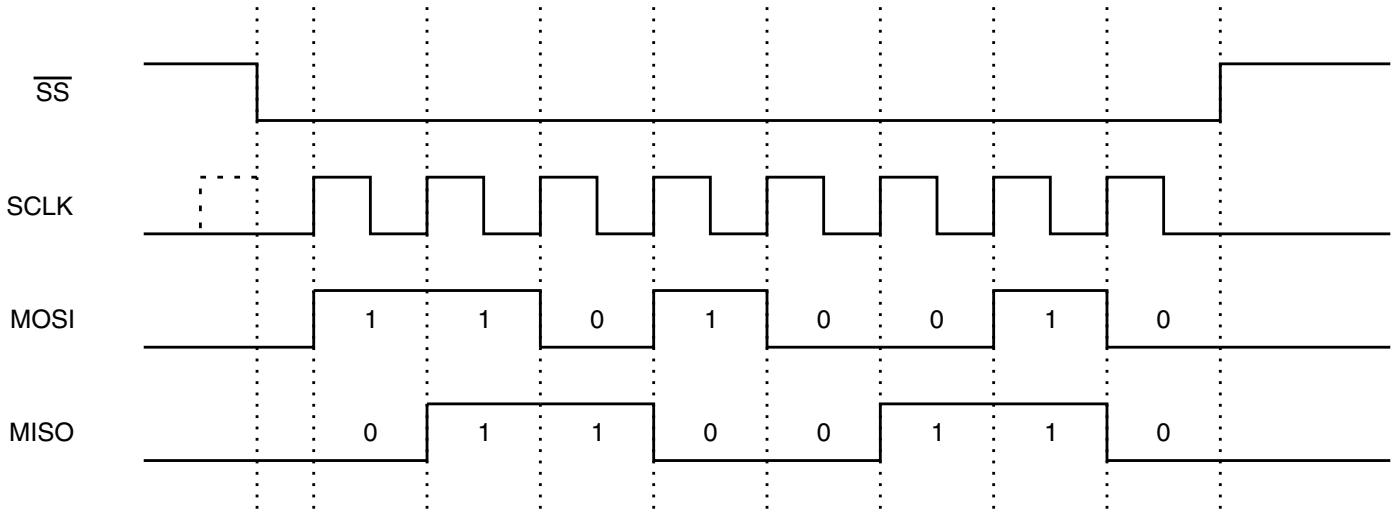

Figure 10-4. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

10.1.4.4.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

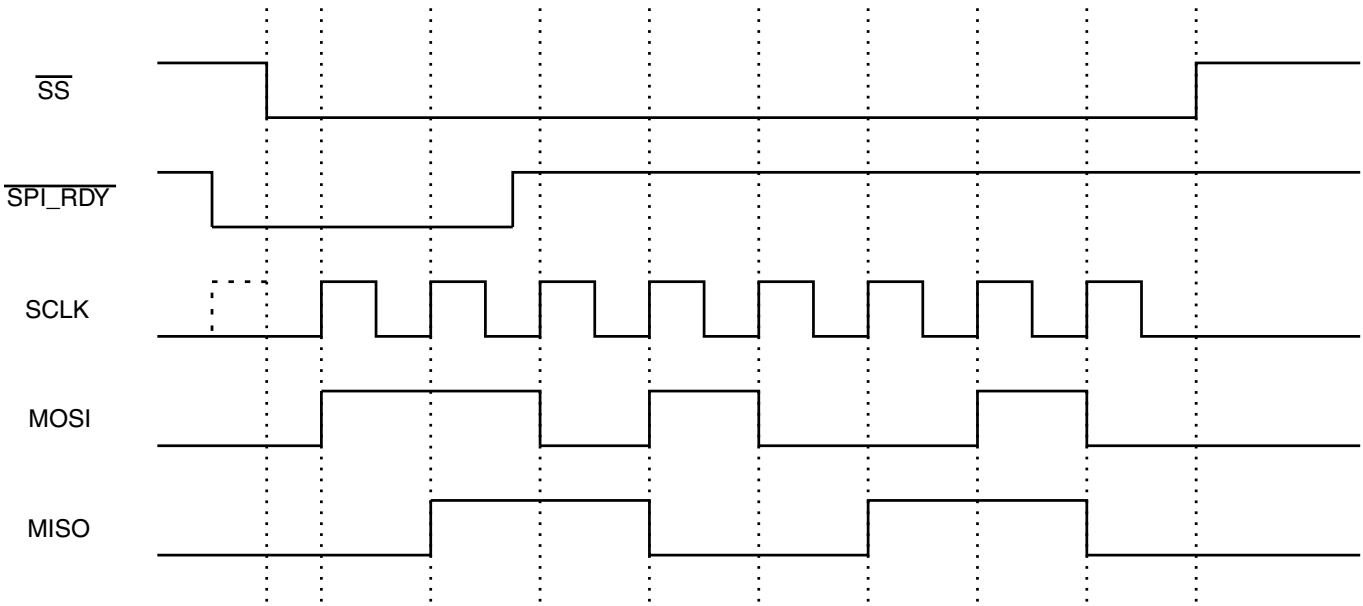

Figure 10-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

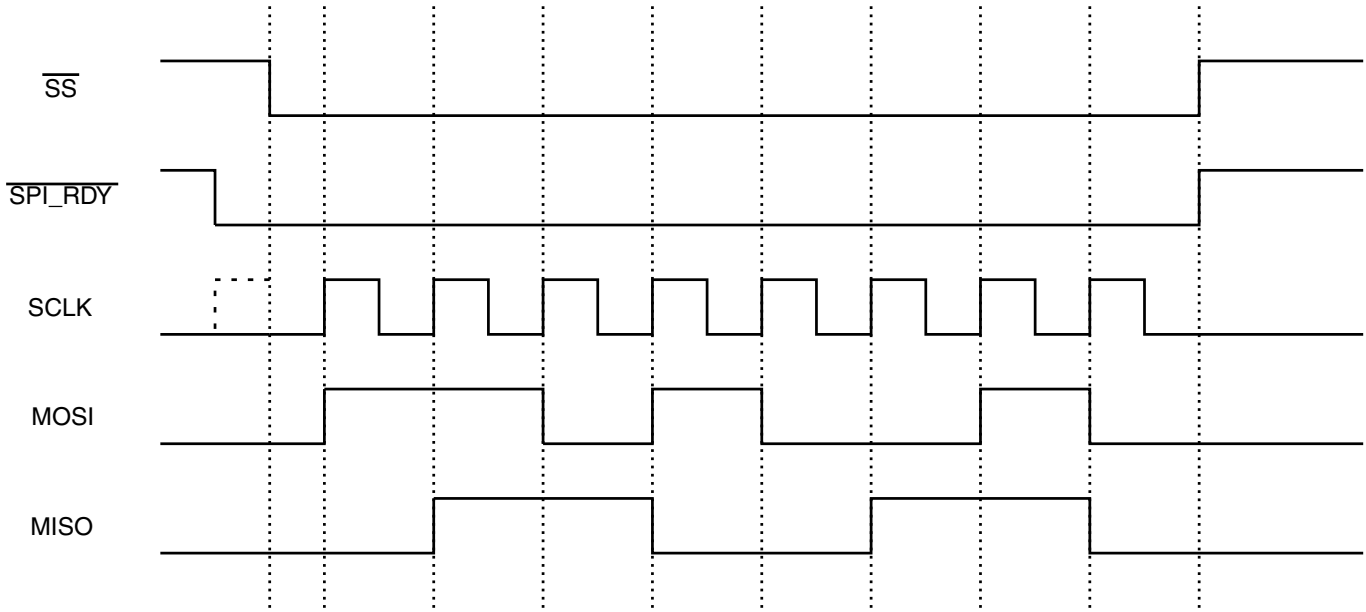

Figure 10-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

10.1.4.4.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

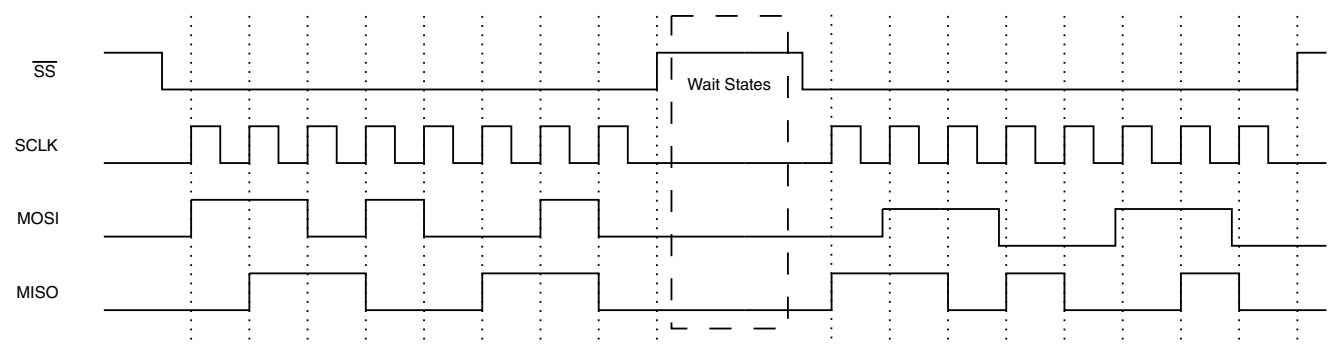

Figure 10-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

10.1.4.4.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts.

When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

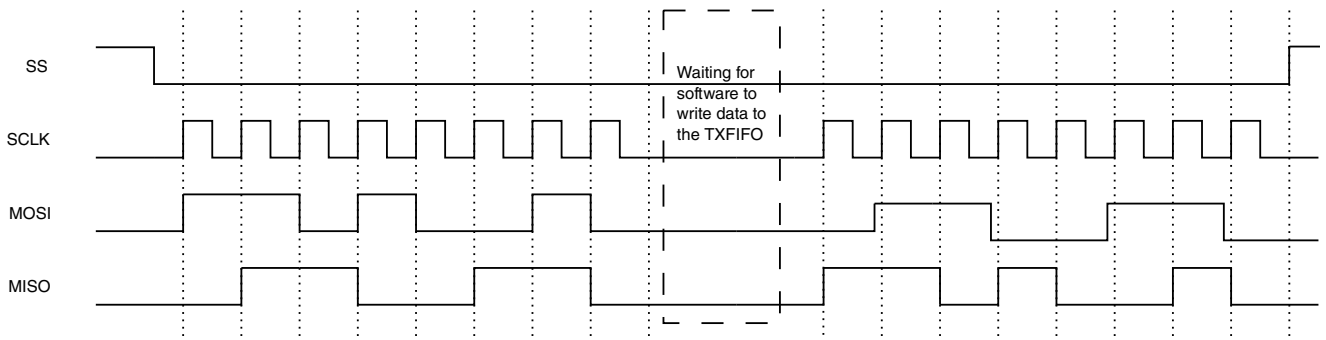

Figure 10-8. SPI Burst While SS_CTL[3:0] is Clear

In Figure 10-8, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the ECSPI_CONREG control register. (Figure 10-8 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

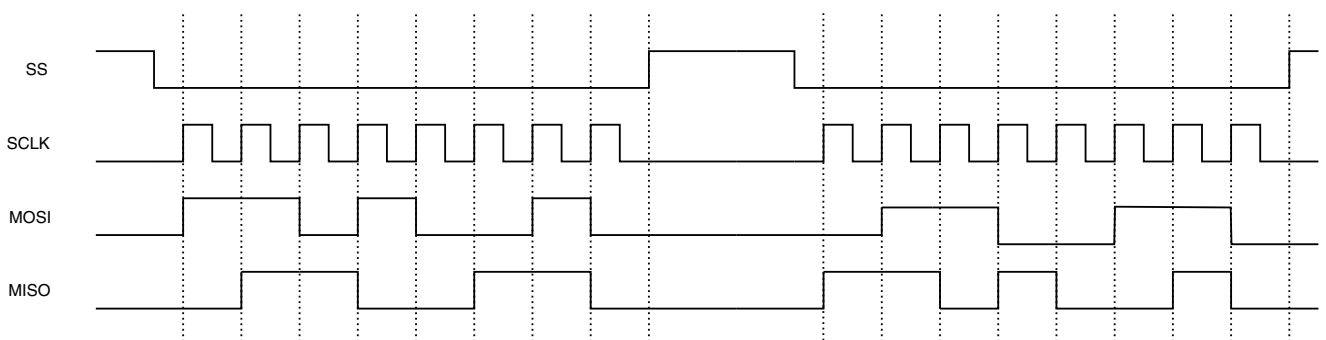

Figure 10-9. SPI Bursts While SS_CTL[3:0] is Set

In Figure 10-9, two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

10.1.4.4.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 10-10 shows how SPI burst works with different POL and PHA configuration.

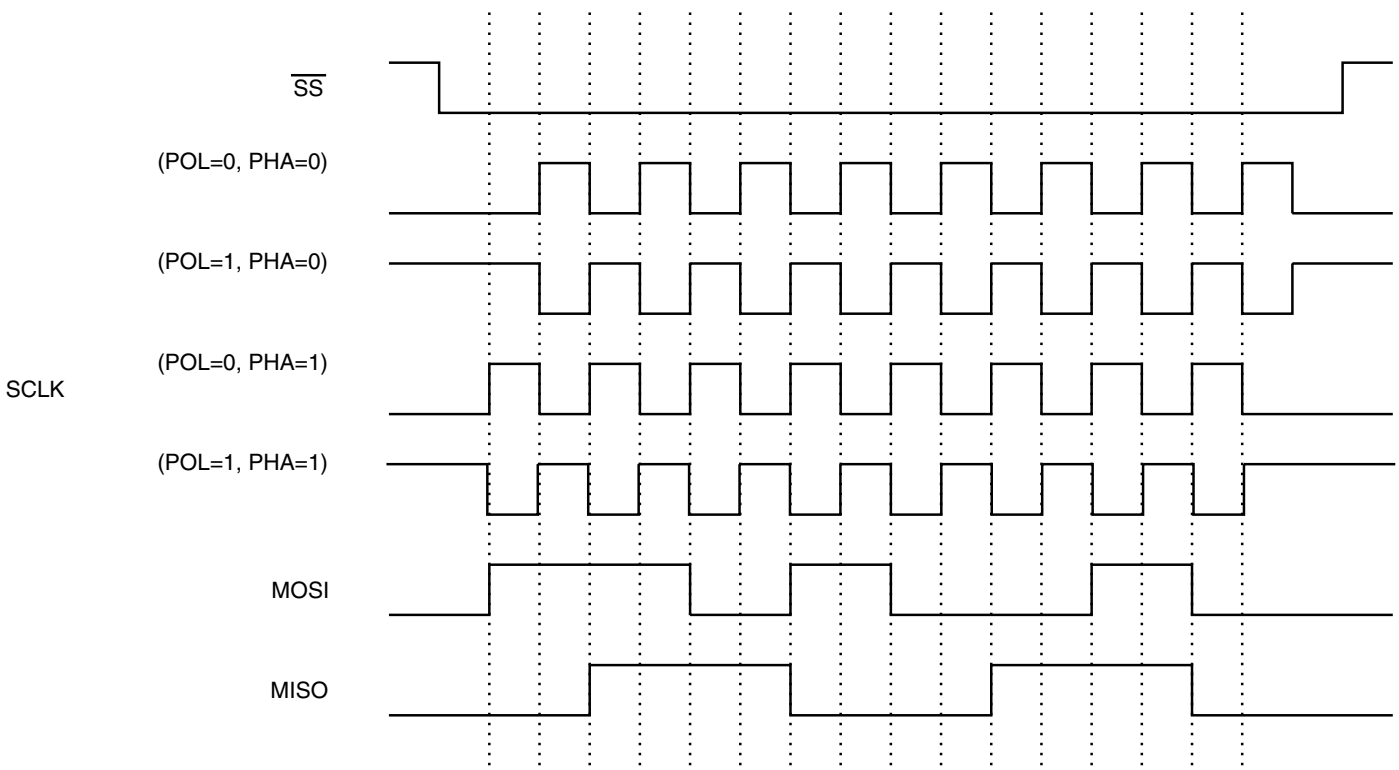

Figure 10-10. SPI Burst with Different POL and PHA Configurations

10.1.4.4.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_POL=0 while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SS_POL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

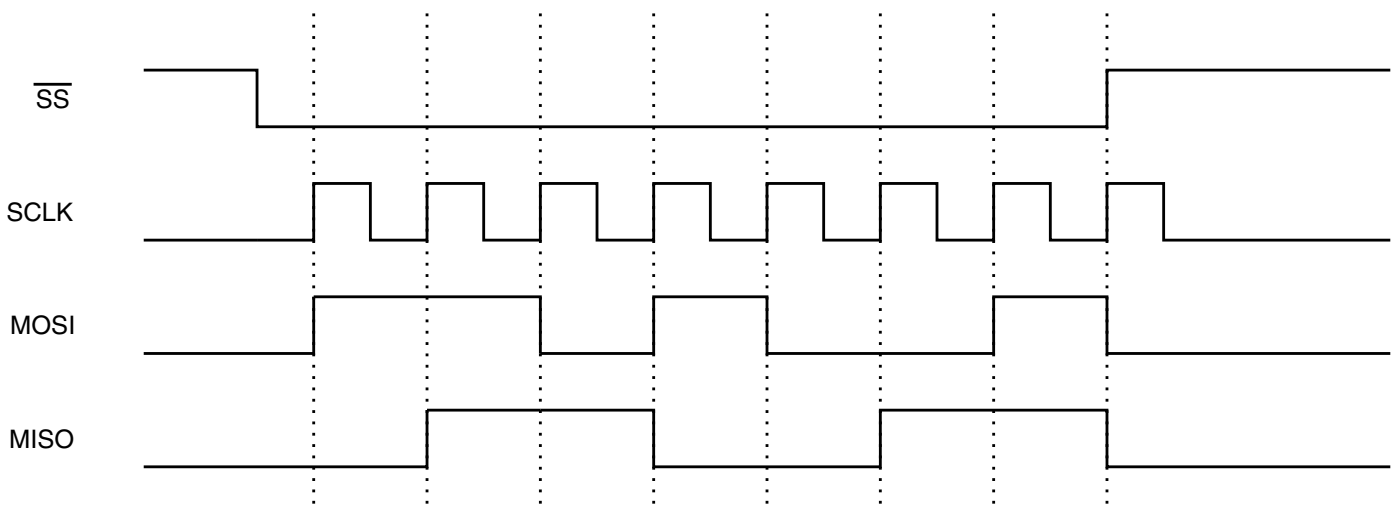

Figure 10-11. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

10.1.4.5 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see ECSPI.

10.1.4.6 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

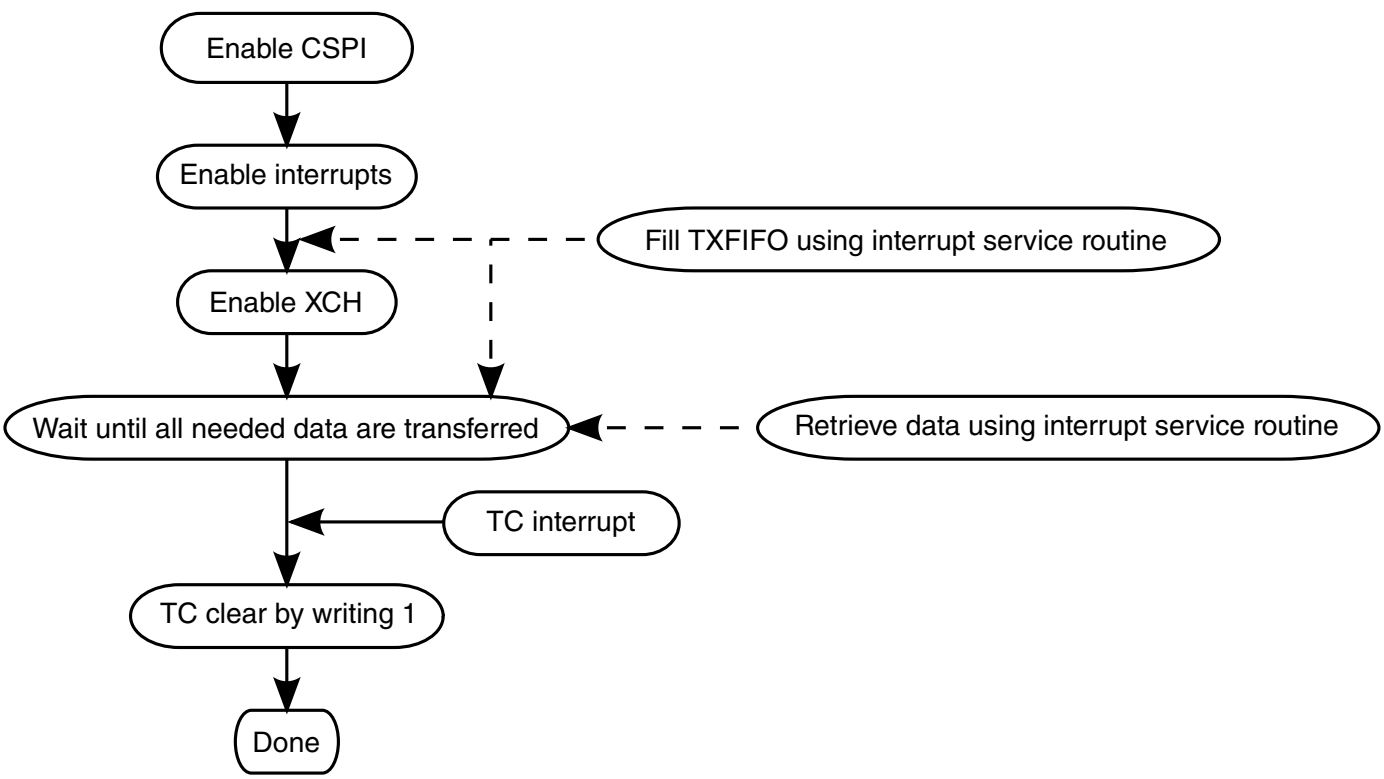

Figure 10-12. Program Sequence of SPI Burst Using Interrupt Control

10.1.4.7 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

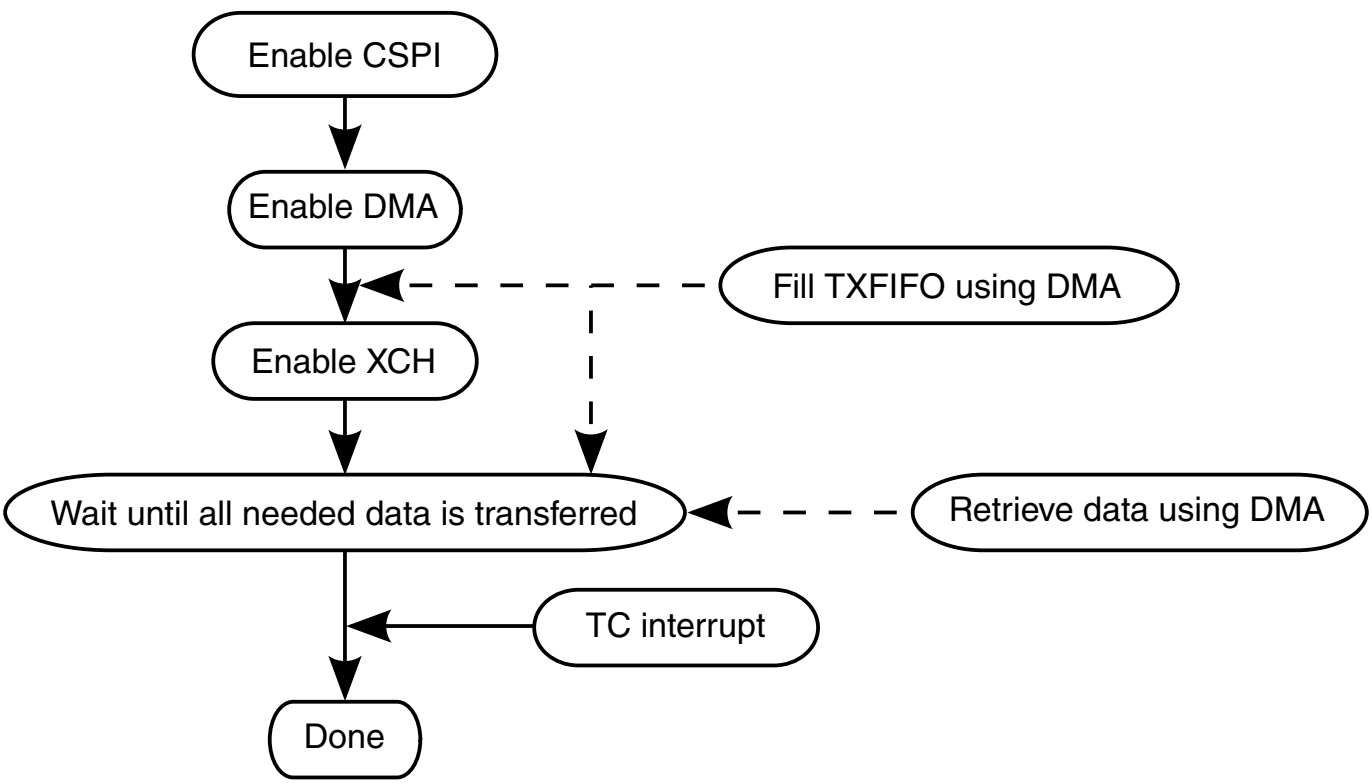

Figure 10-13. Program Sequence of SPI Burst Using DMA

10.1.4.8 Byte Order

The ECSPI does not support byte re-ordering in hardware.

10.1.5 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.
2. Enable the clocks for ECSPI.
3. Set the EN bit in ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

10.1.6 Applications

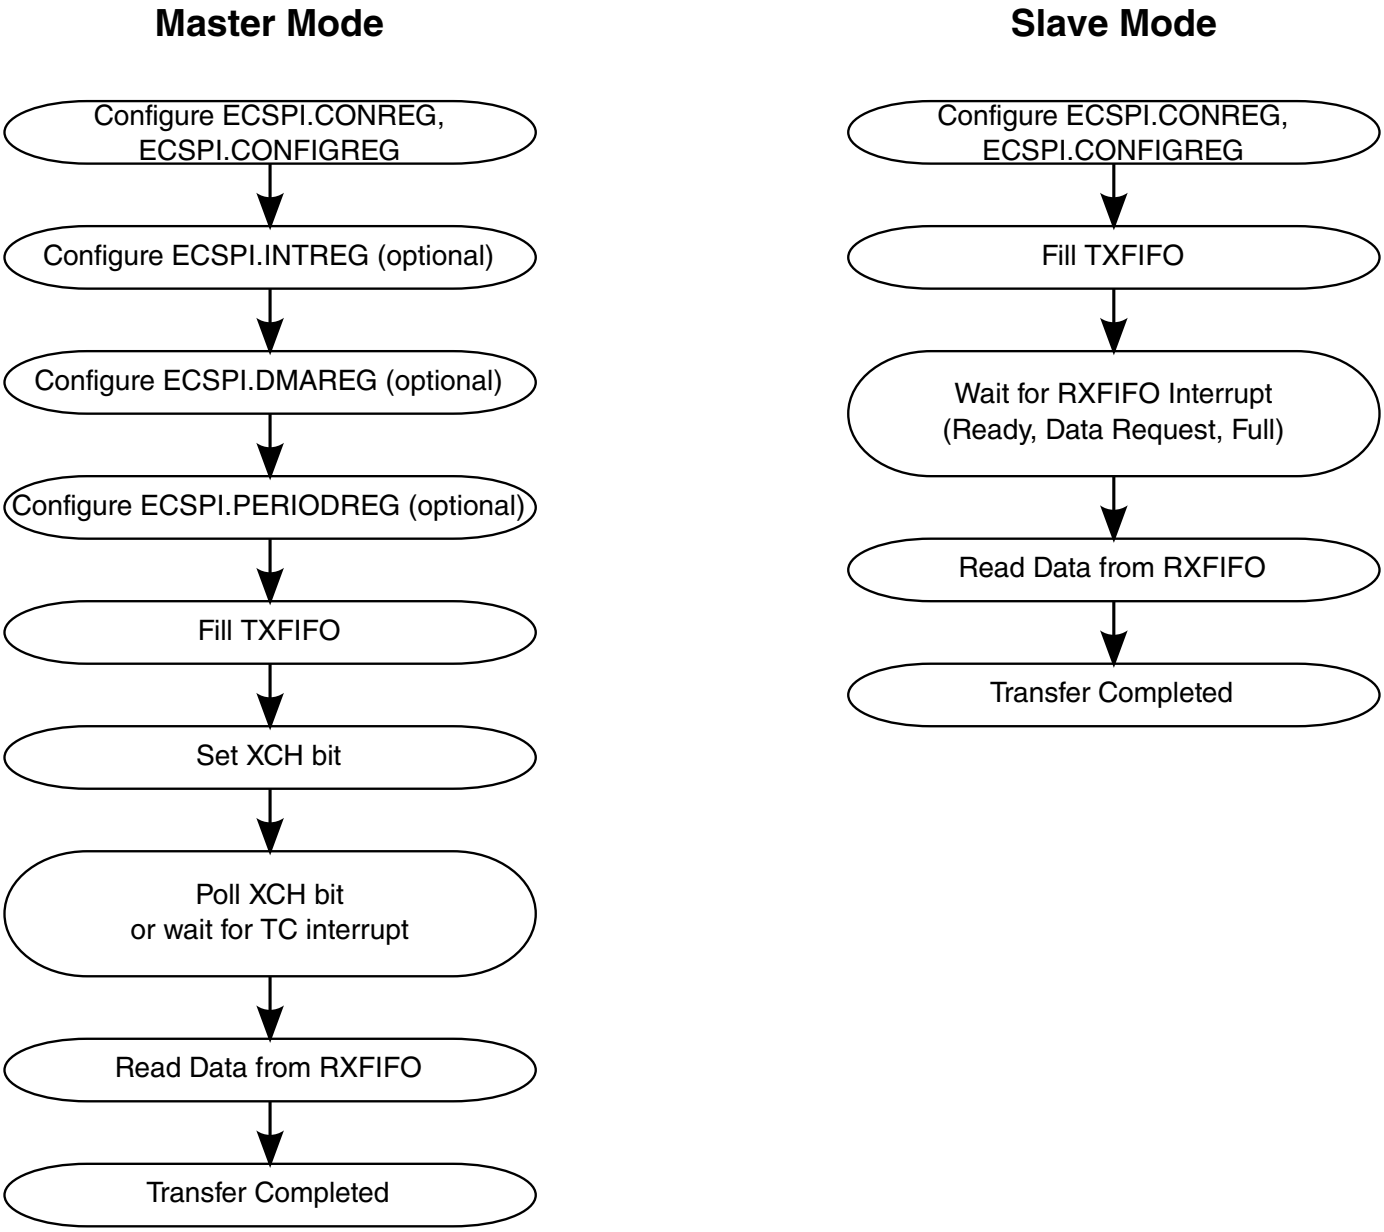

Figure 10-14. Flowchart of the ECSPI Operation

10.1.7 ECSPI Memory Map/Register Definition

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

ECSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

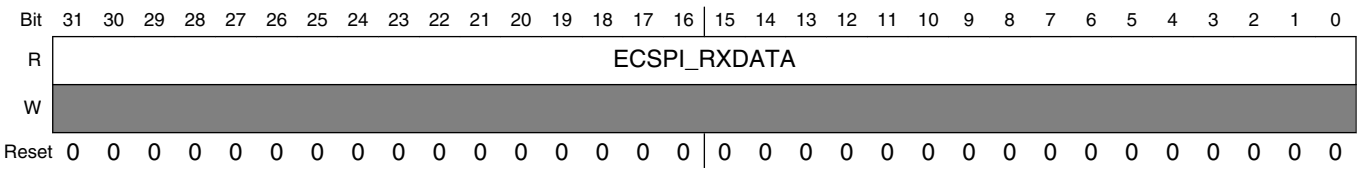
10.1.7.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: Base address + 0h offset



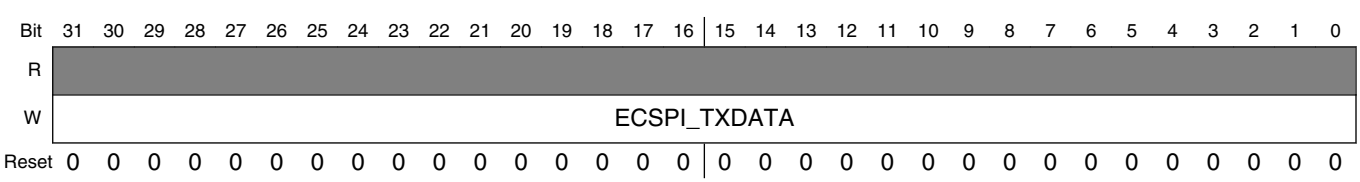
ECSPIx_RXDATA field descriptions

Field	Description
ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

10.1.7.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Address: Base address + 4h offset



ECSPIx_TXDATA field descriptions

Field	Description
ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BURST_LENGTH field of the corresponding SPI Control register. If this field contains more bits than the number specified by BURST_LENGTH, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

10.1.7.3 Control Register (ECSPIx_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI , configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BURST_LENGTH												CHANNEL_ SELECT		DRCTL

R W	PRE_DIVIDER				POST_DIVIDER				CHANNEL_MODE				SMC	XCH	HT	EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONREG field descriptions

Field	Description
31–20 BURST_ LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. ... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. ...

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL_ SELECT	SPI CHANNEL SELECT bits. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. 00 Channel 0 is selected. Chip Select 0 (SS0) will be asserted. 01 Channel 1 is selected. Chip Select 1 (SS1) will be asserted. 10 Channel 2 is selected. Chip Select 2 (SS2) will be asserted. 11 Channel 3 is selected. Chip Select 3 (SS3) will be asserted.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. ECSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE_DIVIDER	SPI Pre Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. ... 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST_DIVIDER	SPI Post Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^n . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. ... 1110 Divide by 2^{14} . 1111 Divide by 2^{15} .
7–4 CHANNEL_ MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1).

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 HT	Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. Note, HT mode is not supported by this product. 0 Disable HT mode. 1 Enable HT mode.
0 EN	SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPI_CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

10.1.7.4 Config Register (ECSPIx_CONFIGREG)

The Config Register (ECSPI_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length. Note, HT mode is not supported by this product.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved			HT_LENGTH					SCLK_CTL				DATA_CTL				SS_POL				SS_CTL				SCLK_POL				SCLK_PHA			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONFIGREG field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28–24 HT_LENGTH	HT LENGTH. This field defines the message length in HT Mode. Note, HT mode is not supported by this product. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK_CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay low. 1 Stay high.
19–16 DATA_CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS_POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is for SPI channel 3. SS POL[2] is for SPI channel 2. SS POL[1] is for SPI channel 1. SS POL[0] is for SPI channel 0. 0 Active low. 1 Active high.
11–8 SS_CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL are ignored if the SMC bit is set. SS CTL[3] is for SPI channel 3. SS CTL[2] is for SPI channel 2. SS CTL[1] is for SPI channel 1. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted.

Table continues on the next page...

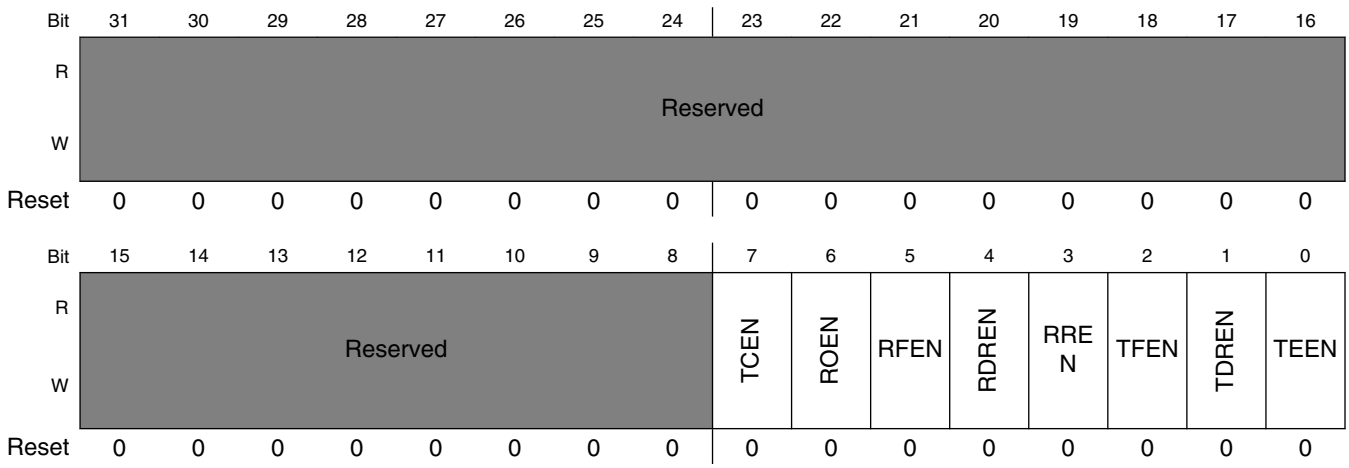
ECSPIx_CONFIGREG field descriptions (continued)

Field	Description
	1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. 0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 Reserved
7–4 SCLK_POL	SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 10-10 for more information. SCLK_POL[3] is for SPI channel 3. SCLK_POL[2] is for SPI channel 2. SCLK_POL[1] is for SPI channel 1. SCLK_POL[0] is for SPI channel 0. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
SCLK_PHA	SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 10-10 for more information. SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

10.1.7.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Address: Base address + 10h offset



ECSPIx_INTREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX_THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable

Table continues on the next page...

ECSPIx_INTREG field descriptions (continued)

Field	Description
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX_THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

10.1.7.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RXTDEN	Reserved	RX_DMA_LENGTH						RXDEN	Reserved	RX_THRESHOLD					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								TEDEN	Reserved	TX_THRESHOLD					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request is generated even if it is less than or equal to RX_THRESHOLD. 0 Disable 1 Enable
30 -	This field is reserved. Reserved
29–24 RX_DMA_ LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	This field is reserved. Reserved
21–16 RX_ THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX_THRESHOLD.
15–8 -	This field is reserved. Reserved
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable
6 -	This field is reserved. Reserved
TX_ THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is not greater than TX_THRESHOLD.

10.1.7.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TC	RO	RF	RDR	RR	TF	TDR	TE
W									w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX_THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX_THRESHOLD.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full.

Table continues on the next page...

ECSPIx_STATREG field descriptions (continued)

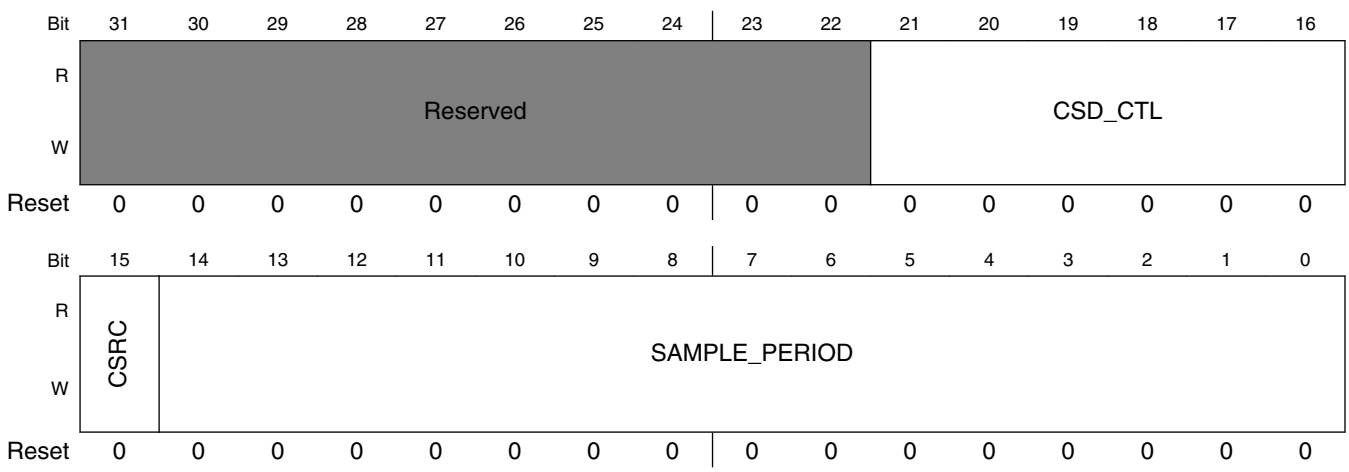
Field	Description
	0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of valid data slots in TXFIFO is greater than TX_THRESHOLD. 1 Number of valid data slots in TXFIFO is not greater than TX_THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

10.1.7.8 Sample Period Control Register (ECSPIx_PERIODREG)

The Sample Period Control Register (ECSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPI_CONREG[CHANNEL MODE] = 1).ECSPI_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Address: Base address + 1Ch offset



ECSPIx_PERIODREG field descriptions

Field	Description
31–22 -	This field is reserved. Reserved

Table continues on the next page...

