ENET1_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	MII/RMII/RGMII	GPIO1_IO11	ALT2	O
			SD2_WP	ALT1	
			UART1_TXD	ALT6	
ENET1_MDIO	Transfers control information between the external PHY and the mediaaccess controller. Data is synchronous to MDC. This signal is an input after reset.	MII/RMII/RGMII	GPIO1_IO10	ALT2	IO
			SD2_CD_B	ALT1	
			UART1_RXD	ALT6	
ENET1_RX_CLK	In MII mode, provides a timing reference for RX_EN, RX_DATA[3:0], and RX_ER.	MII	ENET1_RX_CLK	ALT0	I
ENET1_RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	MII/RMII	ENET1_RXC	ALT1	I
ENET1_TX_CLK	Input clock, which provides a timing reference for TX_EN, TX_DATA[3:0], and TX_ER.	MII	ENET1_TX_CLK	ALT0	O
ENET1_TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	MII	ENET1_TXC	ALT1	O
RGMII1_RD0	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII/RMII/MII	ENET1_RDATA0	ALT0	I
RGMII1_RD1	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII/RMII/MII	ENET1_RDATA1	ALT0	I
RGMII1_RD2	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII/MII	ENET1_RDATA2	ALT0	I
RGMII1_RD3	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RGMII/MII	ENET1_RDATA3	ALT0	I
RGMII1_RX_CTL	In RGMII mode, contains RX_EN on the rising edge of RGMII_RXC, and a logical derivative of RX_EN and RX_ER (RX_EN XOR RX_ER) on the falling edge of RGMII_RXC.	RGMII	ENET1_RX_CTL	ALT0	I
RGMII1_RXC	In RGMII mode, provides a timing reference for RX_DATA[3:0] and RX_CTL.	RGMII/MII	ENET1_RXC	ALT0	I

Table continues on the next page...

Table 11-1. ENET External Signals (continued)

Signal	Description	Mode	Pad	Alt Mode	Direction
RGMII1_TD0	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII/ RMII/MII	ENET1_TD ATA0	ALT0	O
RGMII1_TD1	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII/ RMII/MII	ENET1_TD ATA1	ALT0	O
RGMII1_TD2	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII/MII	ENET1_TD ATA2	ALT0	O
RGMII1_TD3	Serial output Ethernet data. Only valid during TX_EN assertion.	RGMII/MII	ENET1_TD ATA3	ALT0	O
RGMII1_TX_CTL	In RGMII mode, contains TX_EN on the rising edge of RGMII_TXC, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of RGMII_TXC.	RGMII	ENET1_TX_ CTL	ALT0	O
RGMII1_TXC	In RGMII mode, provides a timing reference for TX_DATA[3:0] and TX_CTL.	RGMII	ENET1_TX C	ALT0	O

11.1.4 Clocks

The table found here describes the clock sources for ENET. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 11-2. ENET Clocks

Clock name	Clock Root	Description
ipg_clk	ENET_AXI_CLK_ROO T	Module clock
ipg_clk_mac0	ENET_AXI_CLK_ROO T	MAC peripheral clock
ipg_clk_mac0_s	ENET_AXI_CLK_ROO T	MAC peripheral access clock
ipg_clk_s	ENET_AXI_CLK_ROO T	Peripheral access clock
ipg_clk_time	ENET1_TIME_CLK_R OOT	Peripheral clock
mac0_rxmem_clk	ENET_AXI_CLK_ROO T	MAC receive memory clock
mac0_txmem_clk	ENET_AXI_CLK_ROO T	MAC transmit memory clock

11.1.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 11-3. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

ENET memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30BE_0004	Interrupt Event Register (ENET_EIR)	32	w1c	0000_0000h	11.1.5.1/ 2860
30BE_0008	Interrupt Mask Register (ENET_EIMR)	32	R/W	0000_0000h	11.1.5.2/ 2863
30BE_0010	Receive Descriptor Active Register - Ring 0 (ENET_RDAR)	32	R/W	0000_0000h	11.1.5.3/ 2867
30BE_0014	Transmit Descriptor Active Register - Ring 0 (ENET_TDAR)	32	R/W	0000_0000h	11.1.5.4/ 2868
30BE_0024	Ethernet Control Register (ENET_ECR)	32	R/W	See section	11.1.5.5/ 2869
30BE_0040	MII Management Frame Register (ENET_MMFR)	32	R/W	0000_0000h	11.1.5.6/ 2871
30BE_0044	MII Speed Control Register (ENET_MSCR)	32	R/W	0000_0000h	11.1.5.7/ 2872
30BE_0064	MIB Control Register (ENET_MIBC)	32	R/W	C000_0000h	11.1.5.8/ 2874
30BE_0084	Receive Control Register (ENET_RCR)	32	R/W	05EE_0001h	11.1.5.9/ 2875
30BE_00C4	Transmit Control Register (ENET_TCR)	32	R/W	0000_0000h	11.1.5.10/ 2878
30BE_00E4	Physical Address Lower Register (ENET_PALR)	32	R/W	0000_0000h	11.1.5.11/ 2880

Table continues on the next page...

ENET memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
30BE_00E8	Physical Address Upper Register (ENET_PAUR)	32	R/W	0000_8808h	11.1.5.12/ 2880
30BE_00EC	Opcode/Pause Duration Register (ENET_OPD)	32	R/W	0001_0000h	11.1.5.13/ 2881
30BE_00F0	Transmit Interrupt Coalescing Register (ENET_TXIC0)	32	R/W	0000_0000h	11.1.5.14/ 2881
30BE_00F4	Transmit Interrupt Coalescing Register (ENET_TXIC1)	32	R/W	0000_0000h	11.1.5.14/ 2881
30BE_00F8	Transmit Interrupt Coalescing Register (ENET_TXIC2)	32	R/W	0000_0000h	11.1.5.14/ 2881
30BE_0100	Receive Interrupt Coalescing Register (ENET_RXIC0)	32	R/W	0000_0000h	11.1.5.15/ 2882
30BE_0104	Receive Interrupt Coalescing Register (ENET_RXIC1)	32	R/W	0000_0000h	11.1.5.15/ 2882
30BE_0108	Receive Interrupt Coalescing Register (ENET_RXIC2)	32	R/W	0000_0000h	11.1.5.15/ 2882
30BE_0118	Descriptor Individual Upper Address Register (ENET_IAUR)	32	R/W	0000_0000h	11.1.5.16/ 2883
30BE_011C	Descriptor Individual Lower Address Register (ENET_IALR)	32	R/W	0000_0000h	11.1.5.17/ 2884
30BE_0120	Descriptor Group Upper Address Register (ENET_GAUR)	32	R/W	0000_0000h	11.1.5.18/ 2884
30BE_0124	Descriptor Group Lower Address Register (ENET_GALR)	32	R/W	0000_0000h	11.1.5.19/ 2885
30BE_0144	Transmit FIFO Watermark Register (ENET_TFWR)	32	R/W	0000_0000h	11.1.5.20/ 2885
30BE_0160	Receive Descriptor Ring 1 Start Register (ENET_RDSR1)	32	R/W	0000_0000h	11.1.5.21/ 2886
30BE_0164	Transmit Buffer Descriptor Ring 1 Start Register (ENET_TDSR1)	32	R/W	0000_0000h	11.1.5.22/ 2887
30BE_0168	Maximum Receive Buffer Size Register - Ring 1 (ENET_MRBR1)	32	R/W	0000_0000h	11.1.5.23/ 2888
30BE_016C	Receive Descriptor Ring 2 Start Register (ENET_RDSR2)	32	R/W	0000_0000h	11.1.5.24/ 2889
30BE_0170	Transmit Buffer Descriptor Ring 2 Start Register (ENET_TDSR2)	32	R/W	0000_0000h	11.1.5.25/ 2889
30BE_0174	Maximum Receive Buffer Size Register - Ring 2 (ENET_MRBR2)	32	R/W	0000_0000h	11.1.5.26/ 2890
30BE_0180	Receive Descriptor Ring 0 Start Register (ENET_RDSR)	32	R/W	0000_0000h	11.1.5.27/ 2891
30BE_0184	Transmit Buffer Descriptor Ring 0 Start Register (ENET_TDSR)	32	R/W	0000_0000h	11.1.5.28/ 2892
30BE_0188	Maximum Receive Buffer Size Register - Ring 0 (ENET_MRBR)	32	R/W	0000_0000h	11.1.5.29/ 2892

11.1.5.1 Interrupt Event Register (ENET_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 30BE_0000h base + 4h offset = 30BE_0004h

ENET_EIR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
4 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
7 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
8 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
9 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
10 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
12 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13 PLR	Payload Receive Error

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
	Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
14 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
15 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
16 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
17 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled.
18 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.
19 RXFLUSH_0	RX DMA Ring 0 flush indication. . This ring's RX frame has been flushed due to either RDAR[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_0] is enabled.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 2).
25 TXB2	Transmit buffer interrupt, class 2 This field indicates that a transmit buffer descriptor has been updated (ring/class 2).
26 RXF2	Receive frame interrupt, class 2 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 2).
27 RXB2	Receive buffer interrupt, class 2 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 2).
28 TXF1	Transmit frame interrupt, class 1 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 1).
29 TXB1	Transmit buffer interrupt, class 1 This field indicates that a transmit buffer descriptor has been updated (ring/class 1).
30 RXF1	Receive frame interrupt, class 1 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 1).

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
31 RXB1	Receive buffer interrupt, class 1 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/ class 1).

11.1.5.2 Interrupt Mask Register (ENET_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 30BE_0000h base + 8h offset = 30BE_0008h

ENET_EIMR field descriptions

Field	Description
0 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
1 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
2 BABT	BABT Interrupt Mask

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
	Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
3 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
4 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
5 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
6 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
7 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
8 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
9 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
10 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
11 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
12 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
13 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
18 RXFLUSH_1	Corresponds to interrupt source EIR[RXFLUSH_1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 RXFLUSH_0	Corresponds to interrupt source EIR[RXFLUSH_0] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_0] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 TXF2	Transmit frame interrupt, class 2 Corresponds to interrupt source EIR[TXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
25 TXB2	Transmit buffer interrupt, class 2 Corresponds to interrupt source EIR[TXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
26 RXF2	Receive frame interrupt, class 2 Corresponds to interrupt source EIR[RXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
27 RXB2	Receive buffer interrupt, class 2 Corresponds to interrupt source EIR[RXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
28 TXF1	Transmit frame interrupt, class 1 Corresponds to interrupt source EIR[TXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
29 TXB1	Transmit buffer interrupt, class 1 Corresponds to interrupt source EIR[TXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
30 RXF1	Receive frame interrupt, class 1 Corresponds to interrupt source EIR[RXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
31 RXB1	Receive buffer interrupt, class 1

Table continues on the next page...

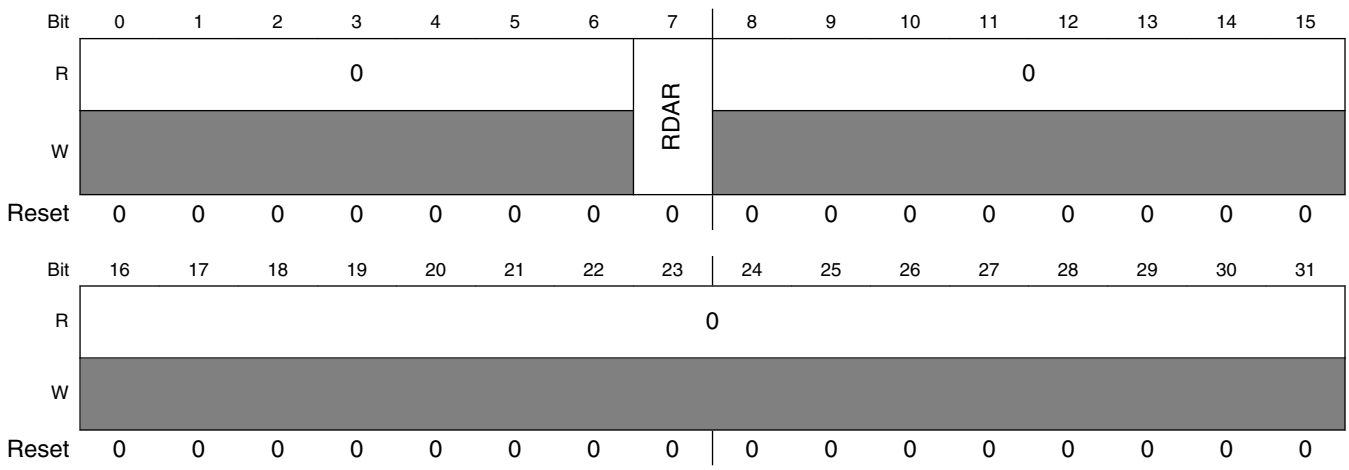
ENET_EIMR field descriptions (continued)

Field	Description
	Corresponds to interrupt source EIR[RXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

11.1.5.3 Receive Descriptor Active Register - Ring 0 (ENET_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 30BE_0000h base + 10h offset = 30BE_0010h



ENET_RDAR field descriptions

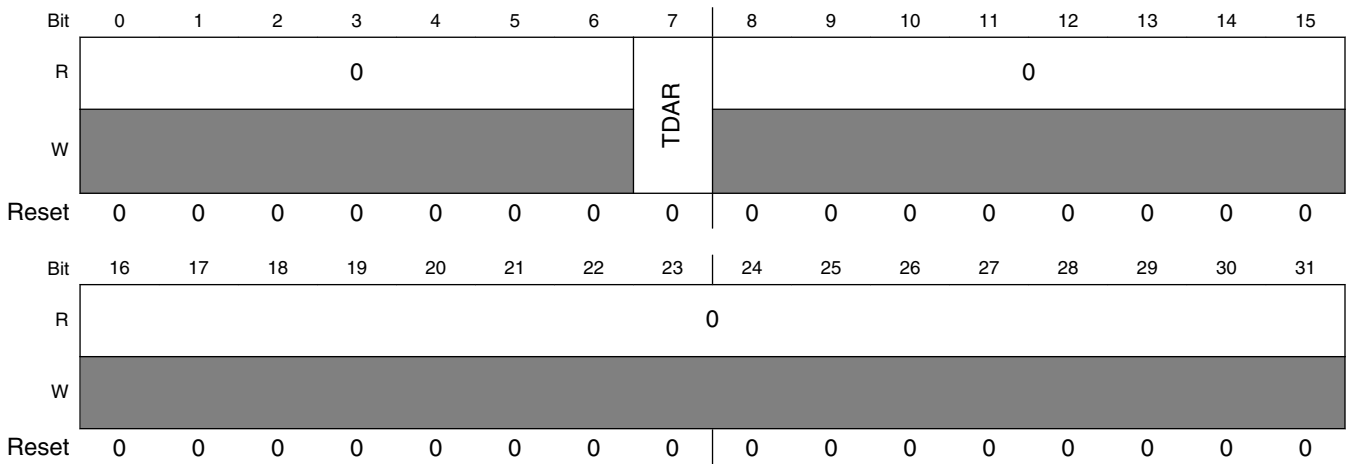
Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.4 Transmit Descriptor Active Register - Ring 0 (ENET_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 30BE_0000h base + 14h offset = 30BE_0014h



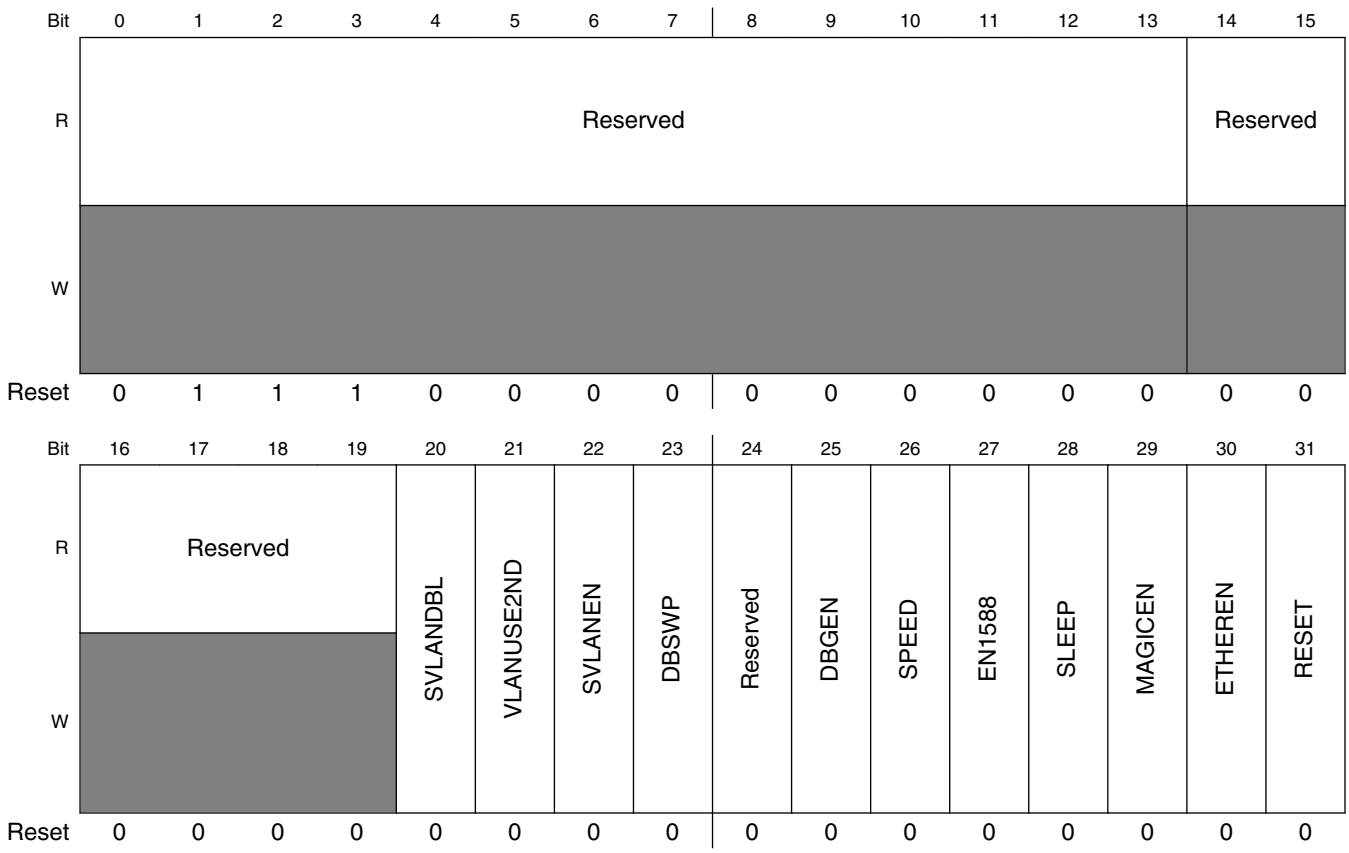
ENET_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.5 Ethernet Control Register (ENET_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 30BE_0000h base + 24h offset = 30BE_0024h



ENET_ECR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This field must be set to 01110000000000b.
14–19 Reserved	This field is reserved. This field must be set to 0.
20 SVLANDBL	S-VLAN double tag If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: • If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame. • If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame. • If the first tag is the C-VLAN type, it is considered a VLAN frame as normal.

Table continues on the next page...

ENET_ECR field descriptions (continued)

Field	Description
	NOTE: VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise.
21 VLANUSE2ND	VLAN use second tag 0 Always extract data from the first VLAN tag if it exists. 1 When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: • The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1) • The second tag must be a C-VLAN
22 SVLANEN	S-VLAN enable Enable additional detection of S-VLAN tag according to IEEE802.1Q. 0 Only the EtherType 0x8100 will be considered for VLAN detection. 1 The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.
23 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. **NOTE:** This field must be written to 1 after reset. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
24 Reserved	This field is reserved. This field must be set to zero.
25 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode. 0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
26 SPEED	Selects between 10/100-Mbit/s and 1000-Mbit/s modes of operation. 0 10/100-Mbit/s mode 1 1000-Mbit/s mode
27 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
28 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
29 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection.

Table continues on the next page...

ENET_ECR field descriptions (continued)

Field	Description
	NOTE: MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.
30 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions: • RESET is set by software • An error condition causes the EBERR field to set. **NOTE:** • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only *after* all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 MAC is enabled, and reception and transmission are possible.
31 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

11.1.5.6 MII Management Frame Register (ENET_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 30BE_0000h base + 40h offset = 30BE_0040h

ENET_MMFR field descriptions

Field	Description
0–1 ST	Start Of Frame Delimiter See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
2–3 OP	Operation Code See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
4–8 PA	PHY Address See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
9–13 RA	Register Address See Table 11-42 (Clause 22) or Table 11-44 (Clause 45) for correct value.
14–15 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

11.1.5.7 MII Speed Control Register (ENET_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

MII clock frequency = 25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 11-4. Programming Examples for MSCR

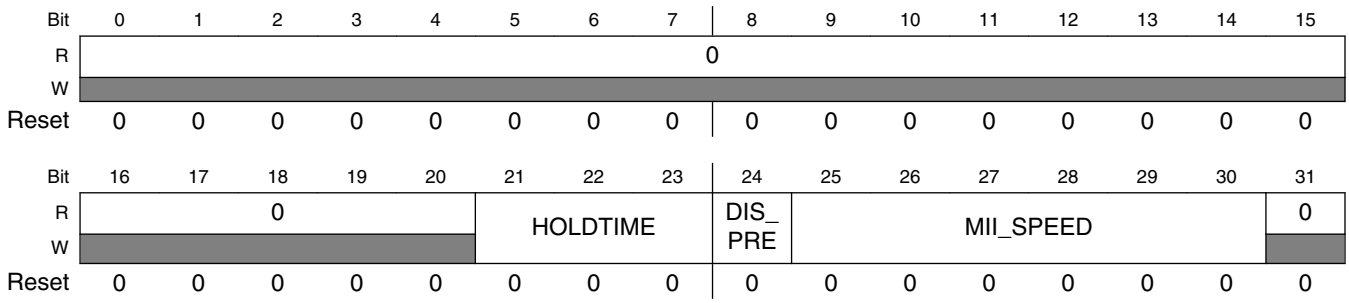
Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz

Table continues on the next page...

Table 11-4. Programming Examples for MSCR (continued)

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Address: 30BE_0000h base + 44h offset = 30BE_0044h



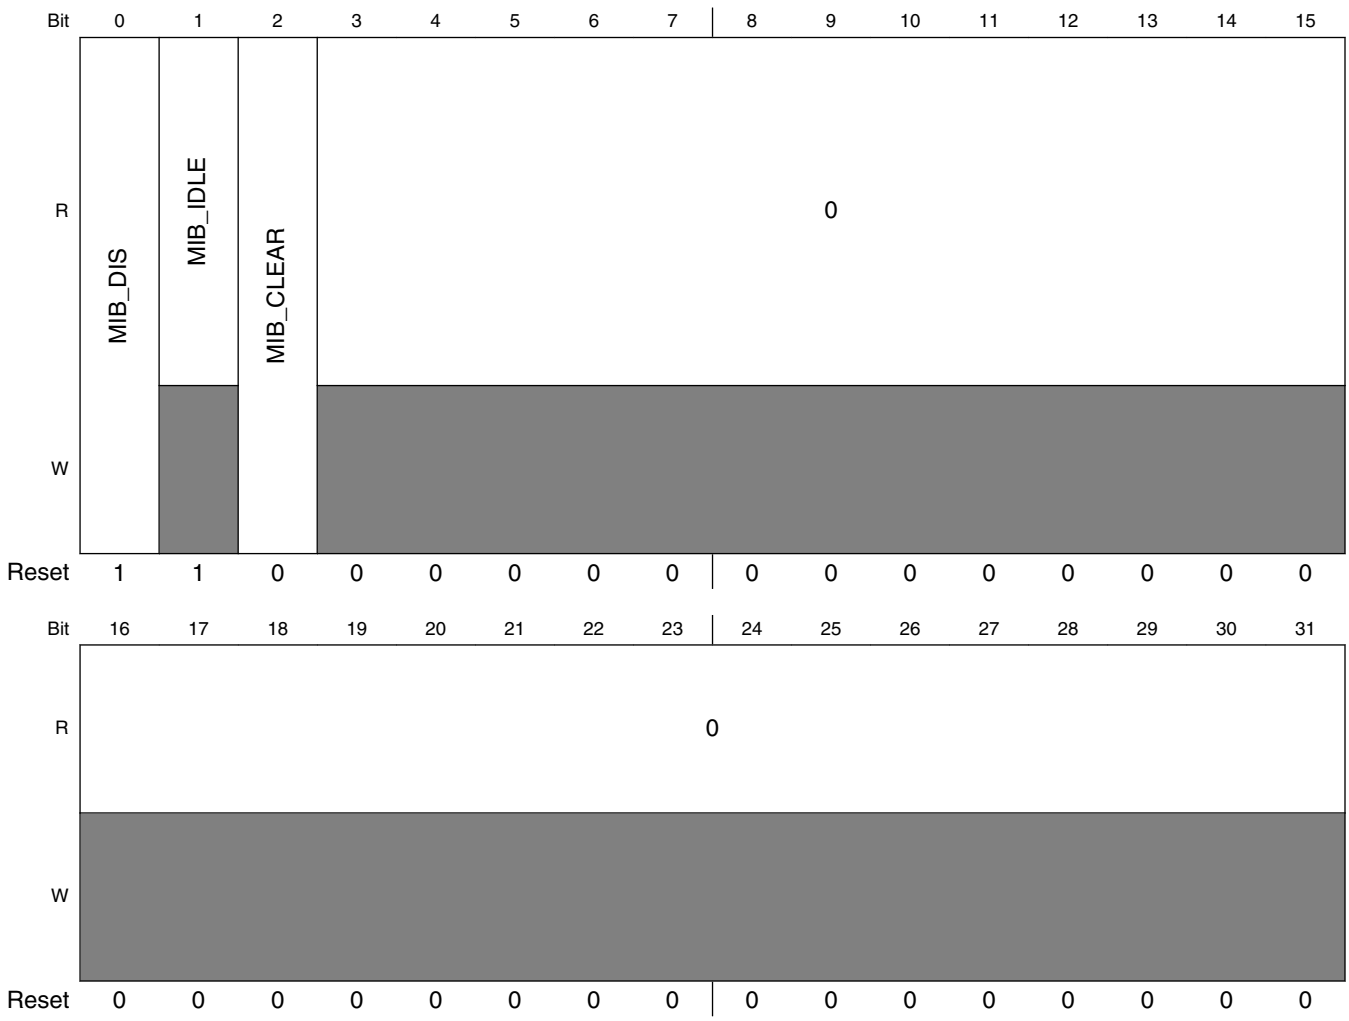
ENET_MSCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
24 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
25–30 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.8 MIB Control Register (ENET_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: 30BE_0000h base + 64h offset = 30BE_0064h



ENET_MIBC field descriptions

Field	Description
0 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.

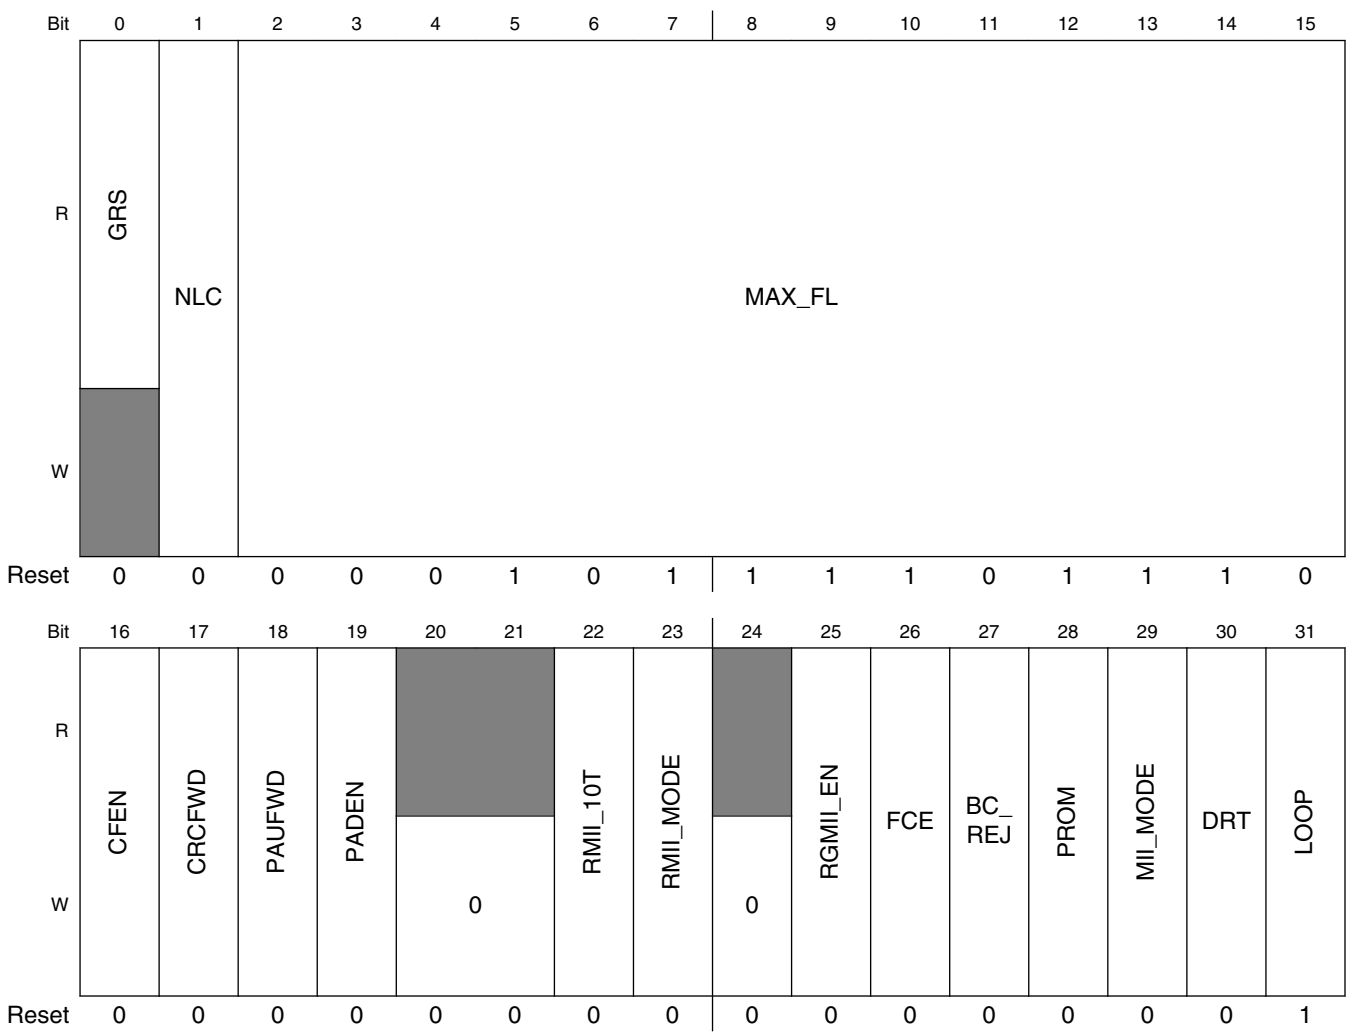
Table continues on the next page...