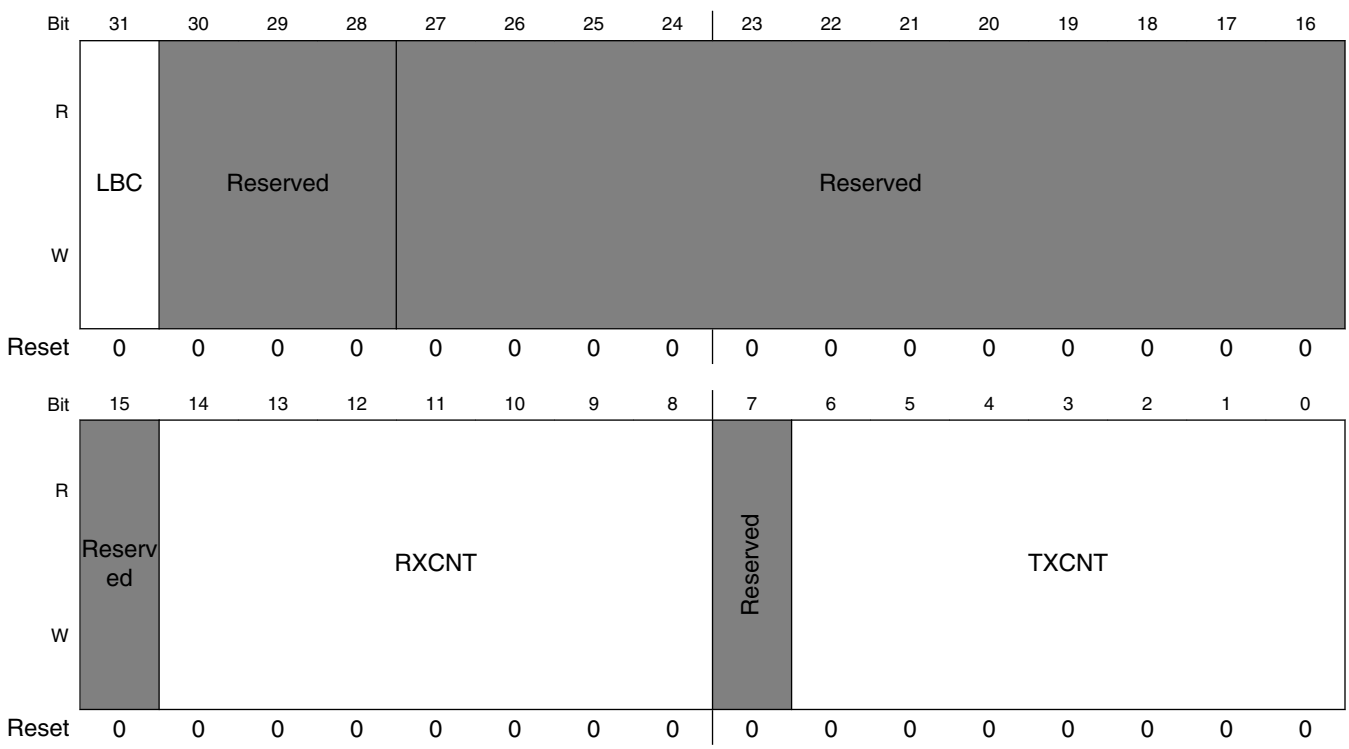
ECSPIx_PERIODREG field descriptions (continued)

Field	Description
21–16 CSD_CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
SAMPLE_ PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPI_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted ... ... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

10.1.7.9 Test Control Register (ECSPIx_TESTREG)

The Test Control Register (ECSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Address: Base address + 20h offset



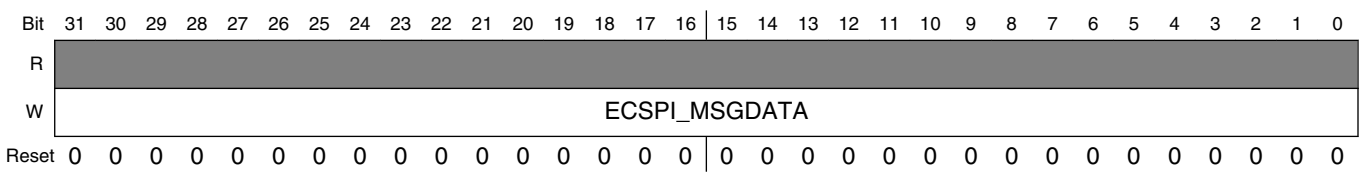
ECSPIx_TESTREG field descriptions

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	This field is reserved. Reserved, all bits should be ignored.
27–15 -	This field is reserved. Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.
7 -	This field is reserved. Reserved
TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

10.1.7.10 Message Data Register (ECSPIx_MSGDATA)

The Message Data Register (ECSPI_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reads to this register return zero, and writes to this register store data in the MSG Data FIFO.

Address: Base address + 40h offset



ECSPIx_MSGDATA field descriptions

Field	Description
ECSPI_ MSGDATA	ECSPI_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

10.2 Quad Serial Peripheral Interface (QuadSPI)

10.2.1 Overview

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines. The following figure is a block diagram of the QuadSPI module.

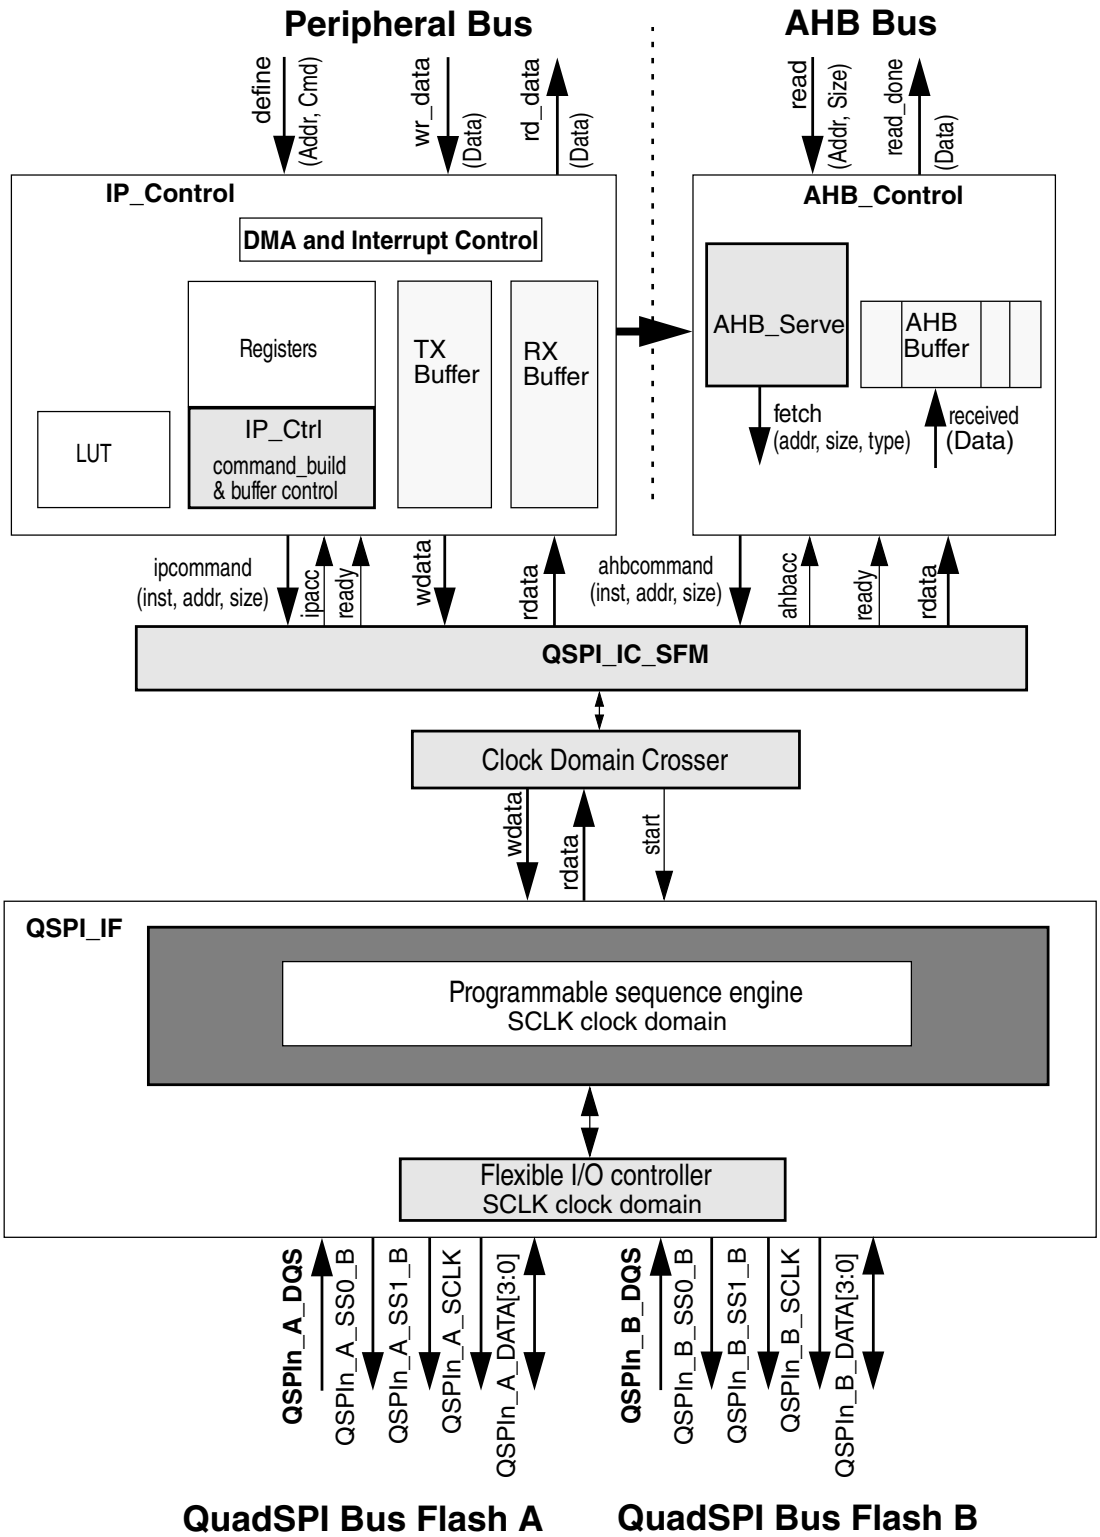


Figure 10-15. QuadSPI Block Diagram

The following figure describes the serial flash clock diagram in QuadSPI:

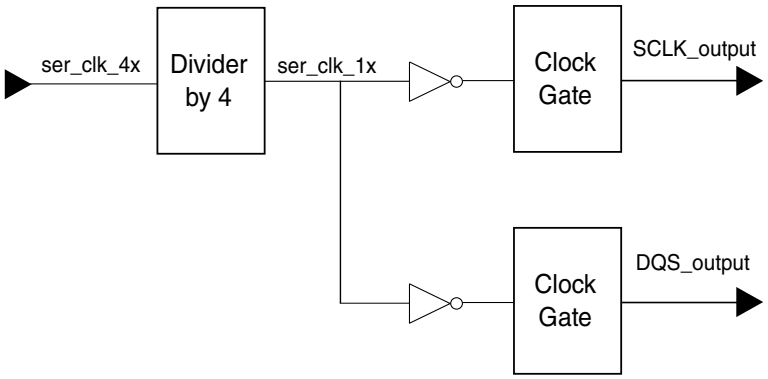

Figure 10-16. Flash Clock Diagram

ser_clk_4x is the serial clock root from CCM

ser_clk_1x' is generated clock from 'ser_clk_4x' divided by 4

SCLK_output is serial output clock generated from 'ser_clk_1x' with inverter and clock gate, it's used as Clock by external serial flash device.

DQS_output is serial flash data strobe signal generated from 'ser_clk_1x' with inverter and clock gate. This signal could be loopback from pad and used as sampling clock for serial flash data.

10.2.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad mode of operation.
- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
    - Inner loop size of DMA access can be configured.
- Multi master accesses with priority

- Flexible and configurable buffer for each master

- Thirteen interrupt conditions (see Table 10-12)
- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
  - Supports 3-byte and 4-byte addressing.
  - TXFIFO size is 512Byte
  - RXFIFO size is 512Byte
  - AHB BUF size is 1KByte

10.2.1.2 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

10.2.1.2.1 Normal Mode

In this mode, one or two external serial flash memory devices can be accessed. Further details about this mode of operation can be found in Modes of Operation (Normal Mode).

10.2.1.2.2 Module Disable Mode

This mode is used for power management of the device containing the QuadSPI module. It is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode.

10.2.1.3 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 10-3. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select
DMA	Direct Memory Access

Table continues on the next page...

Table 10-3. Acronyms and Abbreviations (continued)

Terms	Description
MB	Megabyte. Each MB is 1024 * 1024 bytes
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a 1 to this field resets the flag

10.2.1.4 Glossary for QuadSPI module

Table 10-4. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 10-9. Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.

Table continues on the next page...

Table 10-4. Glossary (continued)

Term	Definition
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 10-22 for details on errors.
Single/Dual/Quad Instructions	Depending on the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. • Single: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module • Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode- and/or dummy bytes, transmit and/or receive data.
LUT	Look-up table.

10.2.2 External Signals

The following table describes the external signals of QSPI:

Table 10-5. QSPI External Signals

Signal	Description	Pad	Mode	Direction
QSPI_A_DATA0	I/O data signal 1 port 0 for serial flash device A	EPDC1_DATA00	ALT2	IO
QSPI_A_DATA1	I/O data signal 1 port 1 for serial flash device A	EPDC1_DATA01	ALT2	IO
QSPI_A_DATA2	I/O data signal 1 port 2 for serial flash device A	EPDC1_DATA02	ALT2	IO
QSPI_A_DATA3	I/O data signal 1 port 3 for serial flash device A	EPDC1_DATA03	ALT2	IO
QSPI_A_DQS	Data strobe signal 1 to serial flash device A	EPDC1_DATA04	ALT2	I

Table continues on the next page...

Table 10-5. QSPI External Signals (continued)

Signal	Description	Pad	Mode	Direction
QSPI_A_SCLK	Serial clock output 1 to serial flash device A	EPDC1_DATA05	ALT2	O
QSPI_A_SS0_B	Chip select 1 port 0 for serial flash device A	EPDC1_DATA06	ALT2	O
QSPI_A_SS1_B	Chip select 1 port 1 for serial flash device A	EPDC1_DATA07	ALT2	O
QSPI_B_DATA0	I/O data signal 1 port 0 for serial flash device B	EPDC1_DATA08	ALT2	IO
QSPI_B_DATA1	I/O data signal 1 port 1 for serial flash device B	EPDC1_DATA09	ALT2	IO
QSPI_B_DATA2	I/O data signal 1 port 2 for serial flash device B	EPDC1_DATA10	ALT2	IO
QSPI_B_DATA3	I/O data signal 1 port 3 for serial flash device B	EPDC1_DATA11	ALT2	IO
QSPI_B_DQS	Data strobe signal 1 to serial flash device B	EPDC1_DATA12	ALT2	I
QSPI_B_SCLK	Serial clock output 1 to serial flash device B	EPDC1_DATA13	ALT2	O
QSPI_B_SS0_B	Chip select 1 port 0 for serial flash device B	EPDC1_DATA14	ALT2	O
QSPI_B_SS1_B	Chip select 1 port 1 for serial flash device B	EPDC1_DATA15	ALT2	O

10.2.2.1 Driving External Signals

The different phases of serial flash access scheme are shown in the following figure.

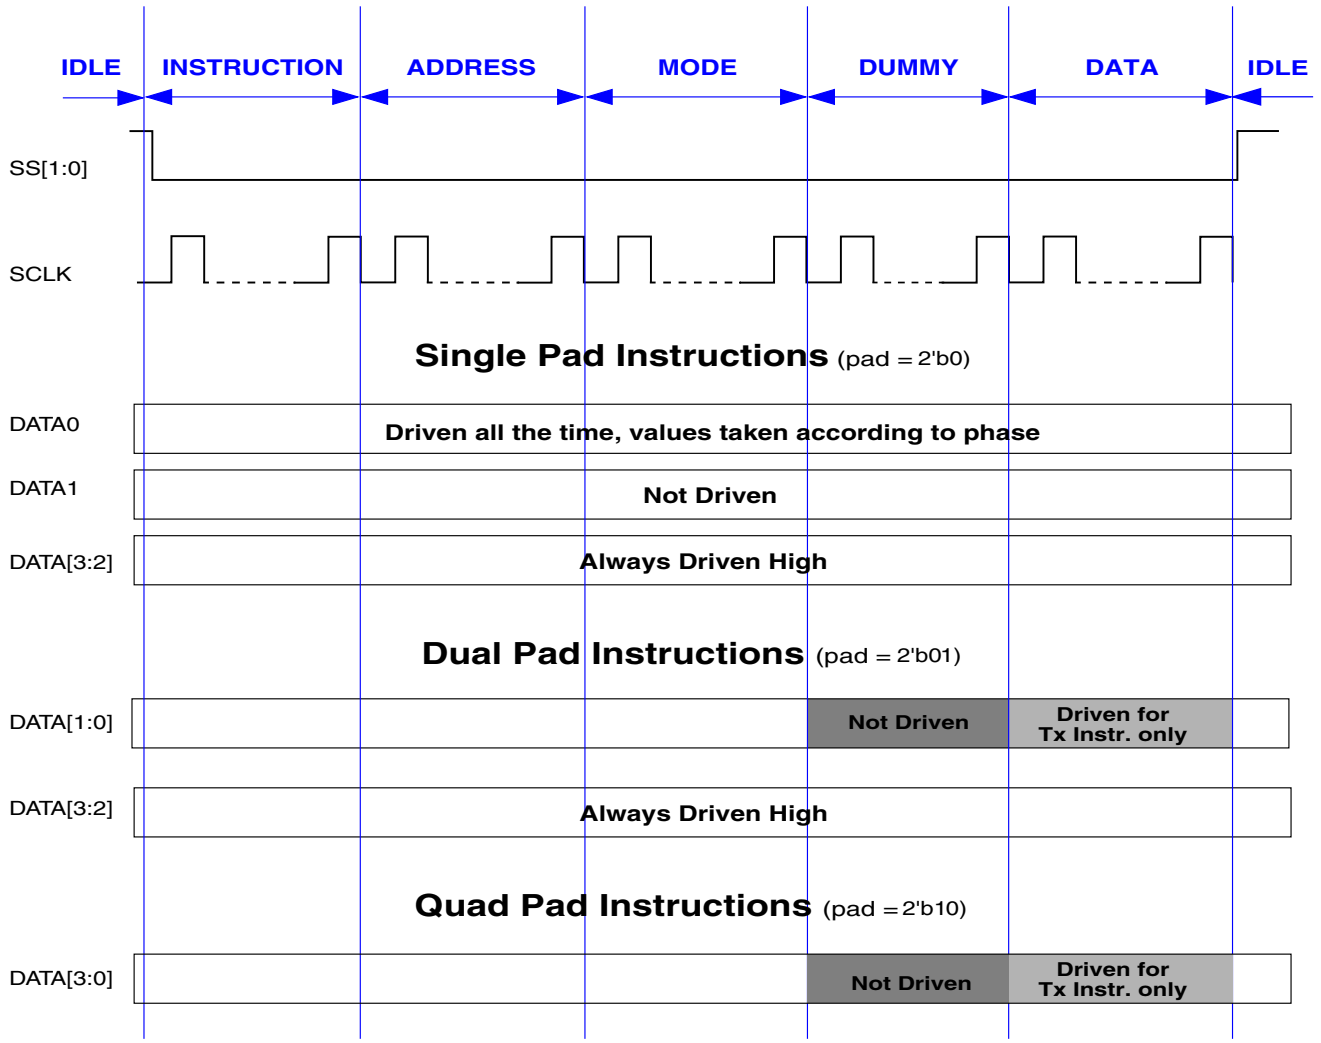

Figure 10-17. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- IDLE: Serial flash device not selected. No interaction with the serial flash device. All DATA signals driven.
- INSTRUCTION: Serial flash device selected. The instruction is sent to the serial flash device. All DATA signals are driven.
- ADDRESS: Serial Flash Address is sent to the device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.
- MODE: Mode bytes are sent to the serial flash device. All DATA signals are driven. Note that this phase is not applicable for all SFM Commands.

- DUMMY: Dummy clocks are provided to the serial flash device. Refer to the Figure 10-17 for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- DATA: Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the DATA signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The SS[1:0] and SCLK signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

10.2.3 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

10.2.3.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

  For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 10-6. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if *QSPI_MCR[MDIS] = 1*.
Normal Mode	Write access only if the module is in *Normal Mode*.

- **Register Write Access Requirements**

  All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

10.2.3.2 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into Serial Flash A1 Top Address (QuadSPI_SFA1AD) and Serial Flash A2 Top Address (QuadSPI_SFA2AD) for device A and into Serial Flash B1Top Address (QuadSPI_SFB1AD) and Serial Flash B2Top Address (QuadSPI_SFB2AD) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 10-7. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to **Serial Flash A1**
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to **Serial Flash A2**
TOP_ADDR_MEMB1(TPADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to **Serial Flash B1**
TOP_ADDR_MEMB2(TPADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to **Serial Flash A2**

10.2.3.3 AMBA Bus Register Memory Map

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

Table 10-8. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 10-16 and Table 10-20 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 10-16 and Table 10-20 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 10-19 and Table 10-20 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)	
QSPI_ARDB_BASE to… (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to Table 10-16 and Table 10-18 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI_BFGENCR[PAR_EN] bit for all masters in AHB driven mode and via the QSPI_IPCR[PAR_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0]as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/ operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

10.2.3.4 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

10.2.3.4.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.
- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

10.2.3.4.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-16 and for 64 bit read access the byte ordering is given in Table 10-20.

Table 10-9. Memory Mapped Individual Flash Mode - Flash A Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
QSPI_AMBA_BASE + 0x00	QSPI_AMBA_BASE + 0x00	0x00_0000 to 0x00_0003	A1
QSPI_AMBA_BASE + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMA1 - 0x08	TOP_ADDR_MEMA1 - 0x08	(TOP_ADDR_MEMA1- 0x08) to (TOP_ADDR_MEMA1 - 0x04 -0x01)	
TOP_ADDR_MEMA1 - 0x04		(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)	
TOP_ADDR_MEMA1 + 0x00	TOP_ADDR_MEMA1 + 0x00_0000	0x00_0000 to 0x00_0003	A2
TOP_ADDR_MEMA1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMA2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)	
TOP_ADDR_MEMA2 - 0x04		(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.3.4.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual

die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-16 and for 64 bit read access the byte ordering is given in Table 10-20.

Table 10-10. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 -0x01)	
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1- TOP_ADDR_MEMA2- 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	B2
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1- 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2- TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.3.4.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 10-18 and for 64 bit read access the byte ordering is given in Table 10-20.

Table 10-11. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes.	0x00_0000 - 0x00_0001	0x00_0000 - 0x00_0001
QSPI_AMBA_BASE + 0x0000_0004		0x00_002 - 0x00_0003	0x00_0002 - 0x00_0003
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0004 - 0x00_0005	0x00_0004 - 0x00_0005
QSPI_AMBA_BASE + 0x0000_000C		0x00_0006 - 0x00_0007	0x00_0006 - 0x00_0007
…	…	…	…
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 +0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE- 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

10.2.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 10-12. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:

Table continues on the next page...

Table 10-12. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
	IUEF	Peripheral Command Usage Error
ipi_int_ored	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF	Logical OR from all the QSPI_FR flags mentioned

10.2.5 Functional Description

This section provides the functional information of the QuadSPI module.

10.2.5.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 10-13. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	**Yes**	**N/a**	**Yes**
Individual Flash Mode: Access to Flash B	**N/a**	**Yes**	**Yes**
Parallel Flash Mode: Read from Flash A and Flash B	**N/a**	**N/a**	**Yes**

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

10.2.5.2 Modes of Operation

Refer to QuadSPI Modes of Operation for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.
  - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to Flash Programming for further details.
  - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see Flash Read.

- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

10.2.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

10.2.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 10-14. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2		Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions .
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (for example, one pad implies that pad 1 is not driven, rest all are driven)

Table continues on the next page...

Table 10-14. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads[1] specified
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads[2] specified
READ	6'd7	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads sepcified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.
ADDR_DDR	6'd10	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Number of address bits to be sent (for example, 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions .
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash[3]
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash[4].
READ_DDR	6'd14	N=2'd{0,1,2} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads	Read data size in bytes (for AHB transactions, the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register

Table continues on the next page...

Table 10-14. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
DATA_LEARN[5]	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern.[6]
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
5. Data learning is not implemented on this chip.
6. t is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

10.2.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated.The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the chip-specific QuadSPI information.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/ fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash.As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. Figure 10-18 shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to Look-up Table for details.

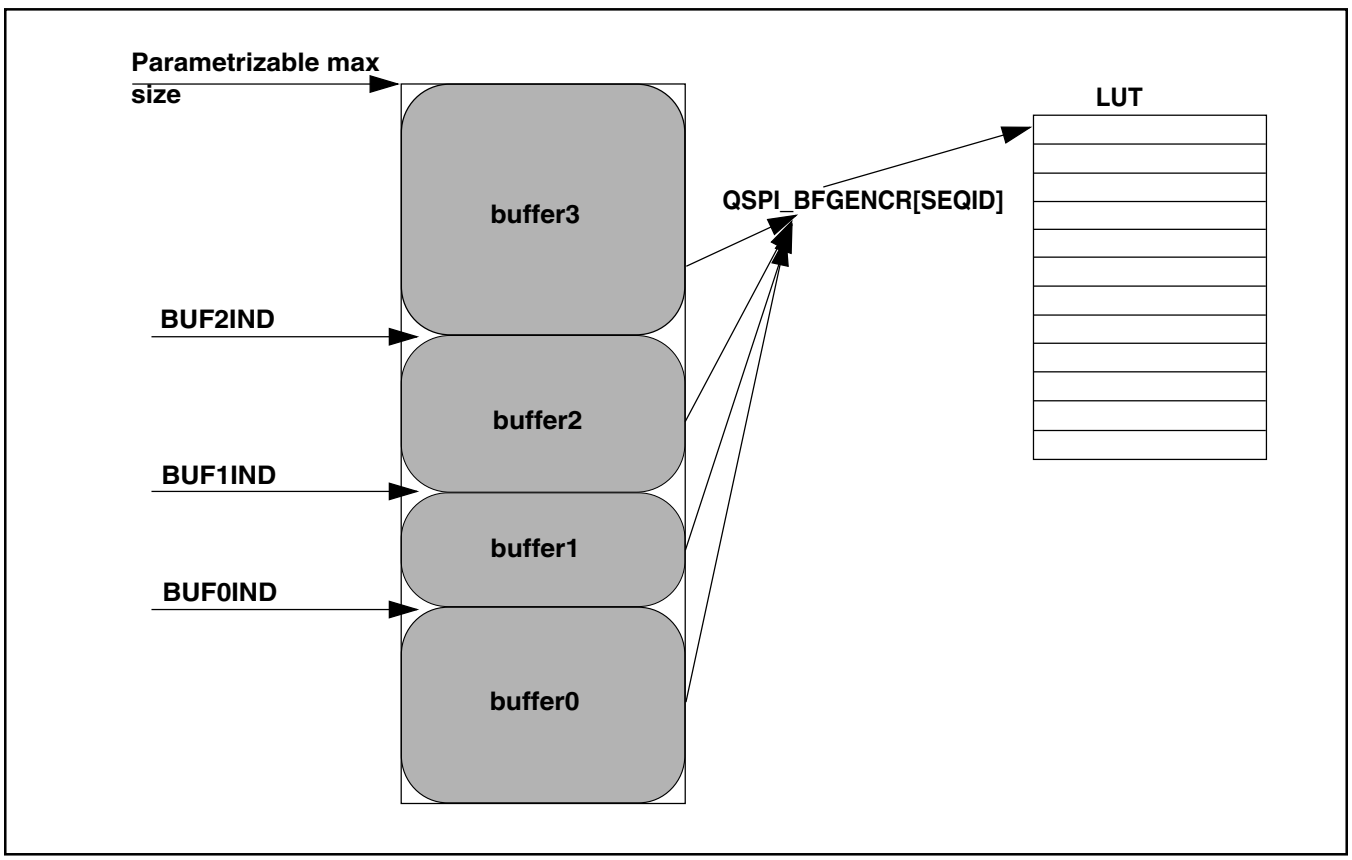

Figure 10-18. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes,

the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from Sequence Suspend Status Register (QuadSPI_SPNDST).

10.2.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

10.2.5.3.4 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

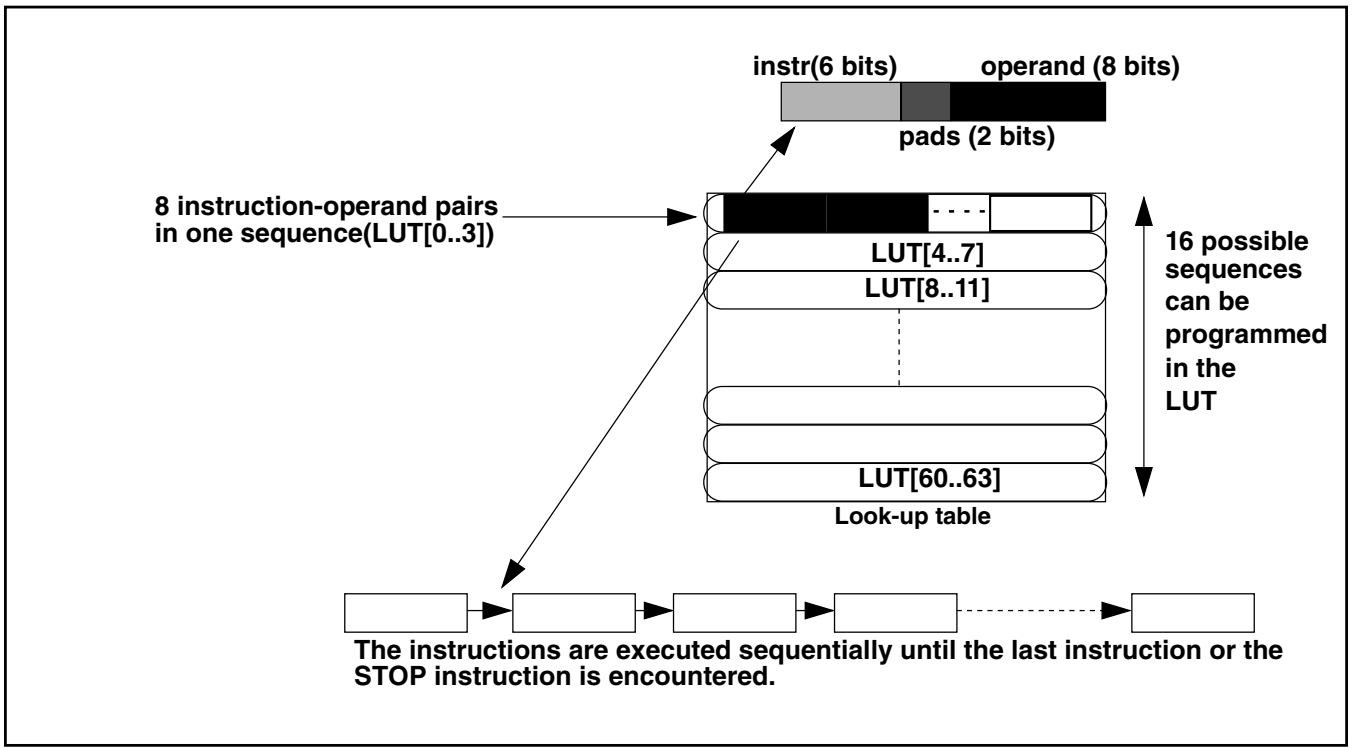

Figure 10-19. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in Table 10-15. After reset the complete LUT may be reprogrammed according to the device connected on board.In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again.The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register (QuadSPI_LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key **(0x5AF05AF0)** into the LUT Key Register (QuadSPI_LUTKEY)
2. Write 0b10 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register unlocks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in Example Sequences. The reset sequence at LUT index 0 is given in the following table.

Table 10-15. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

10.2.5.3.5 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.
4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in Flash Programming and Flash Read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

  For IP Commands the required components need to be written into the following registers:

  - Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to Serial Flash Address Register (QSPI_SFAR). For IP Commands not related to specific addresses, the base address of the related flash need to be

programmed.For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.

- Write the sequence ID and data size details in the IP Configuration Register (QSPI_IPCR).
- Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to IP Configuration Register (QSPI_IPCR) for details.

Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in Command Arbitration.

- **Using AHB commands**

  Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in Flexible AHB buffers.

  An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A and Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B.

  Again the possible error conditions are described in Command Arbitration .

10.2.5.3.6 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXEDA] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.
3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least four word of data must be written into the TX Buffer up to a maximum of 32.

4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed.The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register.The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **32** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented by four after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

10.2.5.3.7 Flash Read

Host access to the data stored in the external serial flash device is done in two steps. First, the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. **Reading Serial Flash Data into the QuadSPI Module Internal Buffers**

   A read access to the external serial flash device can be triggered in two different ways:

   - **IP Command Read**: For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QuadSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

     Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QuadSPI_MCR[CLR_RXF] field.

From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command, the IP_ACC status bit and the BUSY bit are both set (both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read**: For **reading flash data into the AHB Buffer** the user must set up a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence in programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module (refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A, Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B and Parallel Flash Mode.)

  On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. **Data Transfer from the QuadSPI Module Internal Buffers**

   The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers.The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to Block Diagram for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

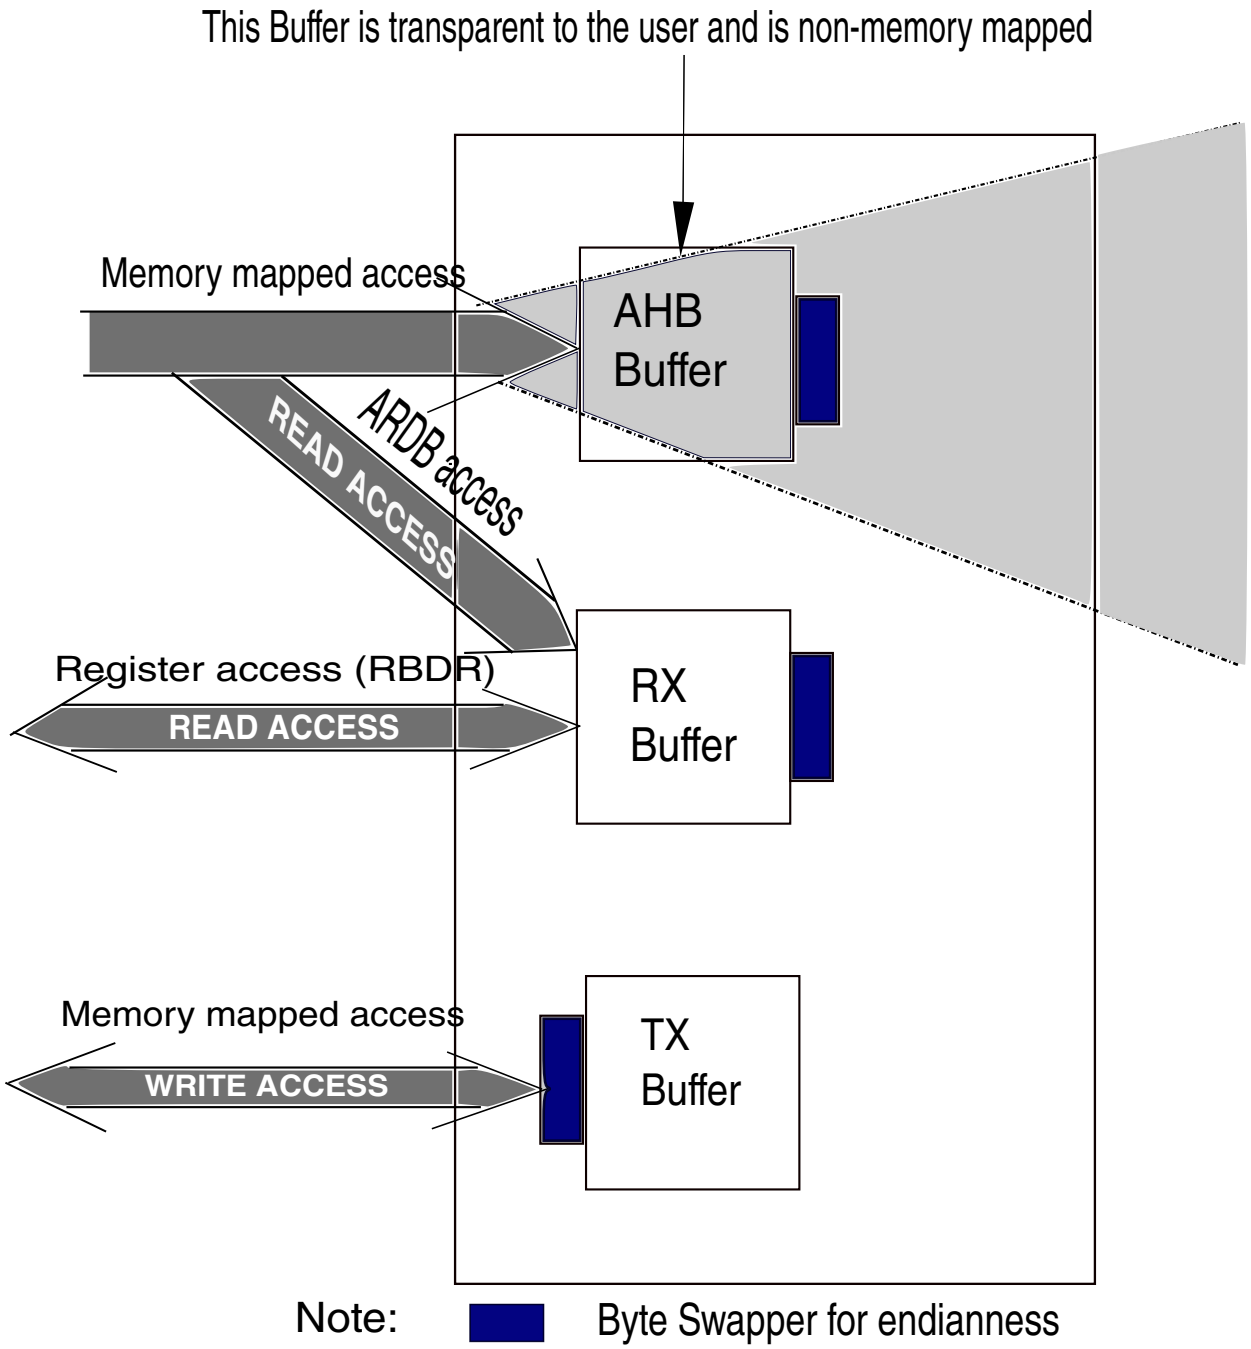

Figure 10-20. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

  In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31

  In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in RX Buffer Data Register (QuadSPI_RBDR*n*) and in AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer will discard 16 bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module.The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in DMA Usage.

  DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in Table 10-8 table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress.* If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

  When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is possible to run sequential reads from the AHB buffer at arbitrary speed without

the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

10.2.5.3.8 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

  The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

  - Flash A or Flash B in Individual Flash Mode
  - All AHB data read commands with access size of 32 bit

Table 10-16. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] (32 Bit data width)	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Byte Ordering in Parallel Flash Mode**

  In Parallel Flash Mode each byte is combined out of 2 half bytes which are read in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 10-17. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbl0
1	fah1	fal1	fbh1	fbl1
2	fah2	fal2	fbh2	fbl2
3	fah3	fal3	fbh3	fbl3
4	fah4	fal4	fbh4	fbl4
5	fah5	fal5	fbh5	fbl5
6	fah6	fal6	fbh6	fbl6
7	fah7	fal7	fbh7	fbl7
8	fah8	fal8	fbh8	fbl8

The table entry naming reflects the half byte positioning in the serial flash devices:

- **<fa>**h0 means **Flash A**, <fb>h0 means Flash B.
- fa**<h>**0 means half byte in **high position**, fa<l>o means half byte in low position.
- fah**<0>** means **physical byte address 0** in the serial flash device, fal<1> means physical byte address 1 in the serial flash device.

Table 10-18. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000

Table continues on the next page...

Table 10-18. Byte Ordering in Parallel Flash Mode - RX Buffer (continued)

QSPI_RBDR0 **QSPI_ARDB0**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_RBDR1 **QSPI_ARDB1**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 **QSPI_ARDB0**	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
QSPI_RBDR1 **QSPI_ARDB1**	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

* Appicable only for single io mode.

Table 10-19. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address **(32 Bit Access)**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB Address 0x800_0004 **(32 Bit Access)**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 10-20. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	Odd (1, 3, 5, ...)	Even (0, 2, 4, ...)

10.2.5.3.9 Normal Mode Interrupt and DMA Requests

The QuadSPI module has different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the Flag Register (QSPI_FR).

Table 10-21. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_FR)	DMA
Data Learn patttern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the Flag Register (QSPI_FR) and a Request Enable bit in the DMA Request Select and Enable Register (QSPI_RSER) . The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- Transmit Buffer Fill Interrupt Request:

  The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to TX Buffer Operation, for details about the assertion of the QSPI_FR[TBFF] flag.

- Receive Buffer Drain Interrupt or DMA Request:

  The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

  Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries.The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer Overflow/Underrun Interrupt Request:

  The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

  - TBUF - TX Buffer Underrun, enabled by TBUIE
  - RBOF - RX Buffer Overflow, enabled by RBOIE
  - ABOF - AHB Buffer Overflow, enabled by ABOIE

    The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

    The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

    The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

    The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

  If the IPAEF, IPIEF, IPGEF or IUEF flags in the QSPI_FR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

  The IP Command Transaction Finished IRQ indicates the completion of the current IP Command.It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

10.2.5.3.10 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least four entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag.The TX buffer underrun flag is also asserted when TX buffer contains less than 128 bits of data and QuadSPI module tries to pull out data from it. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition when QuadSPI module tries to pull out data of empty TX buffer, the data transferred is all F's i.e. once the underrun flag is set under this condition, it will return F's until the required number of bytes are not sent. This has been done to ensure that the software need not to erase whole sector after underrun, just reprogramming from failure point will serve the purpose. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to TX Buffer Status Register (QuadSPI_TBSR) and Flag Register (QuadSPI_FR) for details about the TX Buffer related registers.

10.2.5.3.11 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

  In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8'd32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

  In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

10.2.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

10.2.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

10.2.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

10.2.6.2.1 IP Commands

Refer to IP Configuration Register (QuadSPI_IPCR) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

  Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

  When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

  Refer to Table 10-22 below.

10.2.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in Flash Read for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

  Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

  Refer to Table 10-22 below.

10.2.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 10-22. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flag	ABSEF	Flash transaction is aborted	AHB sequence contains • WRITE instruction • WRITE_DDR instruction
AHB Error Flag	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flag	DLPFF[1]	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
Miscellaneous Error Flag	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.
Command Arbitration Error	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
Command Arbitration Error	IPAEF		• AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
Command Arbitration Error	IPGEF		• Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF	—	• IP Command Usage Error
Buffer Related Error	RBOF	TFF is asserted on completion	• RX Buffer Overrun

Table continues on the next page...

Table 10-22. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Buffer Related Error	TBUF		• TX Buffer Underrun

1. Data learning is not implemented on this chip.

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

10.2.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for a description of the flags and Command Arbitration , for details about possible command collisions.

10.2.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDR*n* register) and the other masters by triggering AHB Commands (via ARDB*n* Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer.Refer to Figure 10-20 To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

10.2.6.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

10.2.6.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0, allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

10.2.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in Exclusive Access to Serial Flash for AHB Commands is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR

register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for details), this command is stalled until the currently running IP Command is finished.

- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to Flag Register (QuadSPI_FR) for the description of these flags.

  When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

10.2.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to Serial Flash Address Register (QuadSPI_SFAR) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to AMBA Bus Register Memory Map for details.

10.2.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

10.2.6.6.1 DMA Usage in Normal Mode

10.2.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side (data read):

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles
- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_RBCT[WMRK] field, therefore the overhead given above distributes among (QSPI_RBCT[WMRK]+1)/2 read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 10-23. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop [1]	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	12+2 = 14	~117ns
1	8	12+2 = 14	~117ns
3	16	12+4 = 16	~133ns
7	32	12+8 = 20	~167ns
11	48	12+12 = 24	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

NOTE

The table figure represents ideal scenario, actual performance will depend on how the system is integrated.

Serial Flash Device Side (data read):

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry (setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad (SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 10-24. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM [2] Quad	IFM Quad DDR	PFM [3] Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

NOTE

The tables mentioned above are only examples which must be correlated with the DMA in the system.

10.2.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Both write and read operations are supported in parallel mode. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

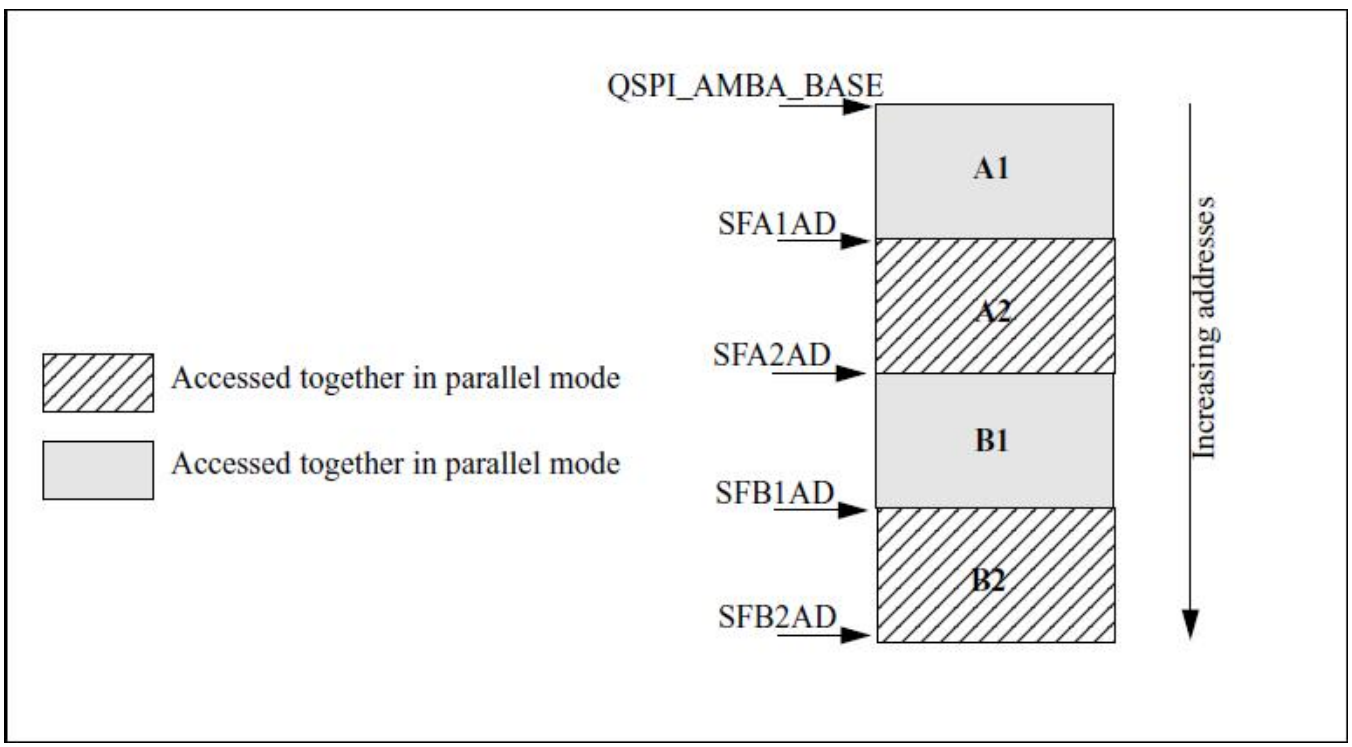

Figure 10-21. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

Flash Address = (Memory mapped address - QSPI_AMBA_BASE)/2

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

Flash Address = (Memory mapped address - SFA2AD)/2

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

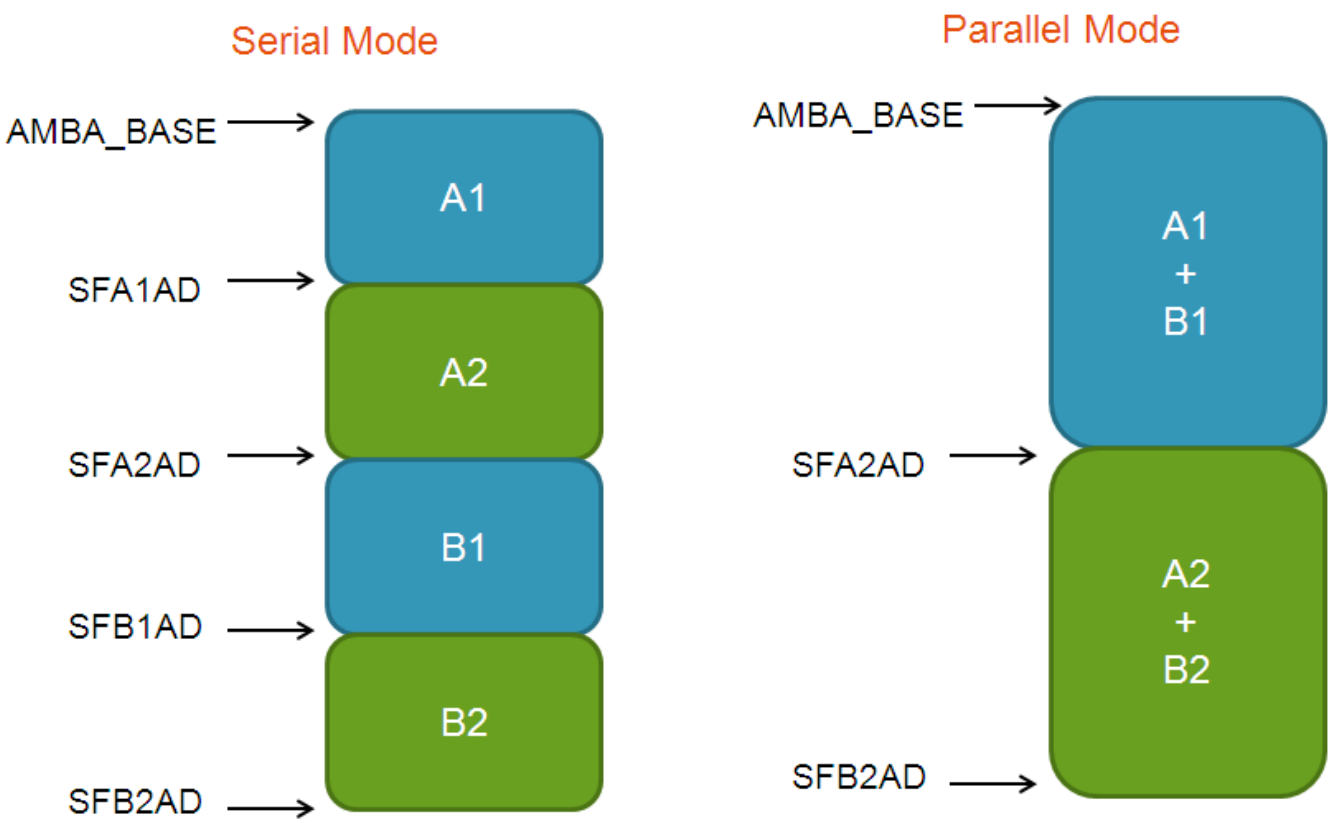

Figure 10-22. Memory map - Serial and Parallel

10.2.7 Byte Ordering - Endianness

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64 bit LE format on the AHB bus and 32 bit LE format on the IPS interface when read via the RX buffer and written in 32 bit LE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions.Refer to figure Figure 10-20

Table 10-25. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 10-26. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 10-27. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

10.2.7.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 10-28. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01…02…03…04…05…06…07…08

10.2.7.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the RX Buffer filled with:

Table 10-29. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

10.2.7.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the Peripheral bus interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

10.2.7.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

10.2.7.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the AHB Buffer filled with:

Table 10-30. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

10.2.7.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

10.2.8 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

10.2.8.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 10-31. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/ Winbond flashes.

Table 10-32. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 10-33. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 10-34. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

10.2.8.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 10-35. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

10.2.8.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 10-36. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 10-37. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

10.2.8.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/ Numonyx/Winbond flashes.

Table 10-38. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

10.2.8.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

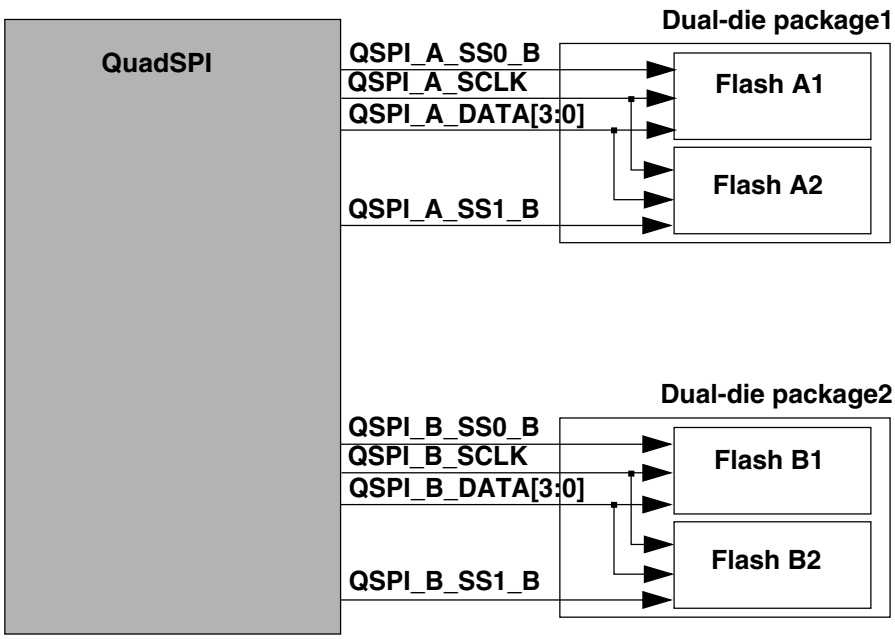

Figure 10-23. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

10.2.8.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI:

- System out of reset and flash available (300us)
- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.

- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation
  - Continuous mode entry sequence
  - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - Parallel enable set
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

10.2.9 Sampling of Serial Flash Input Data

10.2.9.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device.Refer to the following figure for an overview of this scheme.

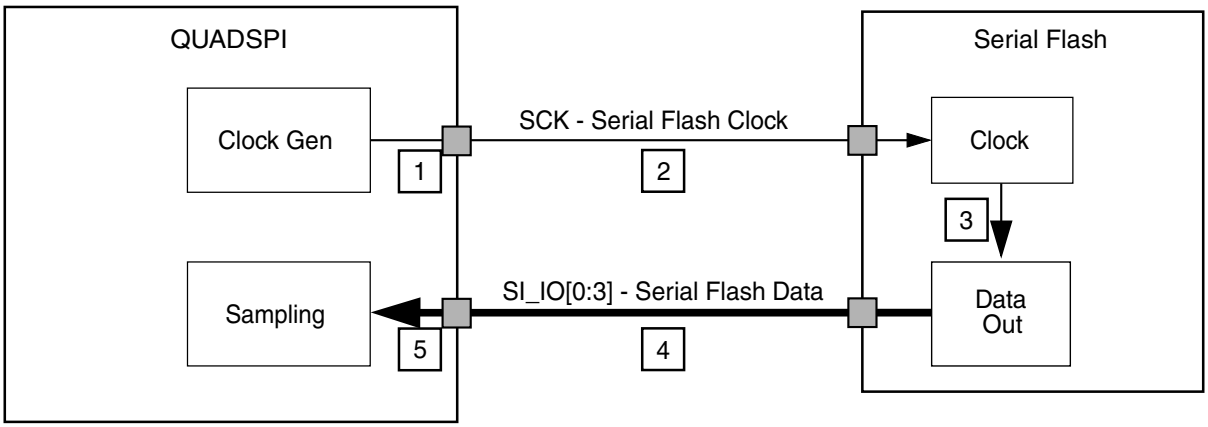

Figure 10-24. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

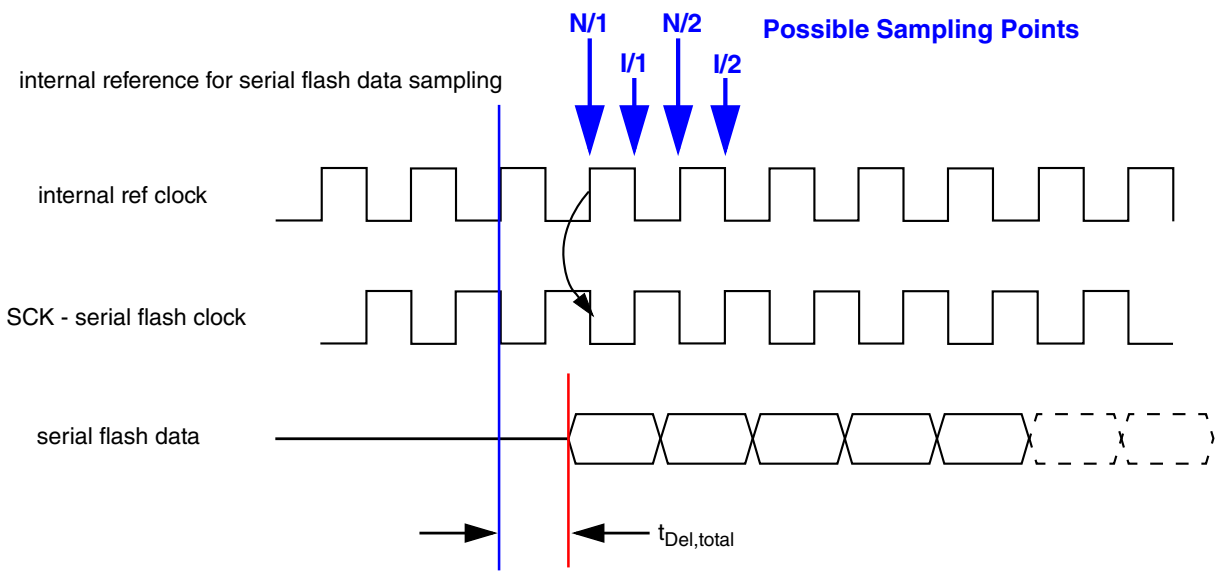

Figure 10-25. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to Sampling Register (QuadSPI_SMPR) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 10-39. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting[1]
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.

- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash date get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SPMPR register.

10.2.9.2 DDR Mode

The increasing requirement of improved throughput has introduced the double data rate (DDR) mode. In DDR mode, the data is transferred on both the rising and falling edges of the serial flash clock. The DDR serial flashes sample as well as drive the data on both rising and falling edges of serial flash clock.

10.2.10 Serial Flash Data Input Timing

There are sampling modes for input flash data:

- Internal sampling - Input serial flash data is captured by internal serial clock. In SDR mode, serial data is sampled by serial clock 1x (ser_clk_1x) rise edge. In DDR mode, serial data is sampled by serial clock 4x (ser_clk_4x) rise edge.
- Loopback DQS sampling - Soc will output serial data strobe with internal serial clock. This serial data strobe would be loopback from pad and used to sample input serial data. In SDR mode, serial data is sampled by loopback DQS rise edge. In DDR mode, serial data is sampled by loopback DQS both edge

NOTE

DQS pad need to be set to force input for loopback.

- Flash DQS sampling - Some serial Flash device provide the data strobe output together with serial data. This strobe signal is used to sample input serial data directly. In SDR mode, serial data is sampled by Flash DQS rise edge. In DDR mode, serial data is sampled by Flash DQS both edge

Following table shows selection for sampling mode:

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Internal sampling	0	doesn't matter

Table continues on the next page...

Sampling mode	DQS_EN	DQS_LOOPBACK_EN
Loopback DQS sampling	1	1
Flash DQS sampling	1	0

Serial flash data and clock path for input timing is shown in the following figure.

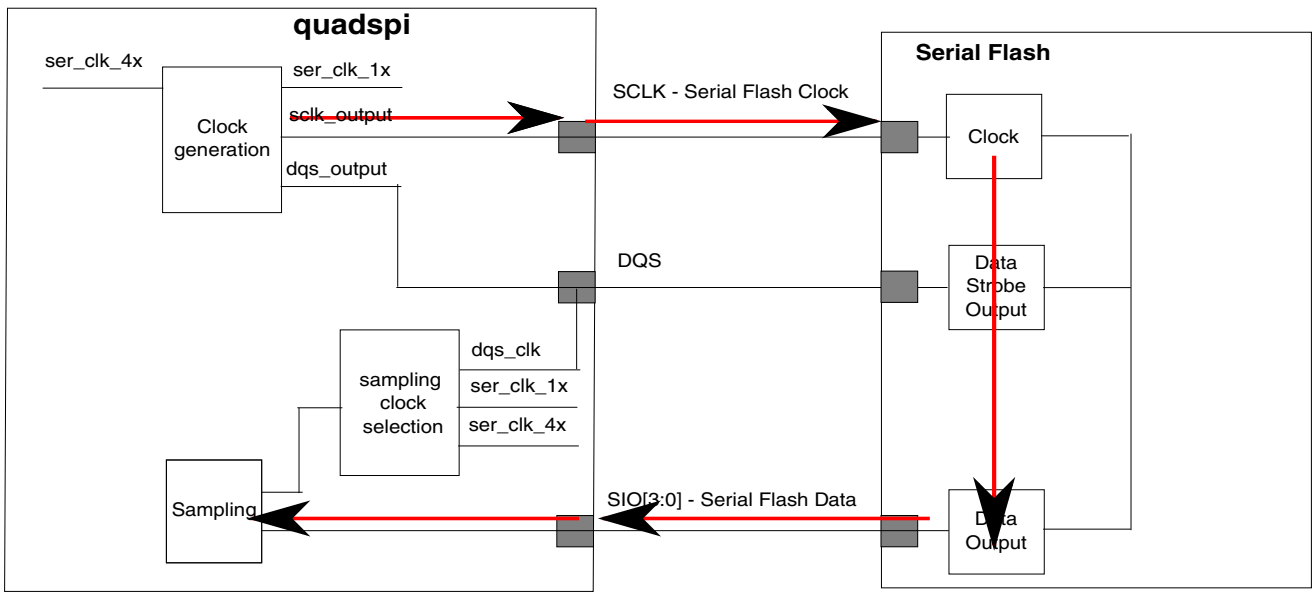

Figure 10-26. Serial flash data and clock path

NOTE

The red line is for data input path, the blue line is for DQS loopback path, and the purple line is for DQS input path from Serial Flash.

Total delay (Ttotal_delay_data) for serial flash data input is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device
3. Clock to Output Valid time of external Serial Flash Device
4. Wire delay of serial flash data (SIO) from external serial Flash Device to SOC
5. Input delay of serial flash data from SIO pad to internal sample register

Total delay (Ttotal_delay_loopback_dqs) for loopback DQS clock is the sum of following delay:

1. Output delay of DQS clock from internal serial clock to DQS pad inside SOC
2. Input delay of DQS clock from DQS pad to internal sample register

Total delay (Ttotal_delay_flash_dqs) for Flash DQS clock is the sum of following delay:

1. Output delay of serial flash clock from internal serial clock to SCLK pad inside SOC
2. Wire delay of serial flash clock (SCLK) from SOC to external Serial Flash Device

3. Clock to DQS Output time of external Serial Flash Device
4. Wire delay of serial flash data strobe (DQS) from external serial Flash Device to SOC
5. Input delay of DQS clock from DQS pad to internal sample register

10.2.10.1 Input timing in SDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the figure below.

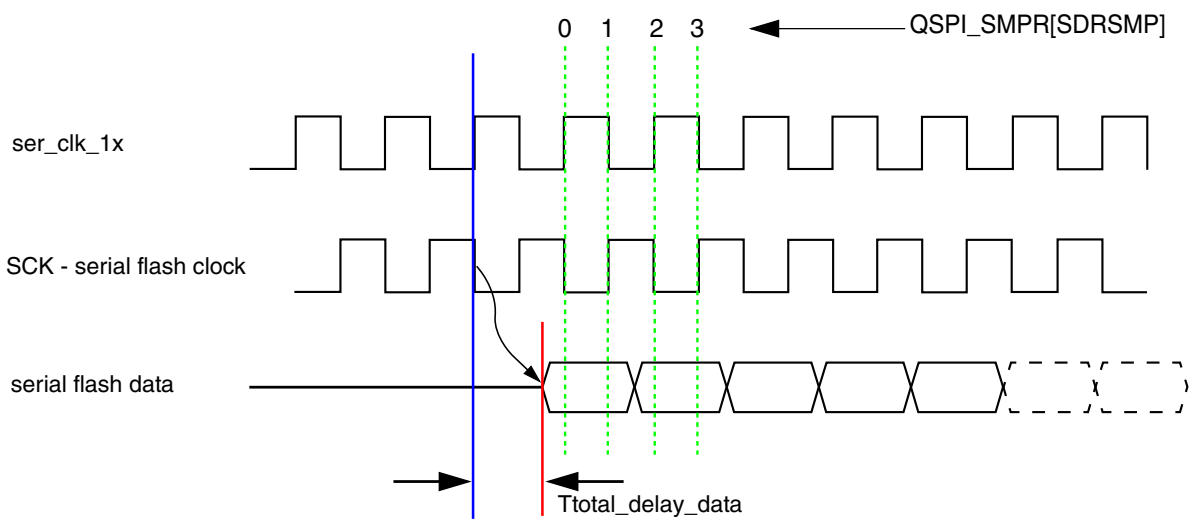

Figure 10-27. Internal sample SDR

There are four sample points for this sampling mode, which is determined by register field QSPI_SMPR.SDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

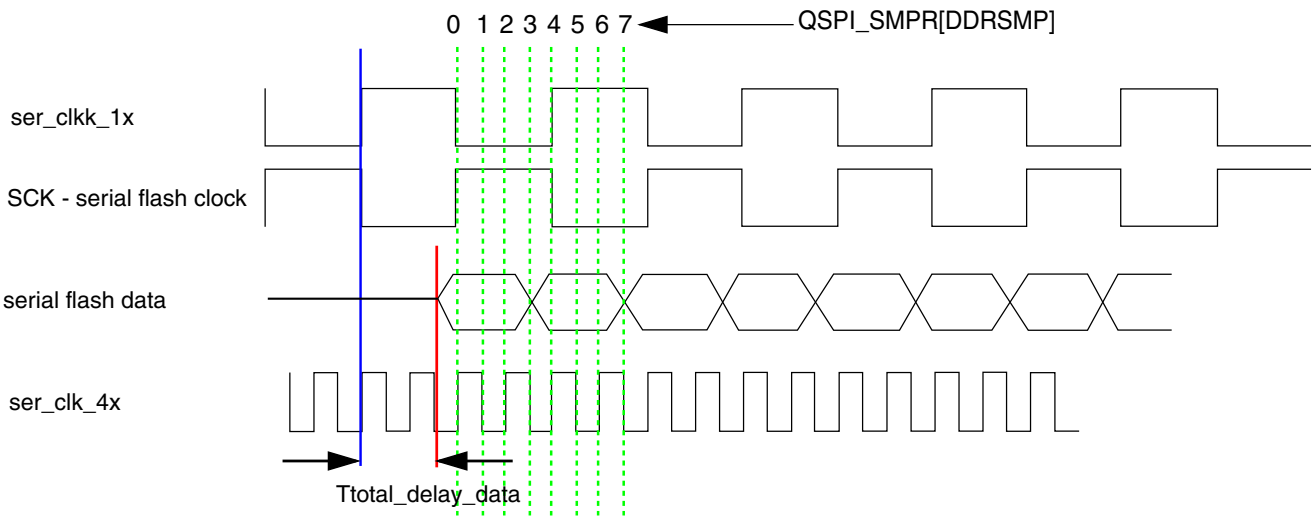
- For sample point N, Setup requirement is: Tcycle*(N+2)/2>Ttotal_delay_data,max
- For sample point N, Hold requirement is: Ttotal_delay_data,min>Tcycle*N/2

NOTE

Tcycle is the cycle of ser_clk_1x. Ttotal_delay_data,max is maximum delay of serial data input path. Ttotal_delay_data,min is the minimum delay of serial data input path. N=0,1,2,3

10.2.10.2 Input timing in DDR mode with internal sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.



There are 8 sample points for this sampling mode, which is determined by register field DDRSMP.

Sampling point need to be select correctly to meet both Setup and Hold timing for internal sample registers:

- For sample point N, Setup requirement is: Tcycle * (N+2)/8 >Ttotal_delay_data,max
- For sample point N, Hold requirement is: Ttotal_delay_data,min> Tcycle * N/8

10.2.10.3 Input timing in SDR mode with loopback DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

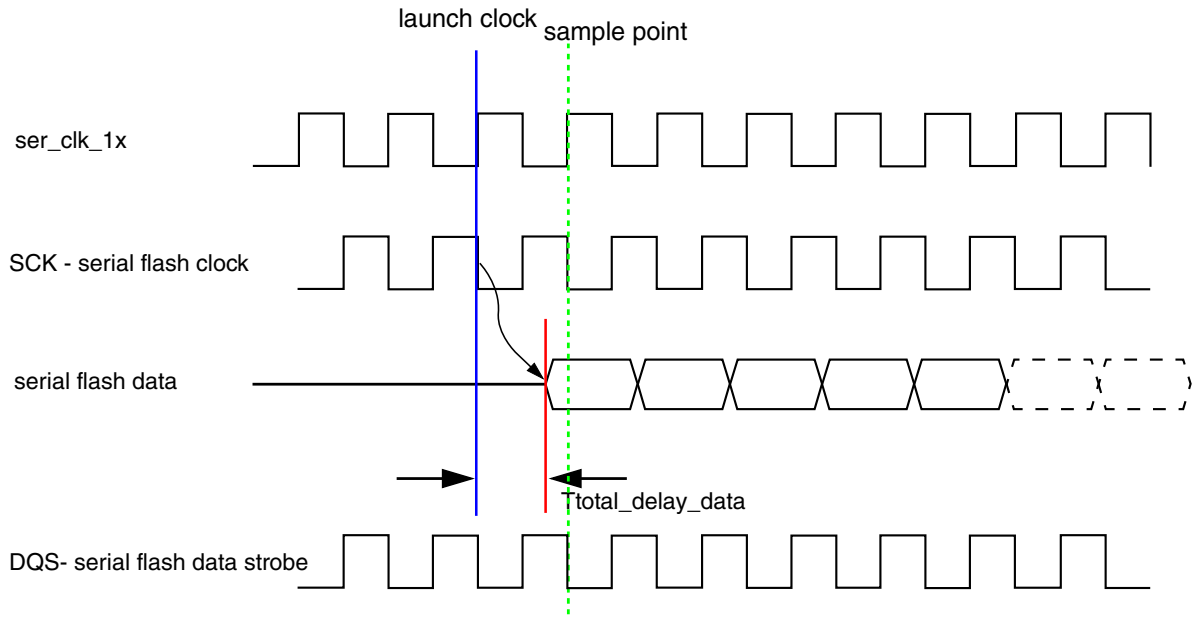


Figure 10-28. Input timing in SDR mode with loopback DQS sampling

In SDR mode and loopback sampling mode, DQS_PHASE_EN should be set 1.

For this sample point, the Setup requirement is: Tcycle >max(Ttotal_delay_data-Ttotal_delay_loopback_dqs). The Hold requirement is: min(Ttotal_delay_data-Ttotal_delay_loopback_dqs)> 0.

10.2.10.4 Input timing in DDR mode with loopback DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

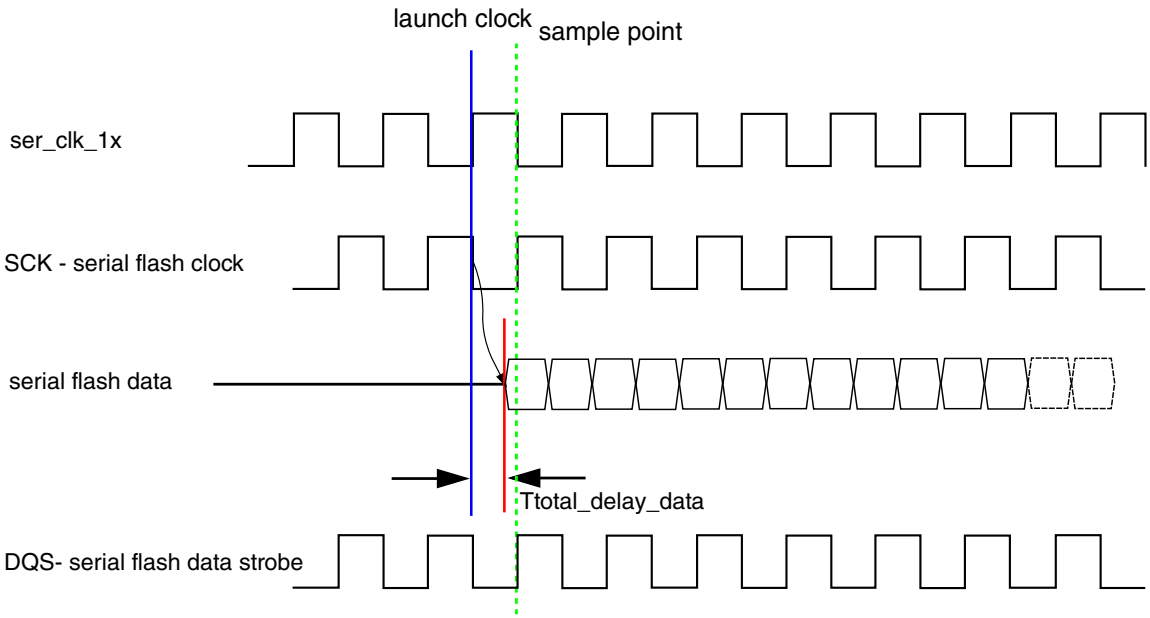

Figure 10-29. Input timing in DDR mode with loopback DQS sampling

In DDR mode and loopback sampling mode, DQS_PHASE_EN should be set 0.

For this sample point, the Setup requirement is: Tcycle >max(Ttotal_delay_data-Ttotal_delay_loopback_dqs). The Hold requirement is: min(Ttotal_delay_data-Ttotal_delay_loopback_dqs)> 0.

10.2.10.5 Input timing in SDR mode with flash DQS sampling

Input Timing diagram in SDR mode with internal sampling is show in the following figure.

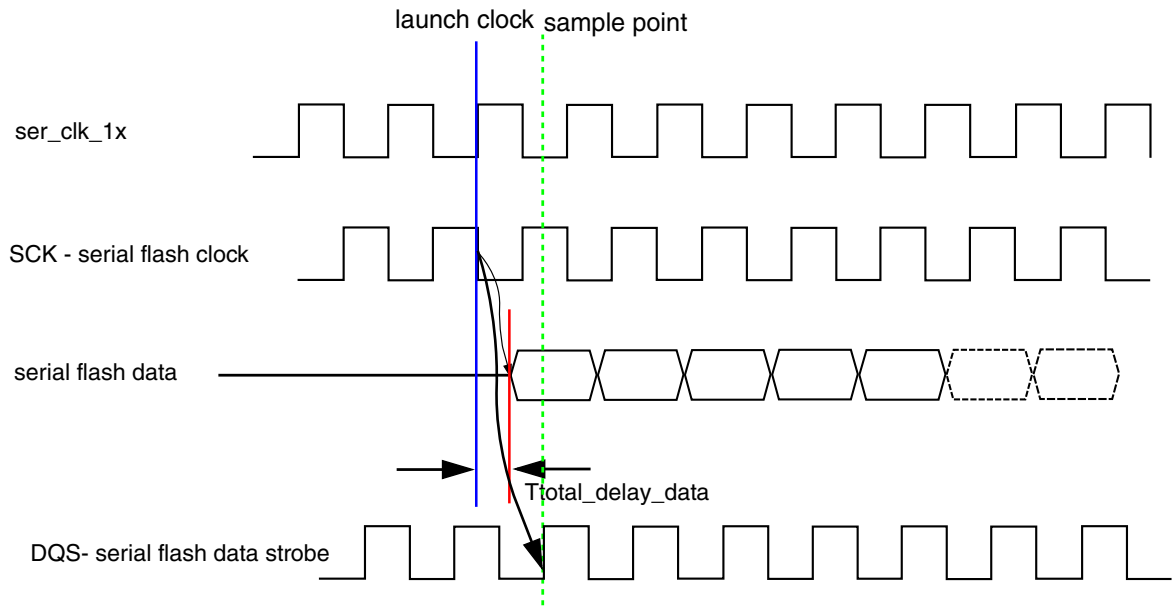

Figure 10-30. Input timing in SDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.10.6 Input timing in DDR mode with flash DQS sampling

Input Timing diagram in DDR mode with internal sampling is show in the following figure.

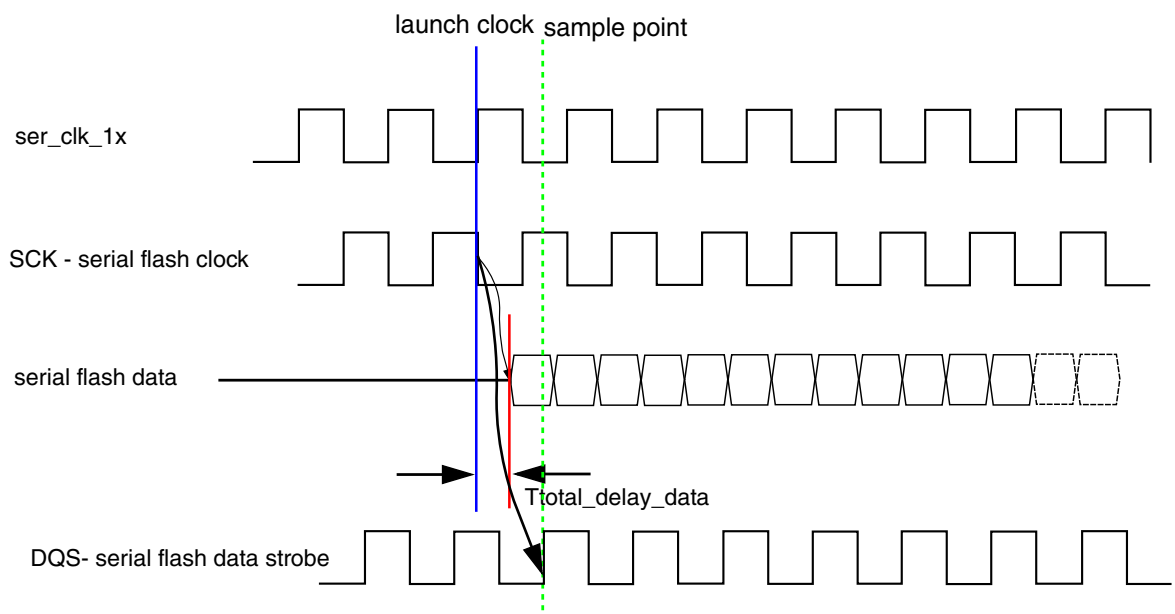

Figure 10-31. Input timing in DDR mode with flash DQS sampling

In this sampling mode, there will be a setup/hold requirement on Flash serial Data and Flash serial Data Strobe. This value will be specified in the data sheet.

10.2.10.7 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

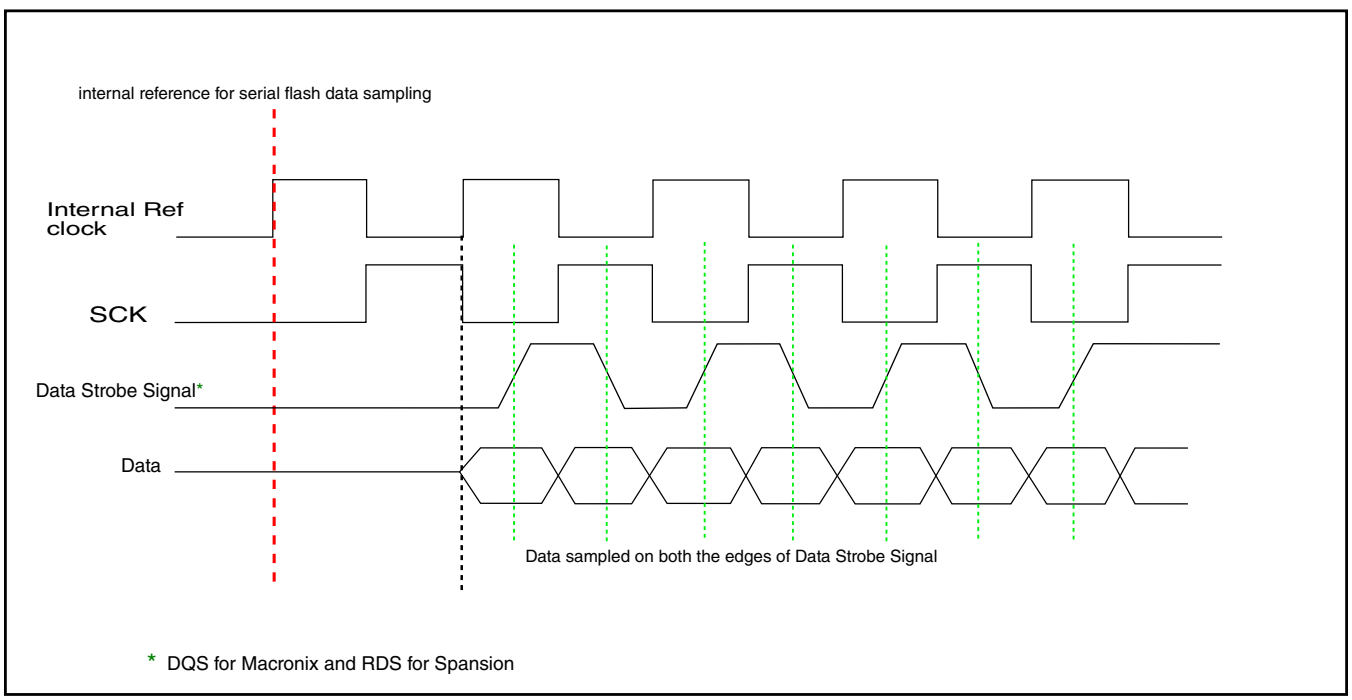

Figure 10-32. Data strobe signal functionality

10.2.11 Output timing in SDR mode

Output timing diagram in SDR mode is show in the following figure.