ENET_MIBC field descriptions (continued)

Field	Description
1 MIB_IDLE	MIB Idle 0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
2 MIB_CLEAR	MIB Clear **NOTE:** This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
3–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.9 Receive Control Register (ENET_RCR)

Address: 30BE_0000h base + 84h offset = 30BE_0084h



ENET_RCR field descriptions

Field	Description
0 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
1 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
2–15 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
17 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
18 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
19 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
20–21 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
22 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

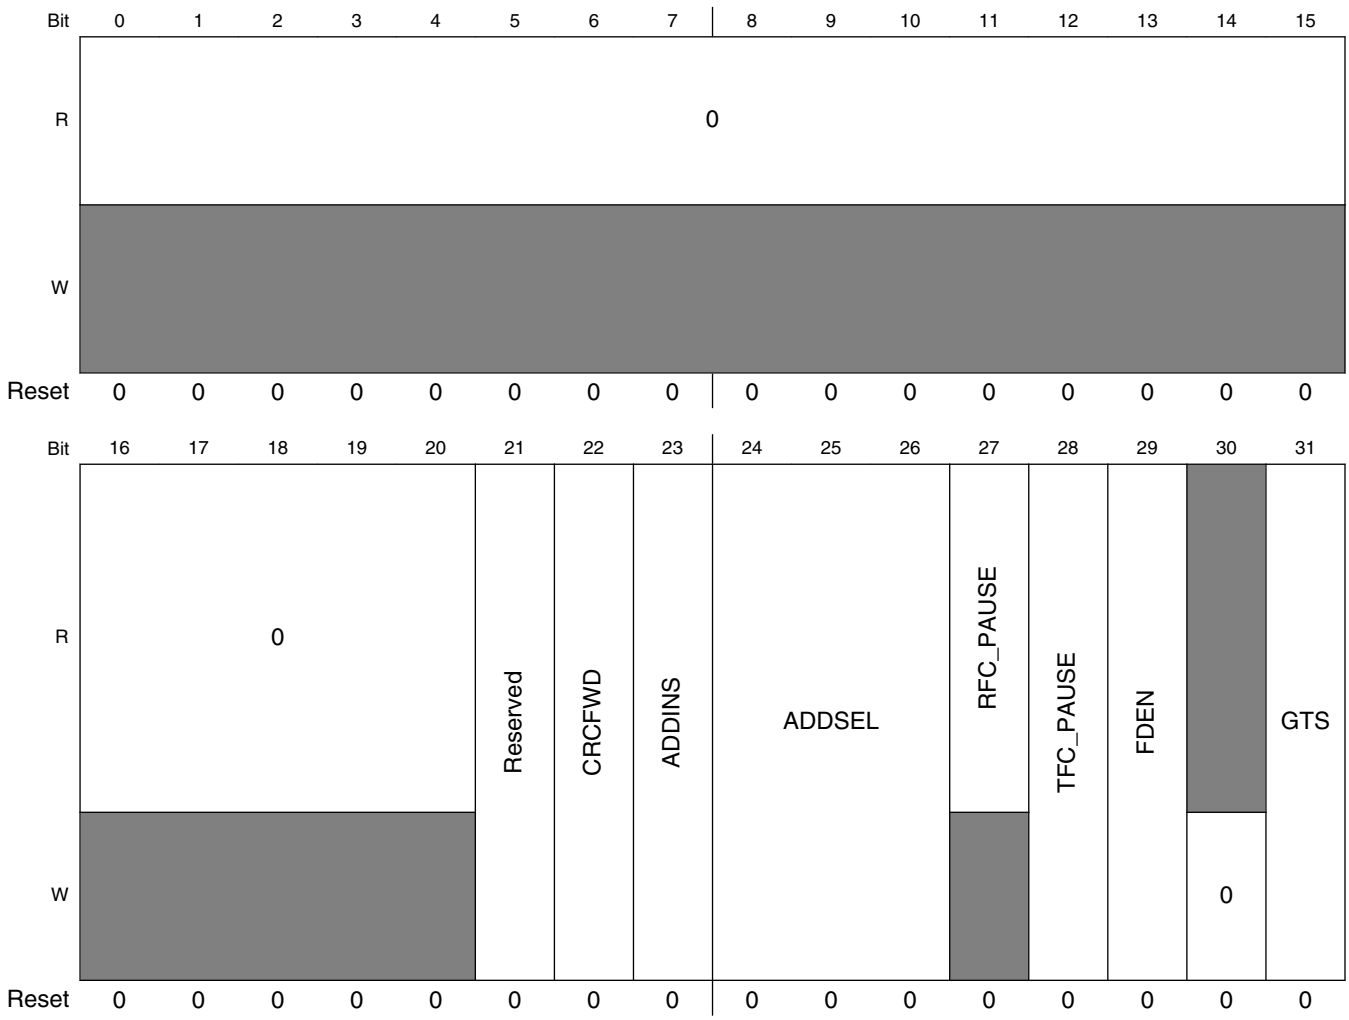
ENET_RCR field descriptions (continued)

Field	Description
23 RMII_MODE	RMII Mode Enable Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared . **NOTE:** Do not set both RCR[RGMII_EN] and RCR[RMII_MODE]. 0 MAC configured for MII mode. 1 MAC configured for RMII operation.
24 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
25 RGMII_EN	RGMII Mode Enable **NOTE:** Do not set both RCR[RGMII_EN] and RCR[RMII_MODE]. 0 MAC configured for non-RGMII operation 1 MAC configured for RGMII operation. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.
26 FCE	Flow Control Enable If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast Frame Reject If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
28 PROM	Promiscuous Mode All frames are accepted regardless of address matching. 0 Disabled. 1 Enabled.
29 MII_MODE	Media Independent Interface Mode This field must always be set. 0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.
30 DRT	Disable Receive On Transmit 0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)
31 LOOP	Internal Loopback This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. 0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

11.1.5.10 Transmit Control Register (ENET_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 30BE_0000h base + C4h offset = 30BE_00C4h



ENET_TCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This field is read/write and must be set to 0.
22 CRCFWD	Forward Frame From Application With CRC

Table continues on the next page...

ENET_TCR field descriptions (continued)

Field	Description
	0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
23 ADDINS	Set MAC Address On Transmit 0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
24–26 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
27 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
29 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

11.1.5.11 Physical Address Lower Register (ENET_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 30BE_0000h base + E4h offset = 30BE_00E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_PALR field descriptions

Field	Description
0–31 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

11.1.5.12 Physical Address Upper Register (ENET_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 30BE_0000h base + E8h offset = 30BE_00E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

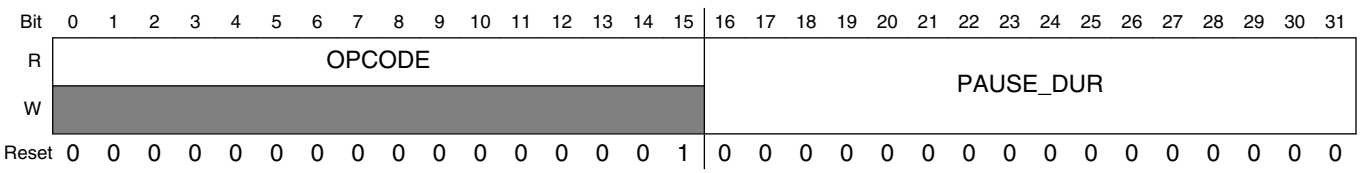
ENET_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

11.1.5.13 Opcode/Pause Duration Register (ENET_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 30BE_0000h base + ECh offset = 30BE_00ECh



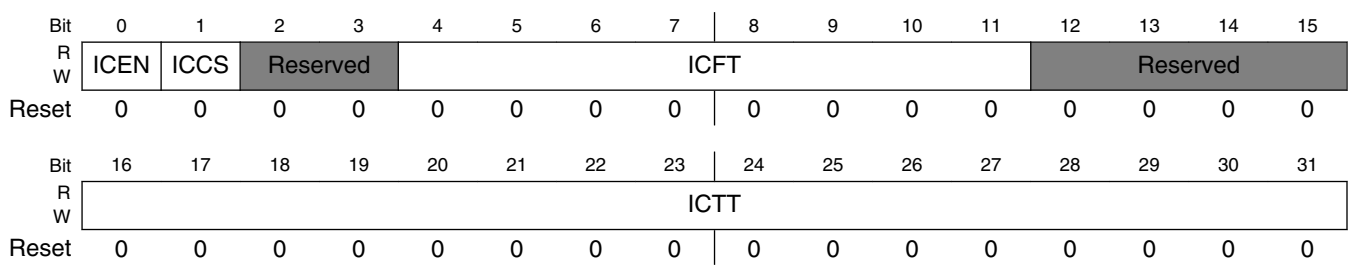
ENET_OPD field descriptions

Field	Description
0–15 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
16–31 PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

11.1.5.14 Transmit Interrupt Coalescing Register (ENET_TXIC*n*)

See Interrupt coalescence for more information.

Address: 30BE_0000h base + F0h offset + (4d × i), where i=0d to 2d



ENET_TXIC*n* field descriptions

Field	Description
0 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

ENET_TXIC*n* field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.1.5.15 Receive Interrupt Coalescing Register (ENET_RXIC*n*)

See Interrupt coalescence for more information.

Address: 30BE_0000h base + 100h offset + (4d × i), where i=0d to 2d

Table continues on the next page...

ENET_RXIC*n* field descriptions (continued)

Field	Description
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.1.5.16 Descriptor Individual Upper Address Register (ENET_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 30BE_0000h base + 118h offset = 30BE_0118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IADDR1

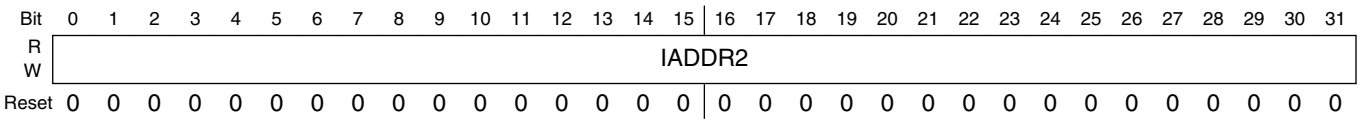
ENET_IAUR field descriptions

Field	Description
0–31 IADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR1 contains hash index bit 63. Bit 0 of IADDR1 contains hash index bit 32.

11.1.5.17 Descriptor Individual Lower Address Register (ENET_IALR)

IALR contains the lower 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the DA field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 30BE_0000h base + 11Ch offset = 30BE_011Ch



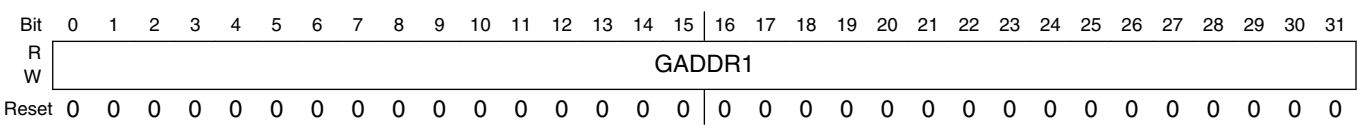
ENET_IALR field descriptions

Field	Description
0–31 IADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a unicast address. Bit 31 of IADDR2 contains hash index bit 31. Bit 0 of IADDR2 contains hash index bit 0.

11.1.5.18 Descriptor Group Upper Address Register (ENET_GAUR)

GAUR contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 30BE_0000h base + 120h offset = 30BE_0120h



ENET_GAUR field descriptions

Field	Description
0–31 GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

11.1.5.19 Descriptor Group Lower Address Register (ENET_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 30BE_0000h base + 124h offset = 30BE_0124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_GALR field descriptions

Field	Description
0–31 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

11.1.5.20 Transmit FIFO Watermark Register (ENET_TFWR)

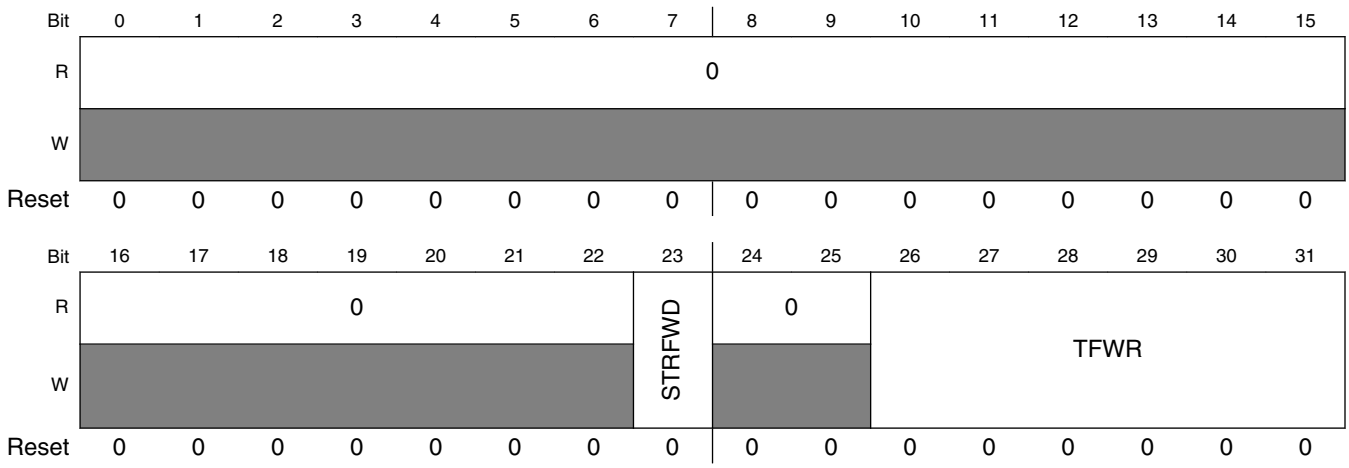
If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: 30BE_0000h base + 144h offset = 30BE_0144h



ENET_TFWR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... ... 111111 4032 bytes written.

11.1.5.21 Receive Descriptor Ring 1 Start Register (ENET_RDSR1)

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

Address: 30BE_0000h base + 160h offset = 30BE_0160h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENET_MRBR1)

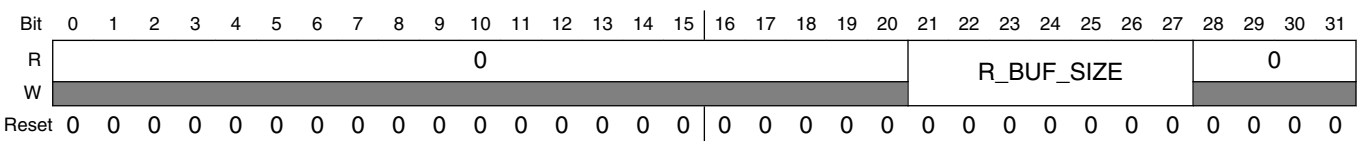
MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_ZIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 30BE_0000h base + 168h offset = 30BE_0168h



ENET_MRBR1 field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–27 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
28–31 Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size. This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.24 Receive Descriptor Ring 2 Start Register (ENET_RDSR2)

RDSR points to the beginning of circular receive buffer descriptor queue 2 in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation

Address: 30BE_0000h base + 16Ch offset = 30BE_016Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ENET_TDSR field descriptions

Field	Description
0–28 X_DES_START	Pointer to the beginning of the transmit buffer descriptor queue.
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.29 Maximum Receive Buffer Size Register - Ring 0 (ENET_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all ring-0 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

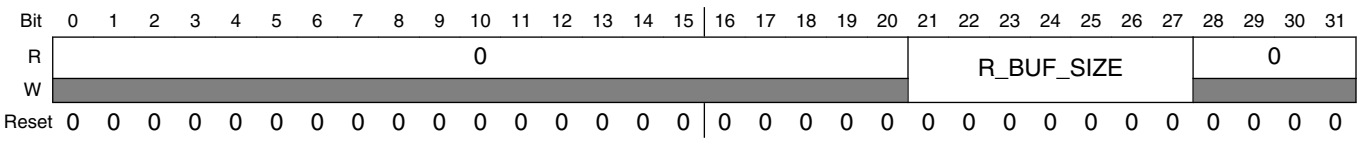
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX_FL] or larger.

- To properly align the buffer, MRBR must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits of this register are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 30BE_0000h base + 188h offset = 30BE_0188h

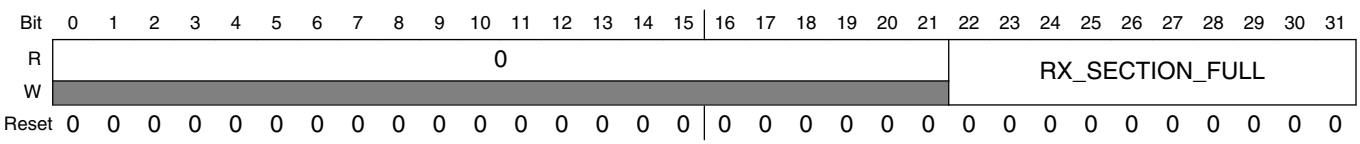


ENET_MRBR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–27 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
28–31 Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size. This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.30 Receive FIFO Section Full Threshold (ENET_RSFL)

Address: 30BE_0000h base + 190h offset = 30BE_0190h

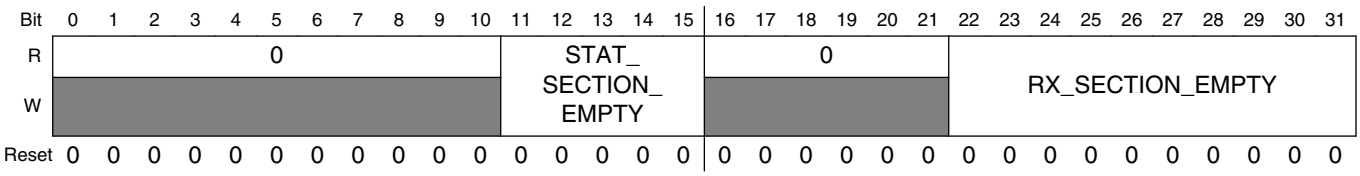


ENET_RSFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_SECTION_ FULL	Value Of Receive FIFO Section Full Threshold Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY]. When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation).

11.1.5.31 Receive FIFO Section Empty Threshold (ENET_RSEM)

Address: 30BE_0000h base + 194h offset = 30BE_0194h

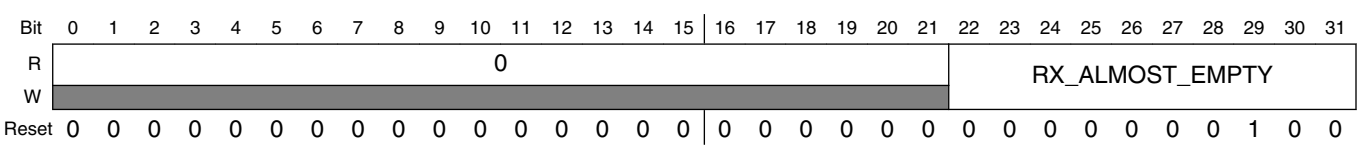


ENET_RSEM field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 STAT_ SECTION_ EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_SECTION_ EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued. A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. **NOTE:** The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

11.1.5.32 Receive FIFO Almost Empty Threshold (ENET_RAEM)

Address: 30BE_0000h base + 198h offset = 30BE_0198h



ENET_RAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

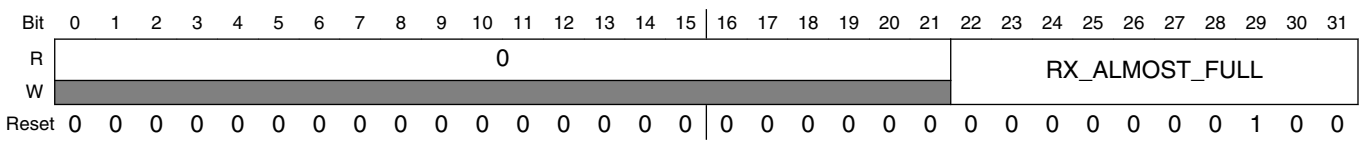
Table continues on the next page...

ENET_RAEM field descriptions (continued)

Field	Description
22–31 RX_ALMOST_ EMPTY	Value Of The Receive FIFO Almost Empty Threshold Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

11.1.5.33 Receive FIFO Almost Full Threshold (ENET_RAFL)

Address: 30BE_0000h base + 19Ch offset = 30BE_019Ch

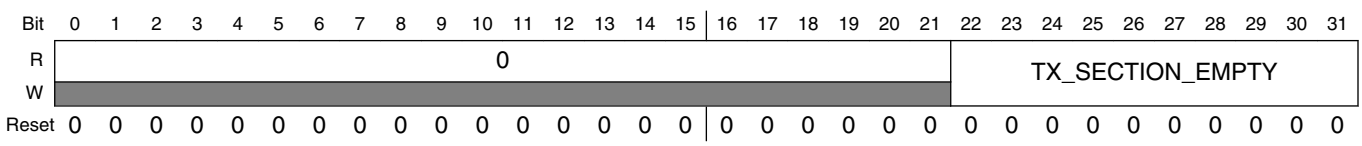


ENET_RAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 RX_ALMOST_ FULL	Value Of The Receive FIFO Almost Full Threshold Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

11.1.5.34 Transmit FIFO Section Empty Threshold (ENET_TSEM)

Address: 30BE_0000h base + 1A0h offset = 30BE_01A0h



ENET_TSEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

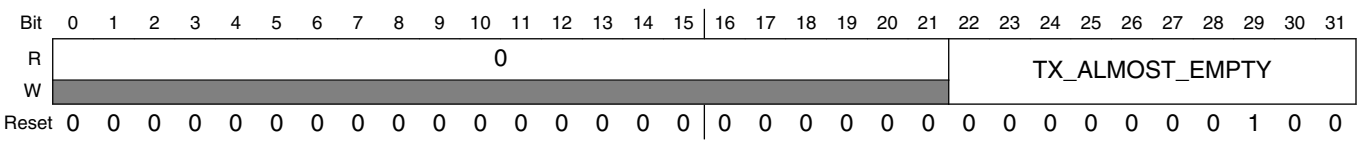
Table continues on the next page...

ENET_TSEM field descriptions (continued)

Field	Description
22–31 TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold Value, in 64-bit words, of the transmit FIFO section empty threshold. See Transmit FIFO for more information.

11.1.5.35 Transmit FIFO Almost Empty Threshold (ENET_TAEM)

Address: 30BE_0000h base + 1A4h offset = 30BE_01A4h

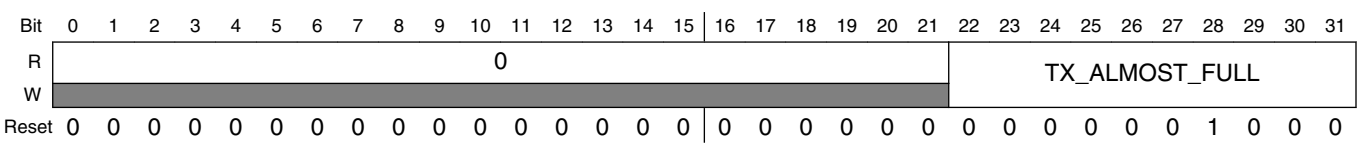


ENET_TAEM field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See Transmit FIFO for more information. A minimum value of 4 should be set.

11.1.5.36 Transmit FIFO Almost Full Threshold (ENET_TAFL)

Address: 30BE_0000h base + 1A8h offset = 30BE_01A8h



ENET_TAFL field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold

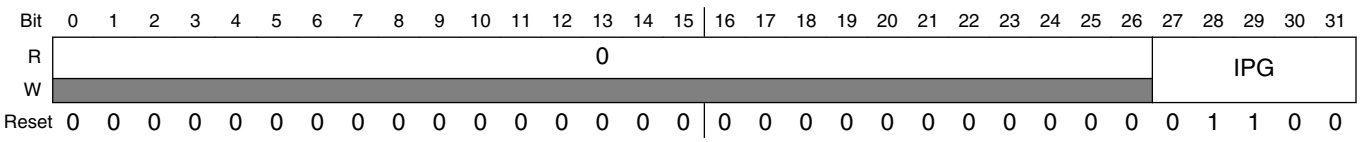
Table continues on the next page...

ENET_TAFL field descriptions (continued)

Field	Description
	Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. **NOTE:** A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

11.1.5.37 Transmit Inter-Packet Gap (ENET_TIPG)

Address: 30BE_0000h base + 1ACh offset = 30BE_01ACh

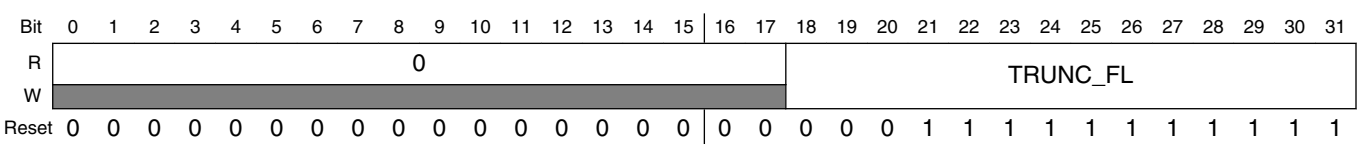


ENET_TIPG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. **NOTE:** The IPG value read will be the value that was written, even if it is out of range.

11.1.5.38 Frame Truncation Length (ENET_FTRL)

Address: 30BE_0000h base + 1B0h offset = 30BE_01B0h



ENET_FTRL field descriptions

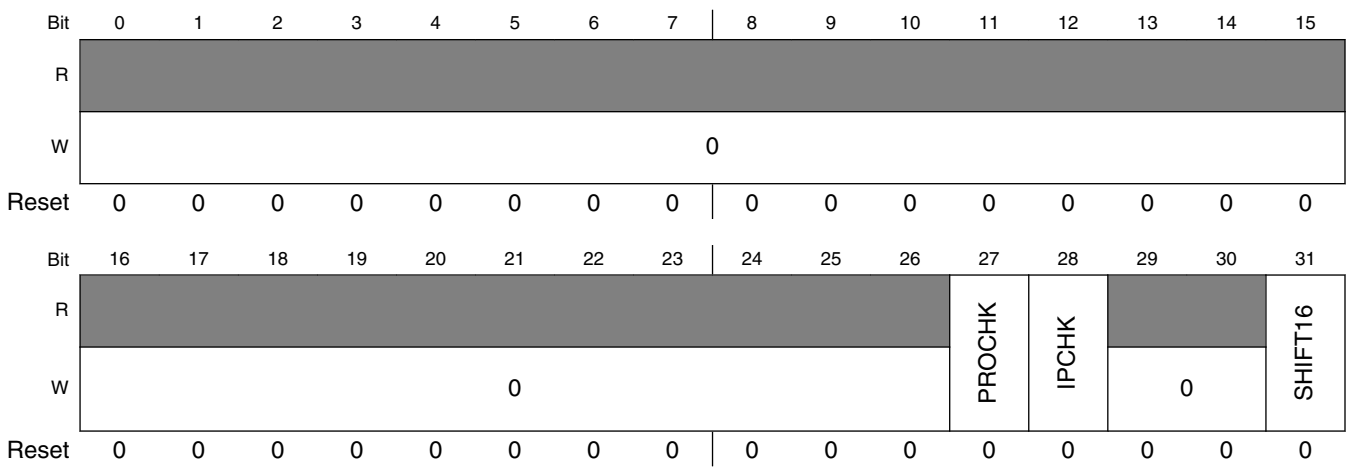
Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. **NOTE:** Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

11.1.5.39 Transmit Accelerator Function Configuration (ENET_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 30BE_0000h base + 1C0h offset = 30BE_01C0h



ENET_TACC field descriptions

Field	Description
0–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
28 IPCHK	Enables insertion of IP header checksum.

Table continues on the next page...

ENET_TACC field descriptions (continued)

Field	Description
	0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
29–30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

11.1.5.40 Receive Accelerator Function Configuration (ENET_RACC)

Address: 30BE_0000h base + 1C4h offset = 30BE_01C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R																
W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R									SHIFT16	LINEDIS				PRODIS	IPDIS	PADREM
W	0										0					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RACC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.

Table continues on the next page...

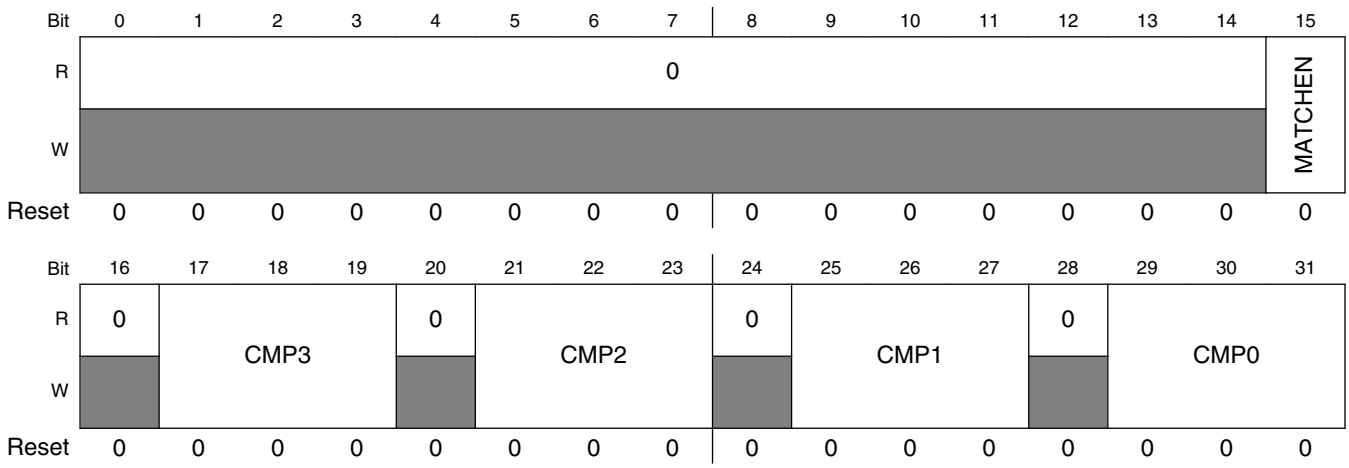
ENET_RACC field descriptions (continued)

Field	Description
25 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
26–28 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
29 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
30 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
31 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

11.1.5.41 Receive Classification Match Register for Class n (ENET_RCMR*n*)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

Address: 30BE_0000h base + 1C8h offset + (4d × i), where i=0d to 1d



ENET_RCMR*n* field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MATCHEN	Match Enable **NOTE:** A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur. If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored. 0 Disabled (default): no compares will occur and the classification indicator for this class will never assert. 1 The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENET_RCMR*n* field descriptions (continued)

Field	Description
21–23 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–27 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). **NOTE:** To implement a single priority match, all four compare values must be set to the same value.

11.1.5.42 DMA Class Based Configuration (ENET_DMA*n*CFG)

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

Address: 30BE_0000h base + 1D8h offset + (4d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								Reserved						CALC_NOIPG	DMA_CLASS_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	IDLE_SLOPE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

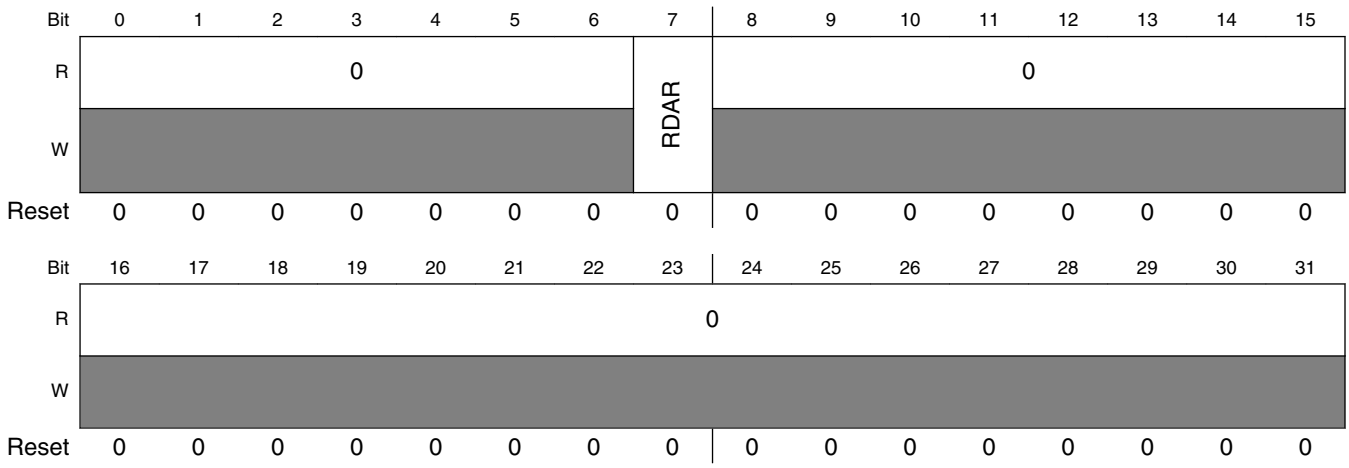
ENET_DMA*n*CFG field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–13 Reserved	This field is reserved. **NOTE:** Write only zeroes to this field.
14 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0 The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
15 DMA_CLASS_EN	DMA class enable 0 The DMA controller's channel for the class is not used. **NOTE:** Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
16–31 IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2^n, where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12. Example 1. BW fraction = 0.20 = 1/(1+(512/128)); therefore idleslope = 128. Example 2. BW fraction = 0.33 = 1/(1+(512/256)); therefore idleslope = 256. Example 3. BW fraction = 0.75 = 1/(1+(512/1536)); therefore idleslope = 1536. **NOTE:** For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

11.1.5.43 Receive Descriptor Active Register - Ring 1 (ENET_RDAR1)

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 30BE_0000h base + 1E0h offset = 30BE_01E0h



ENET_RDAR1 field descriptions

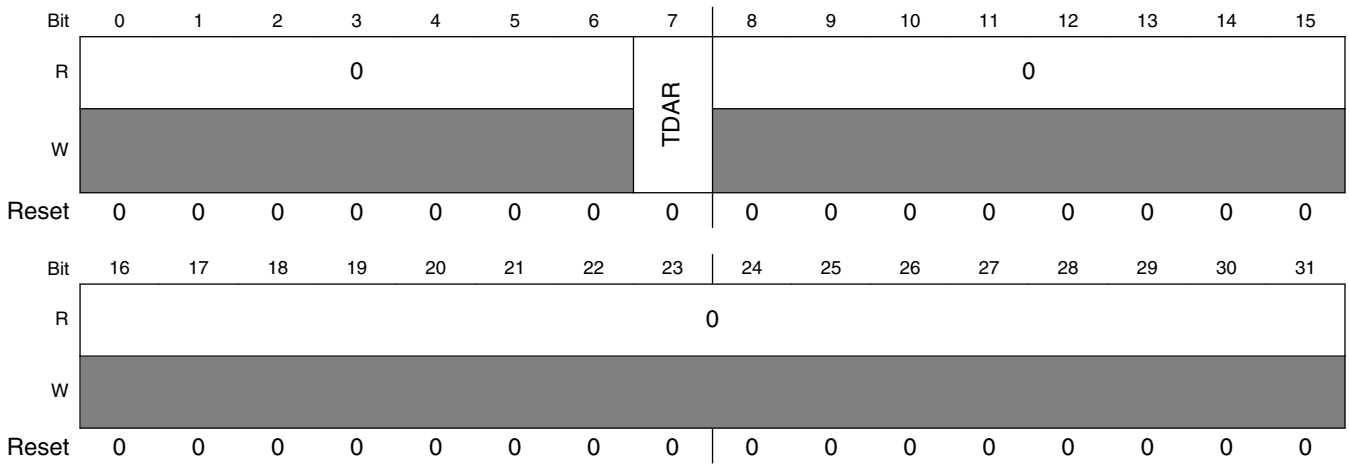
Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.44 Transmit Descriptor Active Register - Ring 1 (ENET_TDAR1)

TDAR1 is a command register that the user writes to indicate that transmit descriptor ring 1 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 30BE_0000h base + 1E4h offset = 30BE_01E4h



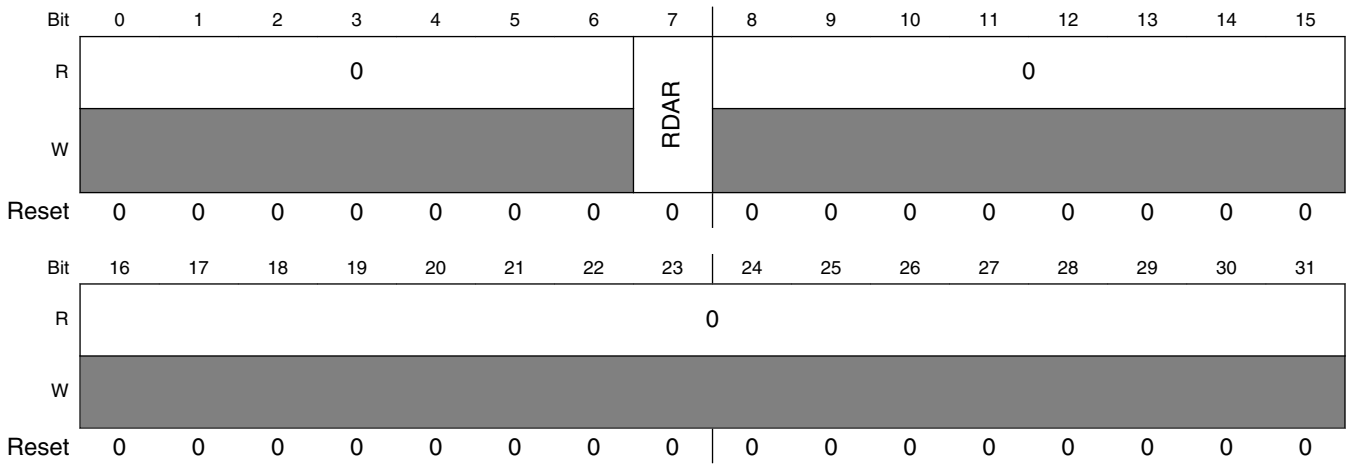
ENET_TDAR1 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.45 Receive Descriptor Active Register - Ring 2 (ENET_RDAR2)

RDAR2 is a command register, written by the user, to indicate that the receive descriptor ring 2 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 30BE_0000h base + 1E8h offset = 30BE_01E8h



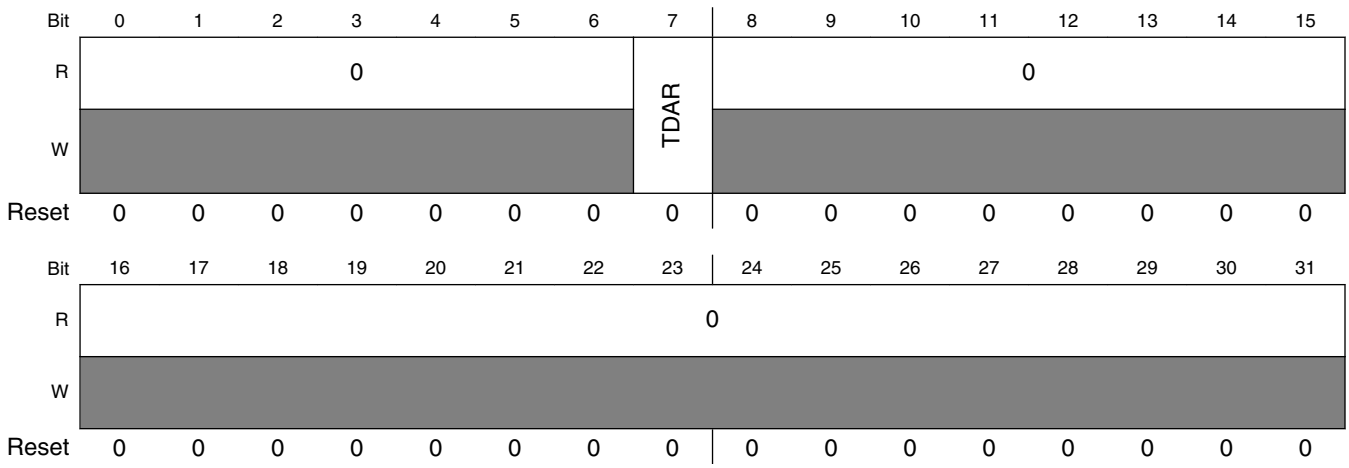
ENET_RDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.1.5.46 Transmit Descriptor Active Register - Ring 2 (ENET_TDAR2)

TDAR2 is a command register that the user writes to indicate that transmit descriptor ring 2 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

Address: 30BE_0000h base + 1ECh offset = 30BE_01ECh



ENET_TDAR2 field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

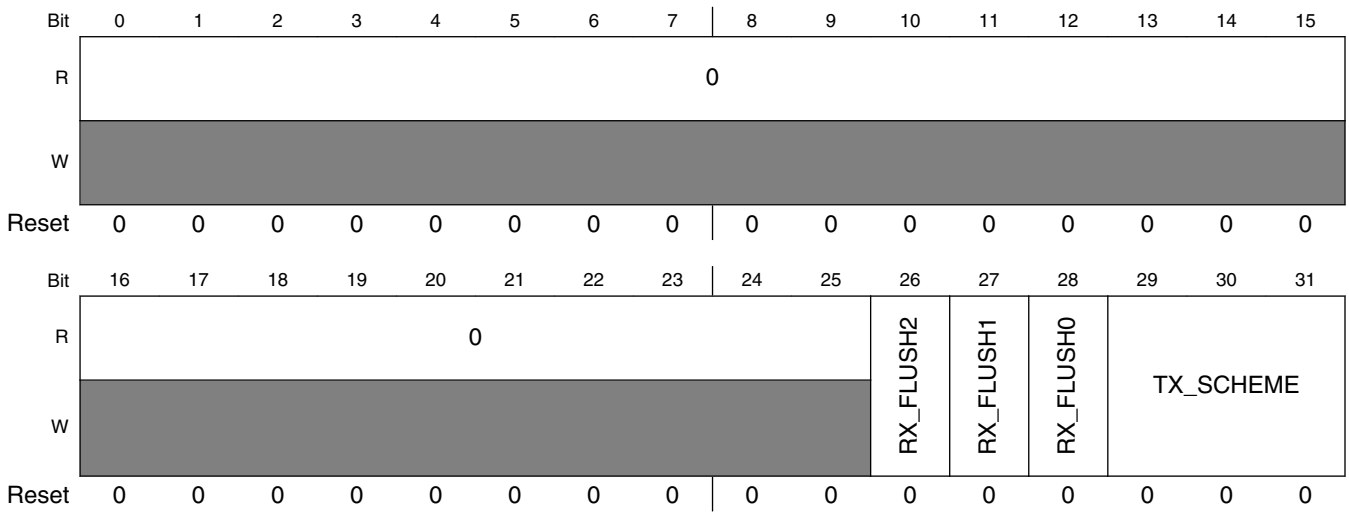
11.1.5.47 QOS Scheme (ENET_QOS)

This register sets the QOS scheme.

NOTE

When both class 1 and class 2 are disabled, RX flushing for these rings must also be disabled.

Address: 30BE_0000h base + 1F0h offset = 30BE_01F0h

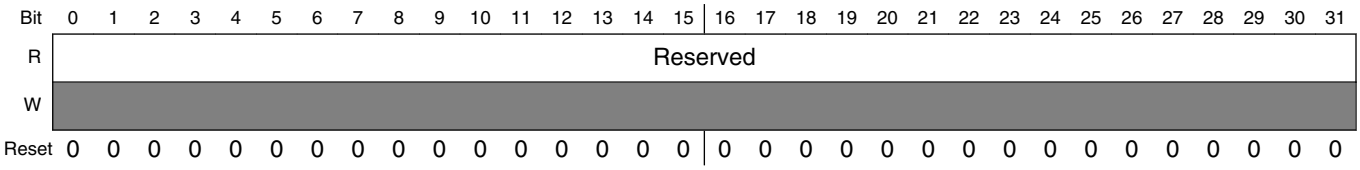


ENET_QOS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 RX_FLUSH2	RX Flush Ring 2 Enable or disable RX Flush for ring 2. See Receive flushing. 0 Disable 1 Enable
27 RX_FLUSH1	RX Flush Ring 1 Enable or disable RX Flush for ring 1. See Receive flushing. 0 Disable 1 Enable
28 RX_FLUSH0	RX Flush Ring 0 Enable or disable RX Flush for ring 0. See Receive flushing. 0 Disable 1 Enable
29–31 TX_SCHEME	TX scheme configuration Configuration information for DMA to select transmitter queue selection/arbitration scheme. 000 Credit-based scheme 001 Round-robin scheme 010-111 Reserved

11.1.5.48 Reserved Statistic Register (ENET_RMON_T_DROP)

Address: 30BE_0000h base + 200h offset = 30BE_0200h

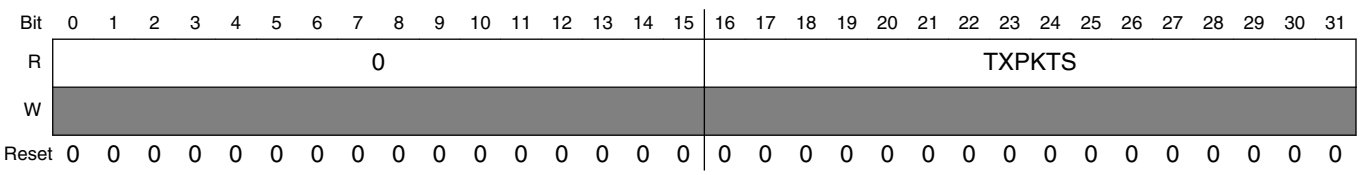


ENET_RMON_T_DROP field descriptions

Field	Description
0–31 Reserved	This read-only field always has the value 0. This field is reserved.

11.1.5.49 Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS)

Address: 30BE_0000h base + 204h offset = 30BE_0204h



ENET_RMON_T_PACKETS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Packet count Transmit packet count

11.1.5.50 Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT)

RMON Tx Broadcast Packets

Address: 30BE_0000h base + 208h offset = 30BE_0208h

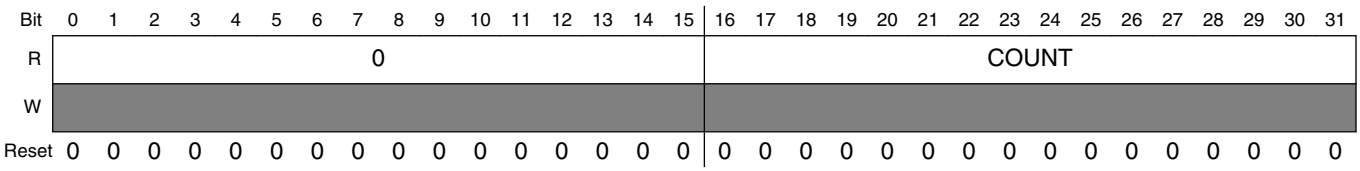
ENET_IEEE_R_CRC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames received with CRC error

11.1.5.98 Frames Received with Alignment Error Statistic Register (ENET_IEEE_R_ALIGN)

Address: 30BE_0000h base + 2D4h offset = 30BE_02D4h

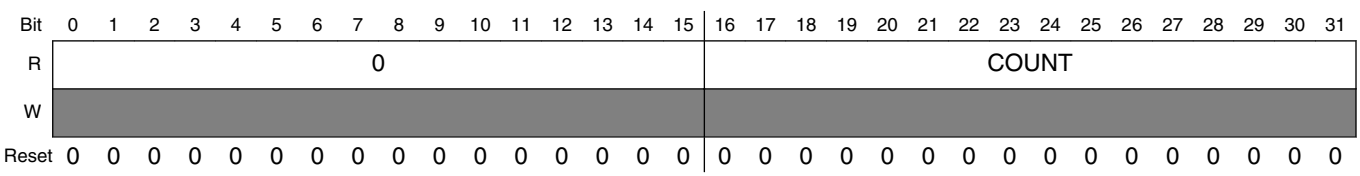


ENET_IEEE_R_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames received with alignment error

11.1.5.99 Receive FIFO Overflow Count Statistic Register (ENET_IEEE_R_MACERR)

Address: 30BE_0000h base + 2D8h offset = 30BE_02D8h

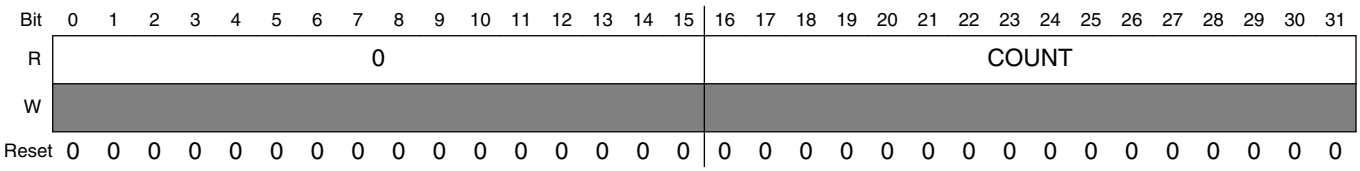


ENET_IEEE_R_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Receive FIFO overflow count

11.1.5.100 Flow Control Pause Frames Received Statistic Register (ENET_IEEE_R_FDXFC)

Address: 30BE_0000h base + 2DCh offset = 30BE_02DCh

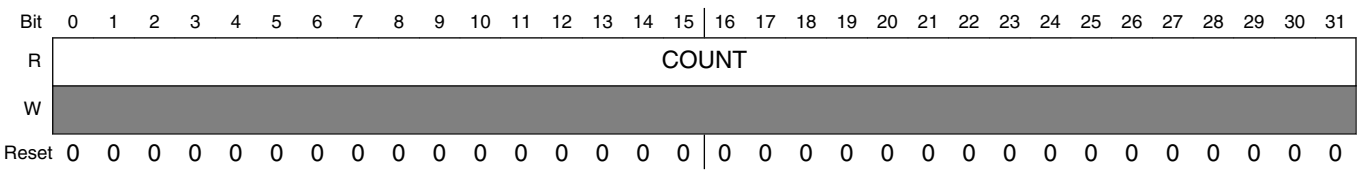


ENET_IEEE_R_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames received

11.1.5.101 Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)

Address: 30BE_0000h base + 2E0h offset = 30BE_02E0h



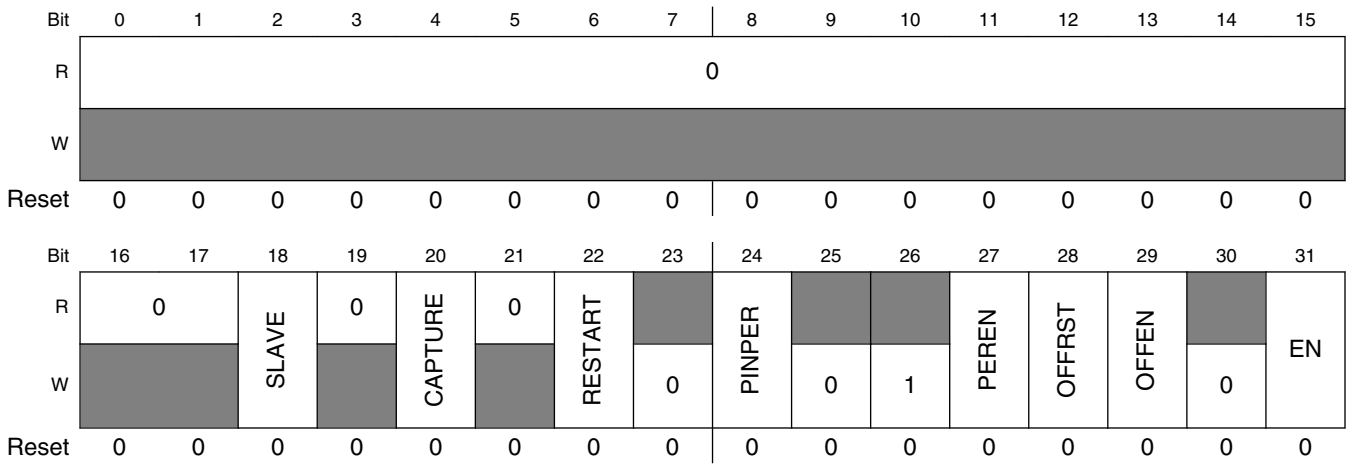
ENET_IEEE_R_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Number of octets for frames received without error **NOTE:** Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

11.1.5.102 Adjustable Timer Control Register (ENET_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

Address: 30BE_0000h base + 400h offset = 30BE_0400h



ENET_ATCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. **NOTE:** To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles. 0 No effect. 1 The current time is captured and can be read from the ATVR register.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENET_ATCR field descriptions (continued)

Field	Description
22 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. **NOTE:** The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.
23 Reserved	This field is reserved.
24 PINPER	Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details. 0 Disable. 1 Enable.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved. **NOTE:** This field must be written always with one.
27 PEREN	Enable Periodical Event 0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. **NOTE:** Not all devices contain the event signal output. See the chip configuration details.
28 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
29 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
30 Reserved	This field is reserved.
31 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

11.1.5.103 Timer Value Register (ENET_ATVR)

Address: 30BE_0000h base + 404h offset = 30BE_0404h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ATIME

ENET_ATOFF field descriptions

Field	Description
0–31 OFFSET	Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds.

11.1.5.105 Timer Period Register (ENET_ATPER)

Address: 30BE_0000h base + 40Ch offset = 30BE_040Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PERIOD																															
Reset	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

ENET_ATPER field descriptions

Field	Description
0–31 PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.

ENET_ATPER field descriptions (continued)

Field	Description
	NOTE: The value of PERIOD has the following constraint: 2^{32} – ENET_ATINC[INC_COR] – 3×ENET_ATINC[INC] ≥ PERIOD > 0.

11.1.5.106 Timer Correction Register (ENET_ATCOR)

Address: 30BE_0000h base + 410h offset = 30BE_0410h

ENET_ATCOR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–31 COR	Correction Counter Wrap-Around Value Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur. **NOTE:** This value is given in clock cycles, not in nanoseconds as all other values.

11.1.5.107 Time-Stamping Clock Period Register (ENET_ATINC)

Address: 30BE_0000h base + 414h offset = 30BE_0414h

ENET_ATINC field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 INC_CORR	Correction Increment Value This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 INC	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz. **NOTE:** For highest precision, use a value that is an integer fraction of the period set in ATPER.

11.1.5.108 Timestamp of Last Transmitted Frame (ENET_ATSTMP)

Address: 30BE_0000h base + 418h offset = 30BE_0418h

ENET_TCCR*n* field descriptions

Field	Description
0–31 TCC	Timer Capture Compare

ENET_TCCR*n* field descriptions (continued)

Field	Description
	This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag. The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

11.1.6 Functional description

This section provides a complete functional description of the MAC-NET core.

11.1.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field

- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

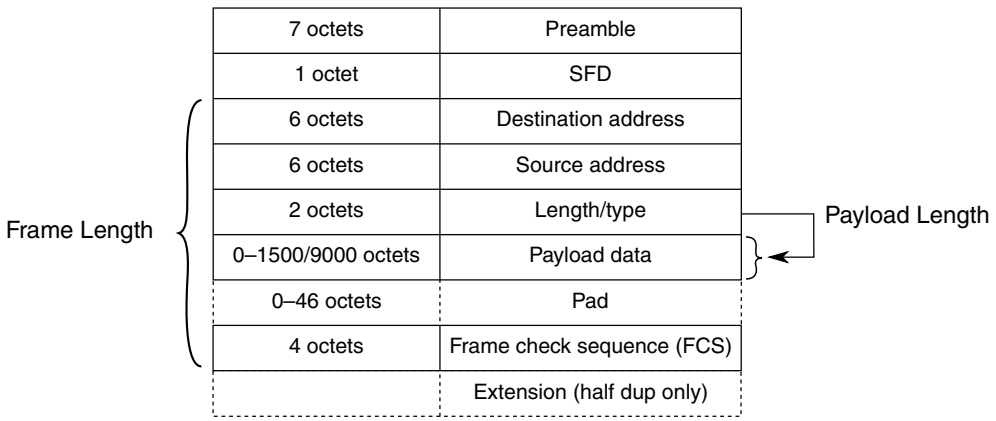

Figure 11-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

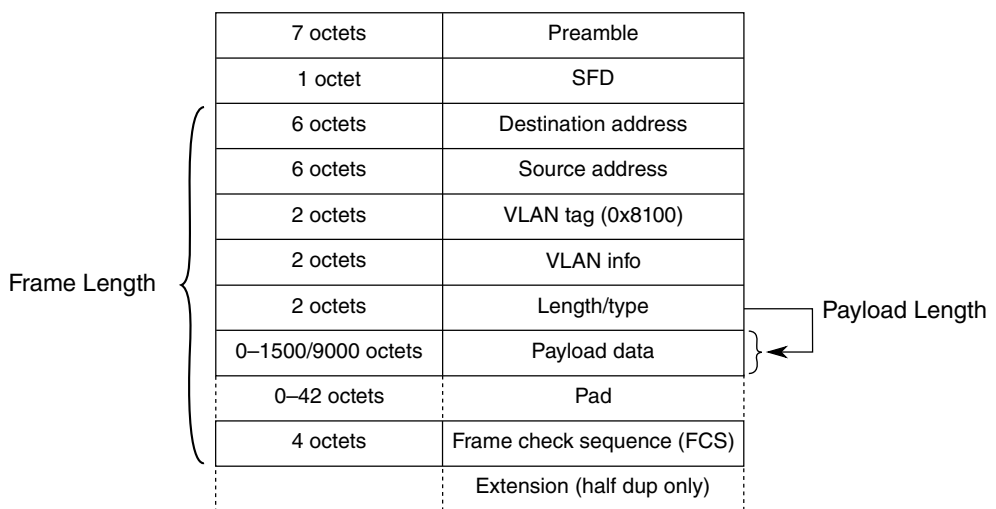

Figure 11-3. VLAN-tagged MAC frame format overview

Table 11-5. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.

Table continues on the next page...

Table 11-5. MAC frame definition (continued)

Term	Description
	• If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

11.1.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 11-6. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

11.1.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

11.1.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

11.1.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 11-7. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

11.1.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 11-8. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Version	IHL	TOS		Length			
Fragment ID				Flags	Fragment offset		
TTL		Protocol		Header checksum			
Source address							
Destination address							
Options							

Table 11-9. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

11.1.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly.The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

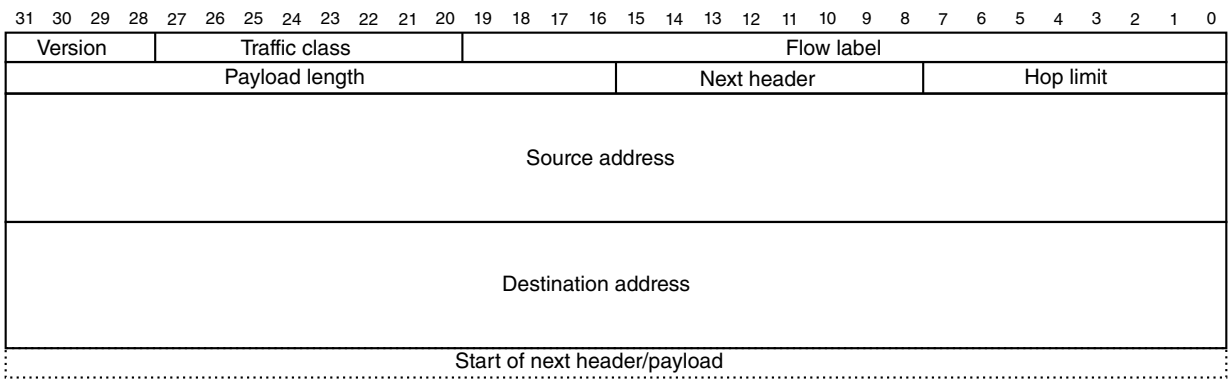

Figure 11-4. IPv6 header format

Table 11-10. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

11.1.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 11-11. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 11-12. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

11.1.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 11-13. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 11-14. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

11.1.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 11-15. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Sequence number							
Acknowledgement number							
Offset	Reserved		Flags	Window			
Checksum				Urgent pointer			
Options							

Table 11-16. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

11.1.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

11.1.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

11.1.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 11-17 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 11-17. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 11-18. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

11.1.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 11-19. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

11.1.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

11.1.6.3.2.1 PTPv1 header

Table 11-20. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 11-21 :

Table 11-21. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

11.1.6.3.2.2 PTPv2 header

Table 11-22. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 11-23. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 11-24. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

11.1.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

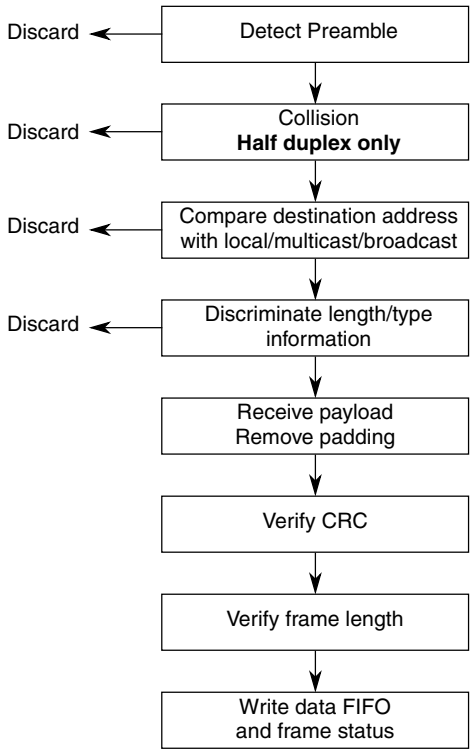

Figure 11-5. MAC receive flow

11.1.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

11.1.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

11.1.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

11.1.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

11.1.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

11.1.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 11-25. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

11.1.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])

- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

11.1.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

11.1.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

11.1.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

11.1.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

11.1.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

11.1.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

11.1.6.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a

classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see Receive Classification Match Register for Class n (ENET_RCMR*n*)) and the following figure.