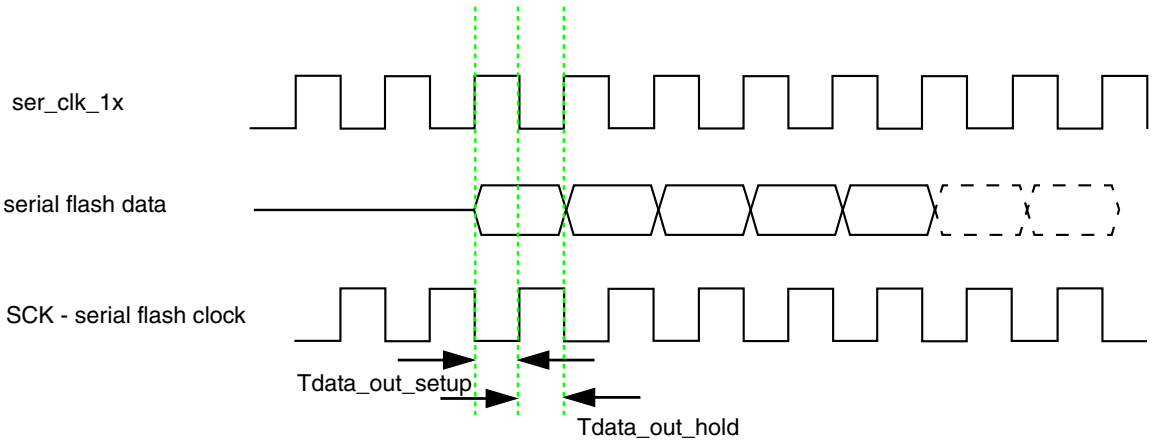

Figure 10-33. Output timing in SDR mode

In SDR mode, quadspi output serial data with internal serial clock rise edge 1x (ser_clk_1x). Flash Device has requirement on Data and Clock setup and hold timing.

10.2.12 Output timing in DDR mode

Output Timing diagram in DDR mode is show in the following figure.

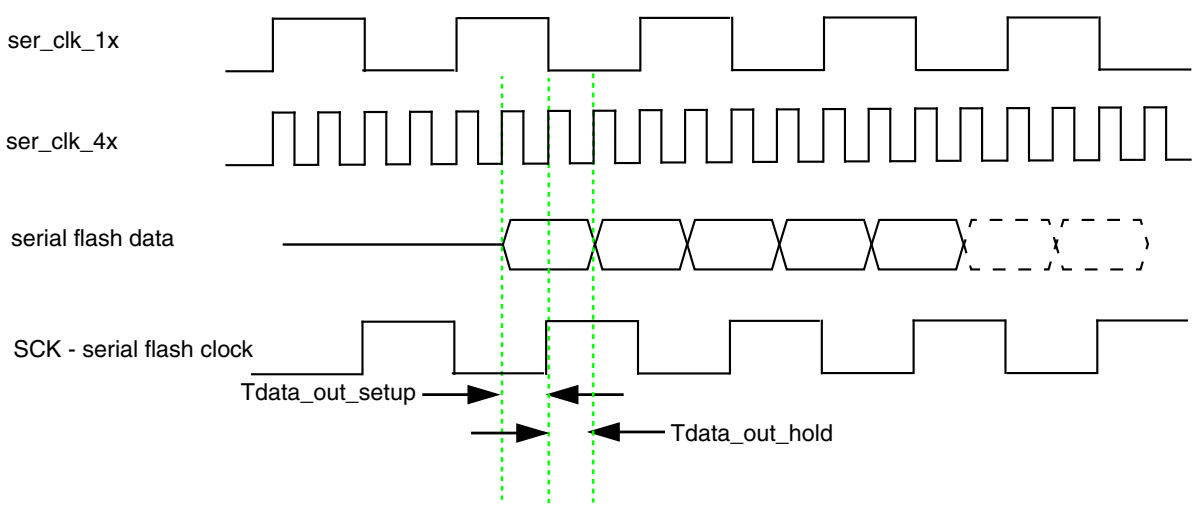

Figure 10-34. Output timing in DDR mode

In DDR mode, quadspi output serial data with internal serial clock both edge 1x (ser_clk_1x) and then delay one ser_clk_4x cycle for hold timing.

NOTE

TX_DDR_DELAY_EN should be set to 1 for DDR mode.

10.2.13 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

10.2.13.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

NOTE

See the System Memory map in this document for the base address of the QSPI AHB RX Data Buffer.

10.2.13.1.1 AHB RX Data Buffer register (ARDB*n*)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to Byte Ordering of Serial Flash Read Data for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 0h offset + (4d × i), where i=0d to 31d

QuadSPIx_MCR field descriptions

Field	Description
31–27 Reserved	This field is reserved.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
26 DQS_PHASE_EN	This bit controls internal DQS output phase. If DQS_EN and DQS_LOOPBACK_EN are both set to 1, this bit should be set in SDR mode, and cleared in DDR mode. If either DQS_EN or DQS_LOOPBACK_EN is set to 0, this bit is ignored.
25 DQS_LOOPBACK_EN	Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback.Quadspi will output serial data strobe signal which will be loopback from pad to sample input flash serial data. Please note pad should be force input for loopback. This bit is a don't care when DQS_EN is set to 0. 1'b1 DQS loopback sampling enabled 1'b0 DQS loopback sampling disabled
24 DQS_LOOPBACK_FROM_PAD	This bit should always be set to '1' when DQS_LOOPBACK_EN is set to '1'. When DQS_LOOPBACK_EN is set to '1', this bit is ignored.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer. 0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid for both SDR and DDR mode.For more details Refer Data Strobe Signal Functionality

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
	0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input when QSPI_MCR[DDR_EN] is set, else, on only one edge when QSPI_MCR[DDR_EN] is 0. The QSPI_SMPR[DDR_SMP] values are ignored.
5–4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QSPI module.For more details refer to Byte Ordering Endianess
1 SWRSTHD	Software reset for AHB domain **NOTE:** Please keep other fields value when write to SWRSTHD and SWRSTSD **NOTE:** These software reset don't reset register setting but only reset internal flip-flops in quadspi controller **NOTE:** To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain **NOTE:** Please keep other fields value when write to SWRSTHD and SWRSTSD **NOTE:** These software reset don't reset register setting but only reset internal flip-flops in quadspi controller **NOTE:** To remove the reset, need to write 0 to SWRSTHD and SWRSTSD 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

10.2.14.2 IP Configuration Register (QuadSPIx_IPCR)

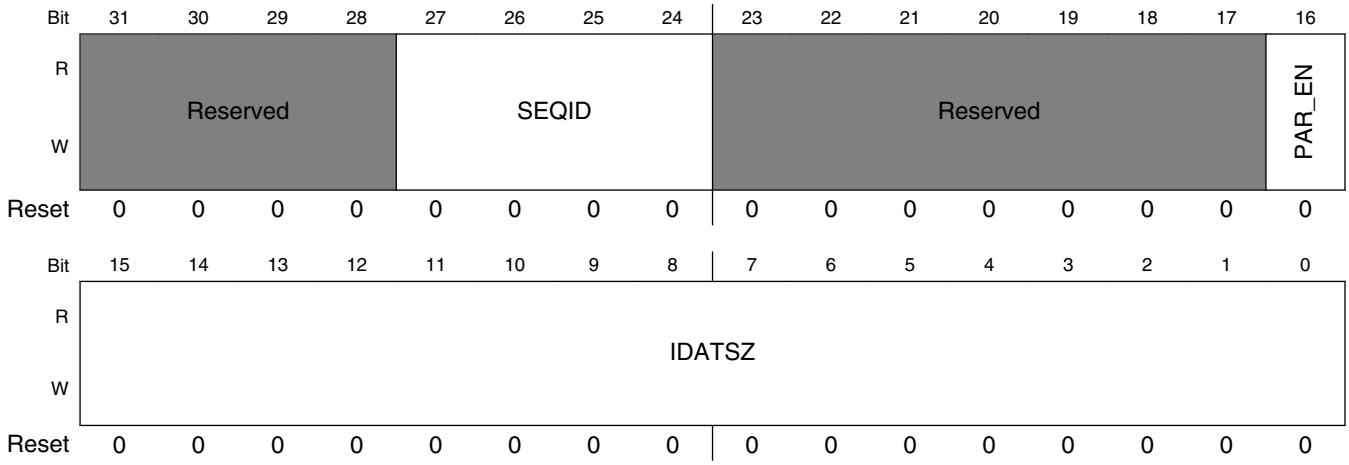
The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to Normal Mode , for details about the command triggering and command execution.

Write:

- *QSPI_SR[IP_ACC]=0*

AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

Address: Base address + 8h offset



QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

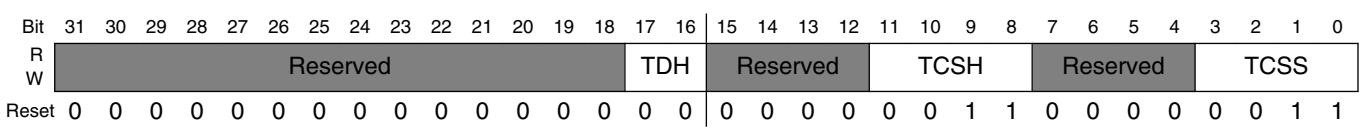
10.2.14.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- *QSPI_SR[AHB_ACC] = 0*
- *QSPI_SR[IP_ACC] = 0*

Address: Base address + Ch offset



QuadSPIx_FLSHCR field descriptions

Field	Description
31–18 Reserved	This field is reserved.
17–16 TDH	Serial flash Data In hold time: This helps in meeting the Data In Hold time requirement of a Flash. This is valid only in DDR mode. Refer to Data input hold requirement of Flash for details. **NOTE:** This field should be set to 01 in DDR mode (DDR_EN=1) and set to 00 in SDR mode (DDR_EN=0). Other value are reserved. 00 Data aligned with the posedge of Internal reference clock of QuadSPI 01 Data aligned with 2x serial flash half clock 10 Reserved 11 Reserved
15–12 Reserved	This field is reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles. **NOTE:** The actual delay between chip select assertion and clock fall edge is defined as: • 1 SCK cycle if TCSH is set 0 or 1 • N SCK cycle if TCSH is set N (N>1)
7–4 Reserved	This field is reserved. Reserved.
TCSS	Serial flash CS setup time in terms of serial flash clock cycles. **NOTE:** 1. The actual delay between chip select assertion and clock fall edge is defined as: • 0.5 SCK cycle if TCSS is set 0 or 1 • N+0.5 SCK cycle if TCSS is set N (N>1) 2. Any update to TCSS register bits is visible on the flash interface only from the second transaction following the update.

10.2.14.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HP_EN	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example,a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

10.2.14.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash.For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.

Table continues on the next page...

QuadSPIx_BUF1CR field descriptions (continued)

Field	Description
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

10.2.14.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

10.2.14.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

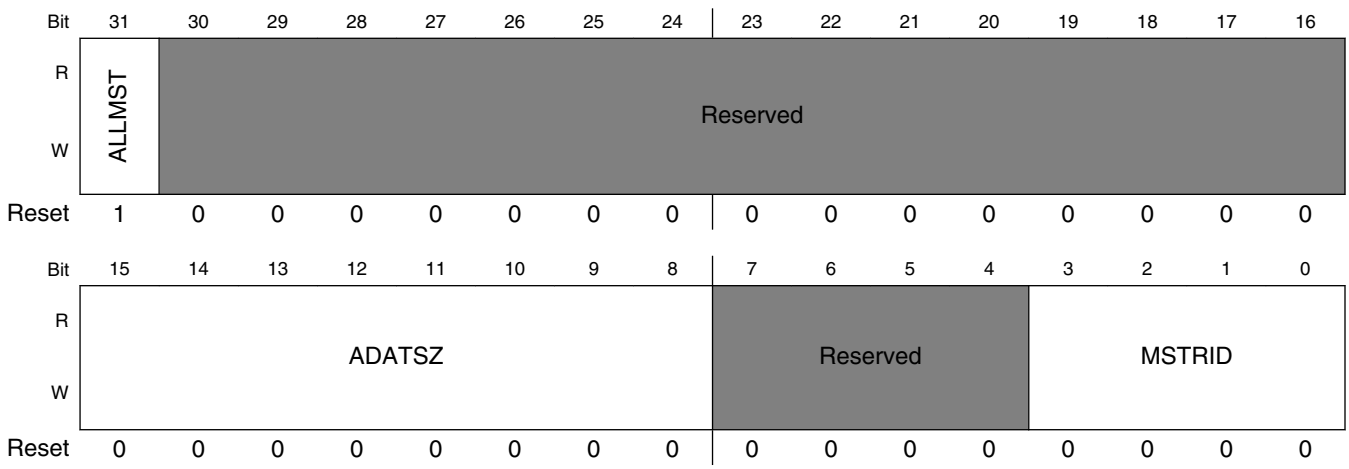
This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- *QSPI_SR[AHB_ACC] = 0*

.

Address: Base address + 1Ch offset



QuadSPIx_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

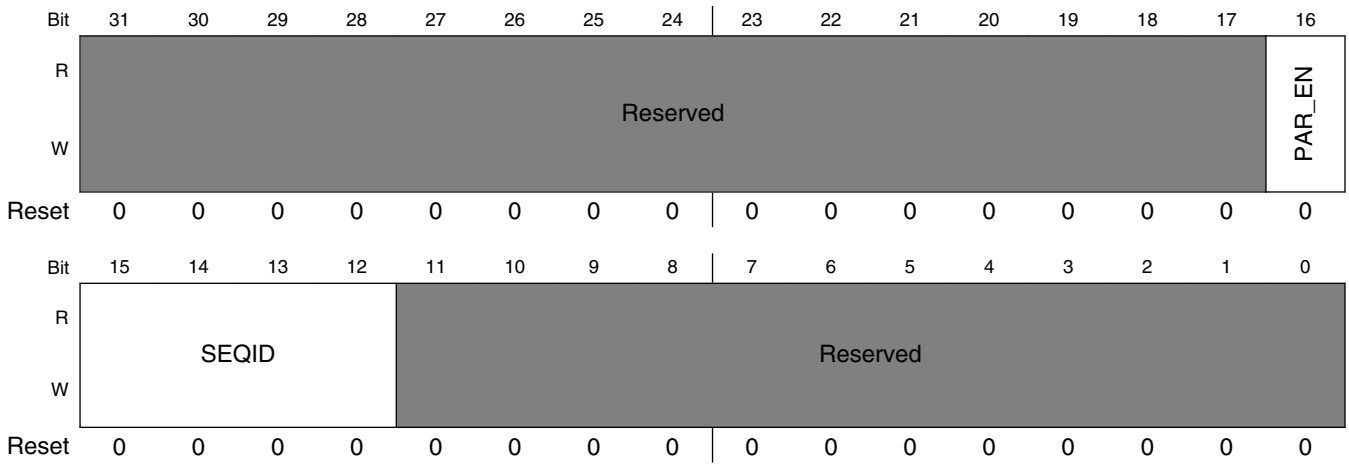
10.2.14.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 20h offset



QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table. **NOTE:** If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
Reserved	This field is reserved.

10.2.14.9 Buffer0 Top Index Register (QuadSPIx_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
Reserved	This field is reserved. Reserved.

10.2.14.10 Buffer1 Top Index Register (QuadSPIx_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF1IND field descriptions

Field	Description
31–3 TPINDX1	Top index of buffer 1.
Reserved	This field is reserved.

10.2.14.11 Buffer2 Top Index Register (QuadSPIx_BUF2IND)

This register specifies the top index of buffer2, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. The size of buffer2 is the difference between the BUF2IND and BUF1IND.

It is the responsibility of the software to ensure that BUF2IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF2IND field descriptions

Field	Description
31–3 TPINDX2	Top index of buffer 2.
Reserved	This field is reserved.

10.2.14.12 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0 Refer to Table 10-7 for the mapping between the access mode and the QSPI_SFAR content and to Normal Mode for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in Table 10-7.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

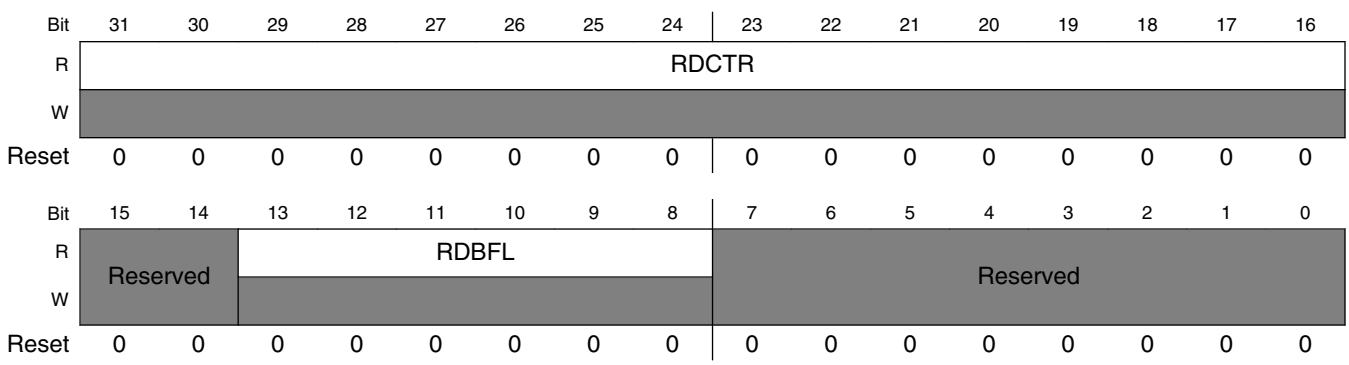
QuadSPIx_SMPR field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 DDRSMP	DDR Sampling point. Select the sampling point for incoming data when serial flash is executing a DDR instruction. Refer to Input timing in DDR mode with internal sampling , for details on the sampling points.
15–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–5 SDRSMP	SDR sampling point.
4–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.2.14.14 RX Buffer Status Register (QuadSPIx_RBSR)

This register contains information related to the receive data buffer.

Address: Base address + 10Ch offset



QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer.For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer.For example a value of 0x2 would indicate 8bytes are available.
Reserved	This field is reserved.

10.2.14.15 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved							RXBRD	Reserved			WMRK				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout. 0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands. 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.
7–5 Reserved	This field is reserved.
WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted.The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to DMA Usage.

10.2.14.16 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
Reserved	This field is reserved.

10.2.14.17 TX Buffer Data Register (QuadSPIx_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 128 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to Table 10-16 for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of four data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- *QSPI_SR[TXFULL] = 0*

32-bit write access required

NOTE

There is no limitation on Flash programming size. But the data size written to TX Buffer should be 64 Byte aligned. If flash programming size is not 64 bytes aligned, please write redundant data to TX Buffers. The redundant data will be ignored by QuadSPI controller.

Address: Base address + 154h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TXDATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

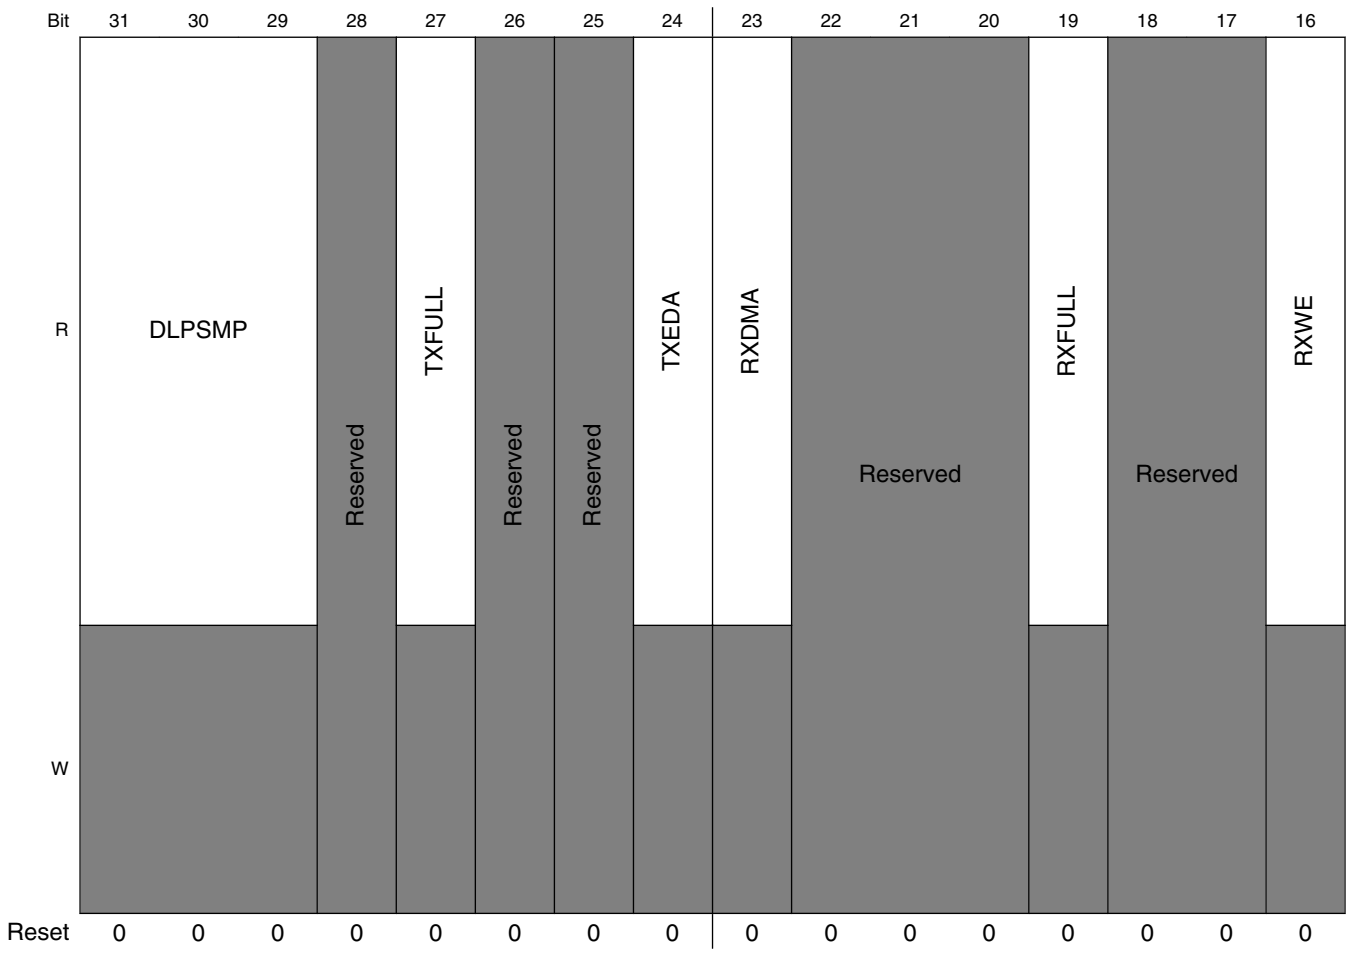
QuadSPIx_TBDR field descriptions

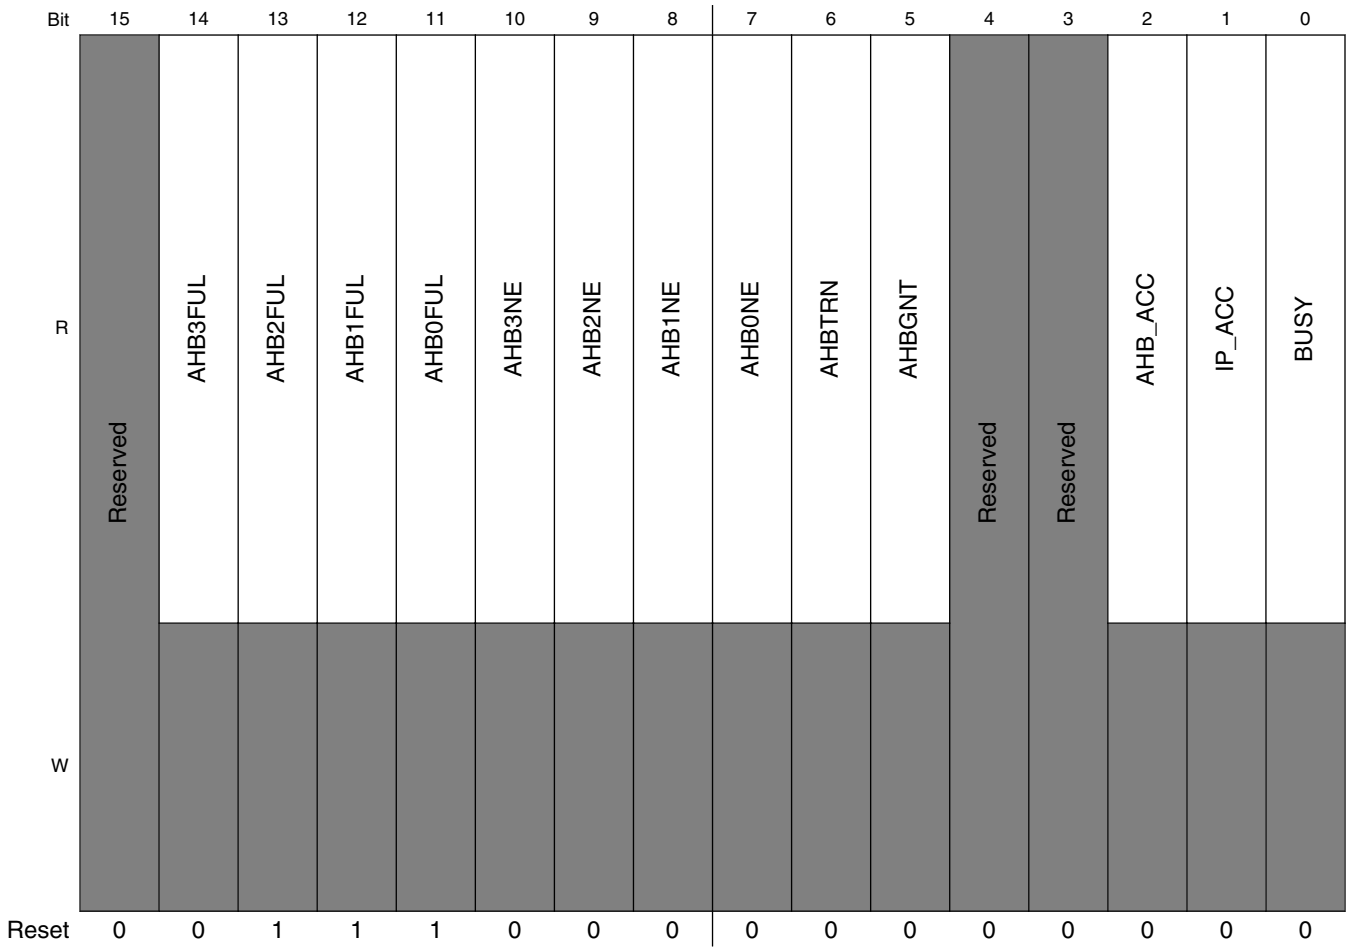
Field	Description
TXDATA	TX Data On write access the data is written into the next available entry of the TX Buffer and the QPSI_TBSR[TRBFL] field is updated accordingly. On a read access, the last data written to the register is returned.

10.2.14.18 Status Register (QuadSPIx_SR)

The QSPI_SR register provides all available status information about SFM command execution and arbitration, the RX Buffer and TX Buffer and the AHB Buffer.

Address: Base address + 15Ch offset





QuadSPIx_SR field descriptions

Field	Description
31–29 DLPSMP	**NOTE:** Data learning is not implemented on this chip. Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern. • This is used for DDR only. • If the learning fails, this field will return garbage and DLPFF bit will be set. •
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26 Reserved	This field is reserved.
25 Reserved	This field is reserved.
24 TXEDA	Tx Buffer Enough Data Available Asserted when TX Buffer contains enough data for any pop operation to take place. There must be atleast 128bit data available in TX FIFO for any pop operation otherwise QSPI_FR[TBUF] will be set.

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration.
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

10.2.14.19 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write:Enabled Mode

Address: Base address + 160h offset

QuadSPIx_FR field descriptions

Field	Description
31 DLPFF	**NOTE:** Data learning is not implemented on this chip. Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30 Reserved	This field is reserved.
29–28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was emptyor the buffer contains less than 128bits of data. The application must ensure that the buffer never goes empty during a transaction expect for the last data fetch. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is all F in case of valid tx underrun. The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 10-14 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
	The content of the RX Buffer is not changed.
16 RBDF	RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted. Writing 1 into this bit triggers one of the following actions: • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.
15 ABSEF	AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR register Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module. The AHB bus request which triggered this command is answered with an ERROR response.
14 Reserved	Reserved This field is reserved.
13 Reserved	Reserved This field is reserved.
12 ABOF	AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly. The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device. The content of the AHB Buffer is not changed.
11 IUEF	IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 10-14 table for the related commands. Communication with the serial flash device is terminated before the execution of WRITE/WRITE_DDR command by the QuadSPI module.
10–8 Reserved	This field is reserved.
7 IPAEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAEF flag is ignored.
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

10.2.14.20 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

>

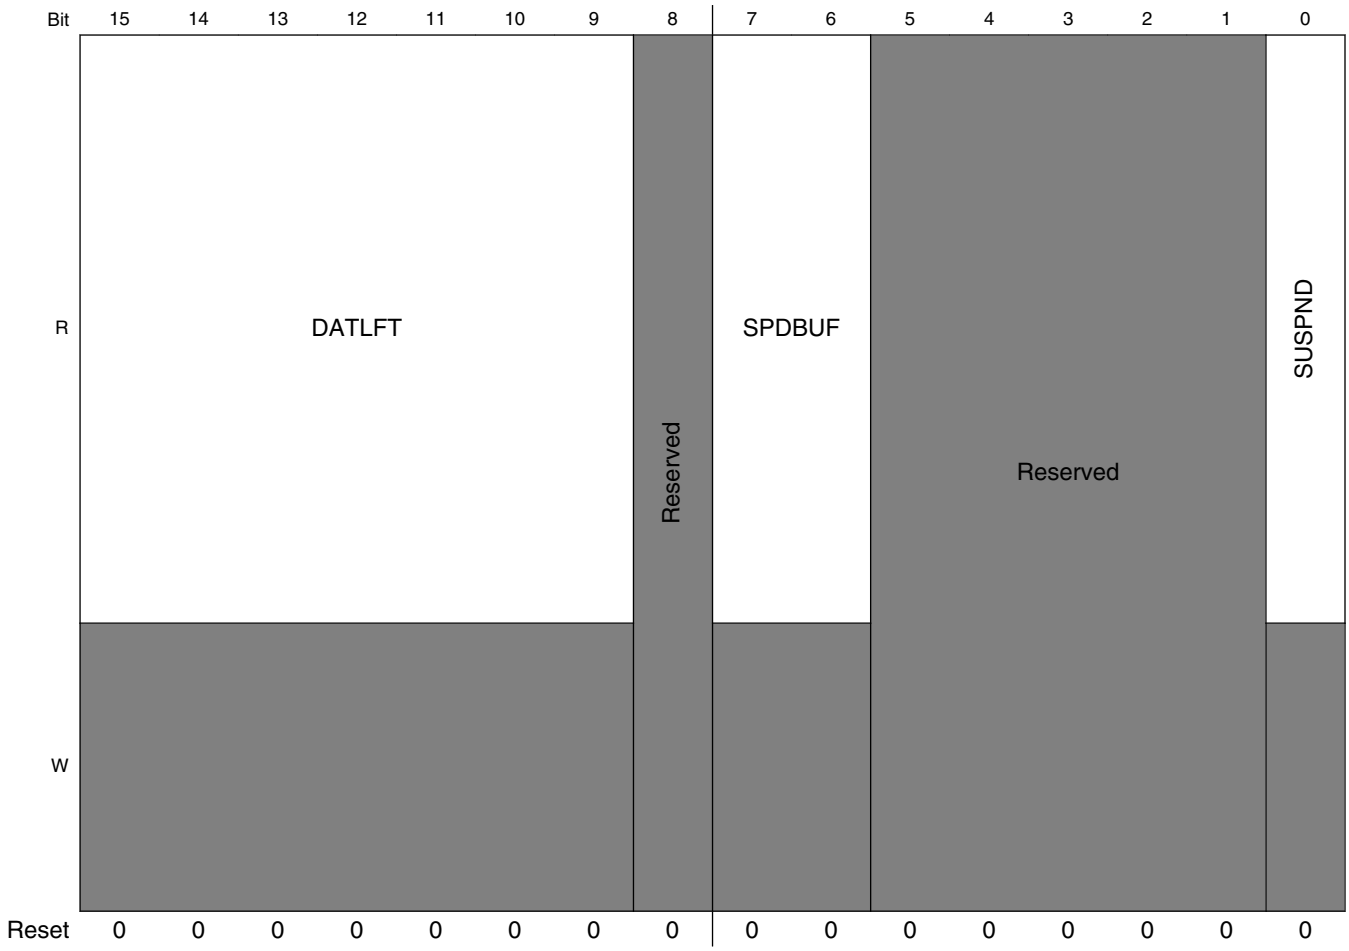
4 IPGEIE	IP Command Trigger during AHB Grant Error Interrupt Enable 0 No IPGEF interrupt will be generated 1 IPGEF interrupt will be generated
3–1 Reserved	This field is reserved. Reserved.
0 TFIE	Transaction Finished Interrupt Enable 0 No TFF interrupt will be generated 1 TFF interrupt will be generated

10.2.14.21 Sequence Suspend Status Register (QuadSPIx_SPNDST)

The sequence suspend status register provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB master makes an access before the AHB sequence completes the data transfer requested.

Address: Base address + 168h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



QuadSPIx_SPNDST field descriptions

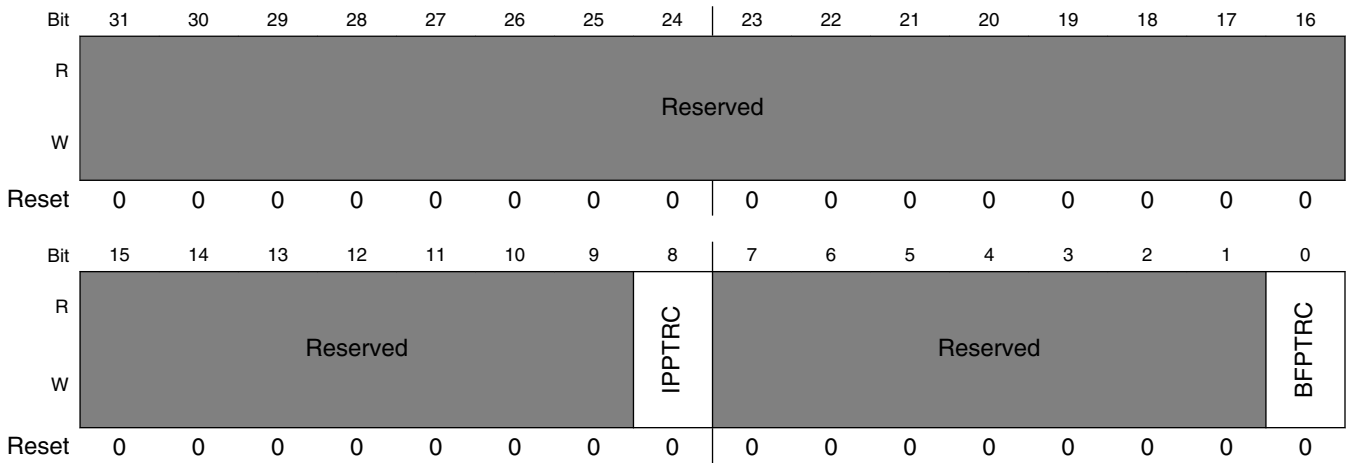
Field	Description
31–16 Reserved	This field is reserved.
15–9 DATLFT	Data left: Provides information about the amount of data left to be read in the suspended sequence. Valid only when SUSPND is set to 1'b1. Value in terms of 64 bits or 8 bytes
8 Reserved	This field is reserved.
7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

10.2.14.22 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: Base address + 16Ch offset



QuadSPIx_SPTRCLR field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 IPPTRC	IP Pointer Clear: 1: Clears the sequence pointer for IP accesses as defined in QuadSPI_IPCR
7–1 Reserved	This field is reserved. Reserved.
0 BFPTRC	Buffer Pointer Clear: 1: Clears the sequence pointer for AHB accesses as defined in QuadSPI_BFGENCR.

10.2.14.23 Serial Flash A1 Top Address (QuadSPIx_SFA1AD)

The QSPI_SFA1AD register provides the address mapping for the serial flash A1.The difference between QSPI_SFA1AD[TPADA1] and QSPI_AMBA_BASE defines the size of the memory map for serial flash A1.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TPADA1																Reserved																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_SFA1AD field descriptions

Field	Description
31–10 TPADA1	Top address for Serial Flash A1. In effect, TPADxx is the first location of the next memory.
Reserved	This field is reserved.

10.2.14.24 Serial Flash A2 Top Address (QuadSPIx_SFA2AD)

The QSPI_SFA2AD register provides the address mapping for the serial flash A2.The difference between QSPI_SFA2AD[TPADA2] and QSPI_SFA1AD[TPADA1] defines the size of the memory map for serial flash A2.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 184h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TPADA2																Reserved																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_SFA2AD field descriptions

Field	Description
31–10 TPADA2	Top address for Serial Flash A2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

10.2.14.25 Serial Flash B1Top Address (QuadSPIx_SFB1AD)

The QSPI_SFB1AD register provides the address mapping for the serial flash B1.The difference between QSPI_SFB1AD[TPADB1] and QSPI_SFA2AD[TPADA2] defines the size of the memory map for serial flash B1.

Write:

- *QSPI_SR[IP_ACC] = 0*
- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 188h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TPADB1																						Reserved

QuadSPIx_SFB2AD field descriptions

Field	Description
31–10 TPADB2	Top address for Serial Flash B2. In effect, TPxxAD is the first location of the next memory.
Reserved	This field is reserved.

10.2.14.27 RX Buffer Data Register (QuadSPIx_RBDR*n*)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to Table 10-16 for the byte ordering scheme.

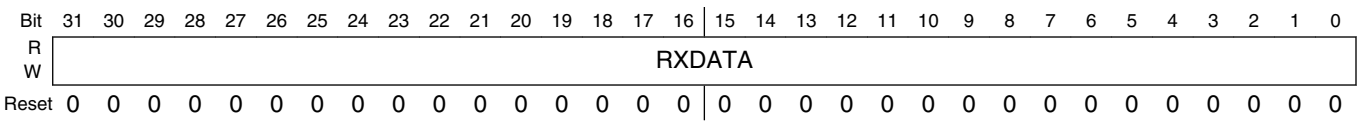
QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d



QuadSPIx_RBDR*n* field descriptions

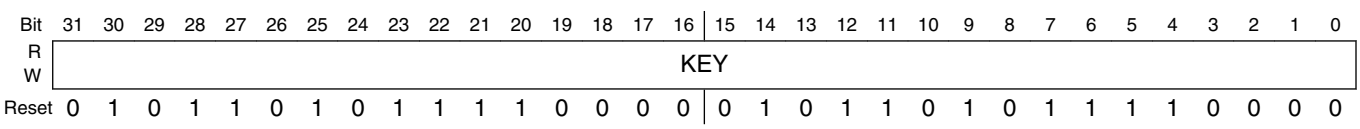
Field	Description
RXDATA	RX Data. The RXDATA field contains the data associated with the related RX Buffer entry. Data format and byte ordering is given in Byte Ordering of Serial Flash Read Data .

10.2.14.28 LUT Key Register (QuadSPIx_LUTKEY)

The LUT Key register contains the key to lock and unlock the Look-up-table. Refer to Look-up Table for details.