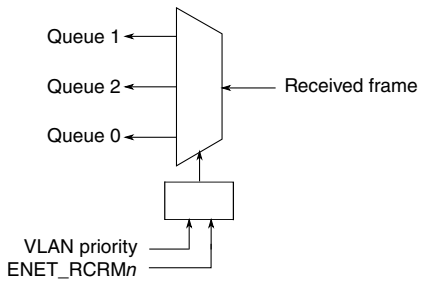

Figure 11-6. AVB frame classification

11.1.6.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's RxBD[EMPTY] is not set or ENET_RDAR*n* is not set. When RX flushing is enabled, via QOS Scheme (ENET_QOS), the blocking frame will be flushed (discarded).

11.1.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required

- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

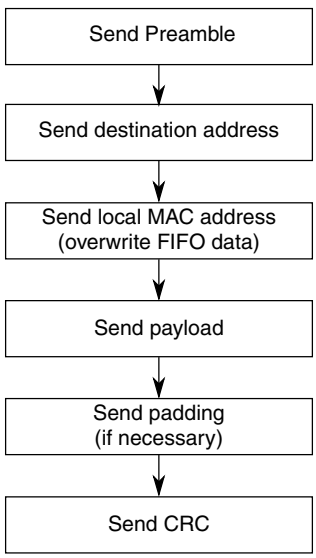

Figure 11-7. Frame transmit overview

11.1.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

11.1.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

11.1.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

11.1.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

11.1.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

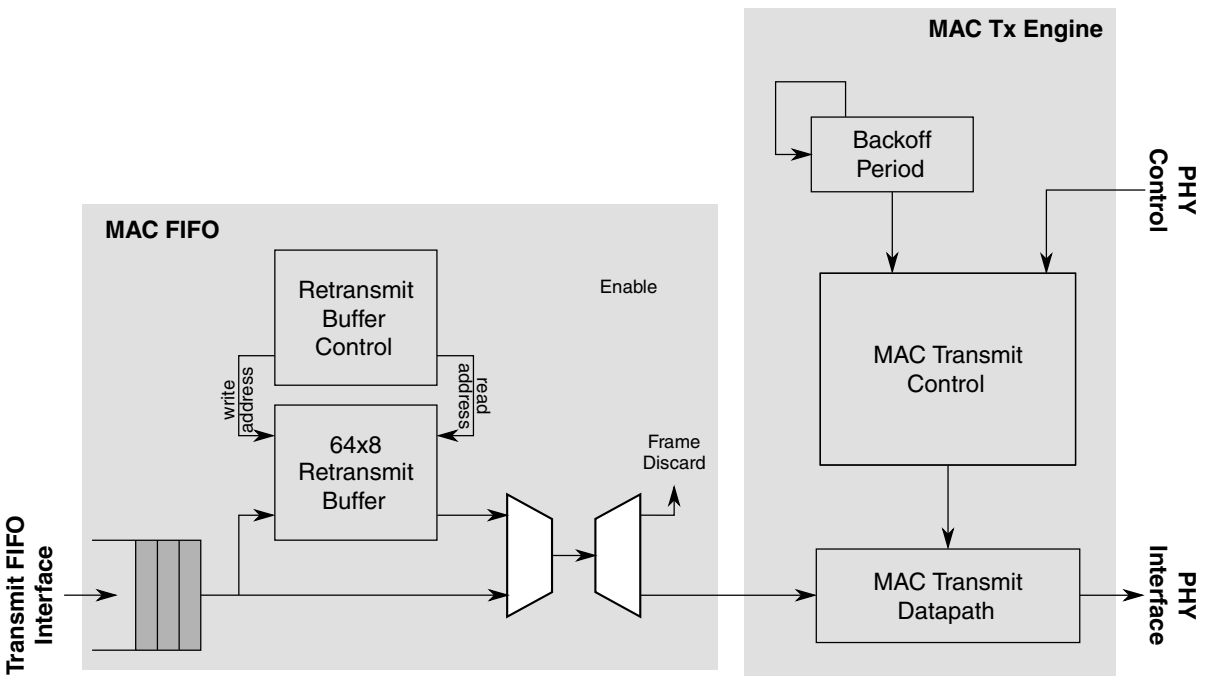

Figure 11-8. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

11.1.6.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

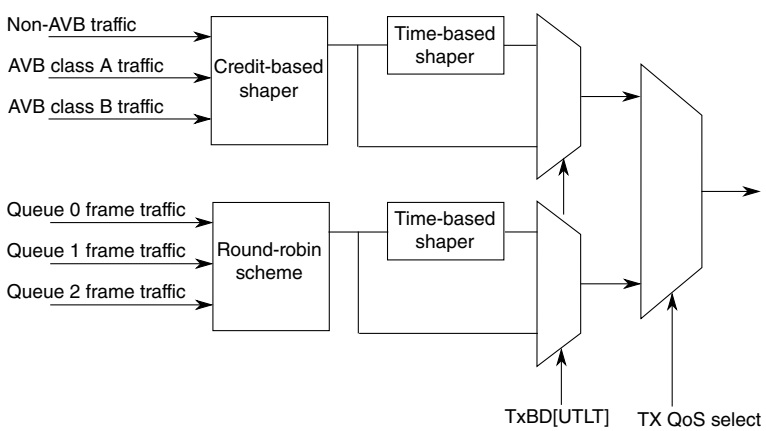

Figure 11-9. Transmit arbitration schemes

11.1.6.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue *n* has a frame to transmit, the queue transmits its frame. After queue *n* has transmitted its frame, or if queue *n* does not have a frame to transmit, queue *n*+1 is then allowed to transmit its frame, and so on.

11.1.6.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 11-26. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See DMA Class Based Configuration (ENET_DMA*n*CFG) for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

11.1.6.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

11.1.6.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See Timer Value Register (ENET_ATVR) and Adjustable Timer Control Register (ENET_ATCR).
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See Enhanced transmit buffer descriptor.
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application can not prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation

(ENET_ATVR + (0.5 × ENET_ATPER)) mod ENET_ATPER

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

11.1.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

11.1.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.

- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

11.1.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

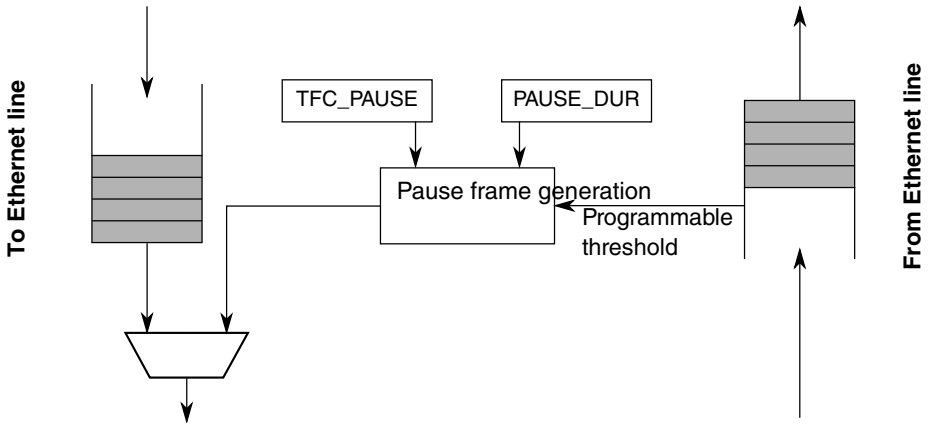

Figure 11-10. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

11.1.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

11.1.6.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET*n*_ECR register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

11.1.6.7.2 Magic packet detection

The core is designed to detect magic packets (see Magic packets) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

11.1.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

11.1.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

11.1.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 11-27. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
Zero		Protocol		TCP/UDP length			

Table 11-28. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
TCP/UDP length							
Zero						Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

11.1.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

11.1.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 11-29.

Table 11-29. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

11.1.6.8.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

11.1.6.8.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

11.1.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL

- Frame received with a CRC-32 error
- Frame truncated due to receive FIFO overflow
- Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)

- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

11.1.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

11.1.6.8.6 IPv6 support

The following sections describe the IPv6 support.

11.1.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

11.1.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

11.1.6.9 Resets and stop controls

The following sections describe the resets and stop controls.

11.1.6.9.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

11.1.6.9.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

11.1.6.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

11.1.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

11.1.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

11.1.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

11.1.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

11.1.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

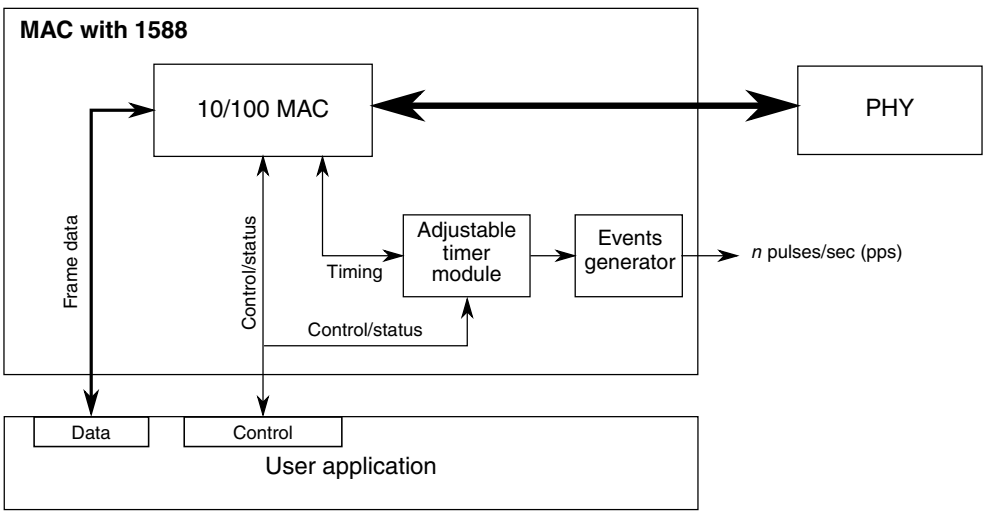

Figure 11-11. IEEE 1588 functions overview

11.1.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

11.1.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

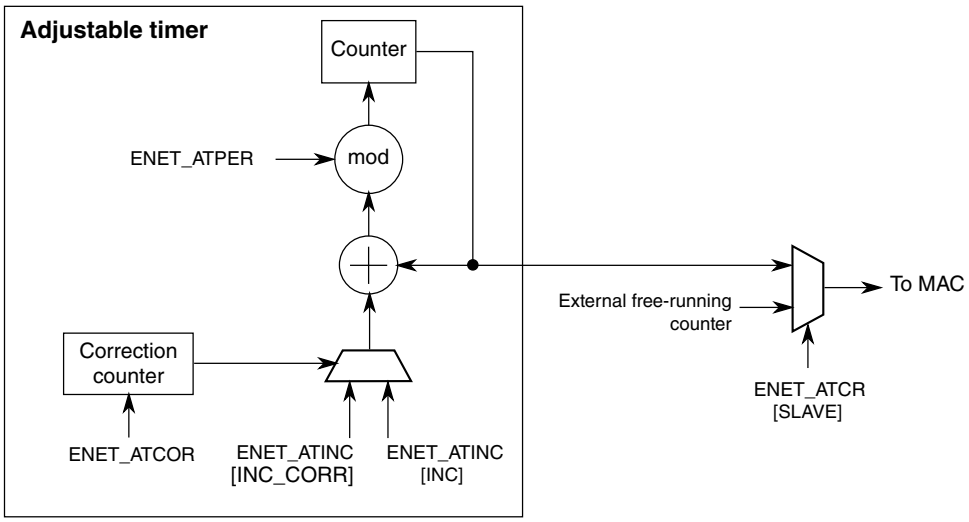

Figure 11-12. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the master, since it is used for internal comparisons.

11.1.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

11.1.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

11.1.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

11.1.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

11.1.6.10.5.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

11.1.6.10.5.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

11.1.6.10.5.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

11.1.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

11.1.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 11-30. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of six.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

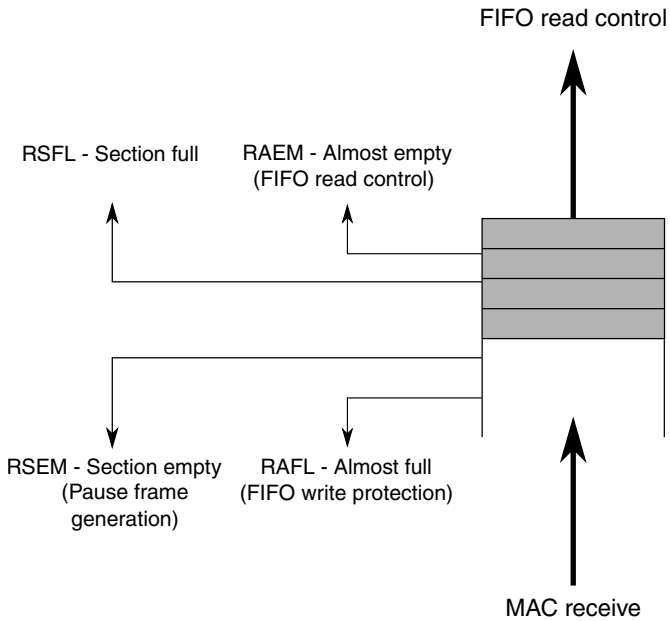

Figure 11-13. Receive FIFO overview

11.1.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 11-31. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).

Table 11-31. Transmit FIFO thresholds definition

Register	Description
	If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

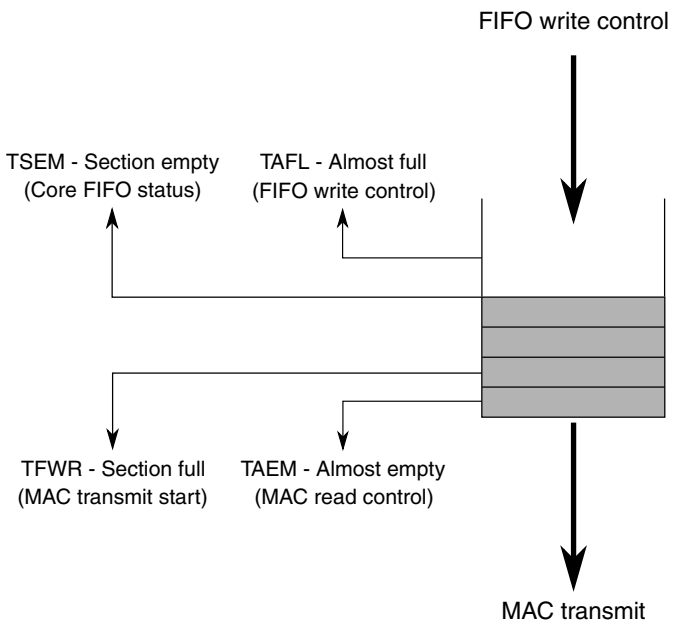

Figure 11-14. Transmit FIFO overview

11.1.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET*n*_RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET*n*_RCR register fields:

Table 11-32. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

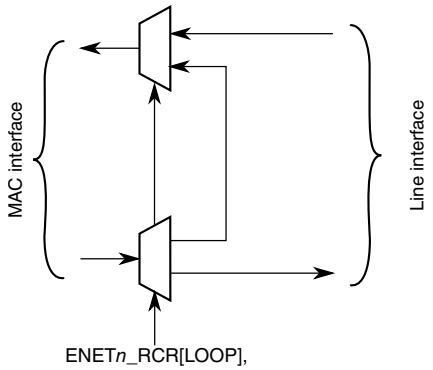

Figure 11-15. Loopback options

11.1.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous Freescale devices, legacy FEC buffer descriptors are available. To enable legacy support, clear ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

11.1.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 11-36 contains the descriptions for each field.

Table 11-33. Legacy FEC receive buffer descriptor (RxBD)

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Offset + 4	Tx Data Buffer Pointer — low halfword															
Offset + 6	Tx Data Buffer Pointer — high halfword															

1. This field is not supported by the uDMA.

11.1.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. DBSWP must be set to 1 after reset to enable little-endian mode.

11.1.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 11-36 contains the descriptions for each field.

Table 11-35. Enhanced uDMA receive buffer descriptor (RxBD)

Table 11-36. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	0–15 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 2	0 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 2	2 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 2	3 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 2	4 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 2	5–6	Reserved, must be cleared.
Offset + 2	7 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM bits are set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 2	8	Set if the DA is broadcast (FFFF_FFFF_FFFF).

Table continues on the next page...

Table 11-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
	BC	
Offset + 2	9 MC	Set if the DA is multicast and not BC.
Offset + 2	10 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 2	11 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 2	12	Reserved, must be cleared.
Offset + 2	13 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 2	14 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 2	15 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 4	0–15 Data buffer pointer low	Receive data buffer pointer, low halfword
0ffset + 6	0–15 Data buffer pointer high	Receive data buffer pointer, high halfword[1]
Offset + 8	0–2 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + 8	3–9	Reserved, must be cleared.
Offset + 8	10 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + 8	11 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + 8	12	Reserved, must be cleared.
Offset + 8	13 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + 8	14 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + 8	15 FRAG	IPv4 Fragment.This is an accelerator option.This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.

Table continues on the next page...

Table 11-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	0 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + A	1–4	Reserved, must be cleared.
Offset + A	5 PE	PHY Error. This field is written by the uDMA. Set to "1"when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + A	6 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + A	7 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + A	8 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + A	9–15	Reserved, must be cleared.
Offset + C	0–15 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + E	0–4 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + E	5–7	Reserved, must be cleared.
Offset + E	8–15 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18 – Offset + 1E	0–15	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

11.1.6.14.2 Enhanced transmit buffer descriptor

Table 11-37. Enhanced transmit buffer descriptor (TxBD)

	Byte 1								Byte 0							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11-38. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	0–15 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 2	0 R	Ready. Written by the MAC and you. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 2	1 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 2	3 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 2	4 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 2	5 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 2	6 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 2	7–15	Reserved, must be cleared.
Offset + 4	0–15 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 6	0–15 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. **NOTE:** For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 8	0 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + 8	1	Reserved, must be cleared.
Offset + 8	2 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + 8	3 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + 8	4 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + 8	5 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + 8	6 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + 8	7 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + 8	8–15	Reserved, must be cleared.
Offset + A	0	Reserved, must be cleared.

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	1 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + A	2 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + A	3 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	4 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + A	5–6	Reserved, must be cleared.
Offset + A	7 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if frame can be transmitted. This field must only be set in the *first* BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with a single BD queue. However, at least one DMA class, DMA*n*CFG[DMA_CLASS_ EN] must be enabled. For example, to use TLT with only queue 0, enable one of the DMA*n*CFG[DMA_CLASS_EN] fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + A	8–11 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2. All other values are reserved.
Offset + A	12–15	Reserved, must be cleared.
Offset + C	0–15 TLT low	Transmit launch time low. Low two bytes of time value that specifies when frame can be transmitted.
Offset + E	0–15 TLT high	Transmit launch time high. High two bytes of time value that specifies when frame can be transmitted.
Offset + 10	0–15	Reserved, must be cleared.
Offset + 12	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 12	1–15	Reserved, must be cleared.
Offset + 14	0–15 1588 timestamp	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16		

Table continues on the next page...

Table 11-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 18–Offset + 1E	0–15	Reserved, must be cleared.

11.1.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

11.1.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 11-39. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 11-40. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 11-41. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

11.1.6.15.2 Data structure examples

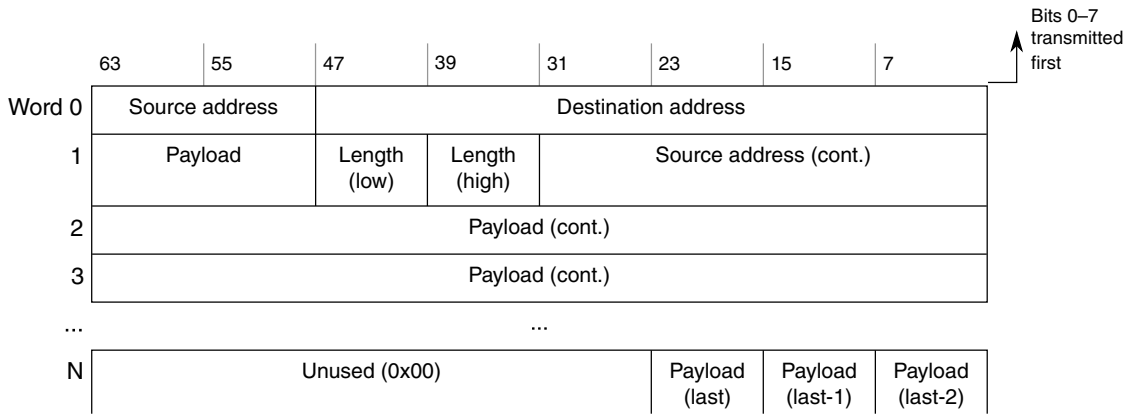

Figure 11-16. Normal Ethernet frame 64-bit mapping example

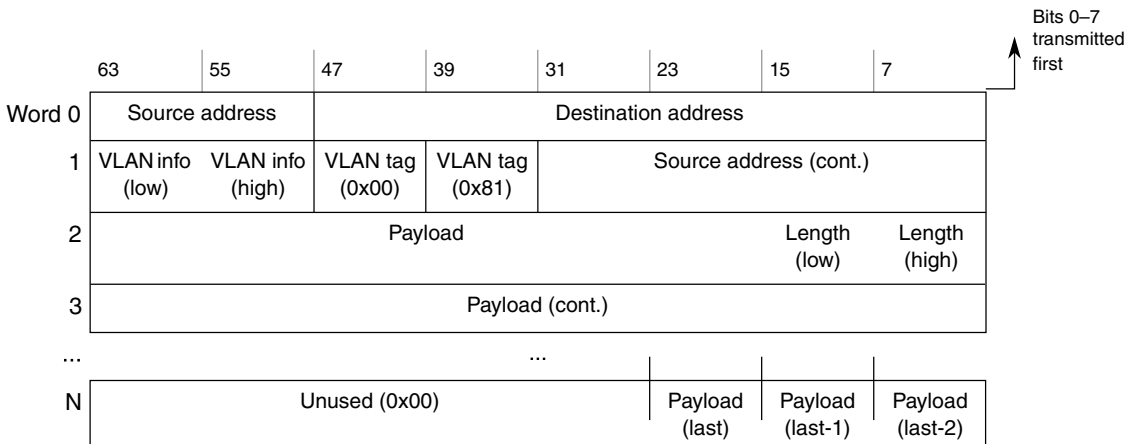

Figure 11-17. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

11.1.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

11.1.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

11.1.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 11-18) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

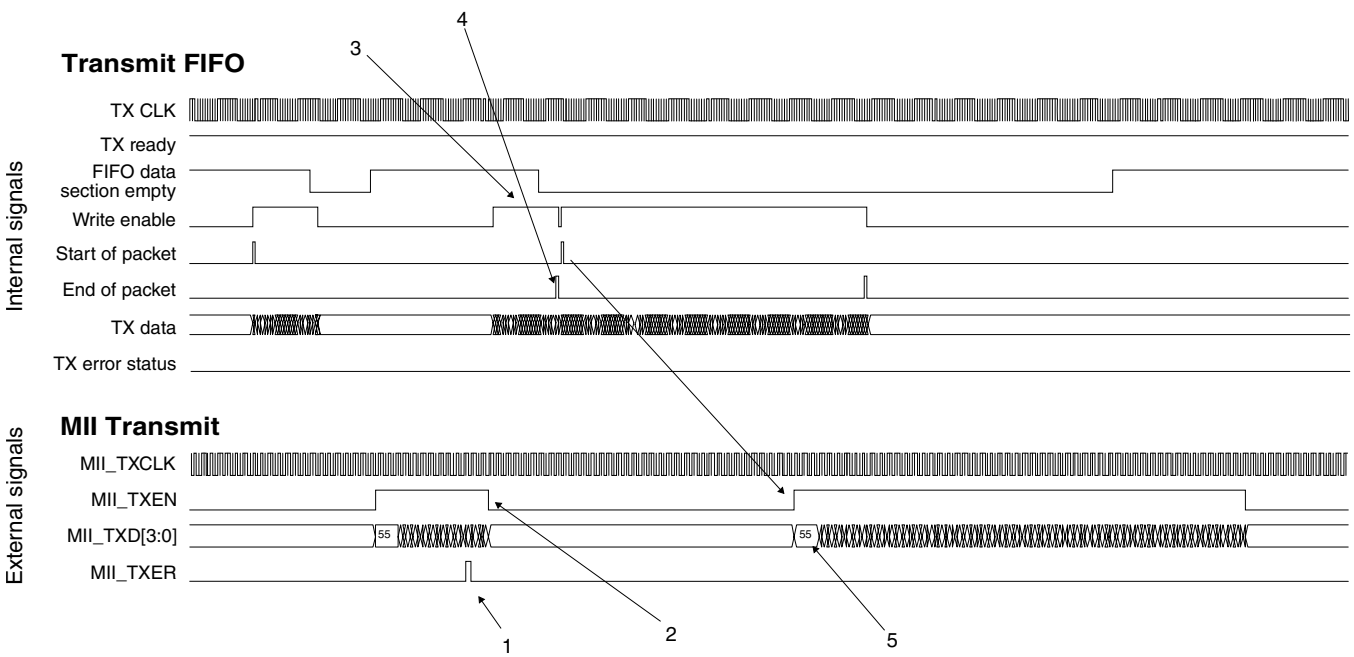

Figure 11-18. Transmit FIFO underflow protection

11.1.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

11.1.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

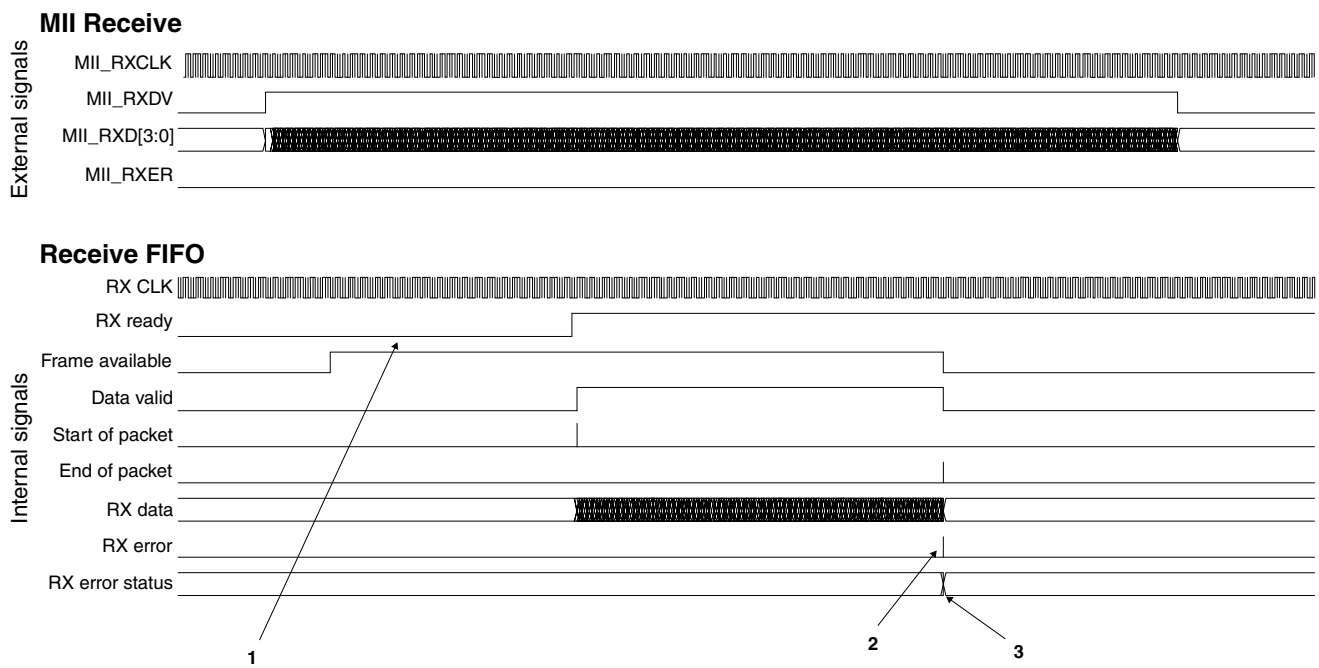

Figure 11-19. Receive FIFO overflow protection

11.1.6.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

11.1.6.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 11-42. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA

Table 11-43. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET*n*_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET*n*_MMFR[DATA]. Written to or read from the PHY

11.1.6.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 11-44. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 11-45. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET*n*_MMFR[OP]. See Table 11-46 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET*n*_MMFR[DATA], written to or read from the PHY.

Table 11-46. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

11.1.6.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

11.1.6.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

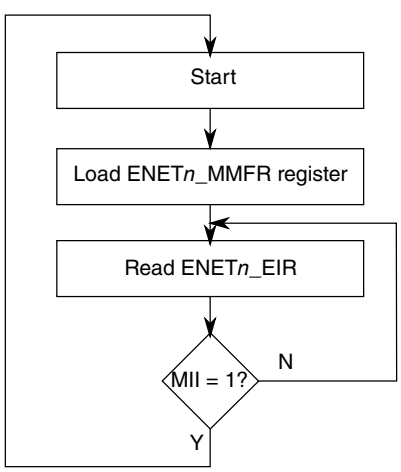

Figure 11-20. MDIO access overview

11.1.6.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMII_EN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

11.1.6.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

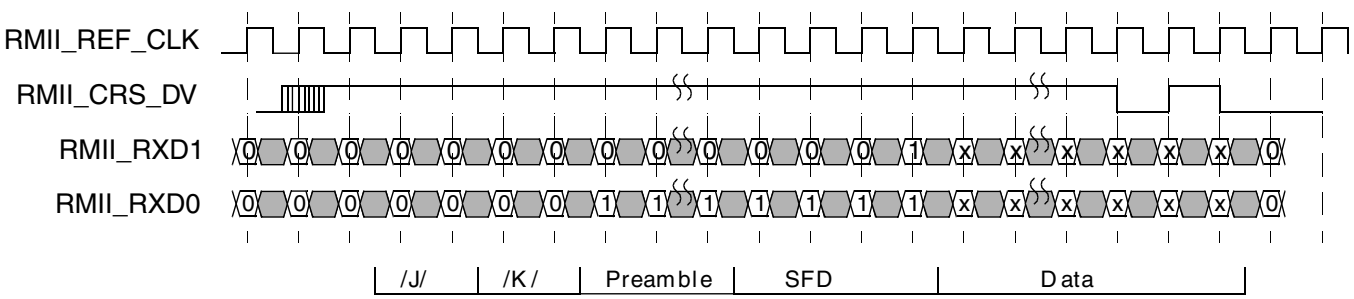

Figure 11-21. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

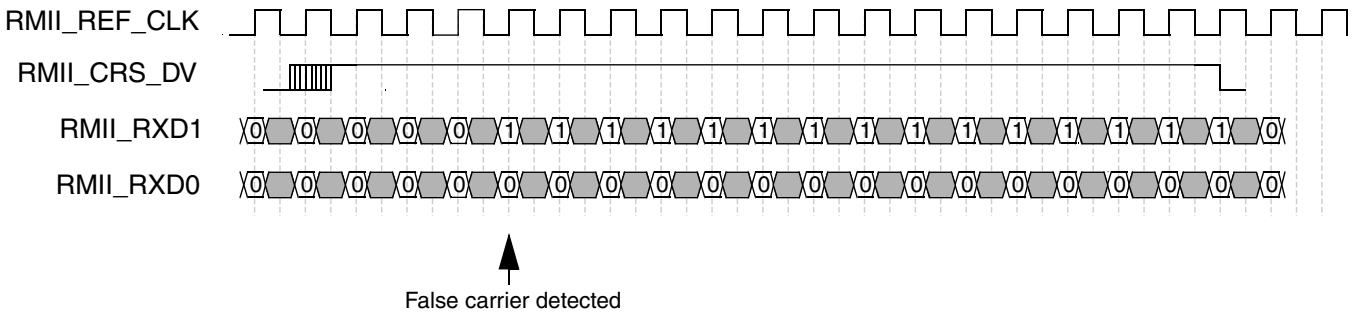

Figure 11-22. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

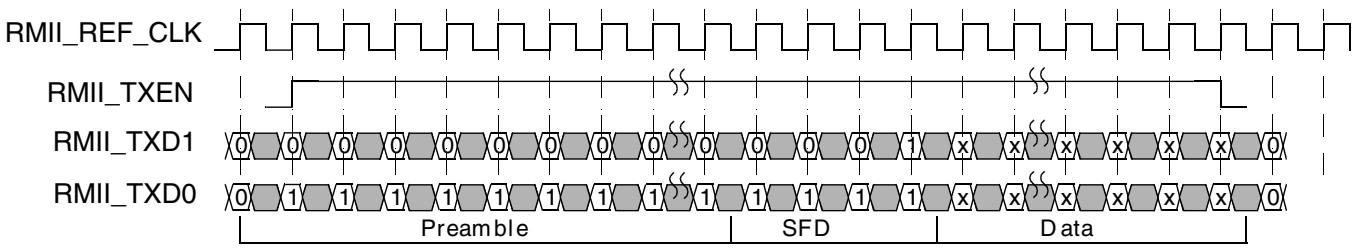

Figure 11-23. RMII transmit operation

11.1.6.18.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

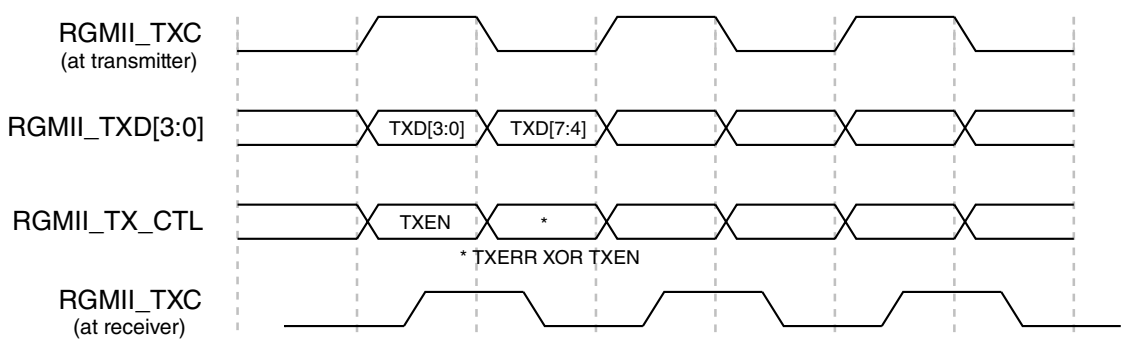

Figure 11-24. RGMII transmit operation

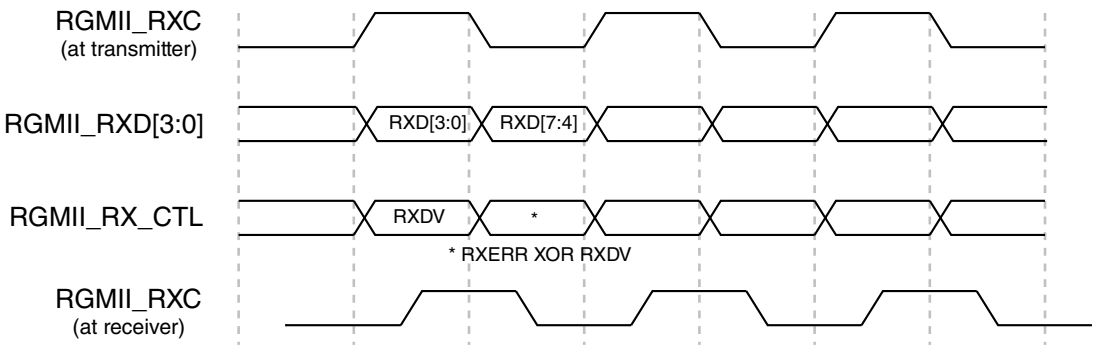

Figure 11-25. RGMII receive operation

11.1.6.18.3 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

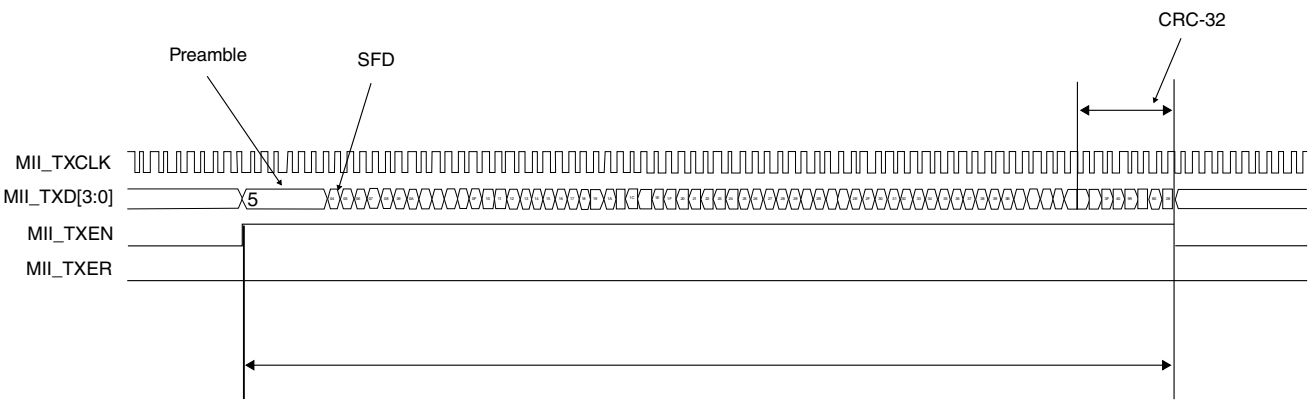

Figure 11-26. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

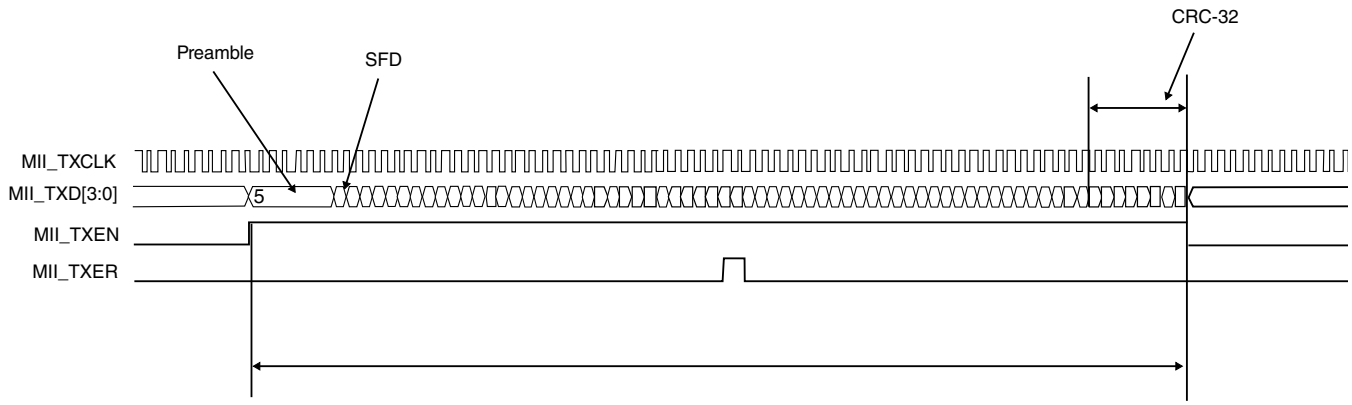

Figure 11-27. MII transmit operation — errored frame

11.1.6.18.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See Collision detection in half-duplex mode for details)

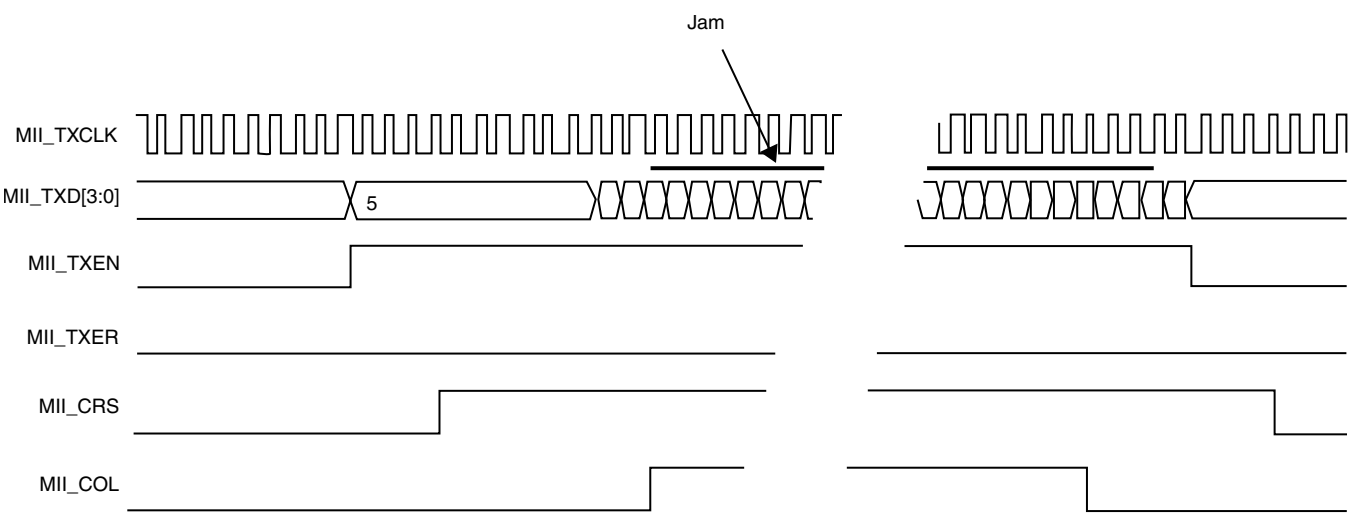

Figure 11-28. MII transmit operation — transmission with collision

11.1.6.18.4 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

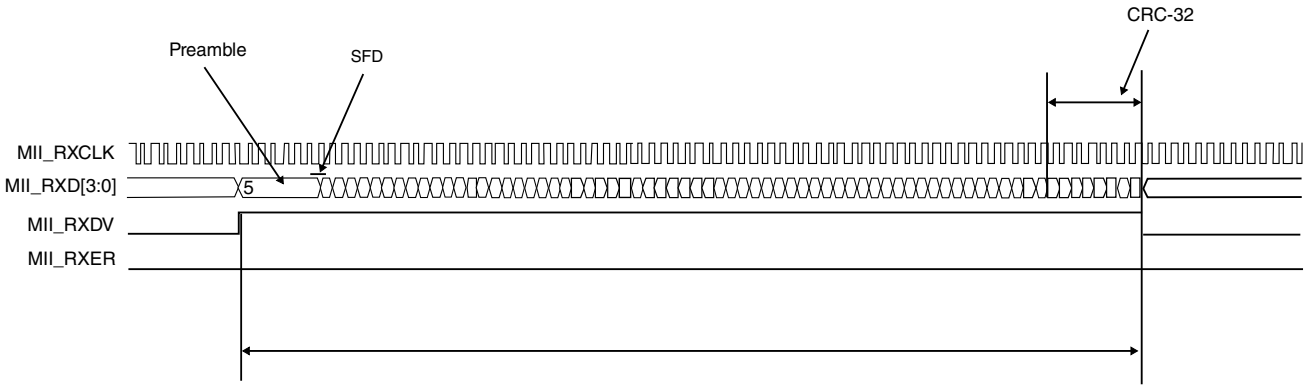

Figure 11-29. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

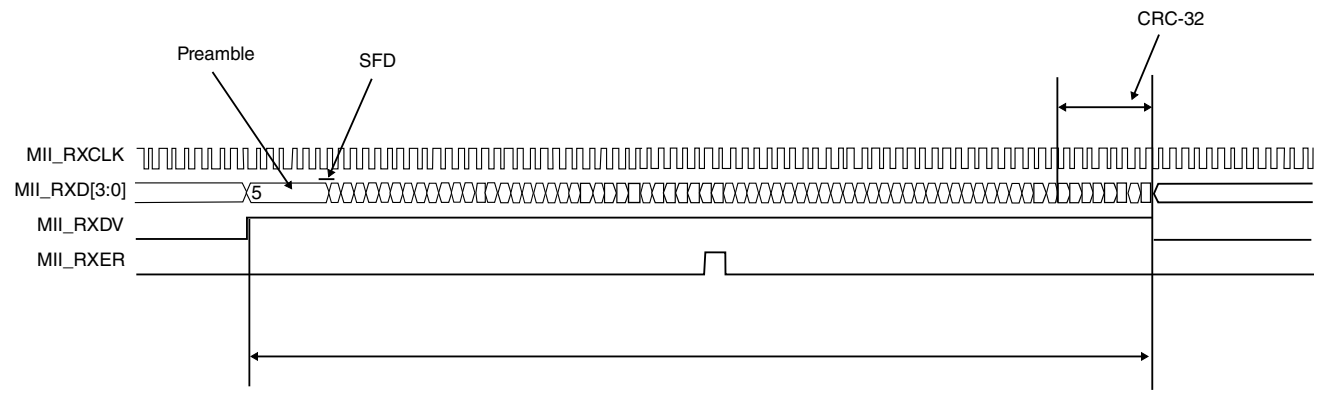

Figure 11-30. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

11.1.6.19 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET_QOS:
   - Set TX_SCHEME to 000b, credit-based scheme.
   - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
   - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
   - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.

- Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
- Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:
- FTYPE = 0h corresponds to ENET_TDSR
- FTYPE = 1h corresponds to ENET_TDSR1
- FTYPE = 2h corresponds to ENET_TDSR2

3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for that class to be enabled. See DMA Class Based Configuration (ENET_DMA*n*CFG) for information on how to program IDLE_SLOPE.
4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA*n*CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

11.1.6.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (ENET_TXIC*n*) where n=0,1,2 for queue/class 0,1,2.
- Receive Interrupt Coalescing Register (ENET_RXIC*n*) where n=0,1,2 for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

11.1.6.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

11.1.6.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

11.1.6.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

11.2 Subscriber Identification Module (SIM)

11.2.1 SIM Overview

The Subscriber Identification Module (SIM) is designed to facilitate communication to SIM cards or Eurochip pre-paid phone cards, and compatible with ISO/IEC 7816-3 standards. See the SIM block diagram in the figure below. The SIM module has one port that can be used to interface with the various cards. The interface with the Micro Controller Unit (MCU) is a 32-bit connection as described in the reference document IP Bus Specification.

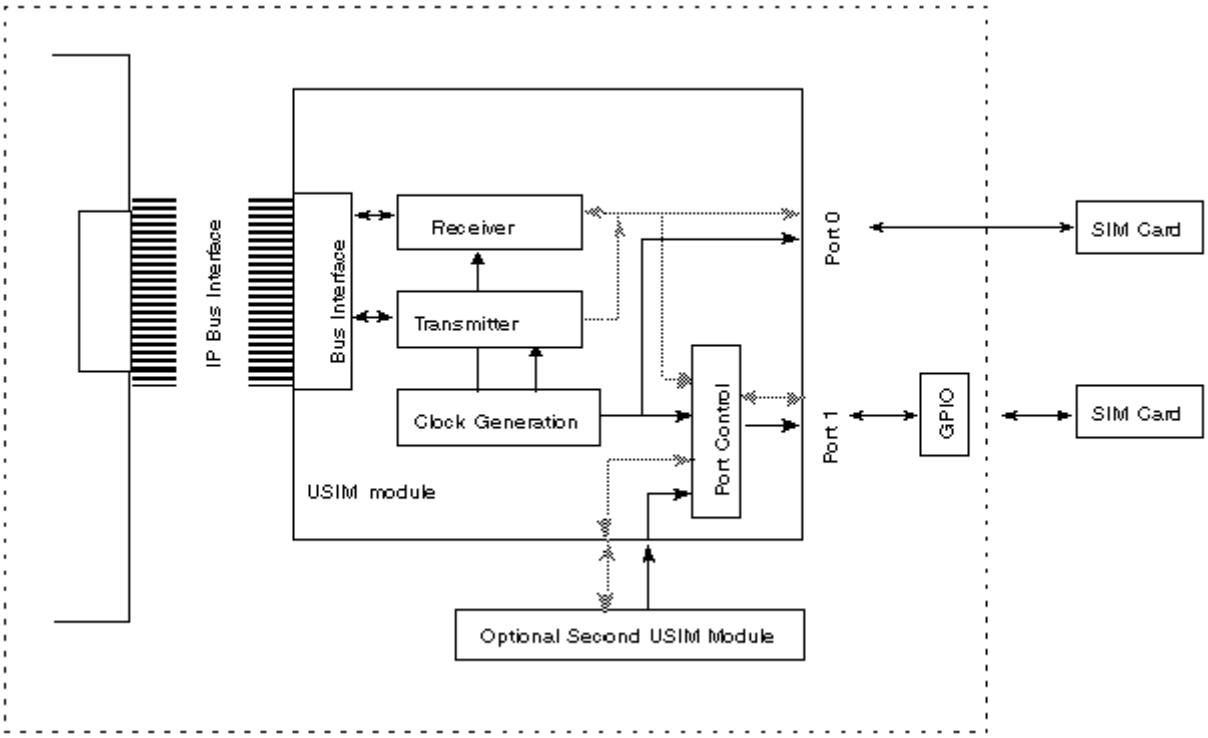

Figure 11-31. SIM Block Diagram

11.2.1.1 Features

The SIM design is summarized in the following sections:

- SIM Bus Interface Overview
- SIM Clock Generator Overview
- SIM Transmitter Overview
- SIM Receiver Overview
- SIM Port Control Overview
- SIM General Purpose Counter Overview
- SIM LRC Block Overview
- SIM CRC Block Overview

11.2.1.2 Modes of Operation

The SIM module I/O interface can be operated in one of three modes of operation summarized below.

- Two wire interface. In this mode both the IC pin RX and TX are used to interface to the SmartCard. This is activated by resetting the 3VOLTx bit in the port control register to a "0".
- External one wire interface. In this mode the IC pins RX and TX are tied together external to the IC and routed to the SmartCard. The 3VOLT bit in the port control register is reset to a "0" and the OD_Px bit in the OD_CONFIG register is set to a "1". For this interface to work properly the IC pin (RX-TX) must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.
- Internal one wire interface. In this mode the IC pin TX is routed to the SmartCard. The receive pin RX is connected to the TX pin internal to the IC. The 3VOLTx bit in the port control register is reset to a "1" and the OD_Px bit in the OD_CONFIG register is set to a "1". For this interface to work properly the IC pin TX must be pulled high by a resistor. The value should be selected small enough to give a fast enough rise time.

NOTE

For the internal one wire interface to work, the bond pad must be capable of simultaneous input and output. (The input path should not be disabled when the output is enabled.)

11.2.1.3 SIM Bus Interface Overview

The SIM module is designed with a separate block that encompasses the interface to the IP bus. The bus interface is built in such a way as to be easily modified to other bus definitions. The SIM module is to be considered a 32-bit peripheral. To avoid endian issues with register access, all read/writes should be done as word access (32-bit). The bus interface has the following features:

- Peripheral Address/chip select decoding
- Illegal Address generation
- Dynamic wait state generation (tied inactive)
- Register organization
- Register bit implementations

See the table below for a summary of SIM top level interrupts.

Table 11-47. SIM Top Level Interrupt Summary

Flag	Interrupt Sources	Interrupt Masks	Description
SIMIRQ_N	XTE, OEF, SDI0, SDI1, TFO, GPCNT, BWT, BGT, CWT, RTE	XTM, OIM, SDIM0, SDIM1, TFOM, GPCNTM, BWTM, BGTM, CWTM, RTM	SIM General Interrupt

Table continues on the next page...

Table 11-47. SIM Top Level Interrupt Summary (continued)

Flag	Interrupt Sources	Interrupt Masks	Description
SIMDAT_N	TC, ETC, TFE, RDRF, TDTF, RFE	TCIM, ETCIM, TFEIM, RIM, TDTFM,RFEM	SIM Data Interrupt

11.2.1.4 SIM Clock Generator Overview

The SIM module contains a block designed specifically for generating the clocks used internal to the SIM module, and the clocks provided to the SIM cards. The clock generator has the following features:

- Programmable Divisor (CLK_PRESCALER[7:0]) for SIM card clock generation (45-55% duty cycle except for divider by 3, 5, 7, 9)
- Receive clock generation (/1, /2, /4, /8, /16, /32, /31) from first stage
- Transmit clock generation (/12, /8) from second stage
- Programmable divisor for receive clock generation
- There are no interrupt sources generated by the SIM clock generator block

11.2.1.5 SIM Transmitter Overview

The SIM transmitter block contains the transmit state machine, transmit shift register, and transmit FIFO. The transmitter has the following features.

- 16 bytes deep transmit FIFO
- Automatic NACK generation on parity and overrun errors
- Hardware data format support (inverse convention or direct convention)
- Retransmission of data upon SIM card NACK request with programmable maximum threshold of retransmissions
- Programmable guard time between transmitted bytes
- Six interrupt sources (see the table below)

Table 11-48. SIM Transmitter Interrupt Summary

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill Error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag

11.2.1.6 SIM Receiver Overview

The SIM receiver block contains the receive state machine, receive FIFO, and control logic. The receiver has the following features.

- 288 bytes deep receive FIFO
- Decoding of initial character mode for setting data format
- Hardware data format support (inverse convention or direct convention)
- NACK detection
- Eleven ETU character support
- Character Wait Time Counter
- Six interrupt sources (see the table below)

Table 11-49. SIM Receiver Interrupt Summary

Flag	Flag register	Mask	Mask register	Description
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive Nack threshold
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time flag
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive Data Register Full
RFE	RCV_STATUS	RFEM	INT_MASK	Receive Fifo Empty

11.2.1.7 SIM Port Control Overview

The SIM module supports numerous port control functions necessary for SIM card interaction. Each of the two SIM card ports has the following I/O: CLK, $\overline{\text{RST}}$, DATA_RCV, DATA_XMT, SIMPD (SIM presence detect), and SVEN (SIM V_{CC} enable). The following list gives a number of the important features of the port logic.

- Open-drain or push pull DATA_XMT pin
- Port 1, port 0, ore alternate port selection
- SIM card presence detect with interrupt capability
- Sleep mode wake-up via SIM card presence detect interrupt
- Manual control of all SIM card interface signals
- Automatic power down of port logic on SIM card presence detect
- Two interrupt sources. See Table 11-50.

Table 11-50. SIM Card Detect Interrupts

Flag	Flag register	Mask	Mask Register	Description
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT	SIM Detect Interrupt for port 0

11.2.1.8 SIM General Purpose Counter Overview

The SIM module provides a 16-bit counter that can be configured to count using clock sources from the card clock, receive clock, or transmitter clock (ETU Clock). A programmable 16-bit register is provided to compare with the counter for interrupt generation:

- Selectable clock source
- 16-bit counter and comparator
- One Interrupt source (see the table below)

Table 11-51. SIM General Purpose Counter Interrupts

Flag	Flag Register	Mask	Mask Register	Description
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	GPCNT Comparator Interrupt

11.2.1.9 SIM LRC Block Overview

The SIM module contains a block designed to generate Linear Redundancy Checking (LRC) information for both received and transmitted characters. The LRC block has the following features:

- 8-bit LRC value
- Valid LRC Detector
- There are no interrupt sources generated by the SIM LRC block

11.2.1.10 SIM CRC Block Overview

The SIM module contains a block designed to generate Cyclic Redundancy Checking (CRC) information for both received and transmitted characters. The CRC block has the following features:

- 16-bit CRC value
- 16-bit CRC Polynomial Generator

- Valid CRC Detector
- There are no interrupt sources generated by the >SIM CRC block

11.2.2 External Signal Description

11.2.2.1 External Signals Overview

See the table below for summary of the SIM module signals.

Table 11-52. Signal Properties

Name	Port	Function	Reset State	Pull-up
External Signals				
SIM_CLK	O	Clock for the smartcard on port0	0	Active
SIM_RST_B	O	Reset signal for port0	0	Active
SIM_SVEN	O	Vcc enable signal for port0	0	Active
SIM_TRXD	O	Transmit/receive data signal for port0	0	Active/Passive
SIM_PD	I	Card insertion detect signal for port0	-	-
sim_pin_sclk1	O	Clock for the smartcard on port1	0	Active
sim_pin_srst1	O	Reset signal for port1	0	Active
sim_pin_sven1	O	Vcc enable signal for port1	0	Active
sim_pin_data1_tx_out	O	Transmit/receive data signal for port1	0	Active/Passive
pin_sim_simpd1	I	Card insertion detect signal for port1	-	-
sim_rcvd1_io	I	I/O Receive data signal for port1	-	-
Module Interrupts				
ipi_int_sim_ipb_int	O	Active high SIM Interrupt. Composed of OEF, XTE, SDI1, and SDI0.	0	-
ipi_int_sim_data_irq	O	Active high SIM Data Interrupt. Composed of TC, ETC, TFE, and RDRF.	0	-
Module DMA Requests				
ipd_sim_tx_dmareq_b	O	Active low. Transmitter DMA request.	1	-
ipd_sim_rx_dmareq_b	O	Active low. Receiver DMA request.	1	-

11.2.2.2 Detailed Signal Descriptions

11.2.2.2.1 SIM_CLK

The SIM_CLK is an output from the chip to the SmartCard. This signal is the clock that the SIM module provides for the SmartCard. Typical frequencies are 1 MHz to 5 MHz. This clock is 372 times the data rate that is on pin SIM_TRXD. There is no required timing relationship between this clock signal and any of the other data signals. This is because of the asynchronous nature of the protocol.

11.2.2.2.2 SIM_RST_B

The SIM_RST_B is the reset signal from the SIM to the SmartCard.

11.2.2.2.3 SIM_SVEN

The SIM_SVEN is the SmartCard power supply enable control signal.

11.2.2.2.4 SIM_TRXD

The SIM_TRXD is the data transmitted/received from the SIM module to the SmartCard. In a 1-wire mode of operating, this output port must be bidirectional with a pull-up resister off chip.

11.2.2.2.5 SIM_PD

The SIM_PD is the SmartCard insertion detect.

11.2.3 SIM Functional Description

To best describe the organization of the SIM module from a user's point of view, it is instructive to view the SIM at a number of different levels of hierarchy. See Figure 11-31 for illustration of the organization of SIM and connection of the signals to the available serial port.

The SIM module is essentially a standard UART with some special provisions made for SIM card communication. The SIM consists of the following main parts:

- IP bus interface
- Bus interface
- Clock generator
- Transmitter
- Receiver
- General purpose counter

- LRC blocks
- CRC blocks

See the figure below for an illustration of the block diagram in detail, specifically the main parts.