Write:Anytime

Address: Base address + 300h offset



QuadSPIx_LUTKEY field descriptions

Field	Description
KEY	The key to lock or unlock the LUT. The KEY is 0x5AF05AF0. The read value is always 0x5AF05AF0

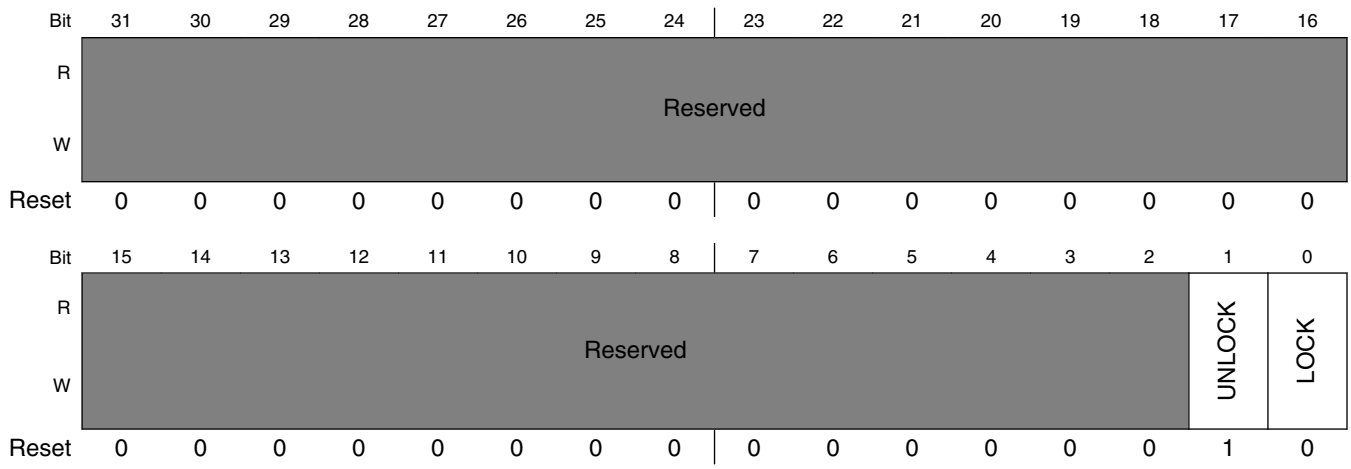
10.2.14.29 LUT Lock Configuration Register (QuadSPIx_LCKCR)

The LUT lock configuration register is used along with QSPI_LUTKEY register to lock or unlock the LUT. This register has to be written immediately after QSPI_LUTKEY register for the lock or unlock operation to be successful. Refer to Look-up Table for details. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

Write:Just after writing the LUT Key Register

(QSPI_LUTKEY)

Address: Base address + 304h offset



QuadSPIx_LCKCR field descriptions

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

10.2.14.30 Look-up Table register (QuadSPIx_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] ..... QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. Look-up Table describes the LUT registers in detail.

Write:Once the LUT is unlocked

Address: Base address + 310h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_LUT*n* field descriptions

Field	Description
31–26 INSTR1	Instruction 1
25–24 PAD1	Pad information for INSTR1. 00 1 Pad 01 2 Pads 10 4 Pads 11 NA
23–16 OPRND1	Operand for INSTR1.
15–10 INSTR0	Instruction 0
9–8 PAD0	Pad information for INSTR0. 00 1 Pad 01 2 Pads 10 4 Pads 11 NA
OPRND0	Operand for INSTR0.

10.3 Ultra Secured Digital Host Controller (uSDHC)

10.3.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 10-35.

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:

The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.

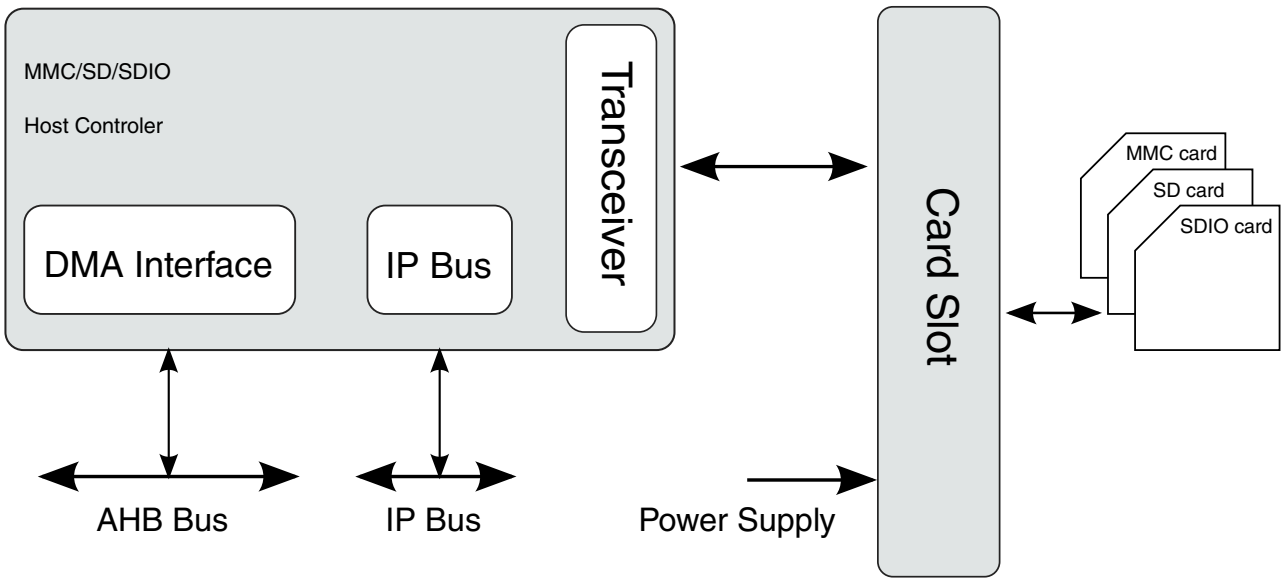

Figure 10-35. System Connection of the uSDHC

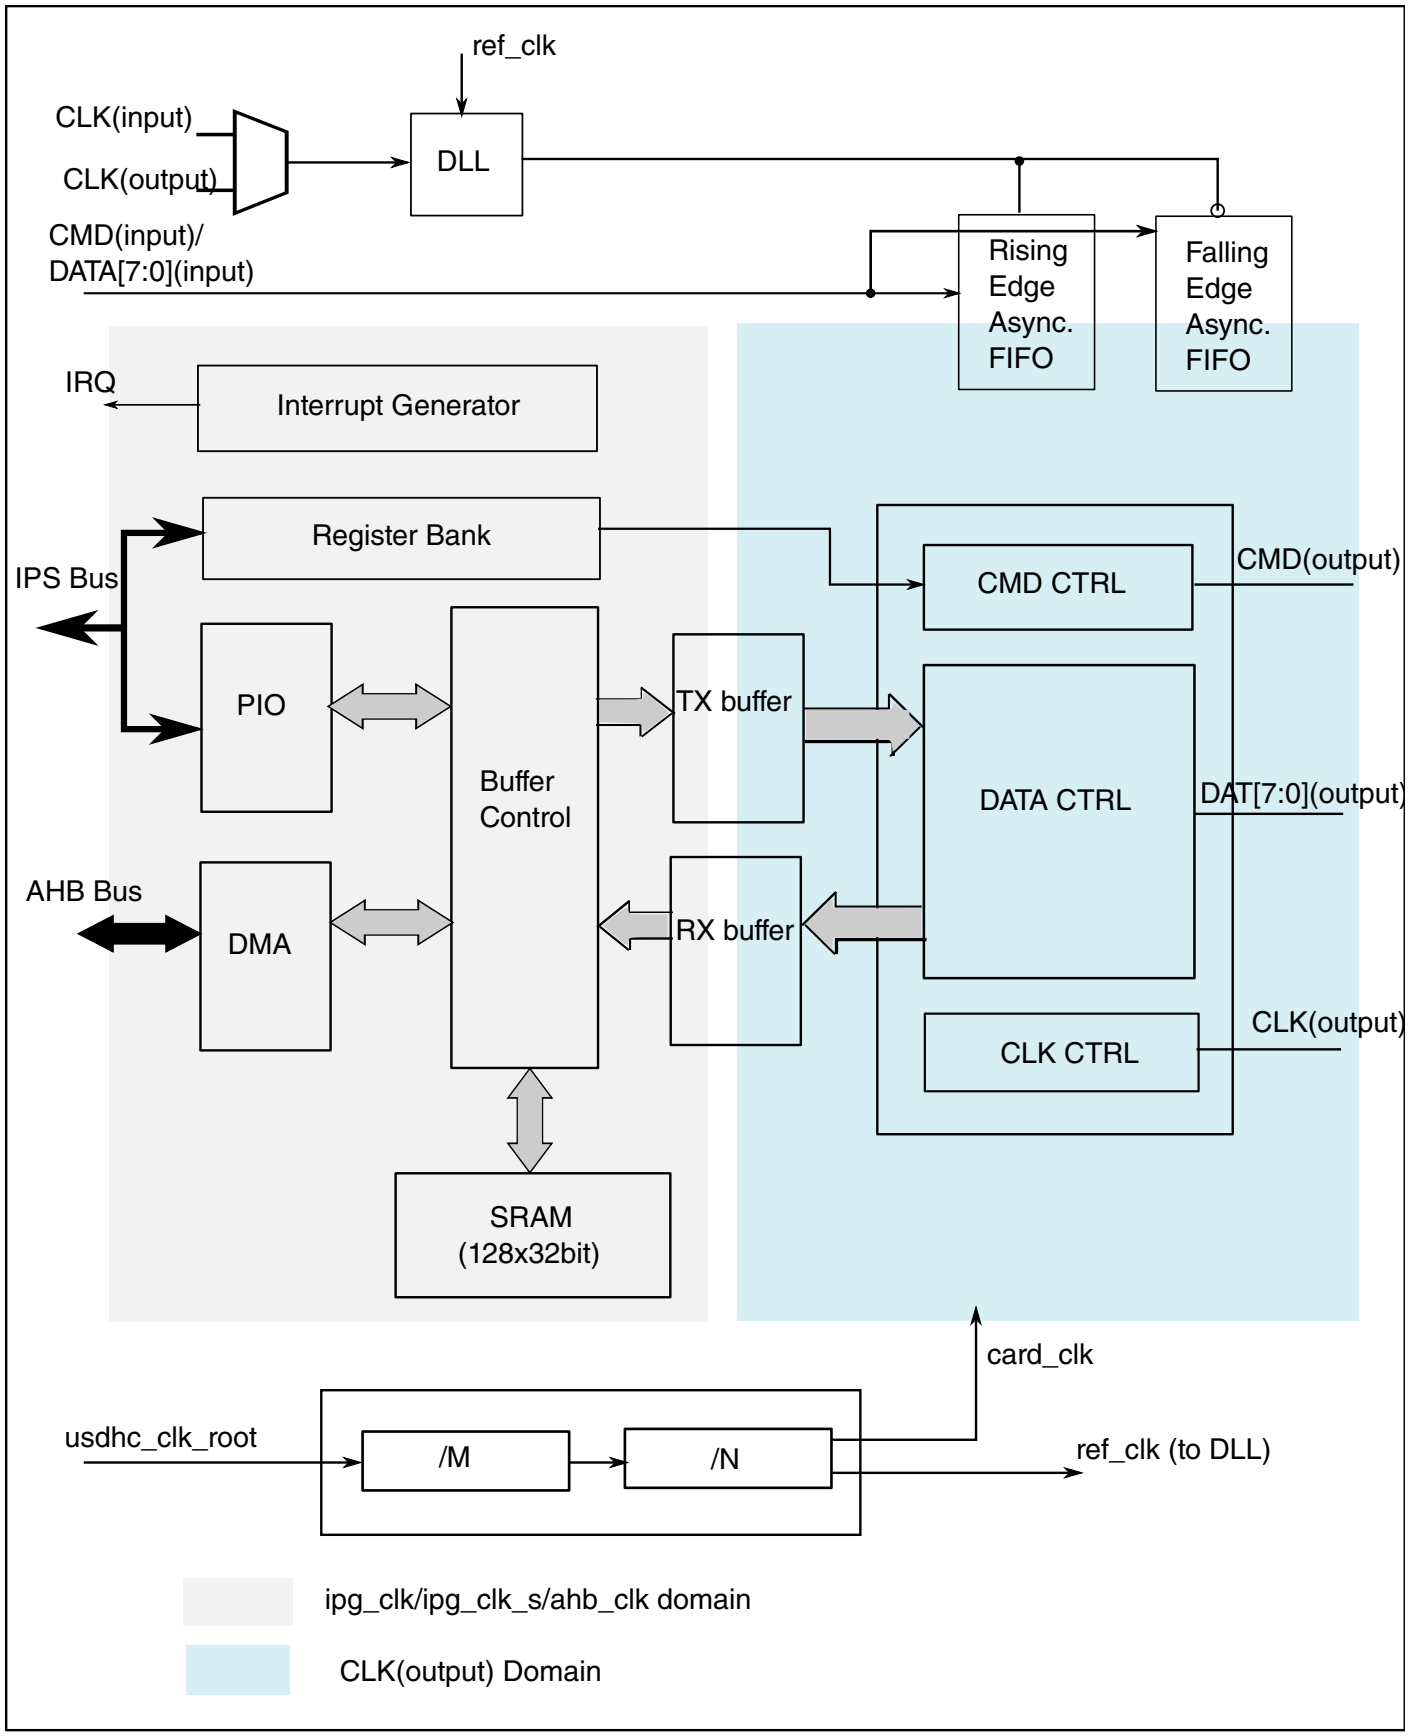

Figure 10-36. ultra Secure Digital Host Controller Block Diagram

10.3.1.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
    - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
    - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
    - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
    - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
    - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
    - Up to 3200 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access

10.3.1.2 Modes and Operations

10.3.1.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

10.3.2 External Signals

The following table describes the external signals of USDHC:

Table 10-40. USDHC External Signals

Signal	Description	Pad	Mode	Direction
SD1_CD_B	Card detection pin If not used(for the embedded memory),tie low to indicate there is a card attached.	SD1_CD_B	ALT0	I
SD1_CLK	Clock for MMC/SD/SDIO card	SD1_CLK	ALT0	O
SD1_CMD	CMD line connect to card	SD1_CMD	ALT0	IO
SD1_DATA0	DATA0 line in all modes Also used to detect busy state	SD1_DATA0	ALT0	IO
SD1_DATA1	DATA1 line in 4/8-bit mode Also used to detect interrupt in 1/4- bit mode	SD1_DATA1	ALT0	IO
SD1_DATA2	DATA2 line or Read Wait in 4-bit mode. Read Wait in 1-bit mode	SD1_DATA2	ALT0	IO
SD1_DATA3	DATA3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	SD1_DATA3	ALT0	IO

Table continues on the next page...

Table 10-40. USDHC External Signals (continued)

Signal	Description	Pad	Mode	Direction
SD1_DATA4	DATA4 line in 8-bit mode, not used in other modes	ECSPI2_SCLK	ALT2	IO
SD1_DATA5	DATA5 line in 8-bit mode, not used in other modes	ECSPI2_MOSI	ALT2	IO
SD1_DATA6	DATA6 line in 8-bit mode, not used in other modes	ECSPI2_MISO	ALT2	IO
SD1_DATA7	DATA7 line in 8-bit mode, not used in other modes	ECSPI2_SS0	ALT2	IO
SD1_LCTL	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	GPIO1_IO09	ALT1	O
		UART3_RXD	ALT6

		SD3_RESET_B	ALT0	
SD3_STROBE	Strobe Signal	SD3_STROBE	ALT0	IO
SD3_VSELECT	IO power voltage selection signal	GPIO1_IO13	ALT1	O
		I2C1_SDA	ALT6	
SD3_WP	Card write protect detect If not used(for the embedded memory), tie	GPIO1_IO15	ALT1	I
		I2C2_SDA	ALT6	

Table continues on the next page...

Table 10-40. USDHC External Signals (continued)

Signal	Description	Pad	Mode	Direction
	low to indicate it's not write protected.	SD3_DATA6	ALT2	

10.3.2.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD# means that a card is inserted, and a high on WP means that the write protect switch is active.
- LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

10.3.3 Clocks

The table found here describes the clock sources for uSDHC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 10-41. uSDHC Clocks

Clock name	Clock Root	Description
hclk	ahb_clk_root	AHB bus clock
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_perclk	usdhc_clk_root	Base clock
ipg_clk_s	ipg_clk_root	Peripheral access clock for register accesses

10.3.4 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

10.3.4.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

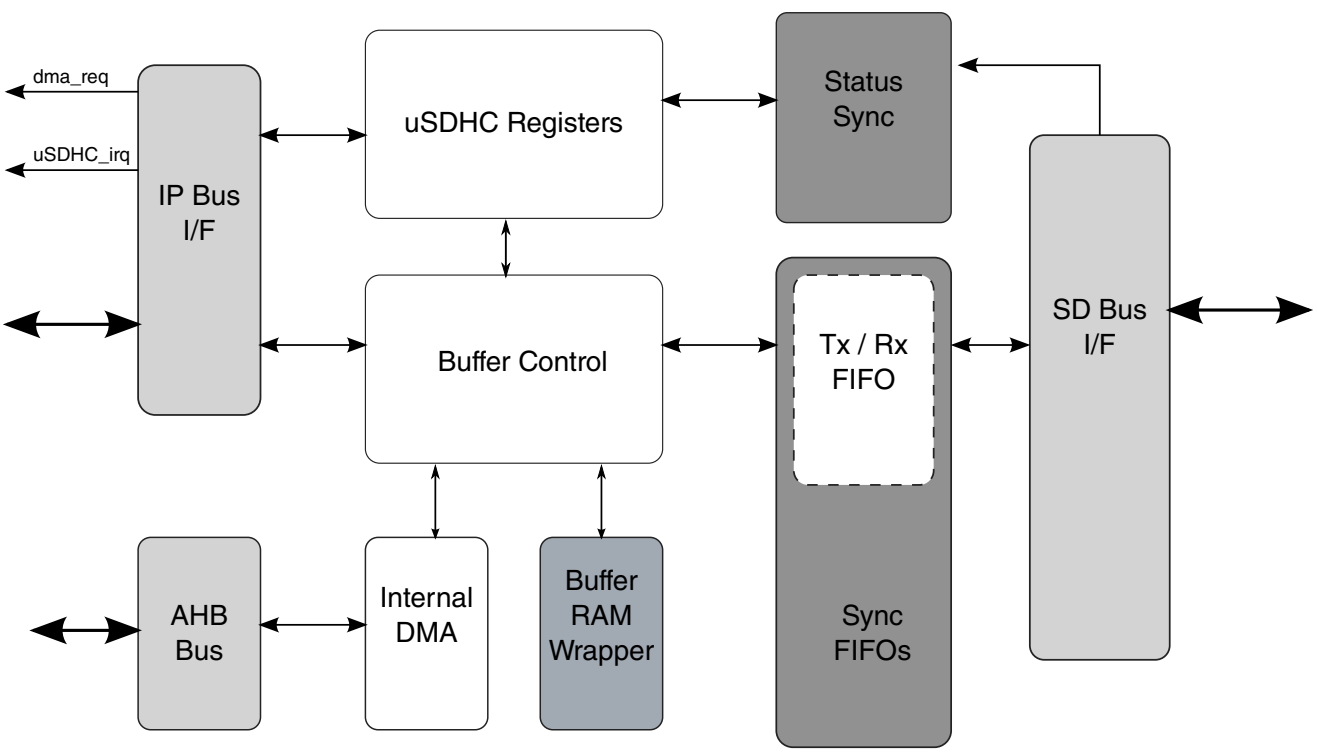

Figure 10-37. uSDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except for INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

- Burst length configured in the burst length field of the Watermark Level register
- Watermark Level boundary
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)
- 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

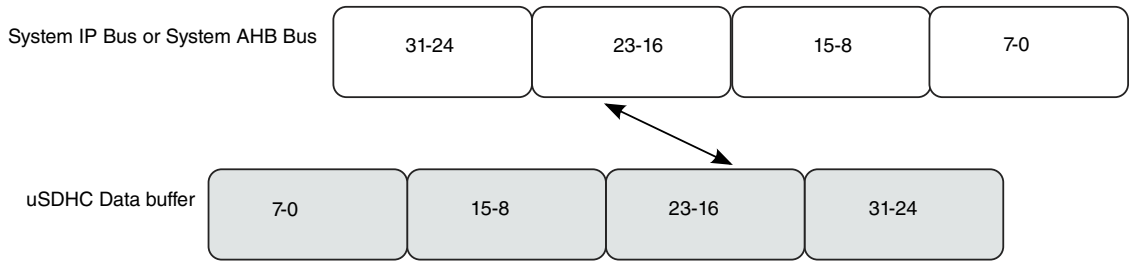

Figure 10-38. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode

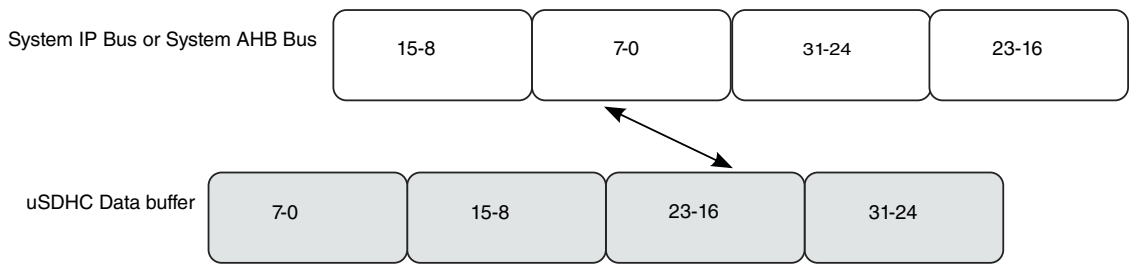

Figure 10-39. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode

10.3.4.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even

though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

10.3.4.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal
- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

10.3.4.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

10.3.4.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).

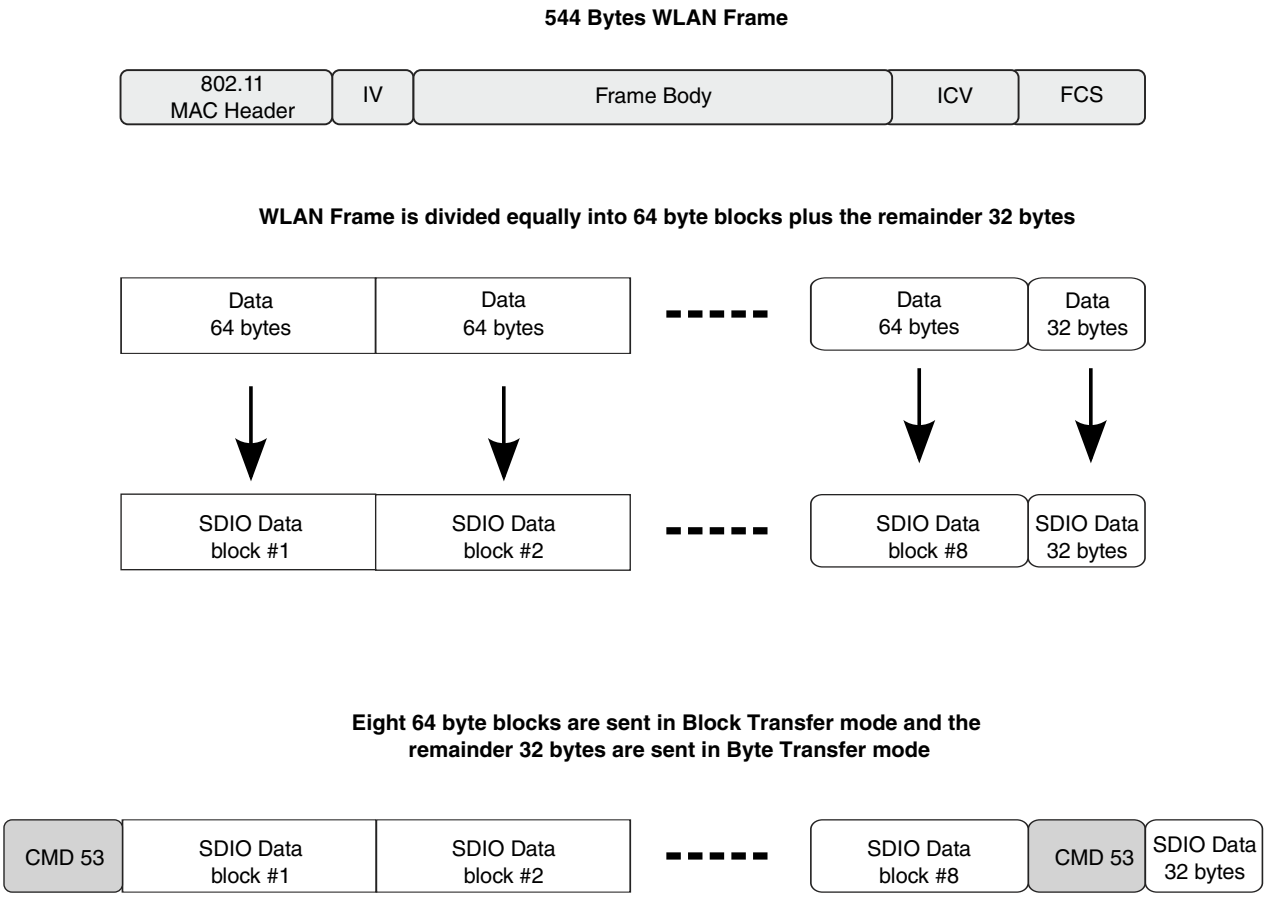

Figure 10-40. Example for Dividing Large Data Transfers

10.3.4.1.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's free space can't meet the watermark condition (free space> write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See DMA Burst Length for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the Data Port register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

10.3.4.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

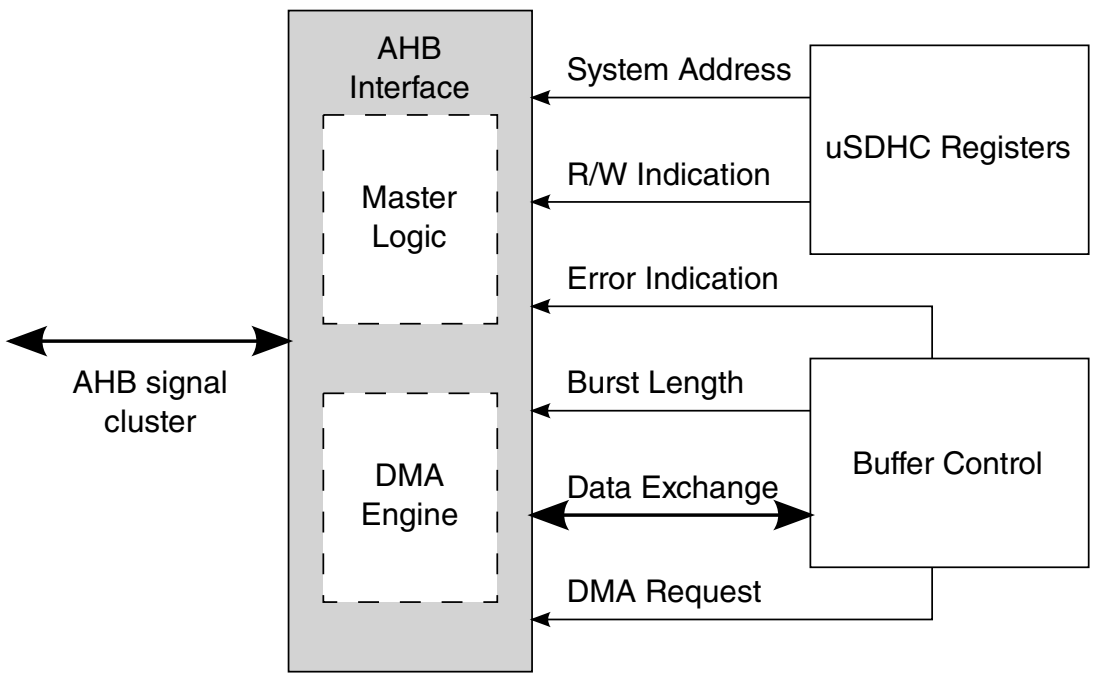

Figure 10-41. DMA AHB Interface Block

10.3.4.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (uSDHC_dreq_b) is disabled.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space(for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

10.3.4.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in Internal DMA Request. After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

10.3.4.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state.At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

10.3.4.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.

The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

10.3.4.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

See Figure 10-42 for the format of the descriptor table for ADMA1.

Figure 10-45 explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned(lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-42. Format of the ADMA1 Descriptor Table

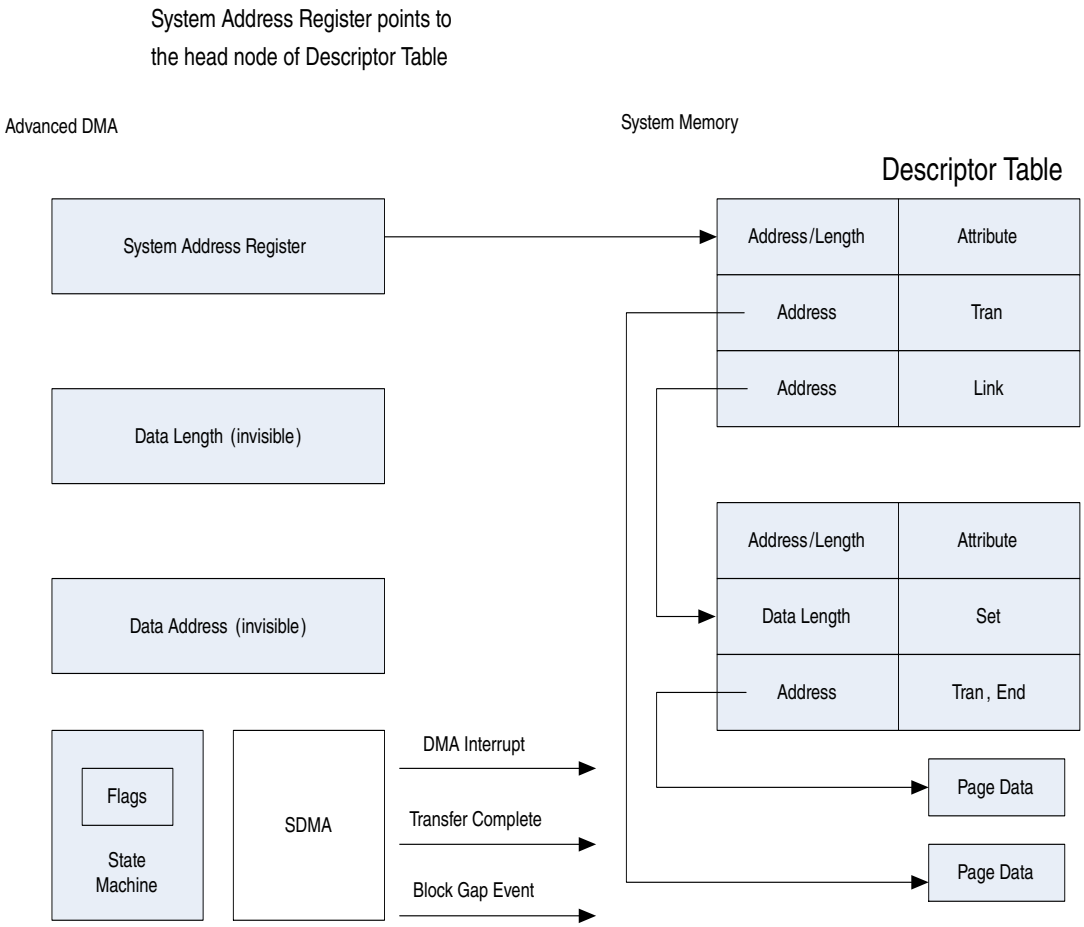

Figure 10-43. Concept and Access Method of ADMA1 Descriptor Table

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-44. Format of the ADMA2 Descriptor Table

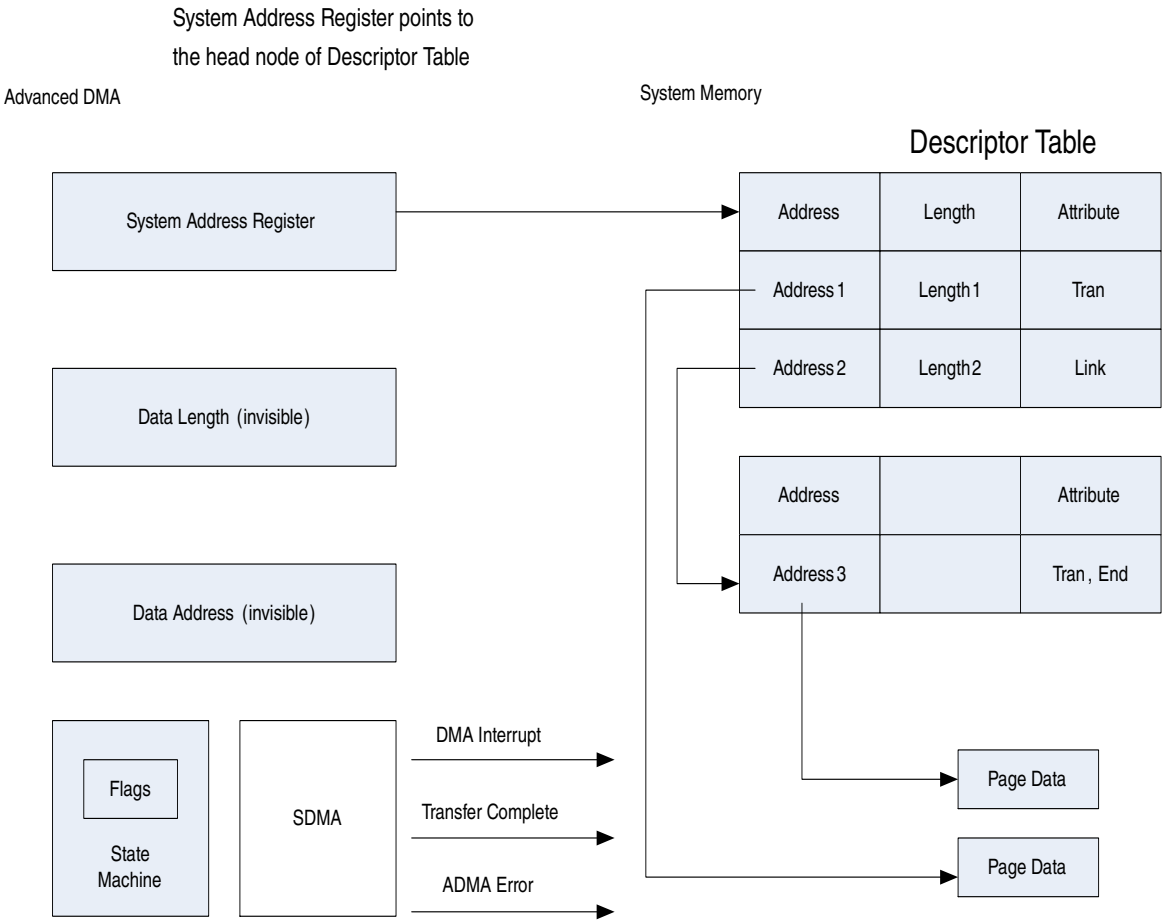

Figure 10-45. Concept and Access Method of ADMA2 Descriptor Table

10.3.4.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

10.3.4.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

10.3.4.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See Figure 10-46 below for the block diagram.

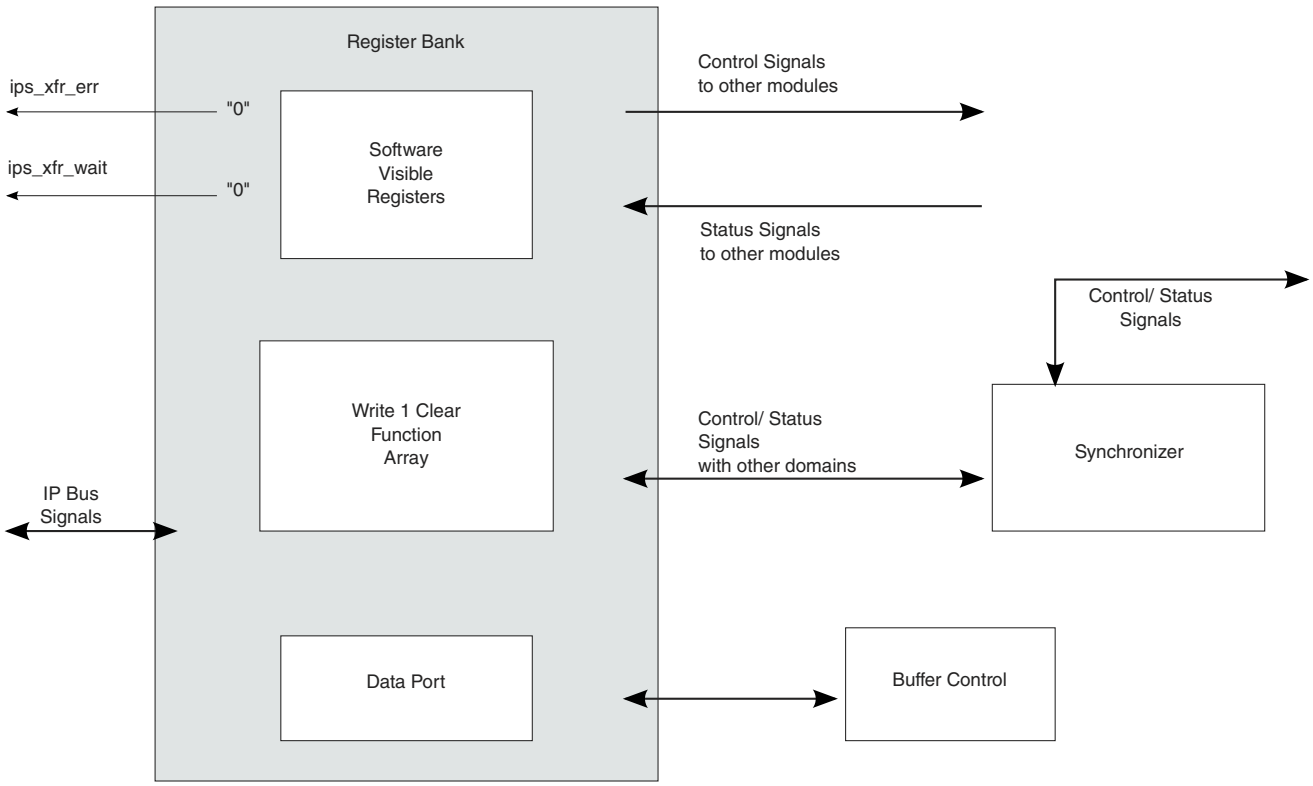

Figure 10-46. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

10.3.4.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.
2. Command control.

3. Data control.
4. Clock control

10.3.4.3.2 SD control misc

In the SD control misc unit, the card detect(include the CD_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

10.3.4.3.3 SD Clock control

If the internal data buffer is near full(for read) or near empty(for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space(for read) or has data(for write), the clock gate of this module will open and the SD clock will be active again.

10.3.4.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.

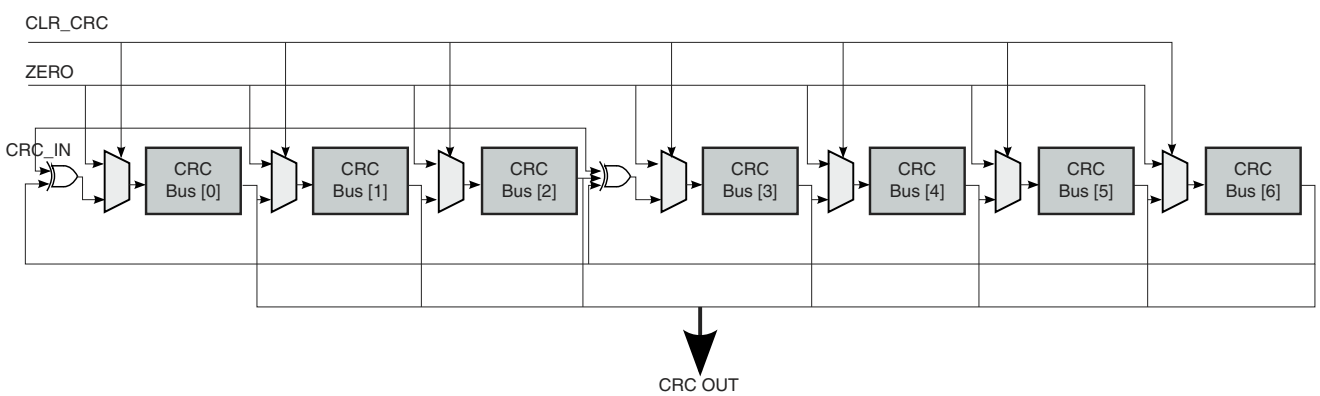

Figure 10-47. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

10.3.4.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$
$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

10.3.4.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

10.3.4.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages.

Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

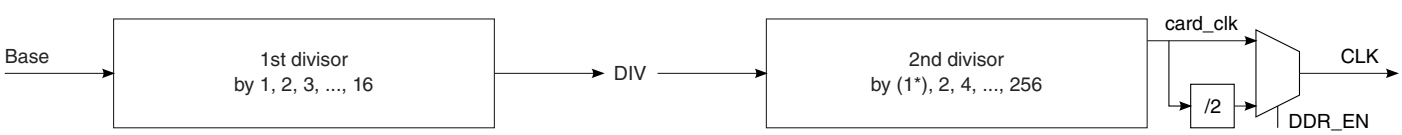

Figure 10-48. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (card_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see Figure 10-37) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the card_clk is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of Base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.

- In SDR mode, CLK is equal to the internal working clock(card_clk).

- In DDR mode, CLK is equal to the card_clk/2.

10.3.4.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

10.3.4.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

10.3.4.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two

clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

10.3.4.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

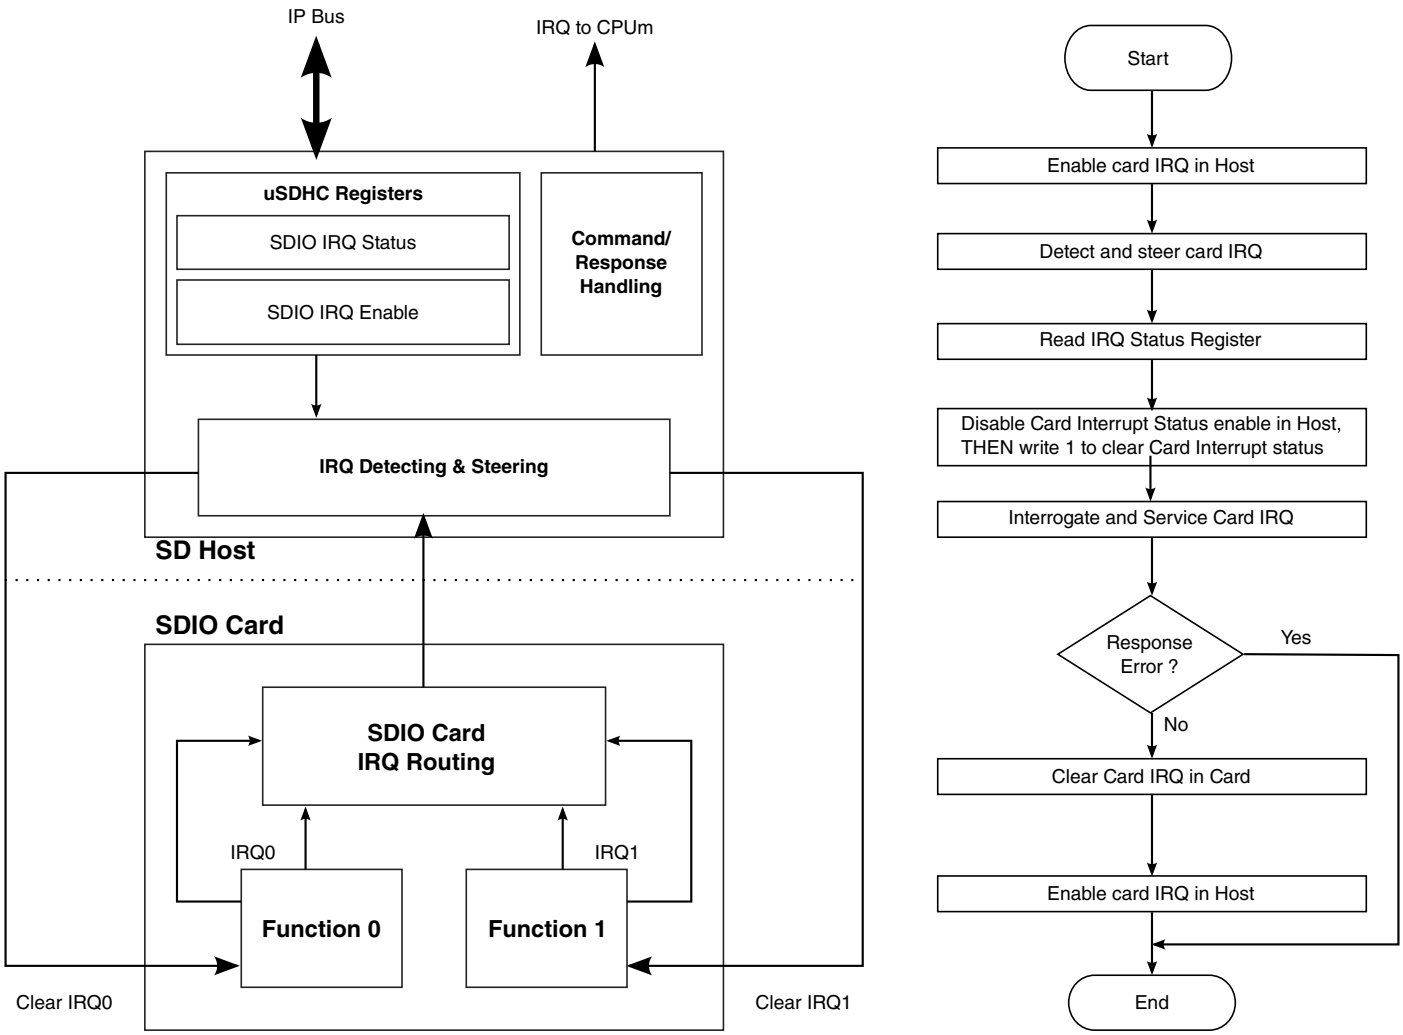

Figure 10-49. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

10.3.4.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

10.3.4.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (uSDHC_PROT_CTRL) for more information on the uSDHC Protocol Control register.

10.3.4.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

10.3.4.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

10.3.4.9.1 Boot operation

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

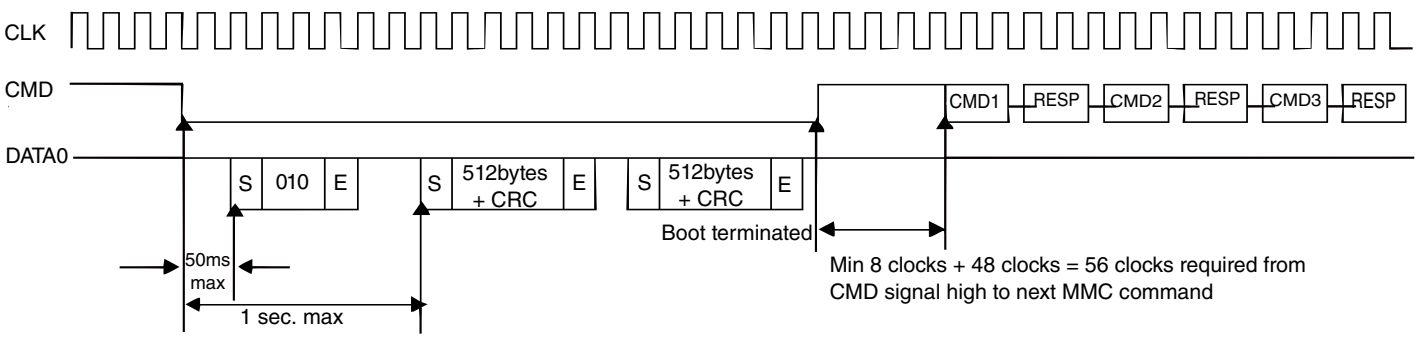

Figure 10-50. MultiMediaCard state diagram (normal boot mode)

10.3.4.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

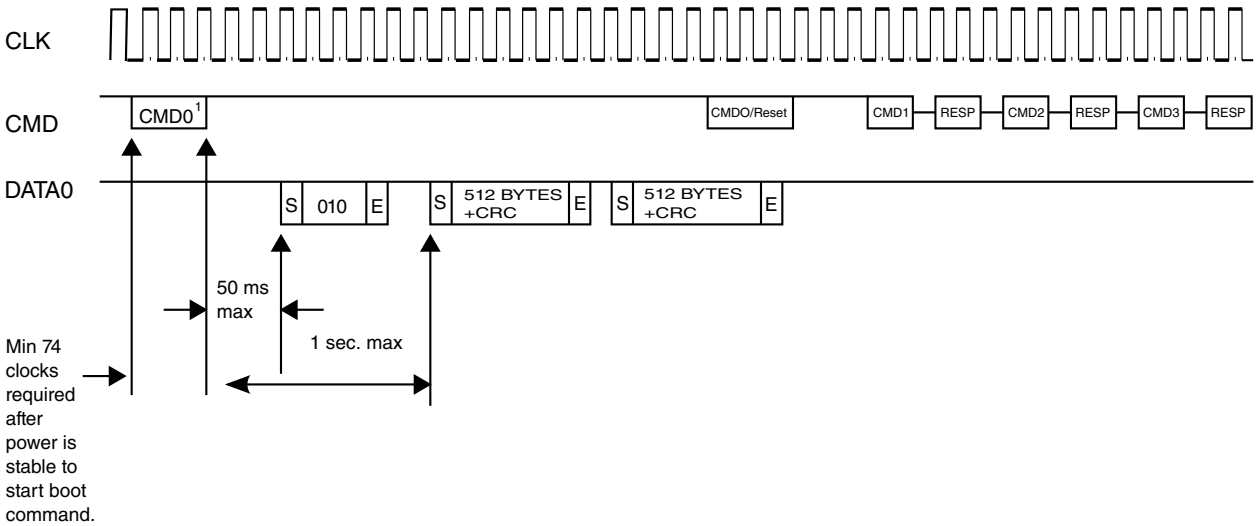
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, theslave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE 1. CMD0 with argument 0xFFFFFFFA

Figure 10-51. MultiMediaCard state diagram (alternative boot mode)

10.3.5 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

10.3.5.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

10.3.5.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

10.3.5.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.

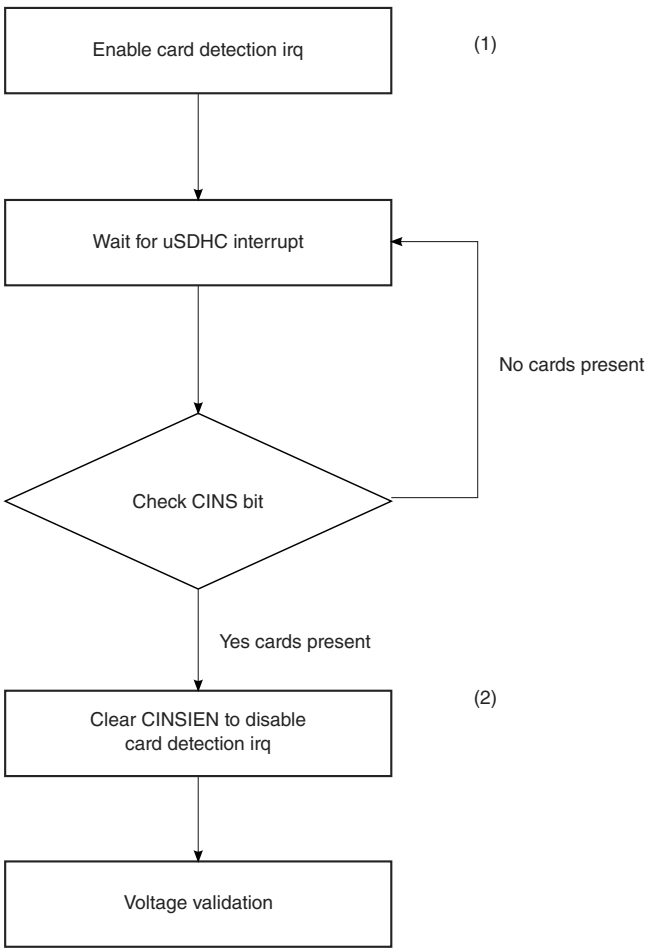


Figure 10-52. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

10.3.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)

- Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

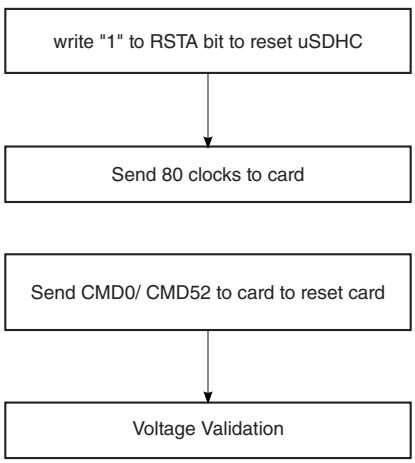

Figure 10-53. Flow Chart for Reset of the uSDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

10.3.5.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card  if (card is already labelled as SDCombo)
{ //
change label
```

```
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
} // of else
}
```

10.3.5.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while

bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

10.3.5.3 Card Access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

10.3.5.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

10.3.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:

- For SD/MMC cards, use SET_BLOCKLEN (CMD16)
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to

send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

10.3.5.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

10.3.5.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

10.3.5.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

10.3.5.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

- For SD/MMC, use SET_BLOCKLEN (CMD16)
- For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

10.3.5.3.2.4 DLL (Delay Line) in Read Path

The DLL(Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns, setting target vaule of 16 means 5ns =(16/32)*10ns. Software can disable automatic update by setting dll_gate_update bit. Please refer to Figure 10-54.

Since the user may change the frequency of the card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL_CTRL_RESET bit

Step 5: Wait until both DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: set DLL_CTRL_SLV_FORCE_UPD

Step 7: clear DLL_CTRL_SLV_FORCE_UPD

NOTE:Software should make sure the DLL_CTRL_SLV_FORCE_UPD is lasted for at least one card_clk. So software may need to add some delay between step6 and step7.

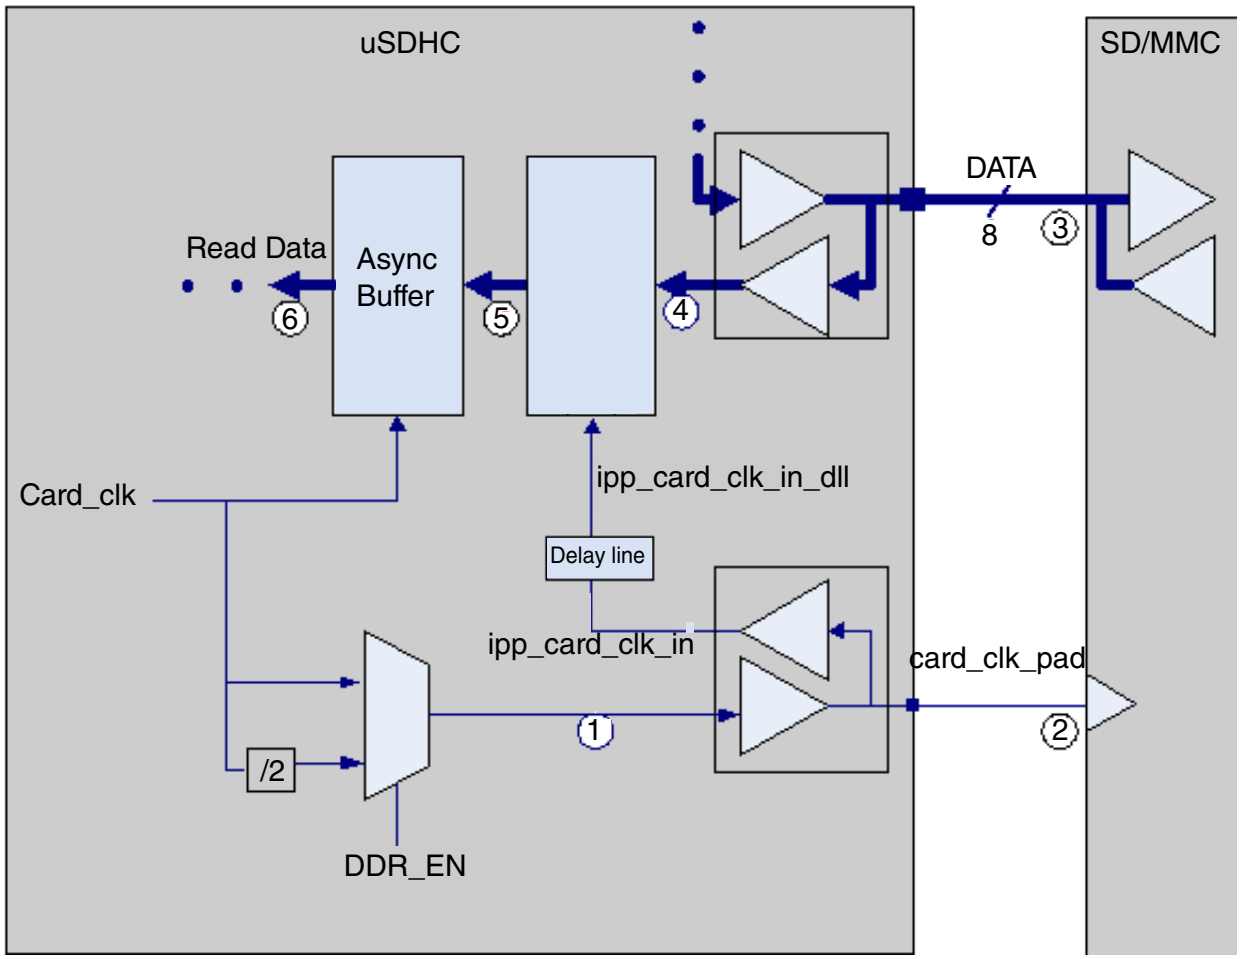

Figure 10-54. DLL(Delay Line) in Read Path

10.3.5.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

10.3.5.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

10.3.5.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

10.3.5.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.

6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

10.3.5.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are detailed in the sections below.

10.3.5.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

10.3.5.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

10.3.5.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

10.3.5.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

10.3.5.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card Interrupt Handling for the card interrupt handling flow.

10.3.5.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards , the high speed mode/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit ,DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

10.3.5.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.5.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/ SDR104/DDR50

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
```

```
(data transactions like normal peers)
}
```

10.3.5.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

10.3.5.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

10.3.5.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.

10.3.5.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
```

```
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

10.3.5.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

10.3.5.6 Fast Boot Operation

10.3.5.6.1 Normal fast boot flow

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.

2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept at the default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.
7. DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.

10.3.5.6.2 Alternative fast boot flow

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.

3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process..
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

10.3.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1).Here VALUE1 is the value of the block count that needs to transfer the

first time, so that that the hostwill stop at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.

3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enbable ADMA2 by configuring Protocol Control Register bits [9-8].
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM)and data length(ie,512byte*VALUE1) of fisrt part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word(record as VALUE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
7. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software needs to configure Transfer Type Register to start the boot process . CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
10. When TC, BGE bit is 1, . SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code(VALUE3 the remain boot code block). Remeber set the last descriptor with END.
11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the *(BLK_CNT - (VALUE1+1+VALUE3))*, that host will stop at block gap when *the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9*. And need to configure bit 3-bit0 to select the ack

timeout value according to the sd clk frequence. Please note, Software doesn't need to configure the *BLK_CNT* again, because it's counted down automatically by the uSDHC controller.

12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

10.3.6 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).

Response: a response is a token which is sent from the card to the host as an answner to a previously received command. A response is transferred serially on the CMD line.

Table 10-42. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).

Table continues on the next page...

Table 10-42. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown below.

Table 10-43. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

10.3.7 Software Restrictions

10.3.7.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

10.3.7.2 Software Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

10.3.7.3 Suspend Operation

In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.

10.3.7.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

10.3.7.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

10.3.7.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or external DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

10.3.7.7 Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

10.3.7.8 Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

10.3.8 uSDHC Memory Map/Register Definition

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

uSDHC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30B4_0000	DMA System Address (uSDHC1_DS_ADDR)	32	R/W	0000_0000h	10.3.8.1/ 2777
30B4_0004	Block Attributes (uSDHC1_BLK_ATT)	32	R/W	0000_0000h	10.3.8.2/ 2778
30B4_0008	Command Argument (uSDHC1_CMD_ARG)	32	R/W	0000_0000h	10.3.8.3/ 2779

uSDHCx_DS_ADDR field descriptions

Field	Description
31–2 DS_ADDR	DMA System Address: This register contains the 32-bit system memory address for a DMA transfer. Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ. Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions .
Reserved	This read-only field is reserved and always has the value 0.

10.3.8.2 Block Attributes (uSDHCx_BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BLKCNT																0			BLKSIZE[12:0]											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_BLK_ATT field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer: This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.

Table continues on the next page...

uSDHCx_BLK_ATT field descriptions (continued)

Field	Description
	When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1. FFFF 65535 blocks 0002 2 blocks 0001 1 block 0000 Stop Count
15–13 Reserved	This read-only field is reserved and always has the value 0.
BLKSIZE[12:0]	Transfer Block Size: This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 1000 4096 Bytes 800 2048 Bytes 200 512 Bytes 1FF 511 Bytes 004 4 Bytes 003 3 Bytes 002 2 Bytes 001 1 Byte 000 No data transfer

10.3.8.3 Command Argument (uSDHCx_CMD_ARG)

This register contains the SD / MMC Command Argument.

.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHCx_CMD_ARG field descriptions

Field	Description
CMDARG[31:0]	Command Argument The SD / MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

10.3.8.4 Command Transfer Type (uSDHCx_CMD_XFR_TYP)

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer invovled, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 10-44. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

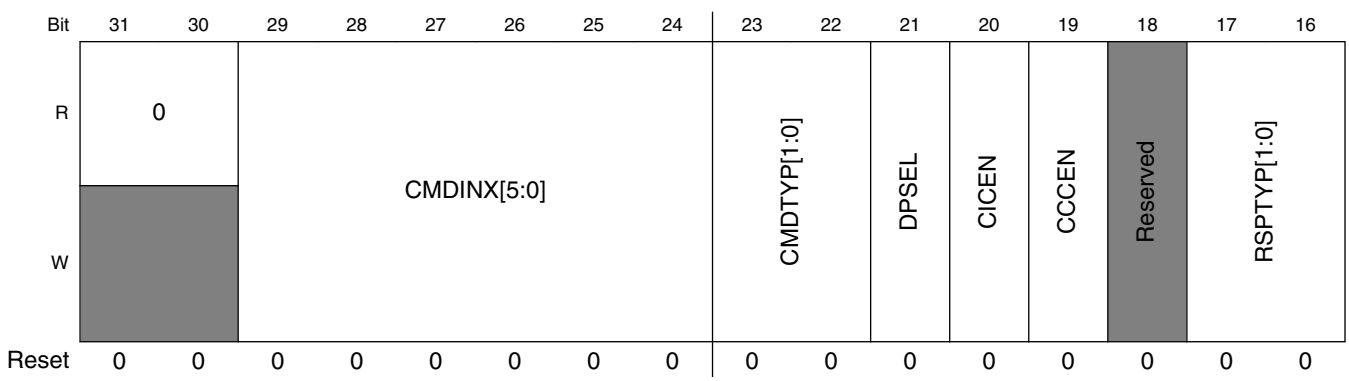
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits as well as the name of the response type.

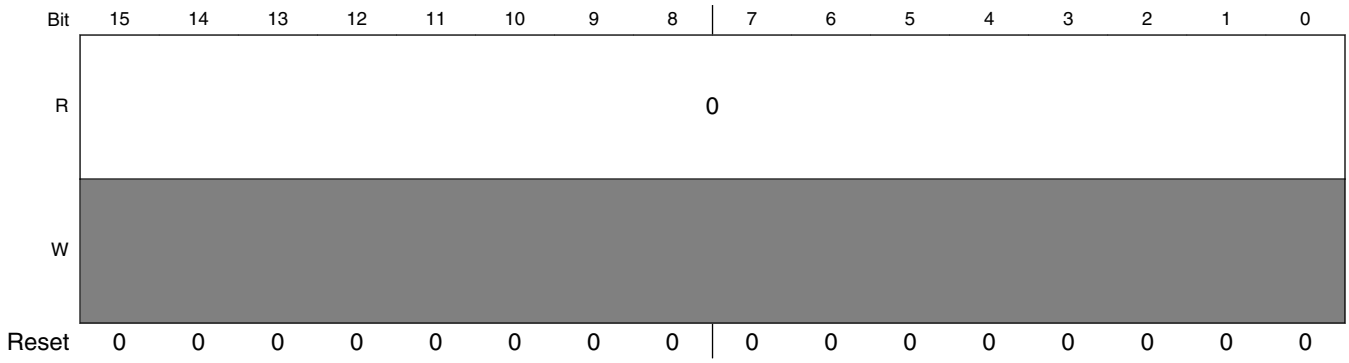
Table 10-45. Relationship Between Parameters and the Name of the Response Type

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Address: Base address + Ch offset





uSDHCx_CMD_XFR_TYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value 0.
29–24 CMDINX[5:0]	Command Index These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. • Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register. • Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers. • Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction). 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal Other commands
21 DPSEL	Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (e.g. CMD52). • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)

Table continues on the next page...

uSDHCx_CMD_XFR_TYP field descriptions (continued)

Field	Description
	NOTE: In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored. 1 Data Present 0 No Data Present
20 CICEN	Command Index Check Enable If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
19 CCCEN	Command CRC Check Enable If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (uSDHC_CMD_XFR_TYP) .) 1 Enable 0 Disable
18 -	This field is reserved. Reserved
17–16 RSPTYP[1:0]	Response Type Select 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response
Reserved	This read-only field is reserved and always has the value 0.

10.3.8.5 Command Response0 (uSDHCx_CMD_RSP0)

This register is used to store part 0 of the response bits from the card.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

uSDHCx_CMD_RSP2 field descriptions

Field	Description
CMDRSP2[31:0]	Command Response 2 Refer to Command Response3 (uSDHC_CMD_RSP3) for the mapping of command responses from the SD Bus to this register for each response type.

10.3.8.8 Command Response3 (uSDHCx_CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

Table 10-46. Response Bit Definition for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows

the uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Address: Base address + 1Ch offset

uSDHCx_DATA_BUFF_ACC_PORT field descriptions

Field	Description
DATCONT[31:0]	Data Content The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

10.3.8.10 Present State (uSDHCx_PRES_STATE)

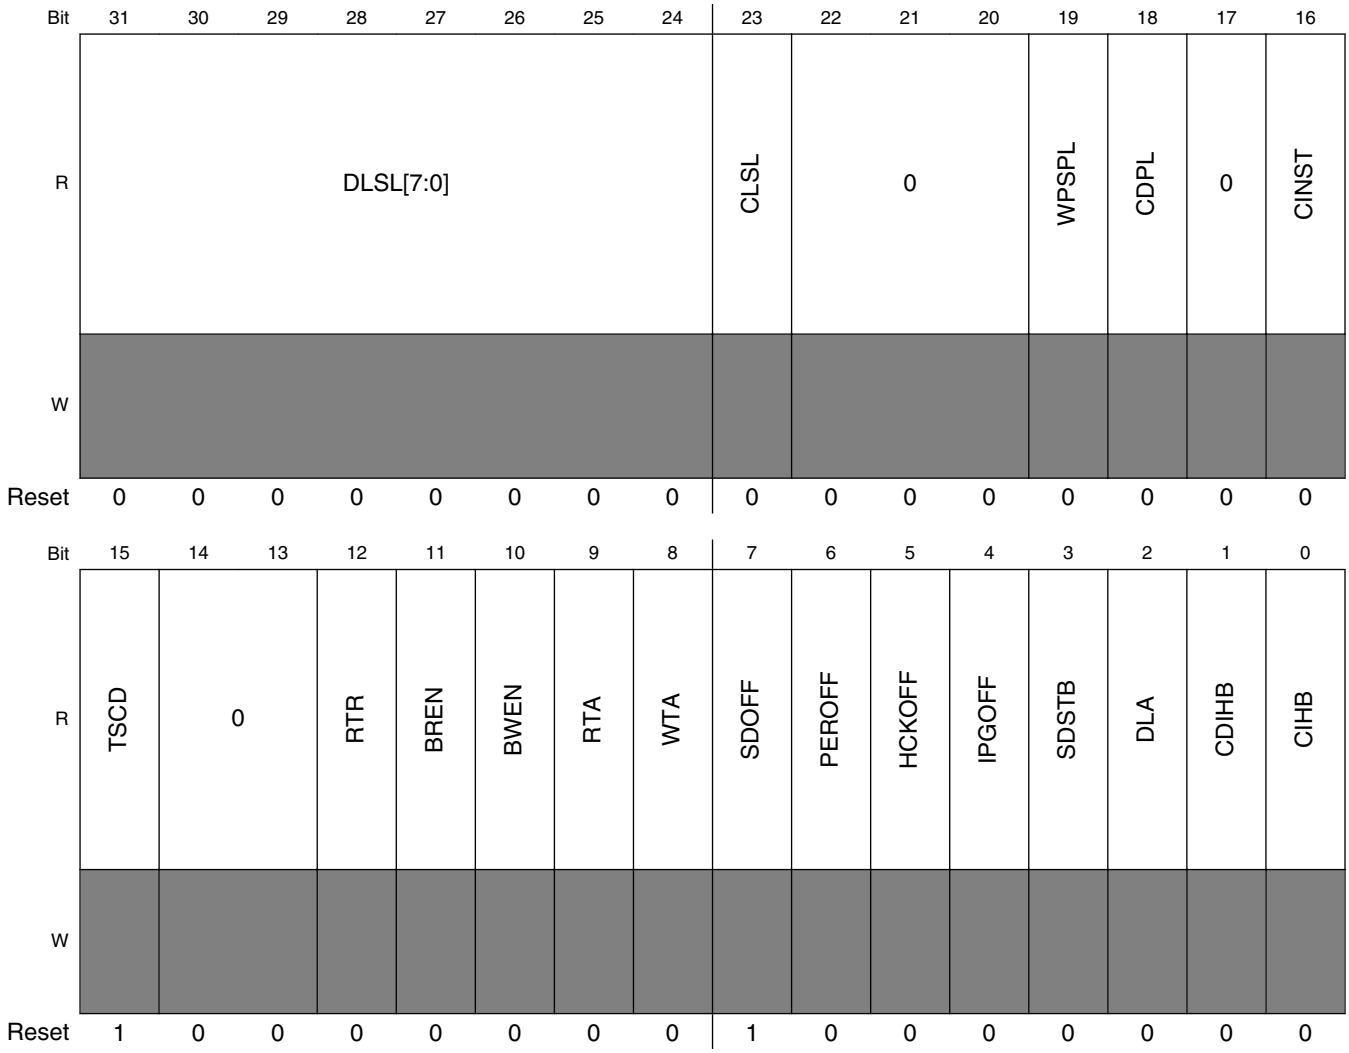
The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be

issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

- Note: the reset value of Present State Register depend on testbench connectivity.

Address: Base address + 24h offset



uSDHCx_PRES_STATE field descriptions

Field	Description
31–24 DLSL[7:0]	DATA[7:0] Line Signal Level This status is used to check the DATA line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. DATA7 Data 7 line signal level DATA6 Data 6 line signal level DATA5 Data 5 line signal level DATA4 Data 4 line signal level DATA3 Data 3 line signal level

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	DATA2 Data 2 line signal level DATA1 Data 1 line signal level DATA0 Data 0 line signal level
23 CLSL	CMD Line Signal Level This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value 0.
19 WPSPL	Write Protect Switch Pin Level The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (WP = 0) 0 Write protected (WP = 1)
18 CDPL	Card Detect Pin Level This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.) 1 Card present (CD_B = 0) 0 No card present (CD_B = 1)
17 Reserved	This read-only field is reserved and always has the value 0.
16 CINST	Card Inserted This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit. A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15 TSCD	Tape Select Change Done This bit indicates the dealy setting is effective after write CLK_TUNE_CTRL_STATUS register. 1 Delay cell select change is finished. 0 Delay cell select change is not finished.
14–13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode) Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting Execute Tuning bit in MIXER_CTRL register. Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Interrupt status registers for more detail. This bit isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock). 1 Sampling clock needs re-tuning 0 Fixed or well tuned sampling clock
11 BREN	Buffer Read Enable This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 1 Read enable 0 Read disable
10 BWEN	Buffer Write Enable This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 1 Write enable 0 Write disable
9 RTA	Read Transfer Active This status bit is used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. 1 Transferring data 0 No valid data

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
8 WTA	Write Transfer Active This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state. 1 Transferring data 0 No valid data
7 SDOFF	SD Clock Gated Off Internally This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus. 1 SD Clock is gated off. 0 SD Clock is active.
6 PEROFF	IPG_PERCLK Gated Off Internally This status bit indicates that the IPG_PERCLK is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK will be gated off, otherwise IPG_PERCLK will be always active. 1 IPG_PERCLK is gated off. 0 IPG_PERCLK is active.
5 HCKOFF	HCLK Gated Off Internally This status bit indicates that the HCLK is internally gated off. This bit is for the Host Driver to debug during a data transfer. 1 HCLK is gated off. 0 HCLK is active.
4 IPGOFF	IPG_CLK Gated Off Internally This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug. 1 IPG_CLK is gated off. 0 IPG_CLK is active.
3 SDSTB	SD Clock Stable

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
	This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON bit in System Control register to remove glitches on the card clock when the frequency is changing. *Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.* 1 Clock is stable. 0 Clock is changing frequency and not stable.
2 DLA	Data Line Active This status bit indicates whether one of the DATA lines on the SD Bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. This bit will be cleared in either of the following cases: (1) When the end bit of the last data block is sent from the SD Bus to the uSDHC. (2) When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released. 1 DATA Line Active 0 DATA Line Inactive

Table continues on the next page...

uSDHCx_PRES_STATE field descriptions (continued)

Field	Description
1 CDIHB	Command Inhibit (DATA) This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DATA line 0 Can issue command which uses the DATA line
0 CIHB	Command Inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line. This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit. 1 Cannot issue command 0 Can issue command using only CMD line

10.3.8.11 Protocol Control (uSDHCx_PROT_CTRL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

uSDHCx_PROT_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 0
30 NON_EXACT_BLK_RD	Current block read is non-exact block read. It is only used for SDIO. 1 The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read. 0 The block read is exact block read. Host driver doesn't need to issue abort command to terminate this multi-block read.
29–27 BURST_LEN_EN	BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side. xx1 Burst length is enabled for INCR x1x Burst length is enabled for INCR4 / INCR8 / INCR16 1xx Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP
26 WECRM	Wakeup Event Enable On SD Card Removal This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt. 1 Enable 0 Disable
24 WECINT	Wakeup Event Enable On Card Interrupt This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt. 1 Enable 0 Disable
23–21 -	Reserved. Always write as 3'b100
20 RD_DONE_NO_8CLK	*Read done no 8 clock:* *According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.* *However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.* *In a summary, this bit should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.*
19 IABG	Interrupt At Block Gap This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. 1 Enabled 0 Disabled
18 RWCTL	Read Wait Control The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation. 1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set
17 CREQ	Continue Request

Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer. The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored. 1 Restart 0 No effect
16 SABGREQ	Stop At Block Gap Request This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined. This bit effects Read Transfer Active, Write Transfer Active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 1 Stop 0 Transfer
15–10 Reserved	This read-only field is reserved and always has the value 0.
9–8 DMASEL	DMA Select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved
7 CDSS	Card Detect Signal Selection This bit selects the source for the card detection. 1 Card Detection Test Level is selected (for test purpose). 0 Card Detection Level is selected (for normal purpose).
6 CDTL	Card Detect Test Level This is bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion. 1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted
5–4 EMODE	Endian Mode

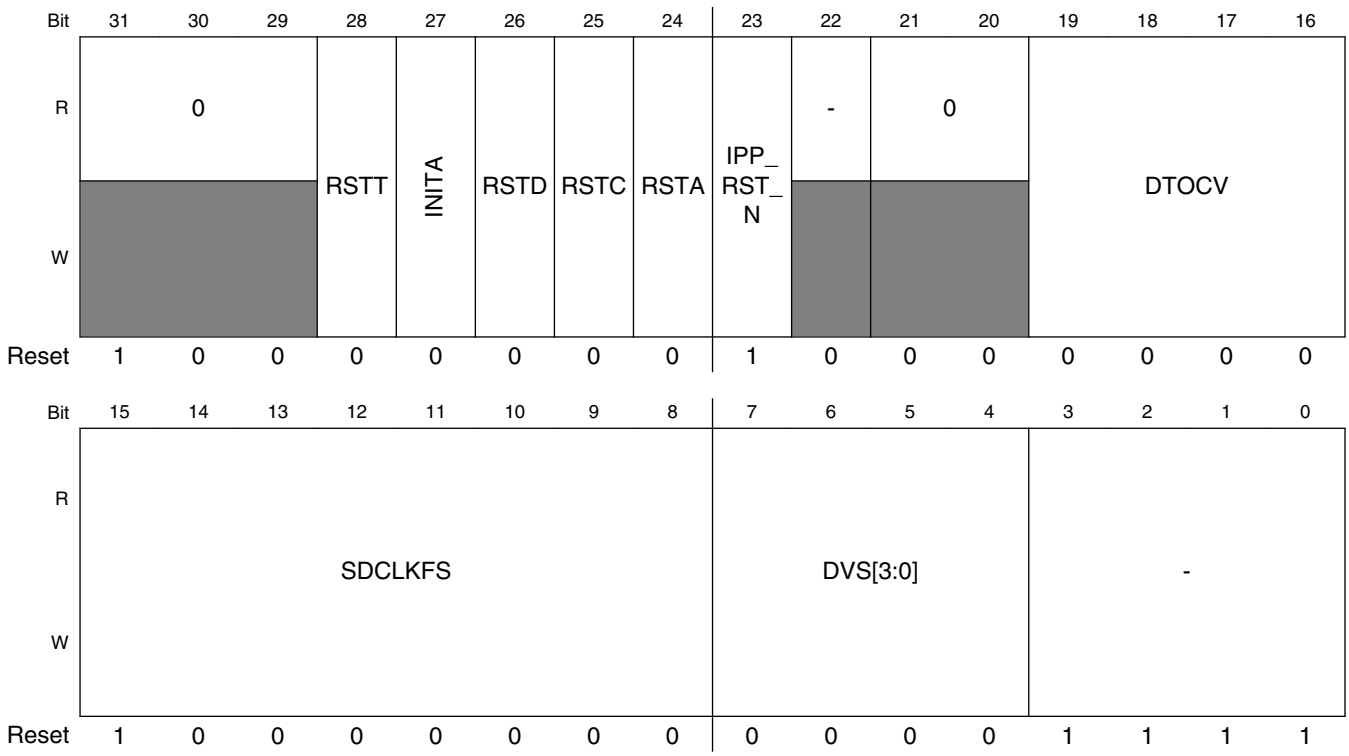
Table continues on the next page...

uSDHCx_PROT_CTRL field descriptions (continued)

Field	Description
	The uSDHC supports all three endian modes in data transfer. Refer to Data Buffer for more details. 00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved
3 D3CD	DATA3 as Card Detection Pin If this bit is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the uSDHC does not support. 1 DATA3 as Card Detection Pin 0 DATA3 does not monitor Card Insertion
2–1 DTW[1:0]	Data Transfer Width This bit selects the data width of the SD bus for a data transfer. The Host Driver shall set it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits. 10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved
0 LCTL	LED Control This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient: it is not necessary to reset the bit between commands. 1 LED on 0 LED off

10.3.8.12 System Control (uSDHC*x*_SYS_CTRL)

Address: Base address + 2Ch offset



uSDHC*x*_SYS_CTRL field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 RSTT	Reset Tuning When set this bit to 1, it will reset tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning bit in AUTOCMD12_ERR_STATUS will also set this bit to 1 to reset tuning circuit
27 INITA	Initialization Active When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (i.e. when command line or data lines are active, write to this bit is not allowed). On the otherhand, when this bit is set, i.e., during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.
26 RSTD	Software Reset For DATA Line

Table continues on the next page...

uSDHC*x*_SYS_CTRL field descriptions (continued)

Field	Description
	Only part of the data circuit is reset. DMA circuit is also reset. After this bit is set, SW waits for self-clear. The following registers and bits are cleared by this bit: • Data Port register • Buffer is cleared and initialized. • Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DATA Line Active • Command Inhibit (DATA) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete **NOTE:** When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set. 1 Reset 0 No Reset
25 RSTC	Software Reset For CMD Line Only part of the command circuit is reset. After this bit is set, SW waits for self-clear. The following registers and bits are cleared by this bit: • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete 1 Reset 0 No Reset
24 RSTA	Software Reset For ALL This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver shall set this bit to 1 to reset the uSDHC. The uSDHC shall reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. After this bit is set, SW should wait for self-clear. In tuning process, after every CMD19 is finished, this bit will be set to retest the uSDHC. **NOTE:** When reset, SW must make sure there is no incomplete data transferring. If there is data transfer going on, SW need wait TC or DC uSDHC_INT_STATUS register is set. 1 Reset 0 No Reset
23 IPP_RST_N	This register's value will be output to CARD from pad directly for hardware reset of the card if the card supports this feature.
22 -	Reserved

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description
21–20 Reserved	This read-only field is reserved and always has the value 0.
19–16 DTOCV	Data Timeout Counter Value This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 1111 SDCLK x 2^{28} 1110 SDCLK x 2^{27} 0001 SDCLK x 2^{14} 0000 SDCLK x 2^{13}
15–8 SDCLKFS	SDCLK Frequency Select This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. *In Single Data Rate mode(DDR_EN bit of MIXERCTRL is '0')* Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 *While in Dual Data Rate mode(DDR_EN bit of MIXERCTRL is '1')* *Only the following settings are allowed:* *80h) Base clock divided by 512* *40h) Base clock divided by 256* *20h) Base clock divided by 128* *10h) Base clock divided by 64* *08h) Base clock divided by 32* *04h) Base clock divided by 16* *02h) Base clock divided by 8* *01h) Base clock divided by 4* *00h) Base clock divided by 2* *When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also!*

Table continues on the next page...

uSDHCx_SYS_CTRL field descriptions (continued)

Field	Description
	In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit. *Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.* *If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.*
7–4 DVS[3:0]	Divisor This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. *Before changing clock divisor value(SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.* The setting are as following: 0000 Divide-by-1 0001 Divide-by-2 ..... 1110 Divide-by-15 1111 Divide-by-16
-	Reserved. Always write as 1.