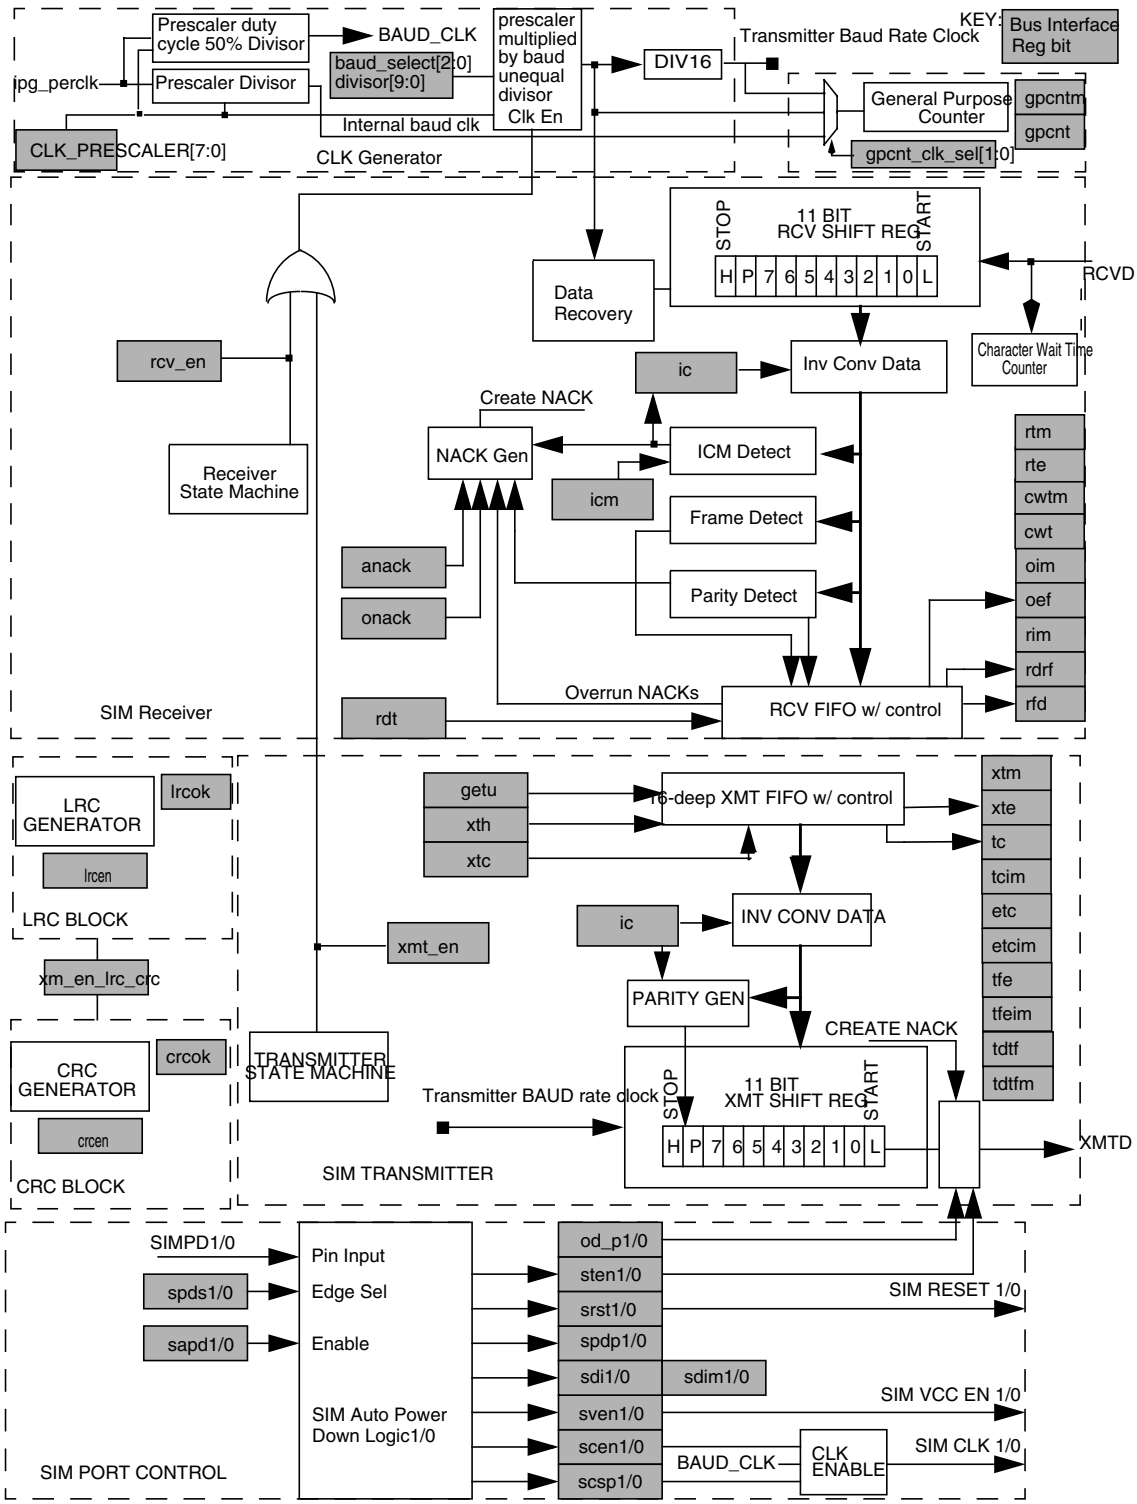

Figure 11-32. SIM Detailed Block Diagram

11.2.3.1 SIM Bus Interface

The IM Bus interface block has been designed to enable the SIM module to be easily ported to other MCU cores. The bus interface block contains all of the logic that uses the bus interface signals. See the figure below.

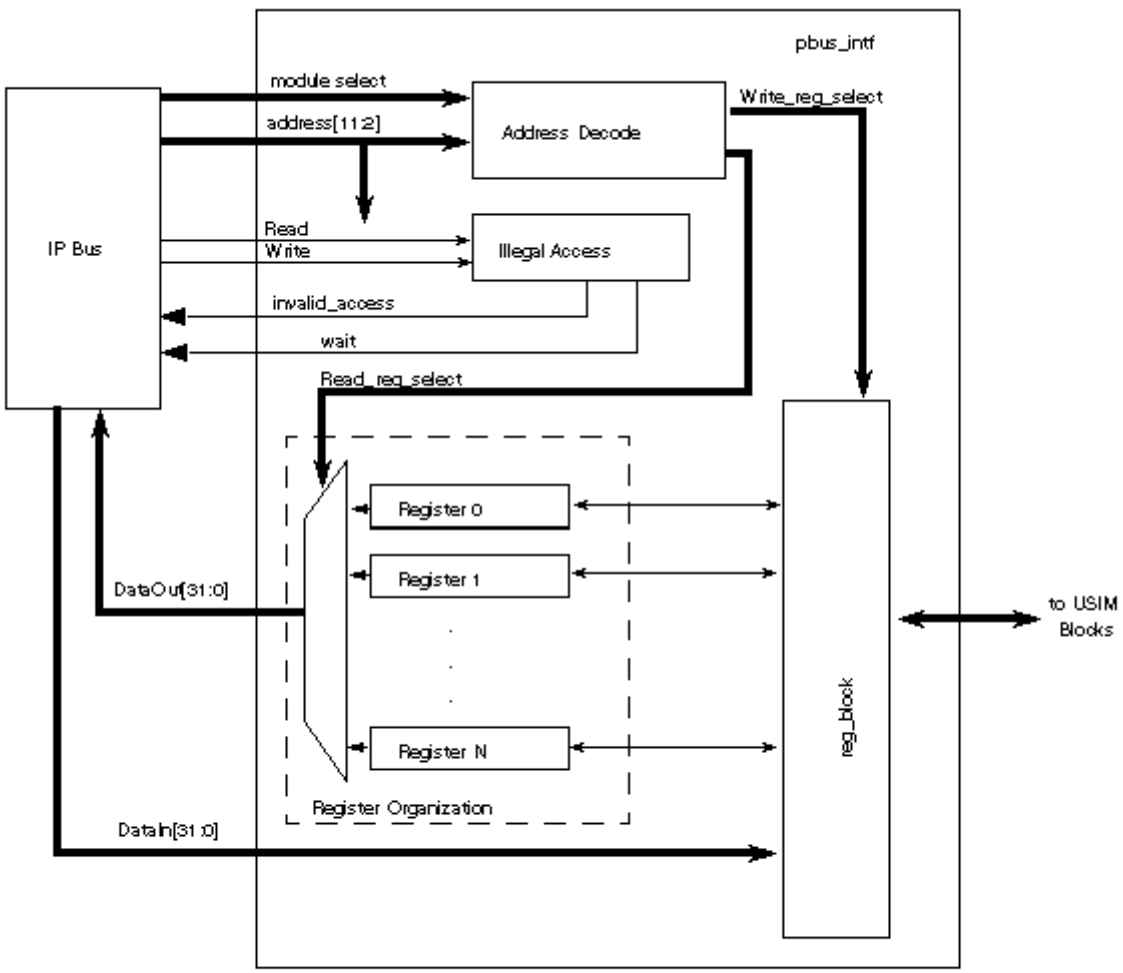

Figure 11-33. SIM Bus Interface

The bus interface block is responsible for peripheral bus address decoding, illegal access detection, dynamic wait-state requests, register organization, and register bit implementations. The address decoding uses the module address bus input along with the module select output of the IP bus to decode if the SIM module is being addressed. This decoding of these signals is done asynchronously. The output of the address decode is used with the read/write signals from the IP bus to determine the action requested by the bus master. If the read signal is active, the data_out bus will be driven with the register

selected by the address decoding. If the write signal is active, the data_in bus will be latched into the register selected by the address decoder at the rising edge of the data_strobe signal.

The illegal access detection is implemented similarly to the address decoding. If the module_select signal becomes active while the address inputs are pointing to an unimplemented address, the invalid signal is asserted asynchronously to the bus master. The invalid signal can also be generated under certain register access conditions such as writing to a full transmit FIFO, or writing to a read-only register. See the figure below.

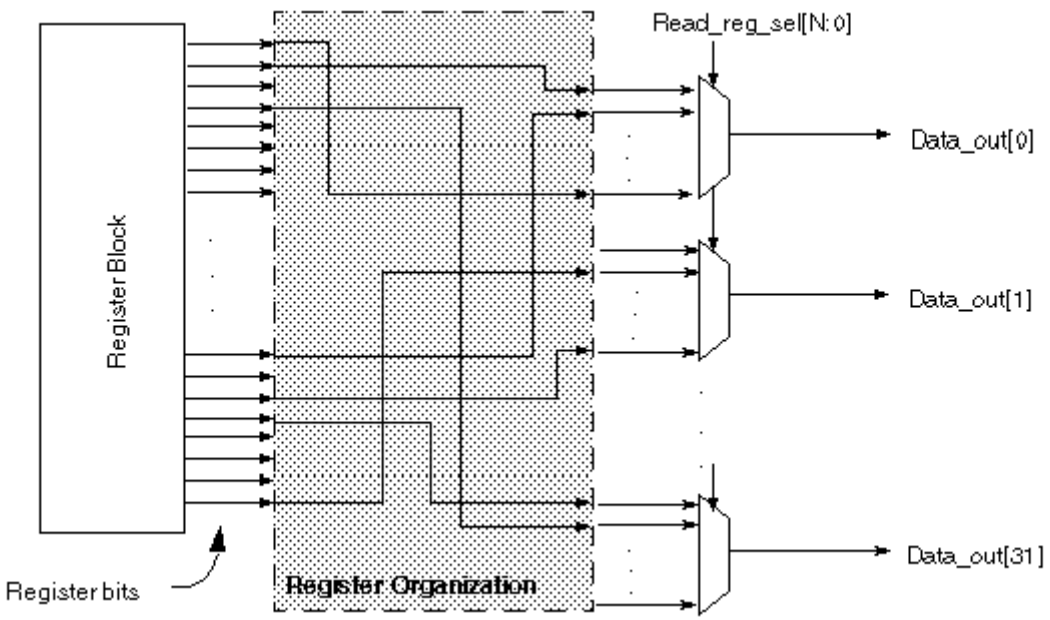

Figure 11-34. SIM Read Registers

The register bit implementations are done inside the reg_block sub-module. This block accepts the decoded read and write signals for the register bits generated in the address decoder. The data_strobe output is used as the clock input to the register bits in order to clock in the new data during a write access. The write_reg_sel signals are used to gate the write action with the address decoding. The clearing mechanisms for status bits are implemented as write-one-to-clear. See the figure below.

.

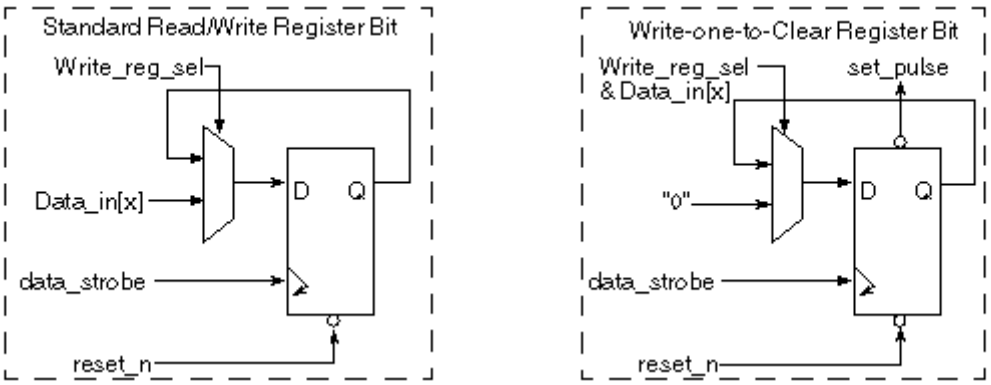

Figure 11-35. Register Bit Diagram

In the "write-one-to-clear" register bit example, "set_pulse" represents a pulsed signal generated in the data_strobe clock domain to set the register output.

11.2.3.2 SIM Clocking

The SIM has three clock inputs:

- ipg_clk-read/write clock; the frequency is half of platform_clk
- ipg_per_clk-reference frequency input clock to generate the SIM card clock and other internal clocks; the frequency is platform_clk divided by 8
- ckil-low frequency clock (32 KHz) used by the auto power down hardware circuit in the SIM. It is generated by dividing the platform_clk by a division factor which is programmed in the SIMCLKCR register in the global utilities. The default value of the divider is 0x3D09, which gives a 32 KHz clock from a platform_clk of 500 MHz.

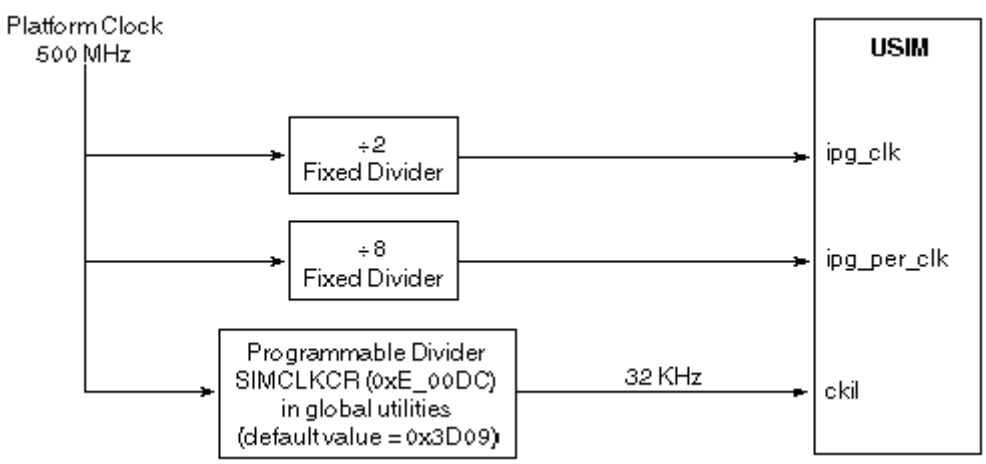

Figure 11-36. SIM Clock Generator

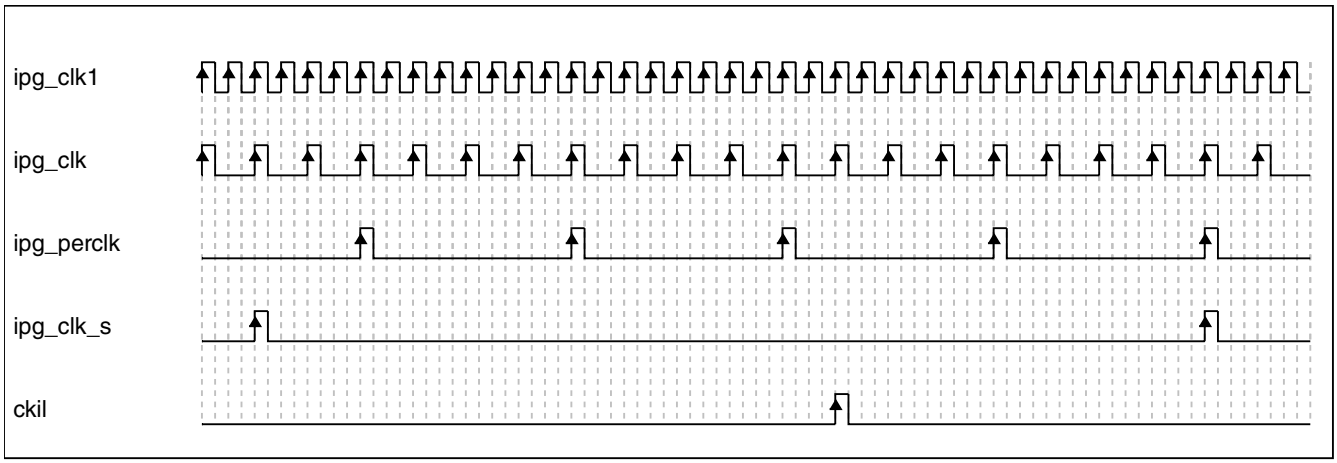

Figure 11-37. SIM Clocking Diagram

11.2.3.3 SIM Clock Generator

The clock generator is responsible for implementing clock tree synthesis constructs, scan clock muxing, baud rate clock (BAUD_CLK) generation, and providing clocks to the transmitter, receiver, and port controller sections of the SIM module. See the figure below for the schematic of the SIM clock generator. The dividers outlined in bold, generate a pulsed (gated) clock of the desired frequency. The pulse is equal in duration to one half the ipg_per_clk period. This clock is used internal to the SIM module to drive the transmit and receive sections of the module.

The dividers outline in normal, generate a clock of 45-55% duty cycle to drive the clock pin of the SmartCard. This clock is not used internal to the SIM module.

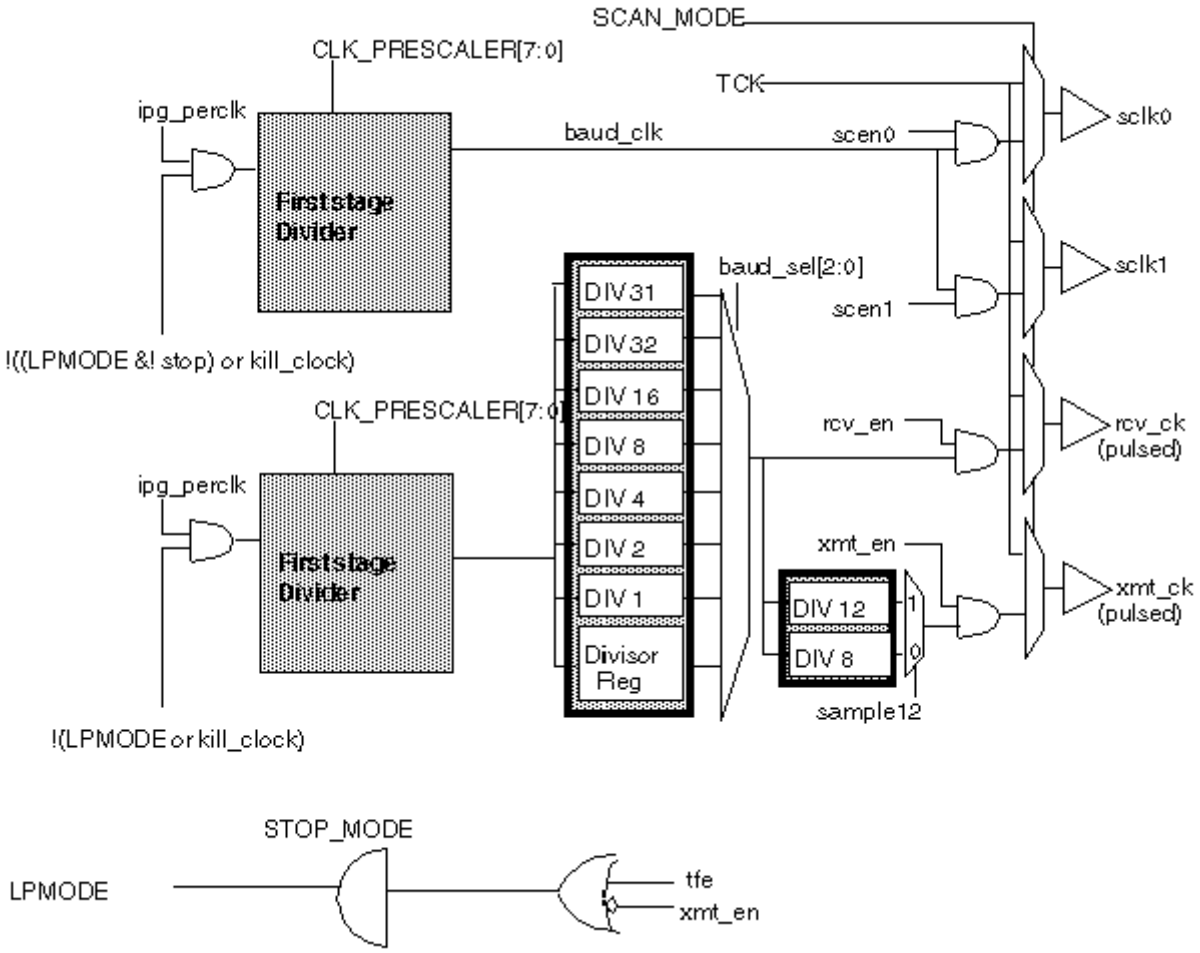

Figure 11-38. SIM Clock Generator

11.2.3.3.1 Scan Test

The scan clock muxing is implemented according to the design for testability rules.

11.2.3.3.2 Baud Clock Generation

The baud rate clock generation performed by the clock generator results in different frequencies. The default frequency is a divide by two of the ipg_perclk input. The baud rate can be programmed to be ipg_perclk divided by the even value using the CLK_PRESCALER[7:0] bits as shown in the CLK_PRESCALER register. The baud rate clock is generated in two forms in the design. The BAUD_CLK that is used by the SIM cards (SCLK0) is generated so that it must be 45-55% duty at the divide values. This is necessary to meet the requirements of the ISO 7816 specification. The BAUD_CLK that is used internal to the SIM module is generated as a gated version of the ipg_perclk clock. The resultant clock will be a pulse of one-half ipg_perclk period in width with the

expected frequency. The gated baud clock complies with the clock methodology initiative. The 50% duty cycle clock does not comply with the clock methodology initiative but this clock is not used as a clock internal to the SIM module. It is only used as a data path.

11.2.3.3.3 Transmitter Clock Generation

The transmitter clock (xmt_clk) is generated by the clock generator based on the values passed to it for the baud rate select (baud_sel[2:0]) and sample12. The transmit clock is gated by the transmit enable (XMT_EN) register bit. When the transmitter is enabled, the clock generator counts the appropriate number of receive clock (rcv_clk) positive edges to determine when to toggle the transmitter clock output. The transmitter clock is always based upon the receive clock.

11.2.3.3.4 Receiver Clock Generation

The receiver clock (rcv_clk) is generated by the clock generator based on the value passed to it for the baud rate select (baud_sel[2:0]). The receiver clock is gated by the receiver enable (RCV_EN) register bit. When the receiver is enabled, the clock generator counts the appropriate number of BAUD_CLK positive edges to determine when to toggle the receiver clock output. The number of BAUD_CLK positive edges is determined by the value of the baud rate select input (baud_sel[2:0]) and is programmable to these divisors: 31 (slowest because used with the 372/1 Fi/Di rate), 32, 16, 8, 4, 2, 1, and divisor[7:0]. The programmable divisor (divisor[7:0]) is programmable via the DIVISOR_REG register.

11.2.3.3.5 Port Control Clock Generation

The port controller clocks are provided by the clock generator for use on the SIM card ports. These clocks are equivalent in frequency to the BAUD_CLK and are gated by the SIM clock enable (scen0, scen1) signals. The level at which the card clocks (SCLK0, SCLK1) are stopped when disabled is determined by the SIM clock select polarity (SCSP0, SCSP1) inputs to the clock generator. Synchronizers are implemented to ensure glitch free operation of the card clocks when enabling/disabling, or changing the clock stopped polarity.

11.2.3.3.6 Low Power Mode Clock Control

The clock generator block is responsible for gating the clocks to the SIM module appropriately whenever a low power mode instruction is decoded. The IP interface provides two signals that encode the two available low-power states of the processor. These states are: STOP and DOZE. The response to the DOZE instruction is controlled

through the use of the DOZE bit in the RESET_CNTL register. See the RESET_CNTL register description. The response to the STOP instruction is controlled through the use of the STOP bit in the RESET_CNTL register. See the RESET_CNTL description

11.2.3.4 SIM Transmitter

The SIM Transmitter block has been designed to localize all transmit related circuitry into one section of hierarchy. The Transmitter block comprises the following sections of logic: transmit state machine, transmit shift register, transmit FIFO, guard time generator, transmit NACK control, and transmit data convention.

11.2.3.4.1 Transmit State Machine

The Transmit state machine is the heart of the transmitter block. The state machine is responsible for sequencing through a transmit operation while reacting to inputs from the receiver, the transmit FIFO, and the guard time circuit. See the figure below for flow diagram of the transmit state machine.

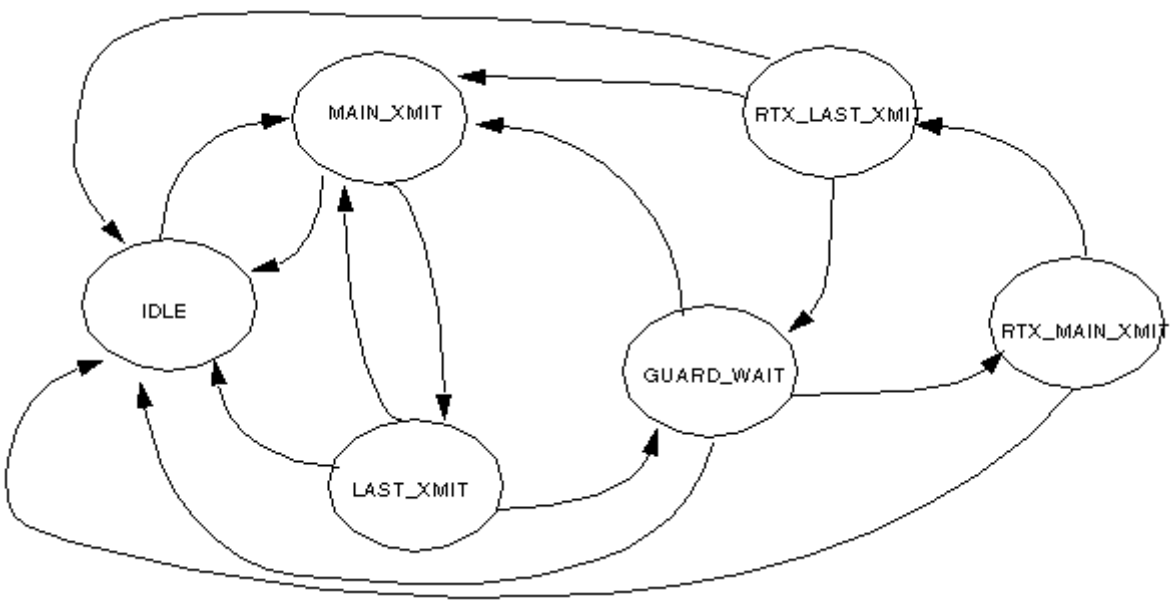

Figure 11-39. Transmit State Machine

The functions performed by each state are:

- IDLE
  - This is the initial state. The state machine waits here until it detects XMT_EN is set and a write to the transmit FIFO has occurred. The data pointed to by the transmit read pointer is loaded into the shift register, and the state machine

transitions to the MAIN_XMIT state. Any time XMT_EN is cleared, the state machine returns to this state.

- MAIN_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the LAST_XMIT state.
- LAST_XMIT
  - This state transmits the last bit of the current transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to MAIN_XMIT state to retransmit the current byte.
    - If no transmit NACK, and GETU[7:0] is zero, load the shift register, jump to MAIN_XMIT to transmit the next byte
    - If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.
- GUARD_WAIT
  - The state machine remains in this state until the Guard time counter has expired.
    - If a transmit NACK error occurred on last transmission, jump to RTX_MAIN_XMIT and re-transmit
    - If no transmit NACK and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte.
    - If no transmit NACK and the FIFO is empty, return to the IDLE state.
    - If transmit NACK threshold is detected, stop transmitter, set XTE flag, and jump to the IDLE state.
- RTX_MAIN_XMIT
  - The transmitter is operating normally in this state. The data in the shift register is shifting once every transmit clock cycle. When the second to last bit of the current transmission is about to be sent, the state machine transitions to the RTX_LAST_XMIT state. This state is identical to the MAIN_XMIT state except that it retransmits the previously NACKed byte.
- RTX_LAST_XMIT
  - This state transmits the last bit of the current re-transmission and determines the next operation. One of the following will occur.
    - If GETU[7:0] is non-zero, jump to the GUARD_WAIT state.
    - If a transmit NACK error occurred, with a zero in GETU[7:0], jump to GUARD_WAIT state to check Transmit NACK threshold.

- If no transmit NACK, GETU[7:0] is zero, and the FIFO is not empty, load the shift register, jump to MAIN_XMIT to transmit the next byte
- If no transmit NACK, GETU[7:0] is zero, and the FIFO is empty, jump to IDLE state; set the transmit complete (TC) flag.

11.2.3.4.2 Transmit Shift Register

The transmit shift register is 11 bits wide and controlled by the transmit state machine described previously. The shift register shifts out data at the transmit clock frequency (xmt_ck).

11.2.3.4.3 Transmit FIFO

The transmit FIFO is implemented inside the transmitter block. The FIFO depth is 16 bytes. The FIFO block is shared by both SIM module ports. The transmit FIFO cannot be accessed by the alternate SIM module through the alternate port. Each write to the transmit FIFO increases the transmit FIFO write pointer. Each time the transmit shift register is loaded from the transmit FIFO, the transmit FIFO read pointer is increased. When the read and write pointers are equal, the transmit FIFO empty flag (TFE) is set. Software has no visibility of the transmit FIFO pointers, but a transmit FIFO threshold value can be set to alert the software when the number of bytes in the FIFO has reached a specified level. A read of the transmit FIFO register (XMT_BUF) will return the last byte written to the FIFO. Writes to the transmit FIFO can occur at any time.