10.3.8.13 Interrupt Status (uSDHCx_INT_STATUS)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

Table 10-47. uSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 10-48. uSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 10-49. uSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

uSDHCx_INT_STATUS field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28 DMAE	DMA Error Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Since any error corrupts the whole data block, the Host Driver shall re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 1 Error 0 No Error
27 Reserved	This read-only field is reserved and always has the value 0.
26 TNE	Tuning Error: (only for SD3.0 SDR104 mode) This bit is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning.
25 Reserved	This read-only field is reserved and always has the value 0.
24 AC12E	Auto CMD12 Error Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 1 Error 0 No Error
23 Reserved	This read-only field is reserved and always has the value 0.
22 DEBE	Data End Bit Error Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC. This bit will be not asserted in tuning process. 1 Error 0 No Error

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
21 DCE	Data CRC Error Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010. This bit will be not asserted in tuning process. 1 Error 0 No Error
20 DTOE	Data Timeout Error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This bit will be not asserted in tuning process. 1 Time out 0 No Error
19 CIE	Command Index Error Occurs if a Command Index error occurs in the command response. This bit will be not asserted in tuning process. 1 Error 0 No Error
18 CEBE	Command End Bit Error Occurs when detecting that the end bit of a command response is 0. This bit will be not asserted in tuning process. 1 End Bit Error Generated 0 No Error
17 CCE	Command CRC Error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. This bit will be not asserted in tuning process. 1 CRC Error Generated. 0 No Error
16 CTOE	Command Timeout Error Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the uSDHC detects a CMD line conflict, in which case a Command CRC Error shall also be set (as shown in Interrupt Status (uSDHC_INT_STATUS)), this bit shall be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the uSDHC.

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	This bit will be not asserted in tuning process. 1 Time out 0 No Error
15 Reserved	This read-only field is reserved and always has the value 0.
14 TP	Tuning Pass:(only for SD3.0 SDR104 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
13 Reserved	This read-only field is reserved and always has the value 0.
12 RTE	Re-Tuning Event: (only for SD3.0 SDR104 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 1 Re-Tuning should be performed 0 Re-Tuning is not required
11–9 Reserved	This read-only field is reserved and always has the value 0.
8 CINT	Card Interrupt This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal This status bit is set if the Card Inserted bit in the Present State register changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register. 1 Card inserted 0 Card state unstable or removed
5 BRR	Buffer Read Ready This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information. This bit indicates that cmd19 is finished in tuning process. 1 Ready to read buffer 0 Not ready to read buffer
4 BWR	Buffer Write Ready This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information. 1 Ready to write buffer: 0 Not ready to write buffer
3 DINT	DMA Interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 1 DMA Interrupt is generated 0 No DMA Interrupt
2 BGE	Block Gap Event If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. In the case of a Read Transaction: This bit is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 1 Transaction stopped at block gap 0 No block gap event
1 TC	Transfer Complete This bit is set when a read or write transfer is completed. In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System).

Table continues on the next page...

uSDHCx_INT_STATUS field descriptions (continued)

Field	Description
	In the case of a Write Transaction: This bit is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this bit is set when busy is deasserted. This bit will be not asserted in tuning process. 1 Transfer complete 0 Transfer not complete
0 CC	Command Complete This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register. This bit will be not asserted in tuning process. 1 Command complete 0 Command not complete

10.3.8.14 Interrupt Status Enable (uSDHCx_INT_STATUS_EN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

10.3.8.15 Interrupt Signal Enable (uSDHCx_INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

10.3.8.16 Auto CMD12 Error Status (uSDHCx_AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01.This register is valid only when the Auto CMD12 Error status bit is set.

The table bwlow shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 10-50. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

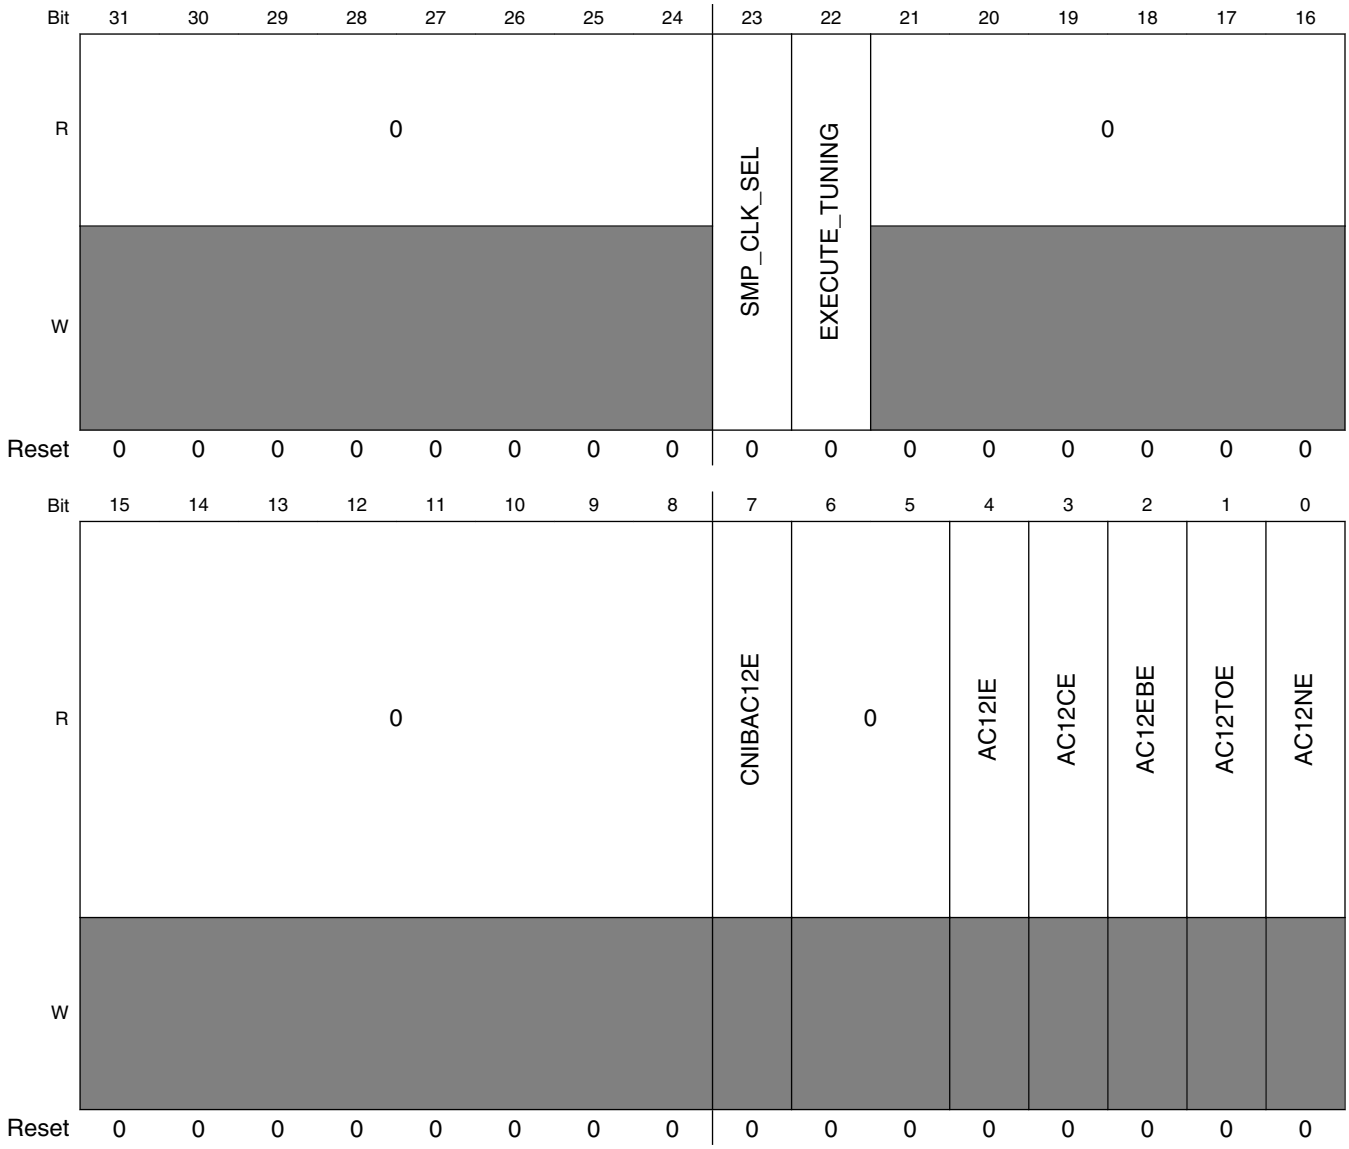
Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
   - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
   - Check errors correspond to bits 1-4.
   - Set bits 1-4 corresponding to detected errors.
   - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
   - Set bit 7 to 1 if there is a command that can't be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Address: Base address + 3Ch offset



uSDHC*x*_AUTOCMD12_ERR_STATUS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23 SMP_CLK_SEL	Sample Clock Select When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by ty tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller us receiving response or a read data block.

Table continues on the next page...

uSDHCx_AUTOCMD12_ERR_STATUS field descriptions (continued)

Field	Description
	1 Tuned clock is used to sample data 0 Fixed clock is used to sample data
22 EXECUTE_ TUNING	Execute Tuning When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when runing procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. 1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 AC12IE	Auto CMD12 / 23 Index Error Occurs if the Command Index error occurs in response to a command. 1 Error, the CMD index in response is not CMD12/23 0 No error
3 AC12CE	Auto CMD12 / 23 CRC Error Occurs when detecting a CRC error in the command response. 1 CRC Error Met in Auto CMD12/23 Response 0 No CRC error
2 AC12EBE	Auto CMD12 / 23 End Bit Error Occurs when detecting that the end bit of command response is 0 which should be 1. 1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 / 23 Timeout Error Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to1, the other error status bits (2-4) have no meaning. 1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 1 Not executed 0 Executed

10.3.8.17 Host Controller Capabilities (uSDHCx_HOST_CTRL_CAP)

This register provides the Host Driver with information specific to the uSDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset.

Address: Base address + 40h offset

25 VS30	Voltage Support 3.0 V This bit shall depend on the Host System ability. 1 3.0V supported 0 3.0V not supported
24 VS33	Voltage Support 3.3V This bit shall depend on the Host System ability. 1 3.3V supported 0 3.3V not supported
23 SRS	Suspend / Resume Support This bit indicates whether the uSDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver shall not issue either Suspend or Resume commands. 1 Supported 0 Not supported

Table continues on the next page...

uSDHCx_HOST_CTRL_CAP field descriptions (continued)

Field	Description
22 DMAS	DMA Support This bit indicates whether the uSDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 1 DMA Supported 0 DMA not supported
21 HSS	High Speed Support This bit indicates whether the uSDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz. 1 High Speed Supported 0 High Speed Not Supported
20 ADMAS	ADMA Support This bit indicates whether the uSDHC supports the ADMA feature. 1 Advanced DMA Supported 0 Advanced DMA Not supported
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 MBL[2:0]	Max Block Length This value indicates the maximum block size that the Host Driver can read and write to the buffer in the uSDHC. The buffer shall transfer block size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–14 RETUNING_ MODE	Retuning Mode This bit selects retuning method. 00 Mode 1 01 Mode 2 10 Mode 3 11 Reserved
13 USE_TUNING_ SDR50	Use Tuning for SDR50 This bit is set to 1. Host controller requires tuning to operate SDR50 1 SDR50 requires tuning 0 SDR does not require tuning
12 -	Reserved
11–8 TIME_COUNT_ RETUNING	Time Counter for Retuning This bit indicates an initial value of the Retuning Timer for Re-Tuning Mode1 and 3.Setting to 0 disables Retuning Timer.

Table continues on the next page...

uSDHCx_HOST_CTRL_CAP field descriptions (continued)

Field	Description
7–3 -	
2 DDR50_ SUPPORT	DDR50 support This bit indicates support of DDR50 mode.
1 SDR104_ SUPPORT	SDR104 support This bit indicates support of SDR104 mode.
0 SDR50_ SUPPORT	SDR50 support This bit indicates support of SDR50 mode.

10.3.8.18 Watermark Level (uSDHCx_WTMK_LVL)

Both write and read watermark levels (FIFO threshold) are configurable. There value can range from 1 to 128 words. Both write and read burst lengths are also Configurable. There value can range from 1 to 31 words.

Address: Base address + 44h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			WR_BRST_LEN[4:0]					WR_WML[7:0]								0			RD_BRST_LEN[4:0]					RD_WML[7:0]							
W																																
Reset	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0

uSDHCx_WTMK_LVL field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value 0.
28–24 WR_BRST_ LEN[4:0]	Write Burst Length [1] The number of words the uSDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
23–16 WR_WML[7:0]	Write Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_WTMK_LVL field descriptions (continued)

Field	Description
12–8 RD_BRST_ LEN[4:0]	Read Burst Length [2] The number of words the uSDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (i.e. it is not able to clear this field).
RD_WML[7:0]	Read Watermark Level The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.

2. Due to system restriction, the actual burst length may not exceed 16.

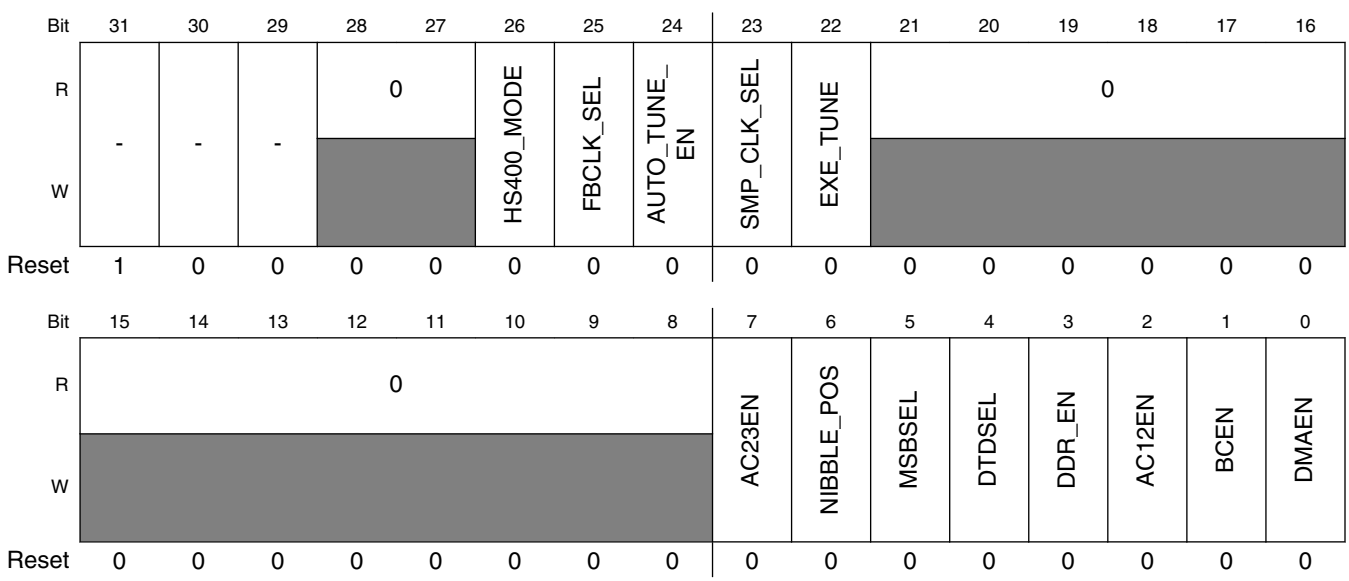
10.3.8.19 Mixer Control (uSDHCx_MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, The software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 10-51. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Address: Base address + 48h offset



uSDHCx_MIX_CTRL field descriptions

Field	Description
31 -	Reserved. Always write as 1
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 0.
28–27 Reserved	This read-only field is reserved and always has the value 0.
26 HS400_MODE	Enable HS400 Mode HS400 Enable
25 FBCLK_SEL	Feedback Clock Source Selection (Only used for SD3.0, SDR104 mode) 1 Feedback clock comes from the ipp_card_clk_out 0 Feedback clock comes from the loopback CLK
24 AUTO_TUNE_EN	Auto Tuning Enable (Only used for SD3.0, SDR104 mode) 1 Enable auto tuning 0 Disable auto tuning
23 SMP_CLK_SEL	When STD_TUNING_EN is 0, this bit is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode) 1 Tuned clock is used to sample data / cmd 0 Fixed clock is used to sample data / cmd
22 EXE_TUNE	Execute Tuning: (Only used for SD3.0, SDR104 mode) When STD_TUNING_EN is 0, this bit is set to 1 to indicate the Host Driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 1 Execute Tuning 0 Not Tuned or Tuning Completed
21–8 Reserved	This read-only field is reserved and always has the value 0.
7 AC23EN	Auto CMD23 Enable When this bit is set to 1, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	In DDR 4-bit mode nibble position indictation. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select This bit enables multiple block DATA line data transfers. For any other commands, this bit can be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Command Transfer Type (uSDHC_CMD_XFR_TYP)). 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select

Table continues on the next page...

uSDHCx_MIX_CTRL field descriptions (continued)

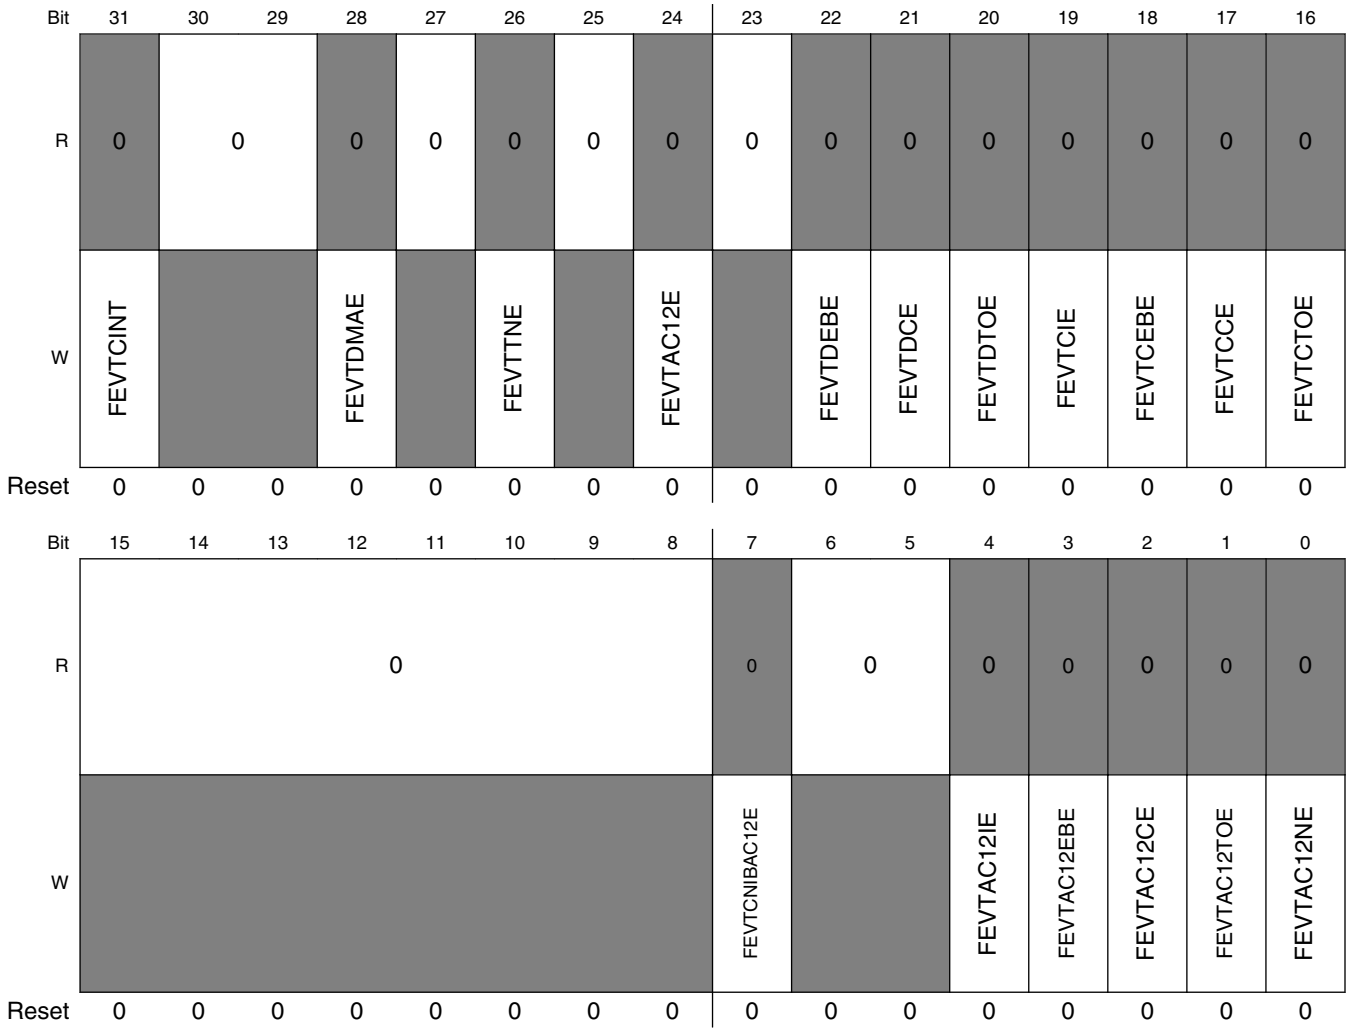
Field	Description
	This bit defines the direction of DATA line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the uSDHC and is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	Auto CMD12 Enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the uSDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the uSDHC will ignore this bit no matter it is set or not. 1 Enable 0 Disable
1 BCEN	Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

10.3.8.20 Force Event (uSDHCx_FORCE_EVENT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

Address: Base address + 50h offset



uSDHC*x*_FORCE_EVENT field descriptions

Field	Description
31 FEVTCINT	Force Event Card Interrupt Writing 1 to this bit generates a short low-level pulse on the internal DATA1 line, as if a self clearing interrupt was received from the external card. If enabled, the CINT bit will be set and the interrupt service routine may treat this interrupt as a normal interrupt from the external card.
30–29 Reserved	This read-only field is reserved and always has the value 0.
28 FEVTDMAE	Force Event DMA Error Forces the DMAE bit of Interrupt Status Register to be set.
27 Reserved	This read-only field is reserved and always has the value 0.
26 FEVTTNE	Force Tuning Error Forces the TNE bit of Interrupt Status Register to be set.
25 Reserved	This read-only field is reserved and always has the value 0.

Table continues on the next page...

uSDHCx_FORCE_EVENT field descriptions (continued)

Field	Description
24 FEVTAC12E	Force Event Auto Command 12 Error Forces the AC12E bit of Interrupt Status Register to be set.
23 Reserved	This read-only field is reserved and always has the value 0.
22 FEVTDEBE	Force Event Data End Bit Error Forces the DEBE bit of Interrupt Status Register to be set.
21 FEVTDCE	Force Event Data CRC Error Forces the DCE bit of Interrupt Status Register to be set.
20 FEVTDTOE	Force Event Data Time Out Error Force the DTOE bit of Interrupt Status Register to be set.
19 FEVTCIE	Force Event Command Index Error Forces the CCE bit of Interrupt Status Register to be set.
18 FEVTCEBE	Force Event Command End Bit Error Forces the CEBE bit of Interrupt Status Register to be set.
17 FEVTCCE	Force Event Command CRC Error Forces the CCE bit of Interrupt Status Register to be set.
16 FEVTCTOE	Force Event Command Time Out Error Forces the CTOE bit of Interrupt Status Register to be set.
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 FEVTCNIBAC12E	Force Event Command Not Executed By Auto Command 12 Error Forces the CNIBAC12E bit in the Auto Command12 Error Status Register to be set.
6–5 Reserved	This read-only field is reserved and always has the value 0.
4 FEVTAC12IE	Force Event Auto Command 12 Index Error Forces the AC12IE bit in the Auto Command12 Error Status Register to be set.
3 FEVTAC12EBE	Force Event Auto Command 12 End Bit Error Forces the AC12EBE bit in the Auto Command12 Error Status Register to be set.
2 FEVTAC12CE	Force Event Auto Command 12 CRC Error Forces the AC12CE bit in the Auto Command12 Error Status Register to be set.
1 FEVTAC12TOE	Force Event Auto Command 12 Time Out Error Forces the AC12TOE bit in the Auto Command12 Error Status Register to be set.
0 FEVTAC12NE	Force Event Auto Command 12 Not Executed Forces the AC12NE bit in the Auto Command12 Error Status Register to be set.

10.3.8.21 ADMA Error Status Register (uSDHCx_ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

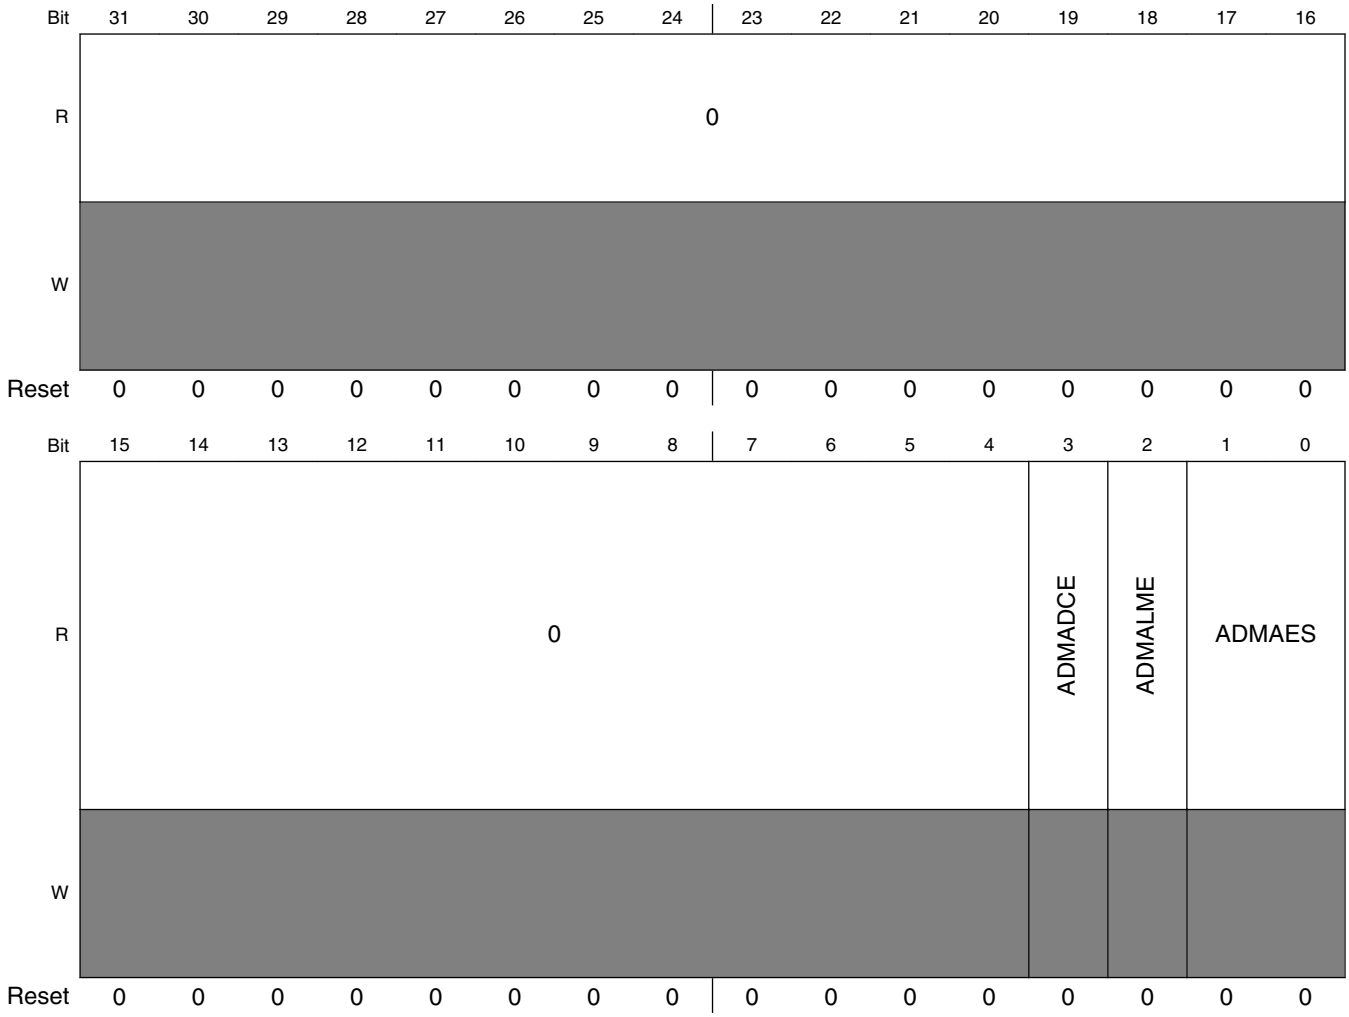
In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 10-52. ADMA Error State Coding

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Address: Base address + 54h offset



uSDHCx_ADMA_ERR_STATUS field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value 0.
3 ADMADCE	ADMA Descritor Error This error occurs when invalid descriptor fetched by ADMA. 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error This error occurs in the following 2 cases: • While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. • Total data length cannot be divided by the block length. 1 Error 0 No Error
ADMAES	ADMA Error State (when ADMA Error is occurred)

Table continues on the next page...

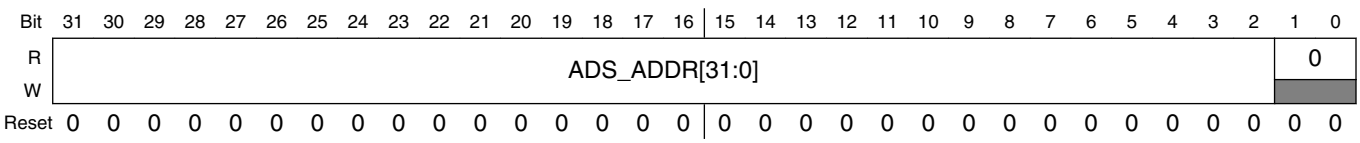
uSDHCx_ADMA_ERR_STATUS field descriptions (continued)

Field	Description
	This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (uSDHC_ADMA_ERR_STATUS) for more details.

10.3.8.22 ADMA System Address (uSDHCx_ADMA_SYS_ADDR)

This register contains the physical system memory address used for ADMA transfers.

Address: Base address + 58h offset



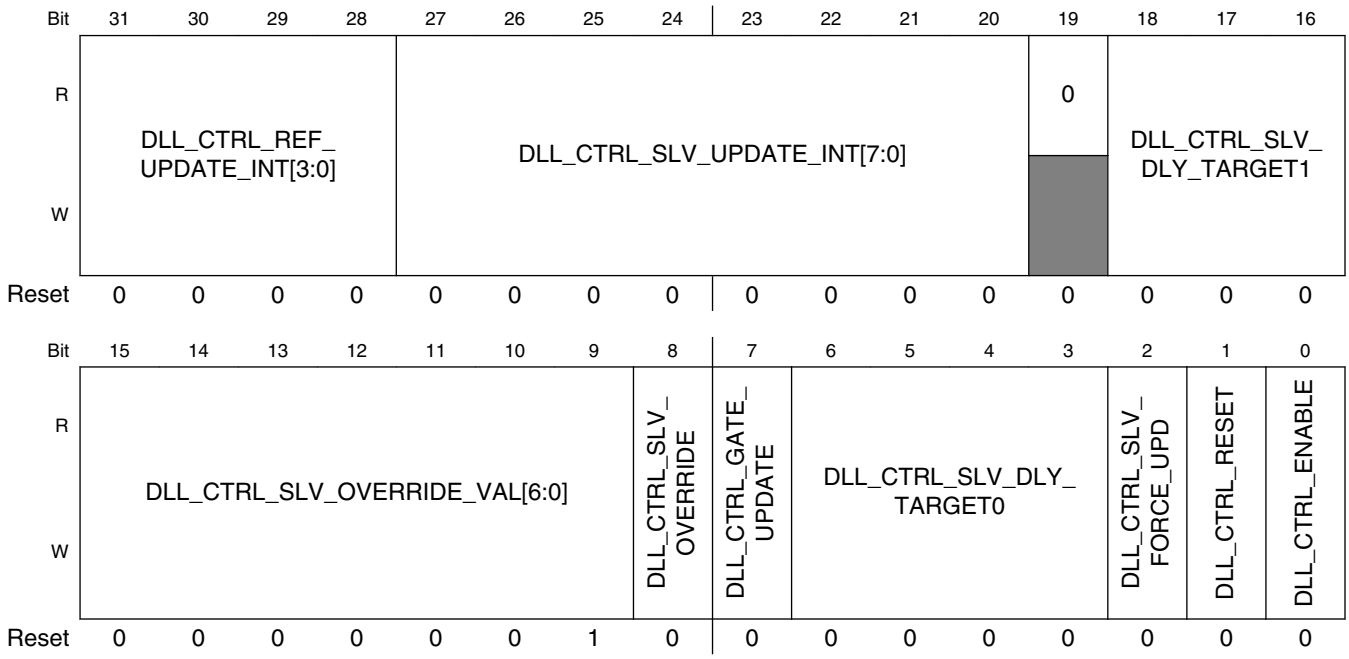
uSDHCx_ADMA_SYS_ADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions .
Reserved	This read-only field is reserved and always has the value 0.

10.3.8.23 DLL (Delay Line) Control (uSDHCx_DLL_CTRL)

This register contains control bits for DLL.

Address: Base address + 60h offset



uSDHCx_DLL_CTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop shall update every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 Reserved	This read-only field is reserved and always has the value 0.
18–16 DLL_CTRL_SLV_DLY_TARGET1	Refer to DLL_CTRL_SLV_DLY_TARGET0 below.
15–9 DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	When SLV_OVERRIDE = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.

Table continues on the next page...

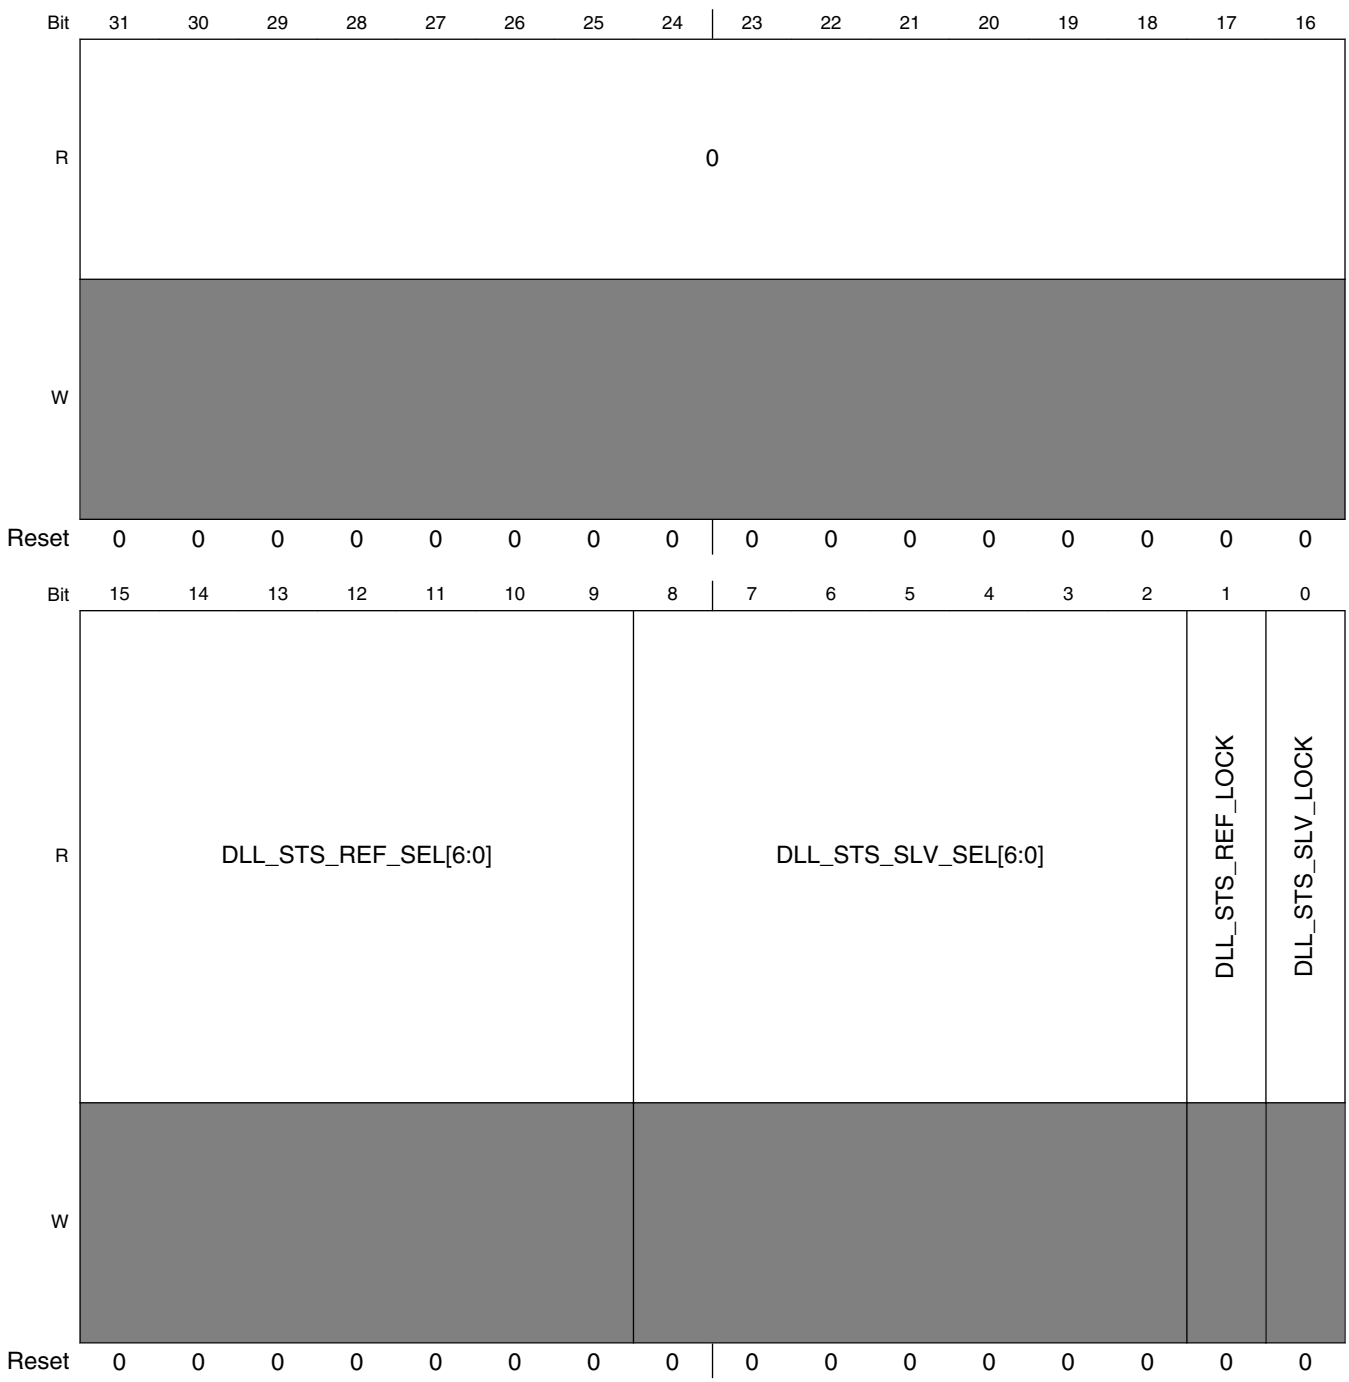
uSDHC*x*_DLL_CTRL field descriptions (continued)

Field	Description
8 DLL_CTRL_ SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_ GATE_UPDATE	Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6–3 DLL_CTRL_ SLV_DLY_ TARGET0	The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is ((DLL_CTRL_SLV_DLY_TARGET1 +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4.
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.8.24 DLL Status (uSDHC*x*_DLL_STATUS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Address: Base address + 64h offset



uSDHC*x*_DLL_STATUS field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–9 DLL_STS_REF_SEL[6:0]	Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 DLL_STS_SLV_SEL[6:0]	Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

10.3.8.25 CLK Tuning Control and Status (uSDHC*x*_CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. All bits are read only and will read the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode.