The transmit FIFO can be flushed by setting the XMT_FLUSH bit in the RESET_CNTL register. A transmit NACK threshold error (XTE) will halt the transmitter, and flush the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The Transmit data threshold flag (TDTF) does not get cleared by the XMT_FLUSH operation.

11.2.3.4.4 Transmit Guard Time Generator

The guard time generator is simply a counter that is clocked by the transmit clock in order to delay the beginning of the next transmission and the setting of the transmit complete interrupt flag (TC) by a programmable amount of transmit bit widths (ETU's). The duration of the count is controlled by the GUARD_CNTL register (GETU[7:0]). See the figure below for depiction of three transmit operations in order to show the effect of the guard time generator logic

.

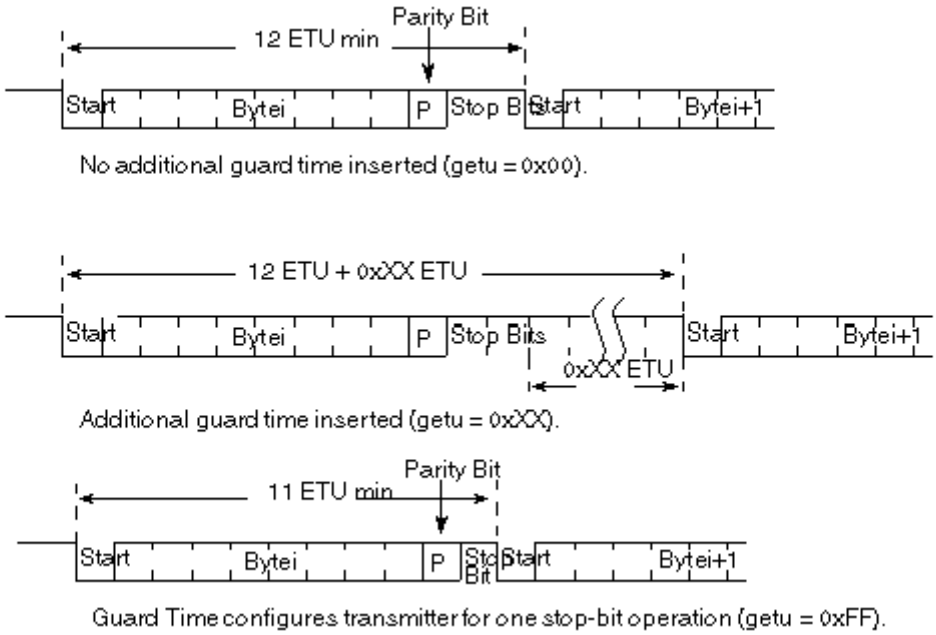

Figure 11-40. Transmit Guard Time

11.2.3.4.5 Transmit NACK Generator

The transmit NACK generator is responsible for driving the transmitter output low during the STOP bit time to signify an error was detected in the received data from the SIM card. This logic responds to a NACK request generated by the receiver block. The figure below shows a typical SIM transaction with the NACK pulse inserted.

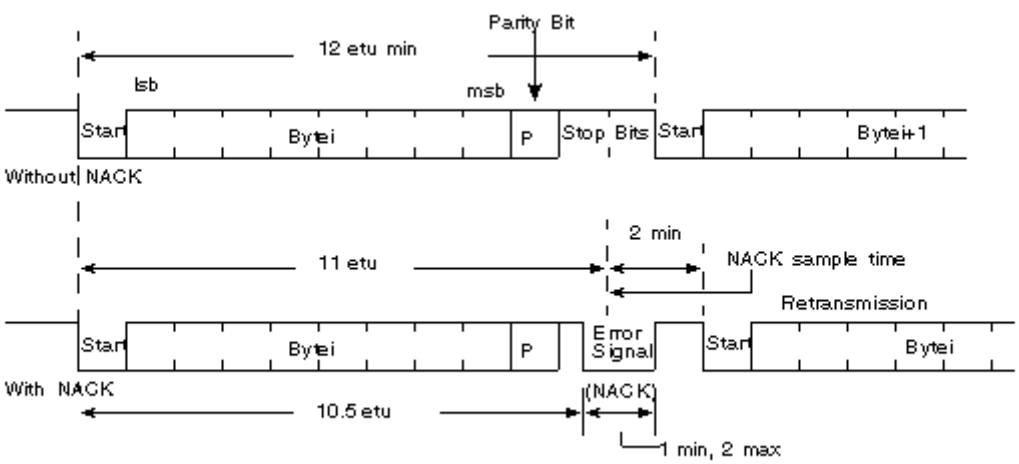

Figure 11-41. Transmit NACK Generator

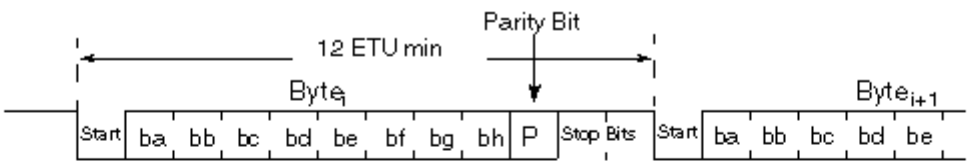
The transmit NACK generator is also responsible for keeping track of the number of NACKs received during a transmit operation. The SIM receive state machine detects NACKs generated by the SIM card, and reports them to the transmit NACK logic. Once the number of detected NACKs has reached the programmed threshold (XTH[3:0]), an interrupt flag is generated, the transmit FIFO is flushed, and the transmitter is disabled.

11.2.3.4.6 Transmit Data Convention Logic

The transmit data convention logic provides the support for the two different data conventions available in SIM cards. See the figure below for an illustration of SIM data conventions.



Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
When configured for inverse convention, the parity bit is inverted by USIM before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
Both the data bits and parity bit are logically inverted by hardware.

Figure 11-42. SIM Data Conventions

The direct data convention is the default. If the inverse convention bit (IC) in the DATA_FORMAT register is set, then the transmit data convention logic will convert the output of the transmit FIFO to the inverse convention before sending it to the transmit shift register.

11.2.3.5 SIM Receiver

The SIM Receiver block has been designed to localize all receive related circuitry into one section of hierarchy. The receiver block is comprised of the following functions: receive state machine and the receive FIFO.

11.2.3.5.1 Receive State Machine

The receive state machine is responsible for sampling the receive data pin and capturing the bit value into the receive shift register. Additionally, the receive state machine can detect the START bit, parity errors, framing errors, and initial character when operating in initial character mode.

Once enabled by the RCV_EN bit in the ENABLE register, the receive state machine sequences through the states as shown in the figure below.

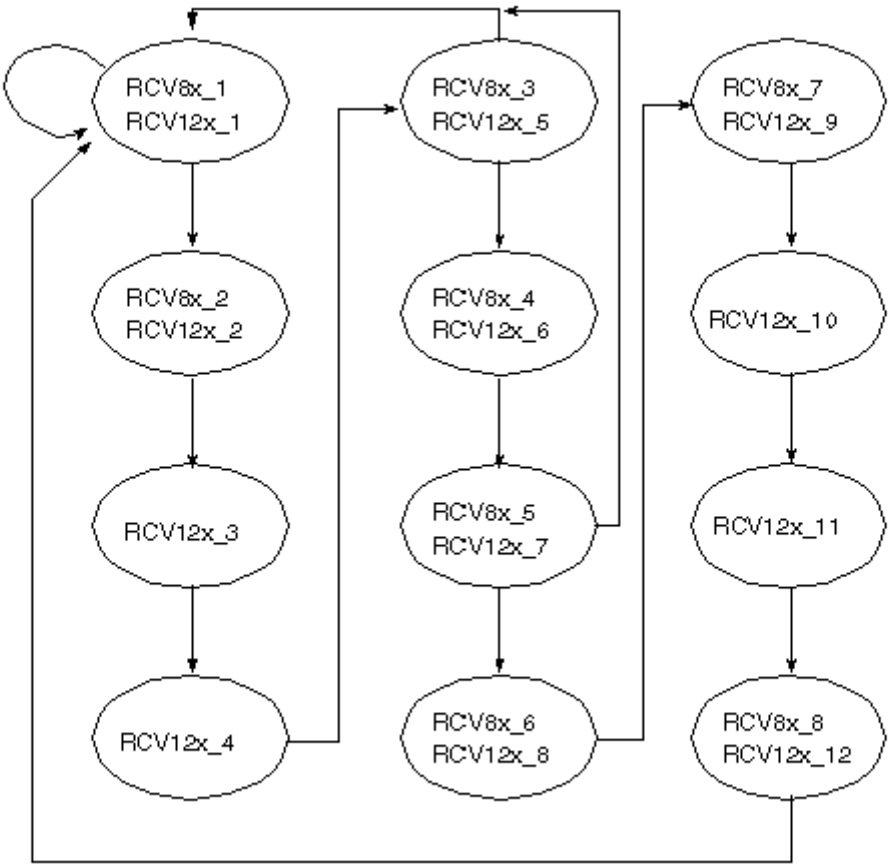


Figure 11-43. Receive State Machine

The states identified with a "8x" are used when operating in a 8x oversampling mode. The states identified with a "12x" are used when operating in a 12x oversampling mode. This mode is only used when sample12 is set to "1". The number following the oversampling mode identifier represents the state number in the current mode. There are 12 states in "12x" mode, and 8 states in "8x" mode. Some states simply implement a one RCV_CK delay. States that perform additional functions are:

- RCV8x_1, RCV12x_1

    - This is the initial state of the receive state machine. If the first bit has not been received, the state machine remains in this state until a valid START bit is detected. For every subsequent bit, this state is simply a one RCV_CK cycle delay.
- RCV8x_2, RCV12x_2
    - This state captures the first sample of the current receive data input.
- RCV12x_3
    - This state captures the second sample of the current receive data input.
- RCV12x_4
    - This state captures the third sample of the current receive data input.
- RCV8x_3, RCV12x_5
    - This state checks if we are receiving a correct START Bit. If not, Then we return to state 1.
- RCV8x_4, RCV12x_6
    - If we are in the 11th Bit, We check for Parity or Initial Character errors and send NACK if needed.
- RCV8x_5, RCV12x_7
    - Store current Bit value in Shift Register. If this is the first bit and the value is not 0, restart the State Machine.
- RCV8x_6, RCV12x_8
    - If the current bit is the last bit of the transfer, Set flag to transfer Shift Register to Receive Buffer.
- RCV8x_7, RCV12x_9
    - Clear flag for transferring Shift Register to Receive Buffer.
- RCV12x_10
    - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV12x_11
    - If the current bit is the last bit of the transfer (first stop bit), this state takes the sample of the NACK window.
- RCV8x_8, RCV12x_12
    - This state represents the end of the current receive input bit. Several operations occur during this state, including:
        - Increment bit counter
        - Perform a majority vote on the NACK samples and notify the transmitter if a NACK pulse was detected.

11.2.3.5.2 Data Sampling / Voting

The receive state machine runs at the receive clock rate (RCV_CK). This clock is used to oversample the received data at either a 8X or 12X sample rate. For each input bit, the receive state machine captures 3 samples. A majority voting algorithm is then applied to determine the value of the bit received. The value common to 2 or more of the samples is determined to be the bit value in the receive shift register.

11.2.3.5.3 Start Bit Detection

The SIM receive input is defined to be high when not active. The data transmission is defined to begin with a low pulse for a bit duration. This is called the START bit. The receive state machine is responsible for detecting and validating the START bit. The receive state machine samples the START bit three times using a majority voting scheme to determine if the START bit is valid. This will effectively filter out any low receive inputs shorter than one RCV_CK period. See the figure below for an illustration of a typical SIM data transaction with the START bit identified.

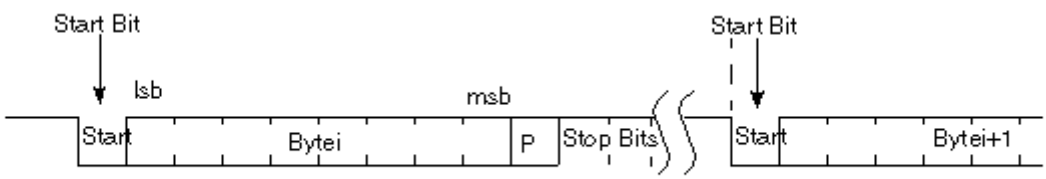

Figure 11-44. Start Bit Diagram

11.2.3.5.4 Parity Error Detection

The receive state machine is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except when in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented making the data appear to be odd parity. The parity bit is defined as the 10th bit of the received data. The parity of the 2nd through 10th received bits is calculated by the receiver parity logic. This logic determines if the parity of the 9 received bits is correct. See the figure below for an illustration of a typical SIM data transaction with the parity bit identified.

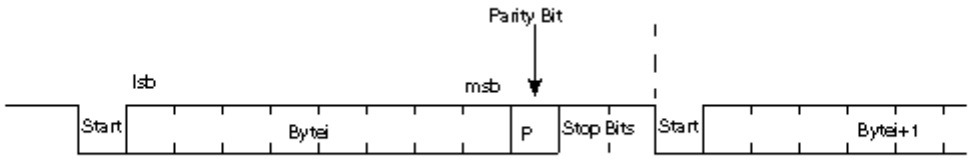

Figure 11-45. Parity Bit Diagram

When a parity error is detected on a given byte, the RCV_PF bit for that byte is set in the receive FIFO if NACK generation on errors is disabled (ANACK = 0 in the CNTL register). A parity error cannot cause an interrupt, but when NACK generation is enabled (ANACK = 1), it can signal the SIM transmitter to create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

11.2.3.5.5 Framing Error Detection

The receive state machine is responsible for detecting framing errors in the received data. A SIM data transaction is defined as 11 or 12 bits long consisting of the START bit, 8 data bits, 1 parity bit and 1 or 2 STOP bits. A framing error occurs when the STOP bit is not detected during the 11th bit time of a data transaction. The STOP bit is generally defined as two bit times (ETU's) of a high pulse following the parity bit. When the GUARD_CNTL register is programmed to 0xFF, the STOP bit is defined as one bit time. A framing error can only occur when the parity bit of the current byte is low, and the STOP bit arrives late. See the figure below for an illustration of a typical SIM data transaction with the STOP bits identified. Also, shown is a SIM data transaction with a late arriving STOP bit indicating a framing error.

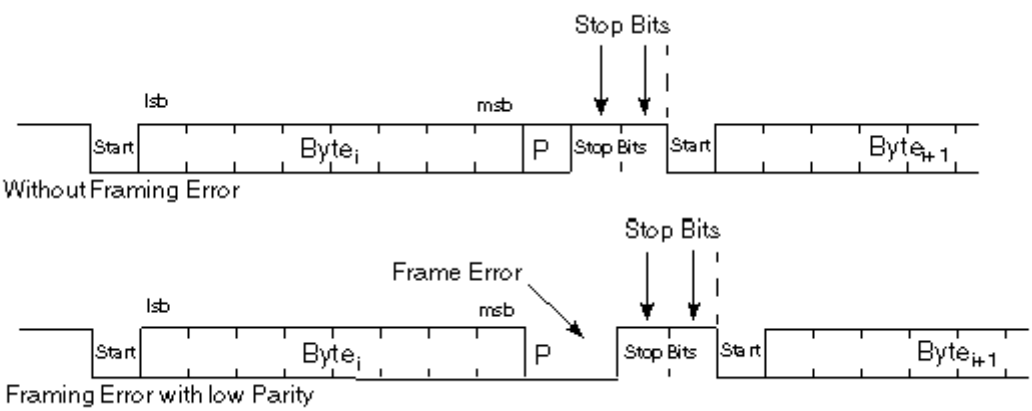

Figure 11-46. Framing Error Diagram

When a framing error is detected on a given byte, the RCV_FE bit for that byte is set in the receive FIFO. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the SIM card asking for a retransmission of the corrupted data.

11.2.3.5.6 NACK Detection

The existence of the NACK pulse is sampled by the receive state machine at 11 Elementary Time Units (ETUs) after the falling edge of the START bit. An ETU is equivalent in time to 1 transmit clock period. Once the receiver detects a NACK, it signals the transmitter that an error occurred. The transmitter will not initiate retransmission for at least another two ETU times as required by the ISO 7816 specification.

11.2.3.5.7 Initial Character Detection

The SIM receive state machine supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential characters that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. The following figures illustrate the differences between the two formats. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

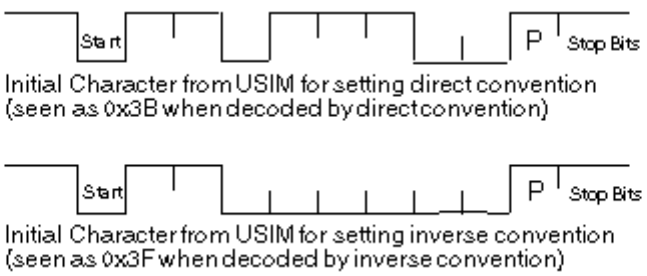

Figure 11-47. Valid Initial Characters

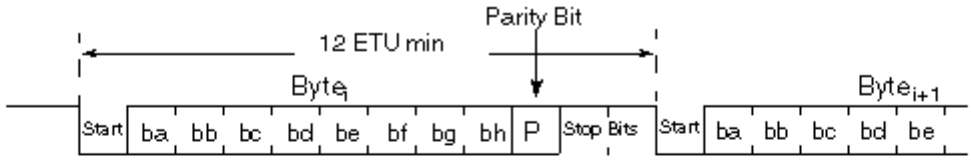

Parity Bit: if configured for even parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be even
if configured for odd parity, total number of logic ones in the 9 bits (8 bits data, 1 parity bit) will be odd
When configured for inverse convention, the parity bit is inverted by SIM card before being transmitted.

Direct Convention: *ba* is lsb of data byte to be sent. *bh* is msb.
Neither the data bits nor parity bit is logically inverted.

Inverse Convention: *ba* is msb of data byte to be sent. *bh* is lsb.
Both the data bits and parity bit are logically inverted by SIM card.

Figure 11-48. Inverse Convention versus Direct Convention

11.2.3.5.8 Receive FIFO

The receive FIFO is implemented inside a sub-block of the receiver block. The FIFO depth is 288 bytes. The FIFO block is shared by both SIM module ports. The receive FIFO cannot be accessed by another SIM module through the alternate port. Only the port1 IO pins can be accessed through the alternate port. The secondary SIM would then uses its own internal FIFO while using the primary SIM IO ports. This is only done if it is required to control two SIM cards at the same time. It the two SIM card access only occurs one at a time, then a single SIM module can control both SIM cards (one on port0 and one on port1). The receive FIFO is accessed through the RCV_BUF register.

The receive FIFO is loaded from the receive shift register after the final bit of the current SIM card transmission has been received. The FIFO contains 10 bits per transmission. The lower eight bits contain the received data byte. Bits 8 and 9 contain the parity and framing status for the received byte.

Each read from the receive FIFO increases the receive FIFO read pointer. Each time the receive shift register is transferred to the receive FIFO, the receive FIFO write pointer is increased. When the difference between the read and write pointers equals the programmed threshold value (RDT), the receive data register full flag (RDRF) will be set. An interrupt can be generated by the RDRF flag if the RIM bit in the INT_MASK register is cleared. Software has no visibility of the receive FIFO pointers. A write to the receive FIFO register (RCV_BUF) will generate an invalid access exception to the processor.

The receive FIFO can be flushed by setting the RCV_FLUSH bit in the RESET_CNTL register. The flush operation resets the receive read and write pointers to equal values. All logic associated with the receiver will be reset by the flush operation except for receiver control registers.

11.2.3.5.9 Overrun Detection

The receive FIFO logic is responsible for detecting an overrun condition. When a received byte is transferred from the receive shift register to a receive FIFO that contains 288 unread bytes, the SIM receiver will flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered. The SIM module will generate a NACK to the SIM card on an overrun condition if the ONACK bit in the CNTL register is set. The SIM module will continually NACK SIM card transmissions until a read of the receive FIFO occurs.

11.2.3.5.10 Character Wait Time Counter

The SIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters. When enabled, the Character Wait Time Counter (CWT) will not start counting until after the START bit(s) of a valid character has been received. The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The Character Wait Time Counter has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag will be set and an interrupt generated if the mask is clear.

11.2.3.6 SIM Port Control

The SIM Port Control block has been designed to localize all port related circuitry into one section of hierarchy. The port control block comprises the following functions: SIM card interface, SIM Card presence detect, and SIM card auto-power down.

11.2.3.6.1 SIM Card Interface

The SIM module allows for direct control of two separate SIM cards. The SIM module does not support simultaneous communication with two SIM cards. To achieve simultaneous communication with two SIM cards, a second SIM module must be used. The SIM module can relinquish control of the inactive port to a secondary SIM module by setting the AMODE bit in the SETUP register. When alternate SIM Card Mode enable, output signals in port1 is directly from the secondary SIM module and input signals in port1 will pass through to the secondary SIM module.

The SIM card clock is generated in the SIM clock generator. The SIM card reset is controlled by software through the PORT0_CNTL register. Since the SIM module does not support a separate transmit data and receive data port, the 3VOLT0 bit should be set to 1.

11.2.3.6.2 SIM Card Presence Detect

The SIMPDx input allows for detection of the insertion or removal of a SIM card. The SPDSx control bit in the PORTx_DETECT register allows the software to configure which edge of the SIMPDx pin will cause a presence detect event. A maskable interrupt can be generated when a SIMPDx event occurs.

An internal pull-down device is present on the SIMPDx pins. This will provide for a high to low transition on the SIMPDx pin when a SIM card is removed.

11.2.3.6.3 SIM Card Automatic Power Down

When interfacing to the SIM cards, it is necessary to follow a particular sequence when powering them up and down. The SIM port control block contains hardware that provides the correct sequence to power down a SIM card (see the figure below). The power up sequence must be done manually by the software using the pin control bits supplied in the PORTx_CNTL registers.

The power down sequence is specified in ISO 7816 as:

1. RST transitions from high to low
2. CLK is turned off to a low
3. I/O transitions from high impedance to low
4. SIM V_{CC} is turned off

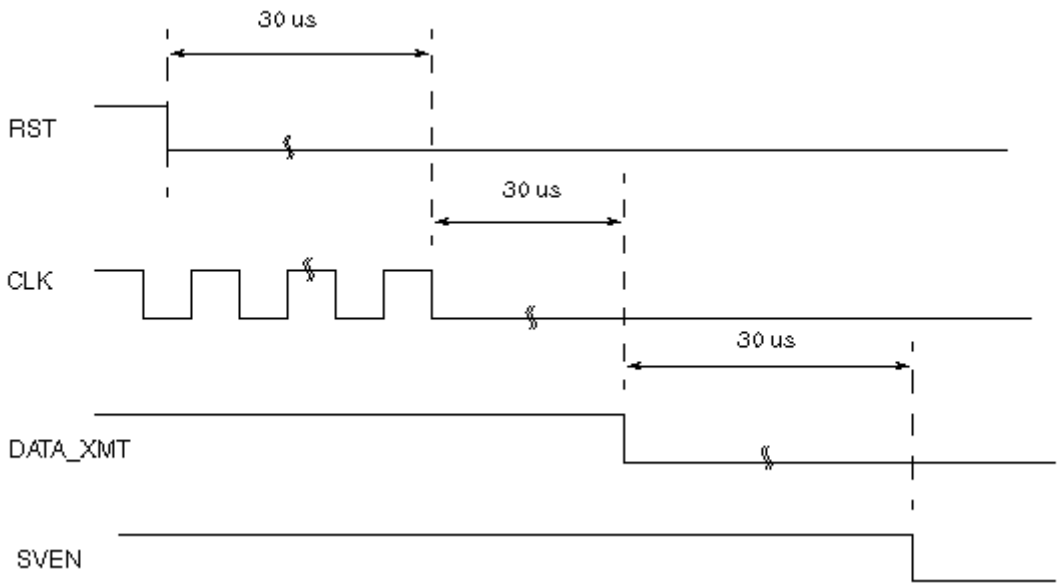

Figure 11-49. Auto Power Down Sequence

11.2.3.7 SIM General Purpose Counter

The SIM module provides a 16-bit counter for use when timing events during SIM card communication. The clock source for the counter is selectable between three sources: BAUD_CLK, RCV_CLK, or XMT_CK (ETU clock). The GPCNT_CLKSEL[1:0] bits in the CNTL register are used to select the clock input. The counter is enabled as soon as the input clock is selected. The starting of the counter is immediate once the input clock is running. Software can control the three input clock sources by using the KILL_CLOCK, RCV_EN and XMT_EN bits provided in the RESET_CNTL and ENABLE registers.

To run the counter from the card clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. 'GPCNT_CLKSET[1:0] = 01' in the CNTL register

The counter will begin to count at the card clock rate as soon as these conditions are met.

To run the counter from the receive clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. 'RCV_EN = 1' or XMT_EN = 1 in the ENABLE register
3. 'GPCNT_CLKSET[1:0] = 10' in the CNTL register

The counter will begin to count at the receive clock rate as soon as these conditions are met.

To run the counter from the ETU (transmit) clock source the following conditions must be met:

1. 'KILL_CLOCK = 0' in the RESET_CNTL register.
2. Either one of the following:
3. "RCV_EN = 1' in the ENABLE register and 'CWT_EN = 1' in the CNTL register

   'XMT_EN = 1' in the ENABLE register

4. 'GPCNT_CLKSET[1:0] = 11' in the CNTL register

The counter will begin to count at the ETU clock rate as soon as these conditions are met.

The counter can be reset by setting GPCNT_CLKSEL[1:0] to 00. A 16-bit comparator value is provided that allows the software to select a count value at which an interrupt flag can be set and an interrupt generated if the mask is clear.

11.2.3.8 SIM LRC Block

The SIM module provides an 8-bit Linear Redundancy Check (LRC) generator / checker. The block is provided for use with T=1 SIM cards that support LRC. This block can be enabled through the LRCEN bit in the CNTL register. This block performs an 8-bit exclusive-OR on all received or transmitted characters. At the end of the reception of a block of characters, the result is expected to be 00. If so, the LRCOK bit is set in the RCV_STAT register. During transmission, the LRC block Exclusive-ORs each character that is transmitted with the current value of the LRC. If the XMT_CRC_LRC bit in the CNTL register is set, the LRC value will automatically be sent by the SIM transmitter as the final character when the transmit FIFO empties.

The LRC value can be reset in multiple ways. Clearing the LCREN bit in the CNTL register will reset the LRC value. At the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the LRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the LRC value.

11.2.3.9 SIM CRC Block

The SIM module provides an 16-bit Cyclic Redundancy Check (CRC) generator / checker. The block is provided for use with T=1 SIM cards that support CRC. This block can be enabled through the CRCEN bit in the CNTL register. This block performs a polynomial based check on all received or transmitted characters. The polynomial description is shown in Figure 4-17. The polynomial used is the standard CRC-CCITT

where g(x) = x^16 + x^12 + x^5 + 1. The CRC register is initialized to all "1" before the data is shifted in. Before transmission the resulting CRC is inverted. For example, transmitting a 0xFA results in the following:

- Data = 0x5F (bit reversal of 0xFA)
- crc = 0x4AEA
- invert the crc = 0xB515 (bit reversal of 0xADA8
- data transmitted = 0xFA, 0xAD, 0xA8

See the figure below for an illustration of the SIM CRC block.

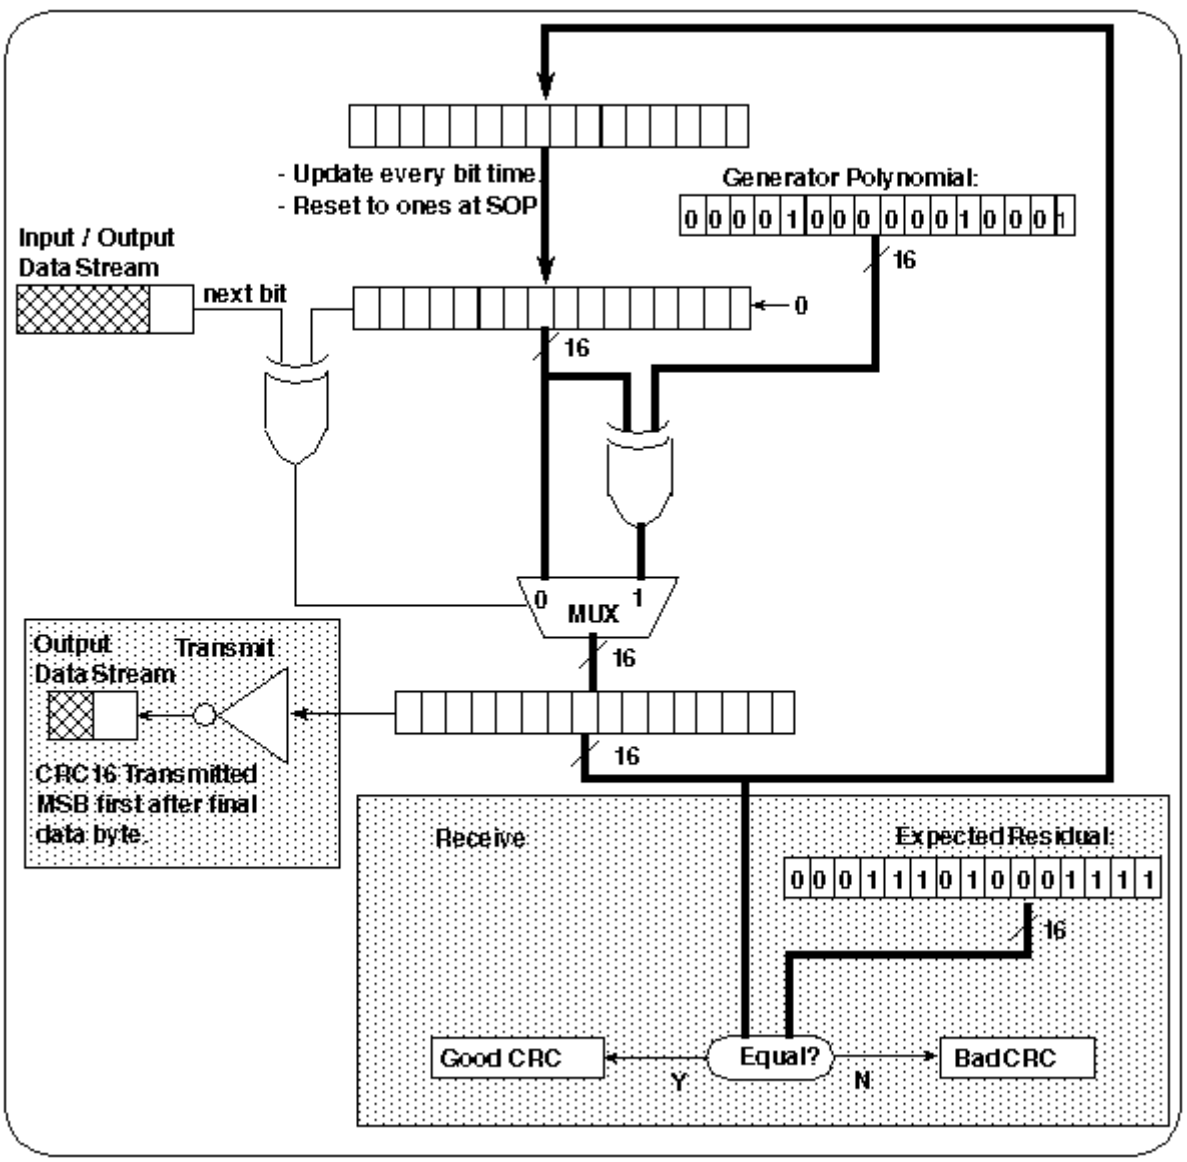

Figure 11-50. CRC Block Diagram

At the end of the reception of a block of characters, the residual from the CRC calculation is compared to 0x1D0F. If so, the CRCOK bit is set in the RCV_STAT register. During transmission, the CRC block updates the current value of the CRC residual using each character. If the XMT_CRC_LRC bit in the CNTL register is set, the CRC value will automatically be inverted and sent by the SIM transmitter as the final two characters when the transmit FIFO empties.