Address: Base address + 68h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRE_ERR	TAP_SEL_PRE[6:0]							TAP_SEL_OUT[3:0]				TAP_SEL_POST[3:0]			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	NXT_ERR	DLY_CELL_SET_PRE[6:0]							DLY_CELL_SET_OUT[6:0]				DLY_CELL_SET_POST[6:0]			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

uSDHC*x*_CLK_TUNE_CTRL_STATUS field descriptions

Field	Description
31 PRE_ERR	PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.

Table continues on the next page...

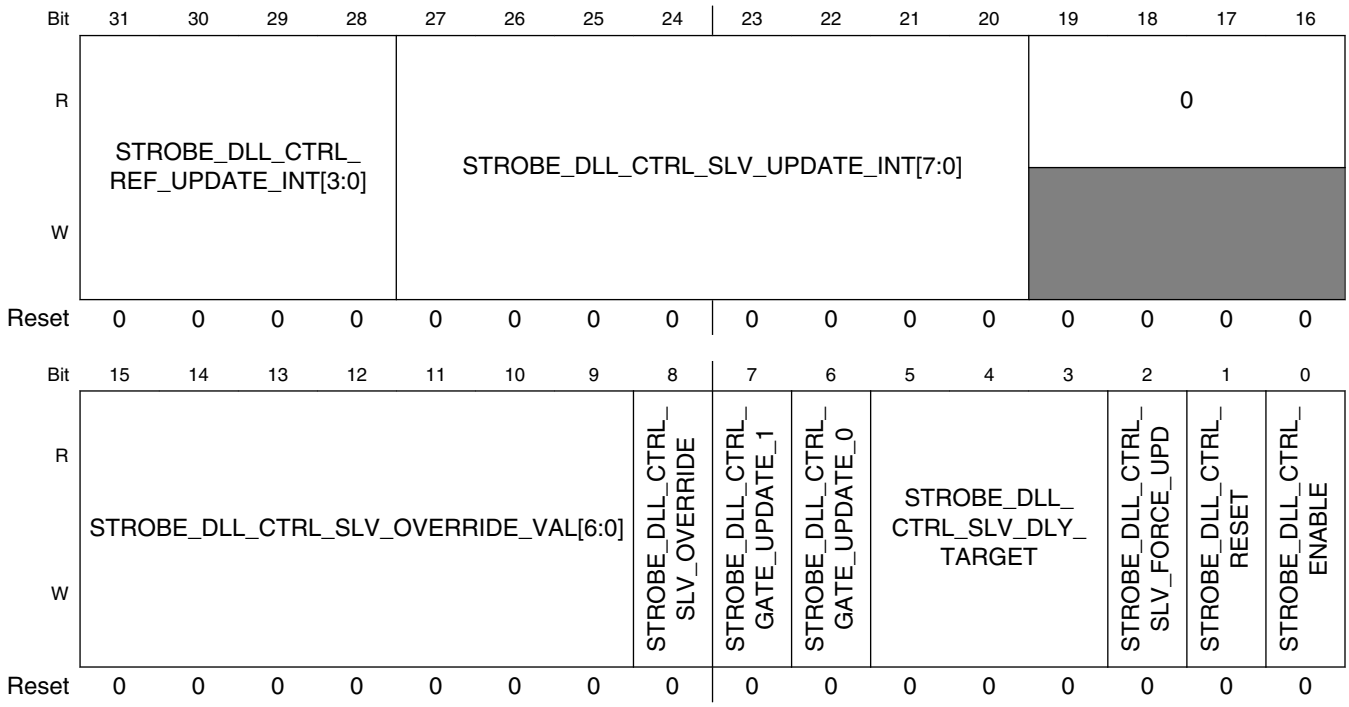
uSDHCx_CLK_TUNE_CTRL_STATUS field descriptions (continued)

Field	Description
30–24 TAP_SEL_ PRE[6:0]	Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE will be updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23–20 TAP_SEL_ OUT[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19–16 TAP_SEL_ POST[3:0]	Reflect the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14–8 DLY_CELL_ SET_PRE[6:0]	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7–4 DLY_CELL_ SET_OUT[6:0]	Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
DLY_CELL_ SET_POST[6:0]	Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

10.3.8.26 Strobe DLL Control (uSDHCx_STROBE_DLL_CTRL)

This register contains the strobe DLL Control information.

Address: Base address + 70h offset



uSDHCx_STROBE_DLL_CTRL field descriptions

Field	Description
31–28 STROBE_DLL_ CTRL_REF_ UPDATE_ INT[3:0]	Strobe DLL Control Reference Update Interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop shall update every two STROBE_REF_CLOCK cycles. **NOTE:** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 STROBE_DLL_ CTRL_SLV_ UPDATE_ INT[7:0]	Strobe DLL Control Slave Update Interval Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE:** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

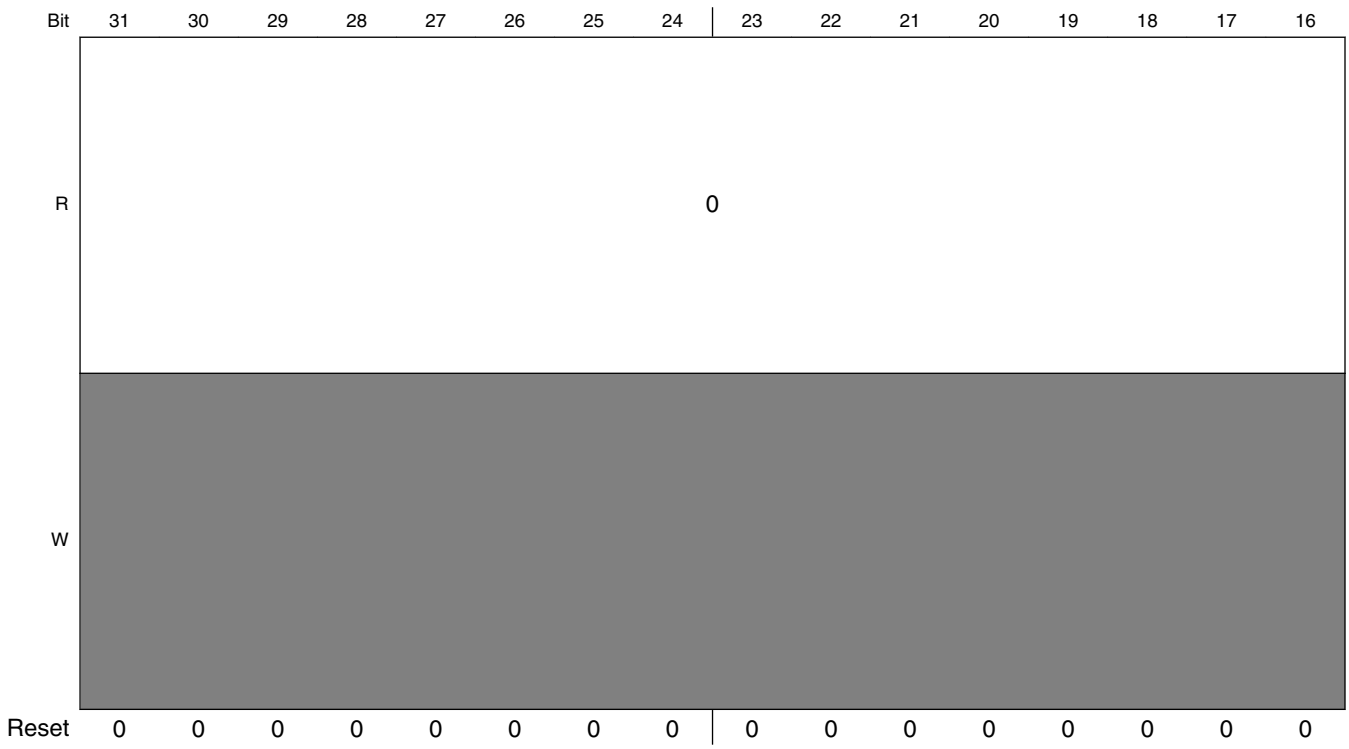
uSDHCx_STROBE_DLL_CTRL field descriptions (continued)

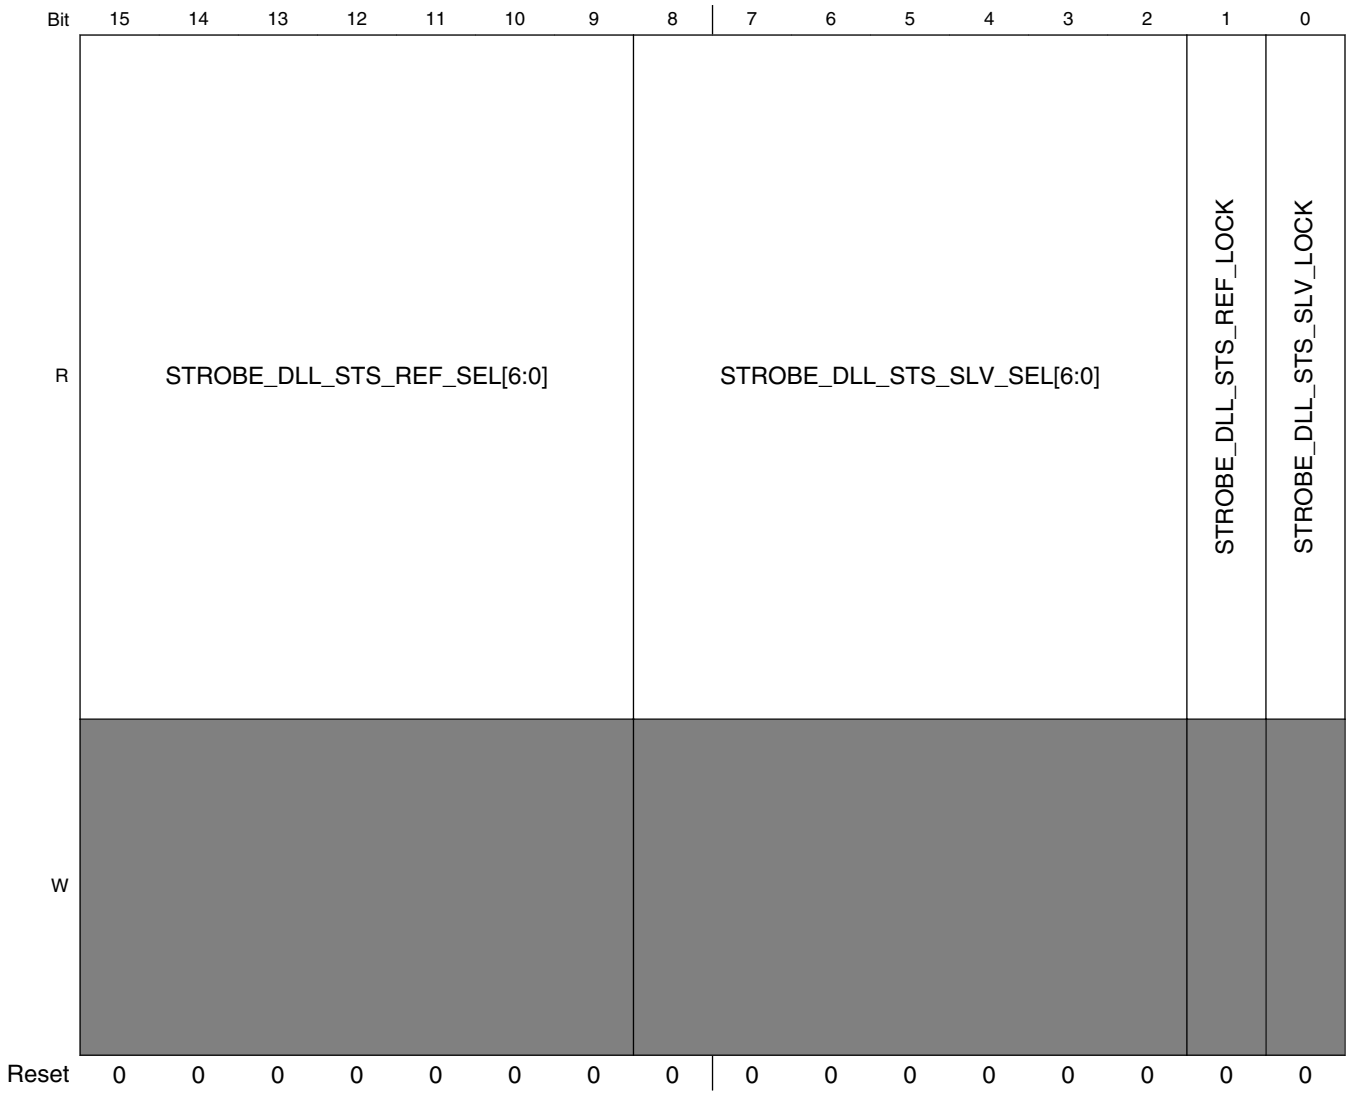
Field	Description
15–9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL[6:0]	Strobe DLL Control Slave Override Value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL Control Slave Override Set this bit to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this bit to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE_1	Strobe DLL Control Gate Update Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6 STROBE_DLL_CTRL_GATE_UPDATE_0	Strobe DLL Control Gate Update Set this bit to 1 to prevent the DLL from updating (since when STROBE_CLOCK_IN exists, glitches may appear during DLL updates). This bit can be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
5–3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *4)/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL Control Slave Force Updated Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL Control Reset Setting this bit to 1 to force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL Control Enable Set this bit to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.8.27 Strobe DLL Status (uSDHCx_STROBE_DLL_STATUS)

This register contains the strobe DLL status information. All bits are read only and read the same as the power-reset value.

Address: Base address + 74h offset





uSDHCx_STROBE_DLL_STATUS field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–9 STROBE_DLL_STS_REF_SEL[6:0]	Strobe DLL Status Reference Select Reference delay line select taps. This is encoded by 7 bits for 127 taps.
8–2 STROBE_DLL_STS_SLV_SEL[6:0]	Strobe DLL Status Slave Select Slave delay line select status. This is the instant value generated from reference chain. Since the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL Status Reference Lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.

Table continues on the next page...

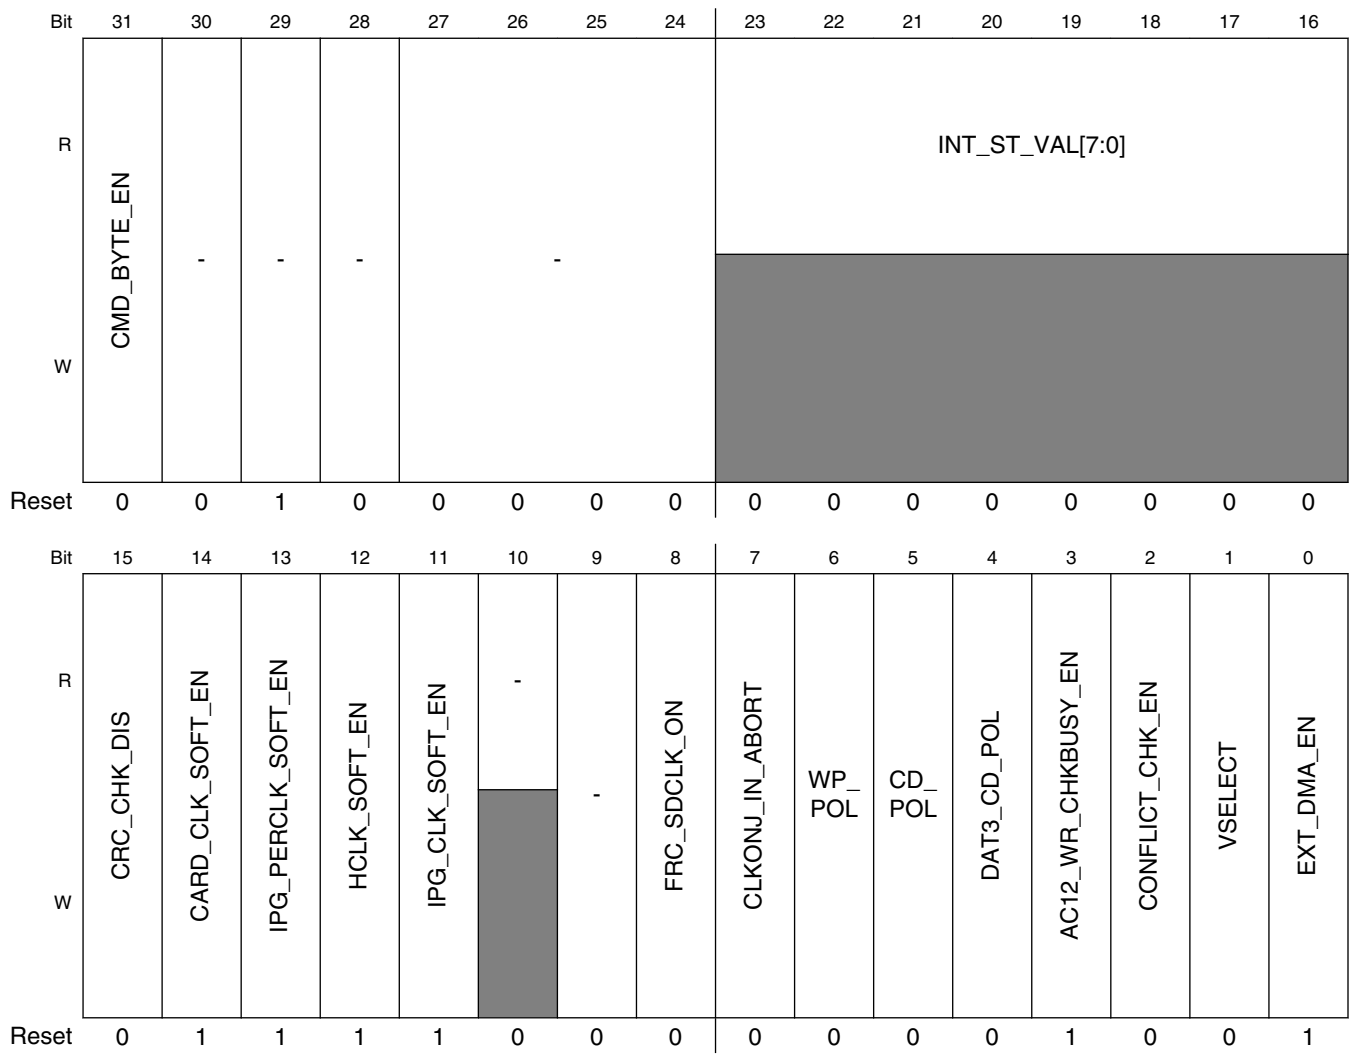
uSDHCx_STROBE_DLL_STATUS field descriptions (continued)

Field	Description
0 STROBE_DLL_ STS_SLV_LOCK	Strobe DLL Status Slave Lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

10.3.8.28 Vendor Specific Register (uSDHCx_VEND_SPEC)

This register contains the vendor specific control / status register.

Address: Base address + C0h offset



uSDHCx_VEND_SPEC field descriptions

Field	Description
31 CMD_BYTE_EN	Byte access 0 Disable 1 Enable
30 -	Reserved. Always write as 0.
29 -	Reserved. Always write as 1.
28 -	Reserved. Always write as 0.
27–24 -	Reserved. Always write as 4'b0000.
23–16 INT_ST_VAL[7:0]	Internal State Value Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.
15 CRC_CHK_DIS	CRC Check Disable 0 Check CRC16 for every read data packet and check CRC bits for every write data packet 1 Ignore CRC16 check for every read data packet and ignore CRC bits check for every write data packet
14 CARD_CLK_ SOFT_EN	Card Clock Software Enable 0 Gate off the sd_clk 1 Enable the sd_clk
13 IPG_PERCLK_ SOFT_EN	IPG_PERCLK Software Enable 0 Gate off the IPG_PERCLK 1 Enable the IPG_PERCLK
12 HCLK_SOFT_EN	AHB Clock Software Enable **NOTE:** Hardware auto-enables the AHB clock when the internal DMA is enabled even if HCLK_SOFT_EN is 0. 0 Gate off the AHB clock. 1 Enable the AHB clock.
11 IPG_CLK_ SOFT_EN	IPG_CLK Software Enable 0 Gate off the IPG_CLK 1 Enable the IPG_CLK
10 -	Reserved. Always write as 0.
9 -	Reserved. Always write as 0.
8 FRC_SDCLK_ ON	Force CLK output active 0 CLK active or inactive is fully controlled by the hardware. 1 Force CLK active.

Table continues on the next page...

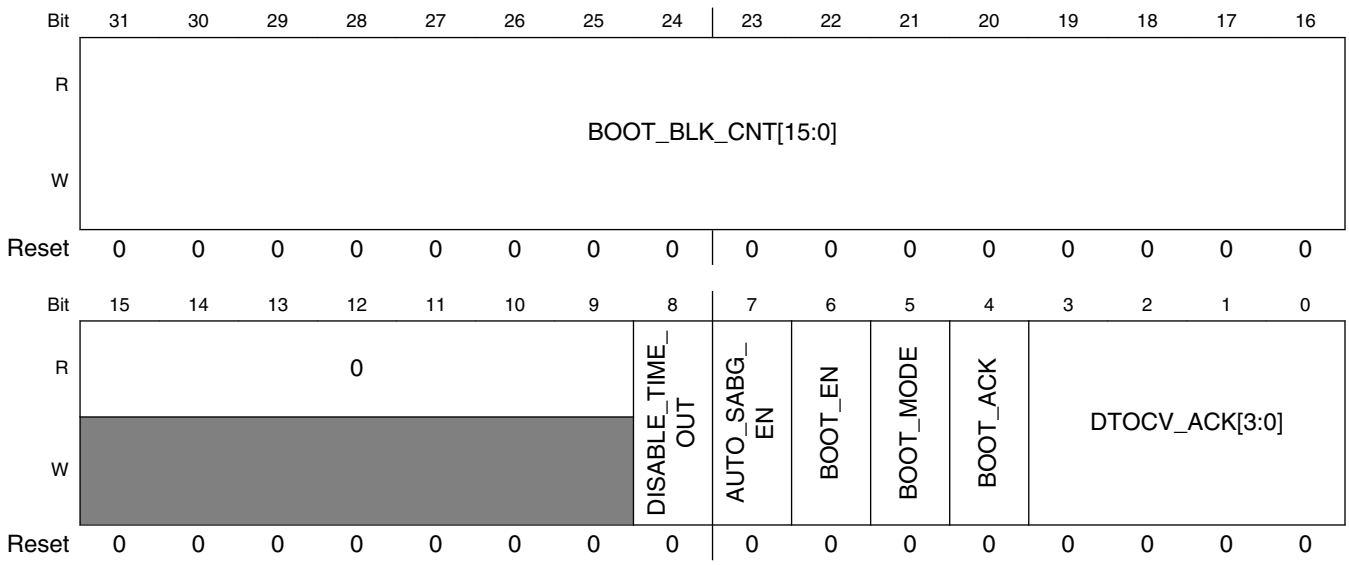
uSDHC*x*_VEND_SPEC field descriptions (continued)

Field	Description
7 CLKONJ_IN_ABORT	Only for debug. Force CLK output active when sending Abort command: 0 The CLK output is active when sending abort command while data is transmitting even if the internal FIFO is full (for read) or empty (for write). 1 The CLK output is inactive when sending abort command while data is transmitting if the internal FIFO is full (for read) or empty (for write).
6 WP_POL	Only for debug. Polarity of the WP pin: 0 WP pin is high active. 1 WP pin is low active.
5 CD_POL	Only for debug. Polarity of the CD_B pin: 0 CD_B pin is low active. 1 CD_B pin is high active.
4 DAT3_CD_POL	Only for debug. Polarity of DATA3 pin when it is used as card detection. 0 Card detected when DATA3 is high. 1 Card detected when DATA3 is low.
3 AC12_WR_CHKBUSY_EN	Check busy enable after auto CMD12 for write data packet 0 Do not check busy after auto CMD12 for write data packet 1 Check busy after auto CMD12 for write data packet
2 CONFLICT_CHK_EN	Conflict check enable. It is not implemented in uSDHC IP. 0 Conflict check disable 1 Conflict check enable
1 VSELECT	Voltage Selection Change the value of output signal VSELECT, to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 1 Change the voltage to low voltage range, around 1.8 V 0 Change the voltage to high voltage range, around 3.0 V
0 EXT_DMA_EN	External DMA Request Enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, uSDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set. 0 In any scenario, uSDHC does not send out external DMA request. 1 When internal DMA is not active, the external DMA request will be sent out.

10.3.8.29 MMC Boot Register (uSDHCx_MMC_BOOT)

This register contains the MMC Fast Boot control register.

Address: Base address + C4h offset



uSDHCx_MMC_BOOT field descriptions

Field	Description
31–16 BOOT_BLK_CNT[15:0]	The value defines the Stop At Block Gap value of automatic mode. When received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Atrributes Register, bit31 - 16 of 0x04.
15–9 Reserved	This read-only field is reserved and always has the value 0.
8 DISABLE_TIME_OUT	Disable Time Out **NOTE:** When this bit is set, there is no timeout check no matter whether BOOT_EN is set or not. 0 Enable time out 1 Disable time out
7 AUTO_SABG_EN	During boot, enable auto stop at block gap function. This function will be triggered, and host will stop at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot mode enable 0 Fast boot disable 1 Fast boot enable
5 BOOT_MODE	Boot mode select

Table continues on the next page...

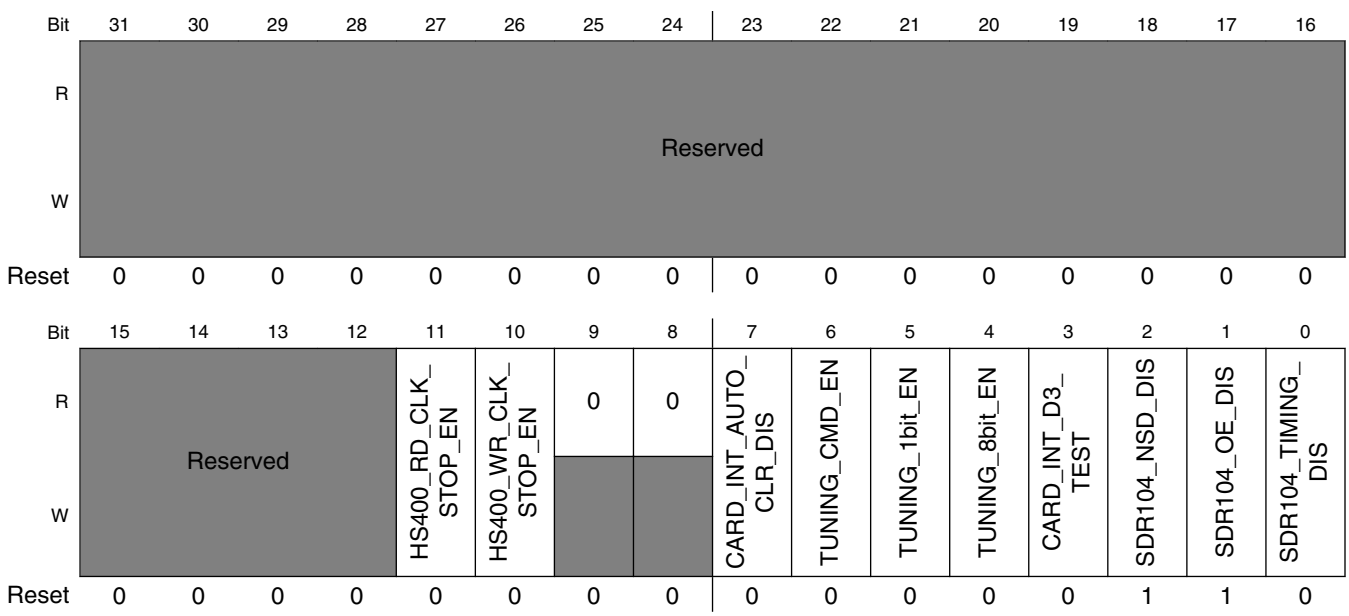
uSDHCx_MMC_BOOT field descriptions (continued)

Field	Description
	0 Normal boot 1 Alternative boot
4 BOOT_ACK	Boot ACK mode select 0 No ack 1 Ack
DTOCV_ ACK[3:0]	Boot ACK time out counter value. 0000 SDCLK x 2^13 0001 SDCLK x 2^14 0010 SDCLK x 2^15 0011 SDCLK x 2^16 0100 SDCLK x 2^17 0101 SDCLK x 2^18 0110 SDCLK x 2^19 0111 SDCLK x 2^20 1110 SDCLK x 2^27 1111 SDCLK x 2^28

10.3.8.30 Vendor Specific 2 Register (uSDHCx_VEND_SPEC2)

This register contains the vendor specific control 2 register.

Address: Base address + C8h offset



uSDHCx_VEND_SPEC2 field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 HS400_RD_CLK_STOP_EN	HS400 Read Clock Stop Enable Only stop clock at read block gap.
10 HS400_WR_CLK_STOP_EN	HS400 Write Clock Stop Enable Only stop clock at write block gap.
9 Reserved	This read-only field is reserved and always has the value 0.
8 Reserved	This read-only field is reserved and always has the value 0.
7 CARD_INT_AUTO_CLR_DIS	Disable the feature to clear the Card interrupt status bit when Card Interrupt status enable bit is cleared. Only for debug. 0 Card interrupt status bit (CINT) can be cleared when Card Interrupt status enable bit is 0. 1 Card interrupt status bit (CINT) can only be cleared by writting a 1 to CINT bit.
6 TUNING_CMD_EN	Enable the auto tuning circuit to check the CMD line. 0 Auto tuning circuit does not check the CMD line. 1 Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. **NOTE:** The format of these two bits are [TUNNING_8bit_EN:TUNNING_1bit_EN]. 00 Tuning circuit only checks the DATA[3:0]. 01 Tuning circuit only checks the DATA0. 10 Tuning circuit checks the whole DATA[7:0]. 11 Invalid.
3 CARD_INT_D3_TEST	Card Interrupt Detection Test This bit only uses for debugging. 0 Check the card interrupt only when DATA3 is high. 1 Check the card interrupt by ignoring the status of DATA3.
2 SDR104_NSD_DIS	Interrupt window after abort command is sent. This bit only uses for debugging. 0 Enable the interrupt window 9 cycles later after the end of the I/O abort command (or CMD12) is sent. 1 Enable the interrupt window 5 cycles later after the end of the I/O abort command (or CMD12) is sent.
1 SDR104_OE_DIS	CMD_OE / DATA_OE logic generation test. This bit only uses for debugging. 0 Drive the CMD_OE / DATA_OE for one more clock cycle after the end bit. 1 Stop to drive the CMD_OE / DATA_OE at once after driving the end bit.

Table continues on the next page...

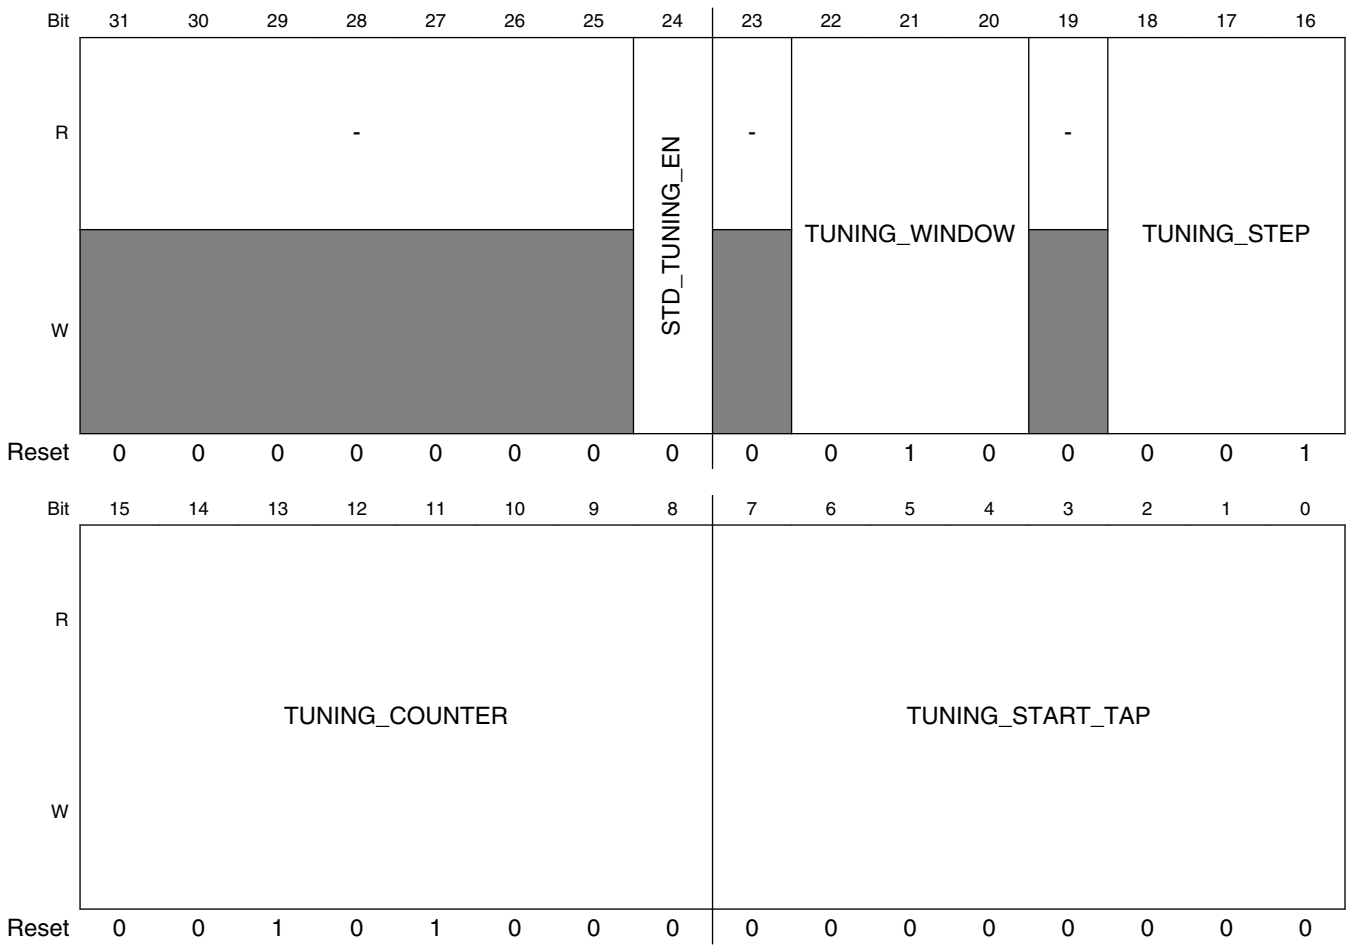
uSDHCx_VEND_SPEC2 field descriptions (continued)

Field	Description
0 SDR104_ TIMING_DIS	Timeout counter test. This bit only uses for debugging. 0 The timeout counter for Ncr changes to 80, Ncrc changes to 21. 1 The timeout counter for Ncr changes to 72, Ncrc changes to 15.

10.3.8.31 Tuning Control Register (uSDHCx_TUNING_CTRL)

The register contains configuration of tuning circuit.

Address: Base address + CCh offset



uSDHCx_TUNING_CTRL field descriptions

Field	Description
31–25 -	Reserved

Table continues on the next page...

uSDHCx_TUNING_CTRL field descriptions (continued)

Field	Description
24 STD_TUNING_EN	Standard tuning circuit and procedure enable: This bit is used to enable standard tuning circuit and procedure.
23 -	Reserved
22–20 TUNING_WINDOW	Select data window value for auto tuning
19 -	Reserved
18–16 TUNING_STEP	The increasing delay cell steps in tuning procedure.
15–8 TUNING_COUNTER	The MAX repeat CMD19 times in tuning procedure.
TUNING_START_TAP	The start dealy cell point when send first CMD19 in tuning procedure.

Chapter 11
Connectivity

11.1 Ethernet MAC (ENET)

11.1.1 Introduction

The MAC-NET core, in conjunction with a 10/100/1000-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

11.1.2 Overview

The core implements a triple-speed 10/100/1000-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

11.1.2.1 Features

The MAC-NET core includes the following features.

11.1.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
  - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism

- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping
  - AVB endpoint talker and listener support
  - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

11.1.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols

- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

11.1.2.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

11.1.2.2 Block diagram

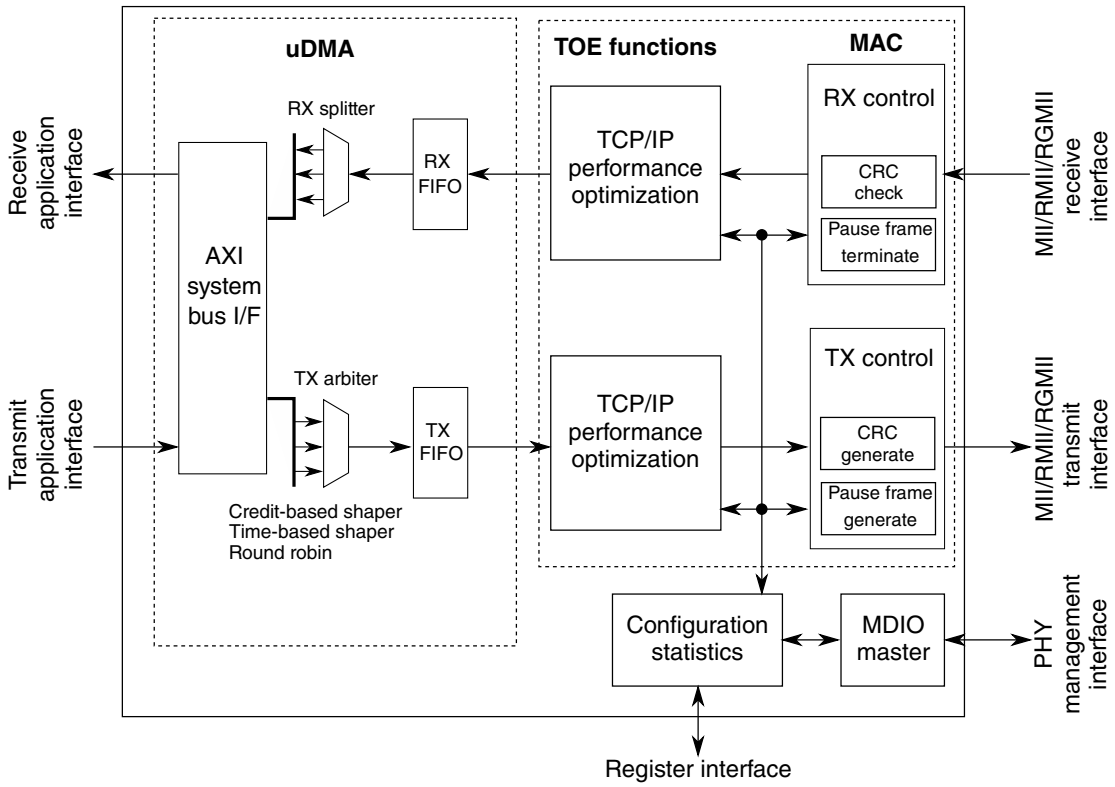


Figure 11-1. Ethernet MAC-NET core block diagram

11.1.3 External Signals

The table found here describes the external signals of ENET.

Table 11-1. ENET External Signals

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_1588_EVENT0_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	UART3_RXD	ALT4	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_1588_EVENT0_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set. **NOTE:** ENET_1588_EVENT0_OUT has a programmable output width, see IOMUXC_GPR0[CLK_STRETCH] delayed one clock cycle in relation to all other EVENTx_OUT signals	MII/RMII/RGMII	UART3_TXD	ALT4	O
ENET1_1588_EVENT1_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	UART3_RTS	ALT4	I
ENET1_1588_EVENT1_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/RGMII	UART3_CTS	ALT4	O
ENET1_1588_EVENT2_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare,	MII/RMII/RGMII	LCD1_CLK	ALT2	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
	the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.				
ENET1_1588_EVENT2_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMII	LCD1_DATA20	ALT2	O
ENET1_1588_EVENT3_IN	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMII	LCD1_ENABLE	ALT2	I
ENET1_1588_EVENT3_OUT	Capture/compare block input/output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	MII/RMII/ RGMII	LCD1_DATA21	ALT2	O
ENET1_COL	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full duplex mode.	MII	ENET1_COL	ALT0	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
ENET1_CRS	Carrier sense. When asserted, indicates transmit or receive medium is not idle.	MII	ENET1_CRS	ALT0	I