The CRC value can be reset in multiple ways. Clearing the CRCEN bit in the CNTL register will reset the CRC value. At the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when XMT_CRC_LRC is clear), the CRC value is automatically reset by the SIM hardware. Finally, when setting the XMT_EN bit, the SIM hardware resets the CRC value.

11.2.3.10 Module Interrupts

See the table below for the list of all possible interrupt sources and their corresponding mask bits. All SIM interrupts are logically ORed to create the active low irq_n and data_irq_n signals that go to the ITC module. All mask bits are such that a logic 1 implies that the corresponding interrupt is disabled (masked), whereas a 0 implies that the interrupt enabled (unmasked). All of these mask bits are logic 1 out of reset (all interrupts are masked).

Table 11-53. SIM Module Interrupts

Flag	Flag Register	Mask	Mask Register	Description
TC	XMT_STATUS	TCIM	INT_MASK	Transmit Complete
ETC	XMT_STATUS	ETCIM	INT_MASK	Early Transmit Complete
TFE	XMT_STATUS)	TFEIM	INT_MASK	Transmit FIFO Empty
XTE	XMT_STATUS	XTM	INT_MASK	Transmit Threshold Error
TFO	XMT_STATUS	TFOM	INT_MASK	Transmit FIFO Overfill error
TDTF	XMT_STATUS	TDTFM	INT_MASK	Transmit Data Threshold Flag
GPCNT	XMT_STATUS	GPCNTM	INT_MASK	General Purpose Counter Comparator Flag
RDRF	RCV_STATUS	RIM	INT_MASK	Receive data register full (FIFO threshold level reached)
OEF	RCV_STATUS	OIM	INT_MASK	Overrun Error Flag
CWT	RCV_STATUS	CWTM	INT_MASK	Character Wait Time Counter Comparator Flag
BWT	RCV_STATUS	BWTM	INT_MASK	Block Wait Time Counter Comparator Flag
BGT	RCV_STATUS	BGTM	INT_MASK	Block Guard Time Counter Comparator Flag
RTE	RCV_STATUS	RTM	INT_MASK	Receive NACK Threshold Error
SDI1	PORT1_DETECT	SDIM1	PORT1_DETECT	SIM Detect Interrupt for port 1
SDI0	PORT0_DETECT	SDIM0	PORT0_DETECT)	SIM Detect Interrupt for port 0

11.2.4 Initialization/Application Information

This section describes the intended programming model for using the SIM module. The section describes how to begin a typical mode of operation using the registers.

11.2.4.1 Configuring SIM for Operation

The following is a list of items that need to be performed in order to configure the SIM module for operation:

1. Port selection in the SETUP register.
   a. Select which SIM module port is active by writing the SPS bit.
   b. Select whether the second SIM module port is active at the same time under the control of an alternate SIM module by writing the AMODE bit.
2. Enable the selected port (for port 1, see PORT1_CNTL register; for port 0, see PORT0_CNTL) following the SIM power up procedure specified in ISO 7816.
   a. Program 3VOLT0 pin of PORT0_CNTRL register to 1.
   b. Enable power to the SIM card using the SVEN1 or SVEN0 bit.
   c. Enable SIM module transmit data output using the STEN1 or STEN0 bit. This is required to allow the SIM receiver to create NACK pulses.
   d. Enable SIM card clock using the SCEN1 or SCEN0 bit.
   e. Release the SIM card reset using the SRST1 or SRST0 bit (assert SRSTx high).
3. Select XMT port driver type (open-drain or push-pull) in the OD_CONFIG register.
   a. Configure the selected port to be open drain or push-pull by using the OD_P1 or OD_P0 bit.
4. Choose the port baud rate in the CNTL register.
   a. Select the SIM card clock rate by using the CLK_PRESCALER[7:0] register.
   b. Select the SIM card baud rate by using the BAUD_SEL[2:0] bits and SAMPLE12.

NOTE

Follow the ISO 7816 spec with regards to card clock frequencies to ensure the maximum frequency specification is not violated.

5. Select Data format type, or place SIM receiver in initial character mode.
   a. Select inverse convention or direct convention by using the IC bit in the DATA_FORMAT register, or
   b. Enable initial character mode by using the ICM bit in the CNTL register.

11.2.4.1.1 Configuring SIM Receiver

The following is a list of items that need to be performed in order to configure the SIM receiver for operation:

1. Enable NACK capability in CNTL register.
   a. Select NACK generation on parity errors, or invalid initial character by using the ANACK bit.
   b. Select NACK generation on overrun conditions by using the ONACK bit.
2. Select the desired Receive NACK threshold and receive FIFO threshold in RCV_THRESHOLD register.
   a. Program the threshold at which the RDRF flag will be set by using the RDT bits.
   b. Program the threshold at which the RTE flag will be set by writing to the RTH[3:0] bits. If an auto power down after RTE flag is set, is desired, then enable the SIM card auto power down by setting the SAPD0,1 bits in the port0,1_cntl register.
3. Configure the Character Wait Time Counter, the Block Wait Timer Counter and the Block Guard Time Counter.
4. Enable interrupts in the INT_MASK register.
   a. Enable the receive data register full interrupt by using the RIM bit
   b. Enable the receive threshold error interrupt by using the RTM bit.
   c. Enable the overrun condition interrupt by using the OIM bit.
   d. Enable the Character Wait Time interrupt by using the CWTM bit
5. Enable enforce reception early stop function in ENABLE register.
   a. Enable the enforce reception early stop enable by using the ESTOP_EN bit.
   b. Enable the enforce reception early stop execution by using the ESTOP_EXE bit.

11.2.4.1.2 Configuring SIM Transmitter

The following is a list of items that need to be performed to configure the SIM transmitter for operation:

1. Select desired re-transmission threshold for NACKed characters in XMT_THRESHOLD register.
   a. Program the threshold at which the XTE flag will be set by using the XTH[3:0] bits.
2. Select the guard time between transmissions in the GUARD_CNTL register.
   a. Program the desired guard time between characters transmitted by the SIM module by using the GETU[7:0] bits.
3. Select the desired Transmit FIFO threshold level in the XMT_THRESHOLD register.
   a. Program the desired threshold using the TDT[3:0] bits.
4. Enable interrupts in the INT_MASK register.

a. Enable the transmit complete interrupt by using the TCIM BIT.
b. Enable the early transmit complete interrupt by using the ETCIM bit.
c. Enable the transmit FIFO empty interrupt by using the TFEIM bit.
d. Enable the transmit threshold error interrupt by using the XTM bit.
e. Enable the transmit FIFO threshold interrupt by using the TDTFM bit.
f. Enable the transmit FIFO overfill interrupt by using the TFOM bit.

5. Enable NACK delay detection in ENABLE register.
   a. Enable the NACK delay detection enable by using the NACK_DD_EN bit.

11.2.4.1.3 Configuring SIM General Purpose Counter

The following is a list of items that need to be performed in order to configure the SIM General Purpose Counter for operation:

1. Select desired clock source for the General Purpose Counter using the CNTL register.
   a. Use the GPCNT_CLKSEL[1:0] bits to select the desired clock source for the counter
2. Program counter comparator using the GPCNT register.
   a. Use the GPCNT[15:0] bits to select the desired count value at which the GPCNT interrupt flag will be set.
3. Enable the selected clock source for the General Purpose Counter using either the RESET_CNTL or ENABLE registers.
   a. If the GP Counter is configured for the card clock, enable the clock by clearing the KILL_CLOCK bit in the RESET_CNTL register.
   b. If the GP Counter is configured for the receive oversample clock, enable this clock by setting the RCV_EN bit or XMT_EN bit in the ENABLE register.
   c. If the GP Counter is configured for the transmit oversample clock, enable this clock by setting the XMT_EN bit in the ENABLE register.
4. Enable interrupts in the INT_MASK register.
   a. Enable the general purpose counter interrupt by using the GPCNTM bit.

11.2.4.1.4 Configuring SIM to Measure WWT (Work Wait Time) for Type=0 Smartcards

The following is a list of items that need to be performed in order to configure the SIM to measure work wait time. This is intended for type=0 SmartCards. Work wait time is a combination of BWT and CWT. The CWT timer is to measure the time between the start bits of two consecutive characters in the block received from the SmartCard. If this time is larger that the value programmed in the cwt[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT and BGT timer are used to measure the delay between the leading edge of the

last character of the block received by the card and the leading edge of the first character of the next block sent by the card. If you want the SIM to enforce a WWT of 100 bits. Then, you must activate both the CWT and BWT, and program both of them for a value of 100 bits. When measuring WWT, the BGT timer will not be used so it will be masked (inactive) by the BGTM bit. Below is the sequence to program the SIM to send and receive data while checking WWT.

1. Program both the CWT and the BWT (low and high) registers to the WWT (work wait time) value that needs to be enforced. Set BGT register to 0 (this is the default value).
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT and BWT interrupts by clearing the CWTM and BWTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should consider that a WWT violation. The software should clear the CWT or BWT interrupt by writing a "1" to the BWT or CWT bit in the RCV_STATUS register.

11.2.4.1.5 Configuring SIM to measure CWT, BWT, BGT for type=1 SmartCards

The following is a list of items that need to be performed in order to configure the SIM to measure CWT, BWT, BGT. This is intended for type=1 SmartCards. The CWT timer is to measure the time between start bits in the consecutive characters received from the SmartCard. If this time is larger that the value programmed in the CWT[15:0] register, then a flag will be set and an interrupt generated. This timer can be used for both type=0 and type=1 SmartCards. The BWT, BGT timer is used to measure the delay between the leading edge of the last character of the block received by the card and the leading edge

of the first character of the next block sent by the card. If this time is larger than the value in the both BWT registers (BWT and BWT_H), then the BWT flag will be set and an interrupt generated. If the time is less than the value in the BGT register, then the BGT flag will be set and an interrupt generated.

1. Program the CWT, BWT, BWT_H and BGT registers to the value that needs to be enforced.
2. Activate both the CWT and BWT functions by setting the CWTEN and BWTEN bit in the CNTL register.
3. Enable the CWT, BWT, BGT interrupts by clearing the CWTM, BWTM, BGTM bits in the INT_MASK register.
4. Program the data to send to the SmartCard by writing data to XMT_BUFFER
5. Activate the SIM transmit and receive by setting bits XMT_EN and RCV_EN in the ENABLE register.
6. If the software has more data to send, then as the FIFO starts to get near empty, it should write more data to the XMT_BUFFER. If the software does not have any more data to send then proceed to the next step.
7. When SmartCard has completed its transmission to the SIM module, disable the BWT by clearing the bit BWTEN in the CNTL register. This will prepare SIM to measure the next block wait time.
8. Disable the SIM transmitter by clearing the XMT_EN bit in the ENABLE register.
9. Program the next data to send by writing data to the XMT_BUFFER.
10. Enable the BWT function by setting the BWTEN bit in the CNTL register.
11. Enable the SIM transmitter by setting the XMT_EN bit in the ENABLE register.
12. Steps 6 to 10 can be repeated for each transmission to the SmartCard.
13. If a CWT or a BWT interrupt occurs, then the software should read the RCV_STATUS register to determine if the error was caused by a CWT, BWT, or a BGT violation. The software should clear the CWT, BWT, BGT interrupt by writing a "1" to the CWT, BWT, BGT bit in the RCV_STATUS register.

11.2.4.1.6 Configuring SIM Linear Redundancy Check (LRC) Block

The following is a list of items that need to be performed in order to configure the SIM Linear Redundancy Check Block for operation:

1. Enable the LRC block by using the CNTL register.
   a. Use the LRCEN bit to enable the LRC block.
   b. Use the XMT_CRC_LRC bit to enable the transmission of the LRC Character after the last character in the Transmit FIFO is sent. Refer to the T=1 programming model for more details.

11.2.4.1.7 Configuring SIM Cyclic Redundancy Check (CRC) Block

The following is a list of items that must be performed to configure the SIM Cyclic Redundancy Check Block for operation:

1. Enable the CRC block by using the CNTL register.
   a. Use the CRCEN bit to enable the CRC block.
   b. Use the XMT_CRC_LRC bit to enable the transmission of the CRC Characters after the last character in the Transmit FIFO is sent. Refer to the T=1 Programming model for more details.

11.2.4.2 Using the SIM Receiver

Once the SIM has been properly configured (such as correct baud rate and correct data format), SIM receptions can be enabled by setting the receive enable bit, RCV_EN, in the ENABLE register. As bytes are received, they will be placed in the 288 byte deep receive data FIFO. Unread bytes can be accessed from this FIFO at any time. There is no need to disable the receiver to access the FIFO. The FIFO should only be read when the receive FIFO data flag, RFD, in the RCV_STATUS register is set. The RFD flag, which cannot create an interrupt, is high any time there is at least one unread byte in the receive FIFO. If the receive FIFO is read when RFD is low, it will simply produce the last byte read.

The receive data register full flag, RDRF, in the RCV_STATUS register can be used to determine when the receive FIFO has reached a given threshold value. This flag will create an interrupt if the RIM bit in the INT_MASK register is clear. To control at which point RDRF is set, program the receive data threshold, RDT, in the RCV_THRESHOLD register. If the number of unread bytes in the receive FIFO is equal to or greater than the value set by RDT, RDRF will be set.

NOTE

A value of 0x0 in RDT implies that there must be 288 unread bytes in the receive FIFO to trigger RDRF.

The standard flow for receiving bytes from the SIM card is to set RDT to the appropriate value, wait for RDRF to cause an interrupt (RIM clear), and then read bytes out of the receive FIFO as long as RFD is high. In addition to checking RFD between every byte, it is also recommended that software check for the existence of a set OEF flag as well.

11.2.4.2.1 Receive Parity Errors and Parity NACK Generation

The SIM receiver checks every byte received for proper parity. The IC control bit in the DATA_FORMAT register controls whether it checks for odd parity or even parity. When checking for odd parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be odd. Likewise, when checking for even parity, the number of logic ones contained in the 9 received bits (8 data bits and 1 parity bit) should be even.

If NACK generation on errors is disabled (ANACK = 0 in the CNTL register), the PORTx_PE bit will be set when the SIM receiver detects a parity error, the received data byte and its PORTx_PE bit are placed into FIFO. There is no need to clear the parity error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A parity error cannot cause an interrupt, and it is up to the software to discard data bytes with parity errors.

If NACK generation on errors is enabled (ANACK =1), the SIM can automatically request the SIM card to re-send a byte that has a parity error by generating a NACK pulse on the SIM XMT pin. In this case, Bytes with parity errors are discarded and will not placed into the FIFO.

To control NACK generation by the SIM receiver use the RTH[3:0], Receive NACK threshold, in the RCV_THRESHOLD register. This set of bits specify the number of consecutive NACK's generated by the SIM module on a received byte, before generating an RTE (receive threshold interrupt flag) in the RCV_STATUS register. The RTE flag would also force the SIM port to power down the card if the SAPD0,1 bit is set in the PORT0,1_CNTL register.

NOTE

The ANACK bit must be set in the CNTL register to enable this feature. The control bit ANACK is also used in initial character mode to enable the retransmission of initial characters in the event that an invalid initial character is received.

When a valid character has been received by the SIM, the internal counter keeping track of the number of NACK's transmitted on the current byte resets to zero. Clearing the receive threshold error (RTE) bit would also clear that counter.

When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

11.2.4.2.2 Receive Frame Errors

The SIM receiver checks every byte received for a proper stop bit. A stop bit should exist during at least the first half of the 11th ETU time after the start of the character. If this is not true, a frame error is flagged. When a frame error is detected on a given byte, the

PORTx_FE bit for that byte is set in the FIFO. The PORTx_FE flag for each byte is read out of the FIFO when the data itself is read. There is no need to clear the frame error flag in the FIFO. It is simply overwritten the next time a byte is received into that position of the FIFO. A frame error cannot cause an interrupt, nor can it create a NACK pulse to the receiver asking for a retransmission of the corrupted data.

11.2.4.2.3 Receive Overrun Errors and Overrun NACK Generation

When there already exists 288 unread bytes in the FIFO, a received character will cause the SIM receiver to flag an overrun condition. This condition will always set the overrun error flag, OEF in the RCV_STATUS register. The received byte will be discarded leaving the 288 unread bytes in the FIFO unaltered.

It is possible for the SIM to automatically request that the SIM card re-send the byte that caused the overrun condition by generating a NACK pulse on the SIM XMT pin. The SIM will generate a NACK pulse for the byte that caused the overrun condition if the control bit ONACK in the CNTL register is set. In this case, the existence of an OEF flag does not indicate the loss of data, but rather a NACK (that is, retransmission request) due to a full receive FIFO. As opposed to transmit NACK generation, there is no limit to the number of times an overrun condition will cause a NACK other than to disable ONACK itself. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETU.

If the control bit ONACK is clear, the existence of a high OEF flag indicates the loss of data. The OEF flag can create an interrupt if the OIM bit in the INT_MASK register is clear.

To clear the OEF flag, software must simply write a "one" to the OEF bit position in the RCV_STATUS register. A high OEF flag has no effect on the operation of the SIM receiver other than to create an interrupt if OIM is clear.

11.2.4.2.4 Using Initial Character Mode and Resulting Receive Data Formats

The SIM receiver supports the detection of special characters that allow it to determine what data format is being used by the connected SIM card. When placed in initial character mode, the SIM expects to receive one of two potential values that it will use to set the data format control bit, IC, in the DATA_FORMAT register.

The two possible data formats are inverse convention and direct convention. Essentially, inverse convention differs from direct convention in that the order of the data is flipped msb for lsb, and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

To place the SIM into initial character mode, set the ICM bit in the CNTL register. Once a valid initial character is received, the IC bit in the DATA_FORMAT register will be set accordingly by the hardware, and the ICM bit will be cleared. Software can read the state of the IC bit to determine which mode the SIM is currently using.

The 0x3B (as decoded by direct convention) with parity bit high will cause direct convention to be used (IC set to logic 0), whereas a 0x3F (as decoded by inverse convention) with parity bit high will cause inverse convention to be used (IC set to logic 1).

When the receiver is in initial character mode, all received bytes will continue to be placed into the receive FIFO whether they be valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes will be decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if the IC bit is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters will be stored in the FIFO after having been decoded using inverse convention (for example, the initial character will be stored as 0x3F).

If the receiver is in initial character mode (ICM is high), and an invalid initial character is received, the SIM can be configured to automatically request that the initial character be retransmitted by setting the ANACK control bit in the CNTL register. When generating a NACK pulse, the SIM will generate the low pulse starting at 10.5 ETUs and lasting for 1 ETUs. The invalid initial character will be placed into the receive FIFO and marked with a parity error to signify that this is an invalid initial character.

11.2.4.2.5 Initial Character Mode Programming Notes

The usage of the initial character mode requires close attention to the programming model. There is a condition where a parity error in the initial byte for direct convention (0x3B) could be decoded as what appears to be a valid initial character for inverse convention (that is, 0x3F). The SIM module will not recognize this as a valid initial character for inverse convention and will mark the character by setting the parity error flag. The software must look for the existence of a parity error before recognizing a character as a valid initial character.

11.2.4.2.6 Automatic Receiver Mode

The SIM module has an automatic receive mode that inhibits the data being transmitted by the SIM module from entering the SIM receive buffer through the feedback path of the SIM data pin. The SIM module receiver should normally be enabled while the transmitter is operational. Automatic receive mode saves the software from having to actively manage the transition from transmitter to receiver. The auto receive mode is always active whenever the receiver is enabled.

11.2.4.2.7 Using the SIM Receiver with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM receiver are as follows:

- 11 ETU Characters
  - "T=1" cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). The SIM module provides the RCVR11 bit in the GUARD_CNTL register in order to configure the receiver state machine to accept 11 ETU characters.
- Character Wait Time Counter
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the SmartCard. The value of CWT can range from 12 ETU to 32779 ETU. The SIM module provides a 16-bit counter with programmable comparator clocked at the ETU bit rate to identify when the CWT has been exceeded by the SIM card.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that is programmable. The SIM module provides a 32-bit Block Wait Timer that can be used to identify when the BWT has been violated (divided in two registers).
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that is programmable. The SIM module provides a 16-bit Block Guard Timer that can be used to identify when the BGT has been violated.
- Error Detection Code
  - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operations.

11.2.4.3 Using the SIM Transmitter

Once the SIM has been properly configured (such as data XMT enabled, correct baud rate, and correct data format), the transmitter can be enabled by setting the XMT_EN bit in the ENABLE register. If data had been previously written to the transmit FIFO, the transmitter will begin to send the first character. If no data is written to the transmit FIFO before enabling the transmitter, then the transmitter will wait until the first character is written before beginning transmission. Clearing the XMT_EN bit while the transmitter is in operation, will halt any transmission in progress, flush the transmit FIFO, and reset the transmit state machine.

Data can be written to the transmit FIFO at any time.

The transmit data threshold flag, TDTF, in the XMT_STATUS register can be used to determine when the transmit FIFO has reached a given threshold value. This flag will create an interrupt if the TDTFM bit in the INT_MASK register is clear. To control at which point TDTF is set, program the transmit data threshold, TDT[3:0], in the XMT_THRESHOLD register. If the number of bytes remaining in the transmit FIFO is equal to or less than the value set by TDT[4:0], TDTF will be set.

NOTE

A value of 0x0 in TDT[3:0] implies that the transmit FIFO must be empty to trigger TDTF.

The value in TDT[3:0] can be changed at any time to alter this threshold level. The comparison between the number of remaining bytes in the transmit FIFO and the value set by TDT[3:0] is continuously updated so that any change in either will be immediately reflected in the state of TDTF. Unlike the RDRF flag for the receive FIFO, TDTF is latched and remains set until the software writes a 1 to the TDTF bit location in the XMT_STATUS register. For instance, if TDT[3:0] is set to 5, and there are 6 bytes remaining in the FIFO, changing TDT[3:0] to 6 will immediately cause TDTF to be set. However, setting TDT[3:0] back to 5 will not cause TDTF to clear.

The standard flow for transmitting bytes from the SIM card is to set TDT[3:0] to the appropriate value, write up to 16 bytes to the transmit FIFO, enable the transmitter, wait for TDTF to cause an interrupt (TDTFM clear), and then write additional bytes to the transmit FIFO.

NOTE

For the SIM module to transmit successfully, the transmit pin must be connected to the receive pin of the same port. This connection is necessary for the SIM to decode transmit NACKs sent to it by the SIM card. Without this connection, all transmissions will appear to have a NACK thereby causing the first byte to be transmitted continuously. When operating in

external one wire interface mode (3VOLT0 or 3VOLT1), this connection is made internal to the SoC.

11.2.4.3.1 Transmit Data Formats

There are two possible data formats that the SIM module uses when transferring data to the SIM: card - inverse convention or direct convention. The format used depends on the state of inverse convention bit (IC in the DATA_FORMAT register). Software can set the IC bit, or it can be set automatically by hardware when using the initial character mode.

11.2.4.3.2 Transmit NACK

The SIM transmitter can respond to NACKs created by the SIM card. A NACK will be decoded if the SIM card creates a logic low level on the SIM receive pin during the STOP bit time at the end of a transmitted byte. To prevent a situation where the SIM interface is stalled by an infinite number of NACK pulses on a given byte, the SIM module can be configured to limit the number of times it will respond to NACKs. The XTH[3:0] control field in the XMT_THRESHOLD register allows software to set a threshold on the number of times a given byte will be retransmitted. If the threshold is reached, a transmit threshold error, XTE in the XMT_STATUS register, is asserted.

When XTE is set, the SIM transmitter is halted, and all pending transfers are aborted, and the TC, ETC, AND TFE flags are set. All bytes remaining in the transmit FIFO are lost. There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until XTE is cleared by software. The only way to clear XTE is to write a 1 to the XTE bit in the XMT_THRESHOLD register. The XTE flag can create an interrupt if the XTM mask in the XMT_THRESHOLD register is clear.

It is possible to disable the detection of NACKs from the SIM card by setting XTH[3:0] to 0x0. By setting XTH[3:0] to 0x1, it is possible to disable all retransmissions while still setting XTE on the first NACK received. In general, XTE is set on the NACK that causes the threshold set by XTH[3:0] to be reached. This final NACK will not cause a retransmission, whereas all previous NACKs will cause a retransmission.

11.2.4.3.3 Transmit Guard Time

The time between data bytes sent from the SIM transmitter can be altered using the transmit guard time control. By default, the minimum time between start bits of successive transmitted bytes is 12 ETUs (Elementary Time Units). An ETU is equivalent in time to 1 bit time. Therefore, the amount of time an ETU consumes is determined by the baud rate chosen. The 12 ETUs that form the default character transmission time consist of a start bit, 8 data bits, a parity bit and two stop bits. The number of stop bits (idle bits) can be extended by an integer number of ETUs. The number of additional

ETUs can be programmed directly into the GETU[7:0] bits of the GUARD_CNTL register. Programming the GETU[7:0] bits to 0xFF will configure the SIM transmitter to use only one stop bit for each character transmission.

11.2.4.3.4 Using SIM Transmit with "T=1" SIM Cards

The SIM module provides hardware support for "T=1" type SIM cards. These type of cards present several requirements above and beyond the standard "T=0" cards. The features provided to meet the requirements that pertain to the SIM transmitter are as follows:

- 11 ETU Characters
  - The SIM module transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (0xFF) in the GETU[7:0] bits in the GUARD_CNTL register will set the number of ETUs per character transmitted to 11.
- Character Waiting Time
  - The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters. The value of CWT can range from 12 ETU to 32779 ETU. The time between transmitted characters is controlled by the programmable guard time in the GUARD_CNTL register. However, the time between the last byte in the transmit FIFO, and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The SIM transmitter provides a Transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters have been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the Transmit FIFO has been sent.
- Block Waiting Time
  - The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The SIM transmitter provides a General Purpose Counter that can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
- Block Guard Time
  - The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The SIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after the XMT_EN bit is set. The BGT

will be determined by the speed at which the software can react to an interrupt and enable the transmitter.

- Error Detection Code
  - "T=1" cards can specify LRC or CRC error detection codes to be used. The SIM module provides hardware support for both the LRC and CRC operation.

11.2.4.4 Suggested "T=1" Compliant Programming Model

This section describes the suggested programming model for supporting "T=1", "T=0", and known "special" cards using the SIM module on the device. This should be used as a rough guide for how to configure the SIM module for use with SIM cards specified by ISO 7816-3 and EMV. Some details are not addressed. Other uses for some of the SIM features are not included (for example, GP Counter uses for some ISO timing requirements).

11.2.4.4.1 Answer To Reset (ATR) Detection

The first step to communicating with a SIM card is to provide power and a clock signal to the card. Once the card is detected as present (using the presence detect features, or some other method), the SIM card should be powered up according to the power up sequence specified in the ISO 7816-3 specification.

1. Apply voltage to the SIM card by setting the SVEN0 or SVEN1 bit in the PORTx_CNTL register
2. Select the appropriate clock frequency for the SIM card by programming the CLK_PRESCALER[7:0] register.
3. Enable the clock to the SIM card by setting the SCEN0 or SCEN1 bit in the PORTx_CNTL register.
4. Remove the card from reset by setting the SRST0 or SRST1 bit in the PORTx_CNTL register.

   The first communication between the SIM card and the SIM module will be a block of data sent from the SIM card to the SIM module after the card is powered and the card reset is removed. This block is called the Answer To Reset (ATR). To receive the ATR, the SIM module should be configured for 12 ETU character reception. According to the ISO 7816-3 spec, both "T=0" and "T=1" cards will communicate initially using 12 ETU character durations.

NOTE

We are aware of some card manufacturers that communicate at 11.5 ETU character durations (Geldkarte).

This will complicate the initial card detection sequence shown below.

5. Clear RCVR11 bit in the GUARD_CNTL register

   The next item to configure for ATR reception is the NACK capability of the SIM module. The ISO 7816-3 spec allows the SIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

NOTE

The Europay Mastercard and VISA (EMV) cards are similar to "T=1", but do not allow the SIM module to NACK during the initial communication. This will again complicate the initial card detection sequence shown below.

6. Set ANACK bit in the CNTL register to enable NACK generation

   In order for the SIM module to notify when characters are received, the receive interrupt(s) can be enabled. A threshold can be set for the number of characters to receive before generating an interrupt.

7. Enable RDRF and OEF interrupts by setting RIM and OIM bits in INT_MASK register
8. Set desired threshold for received characters by writing RDT in RCV_THRESHOLD register.

   The SIM should be setup to perform in initial character mode. This will cause the hardware to identify the first valid character sent during the ATR as an initial character. This character will automatically configure the hardware for the data convention used by the SIM card.

9. Set Initial Character Mode by setting the ICM bit in the CNTL register

   The ISO 7816-3 spec requires that SIM cards meet certain timing restrictions. One of these is the time from the deassertion of the card reset to the beginning of the ATR sequence. The SIM module General Purpose Counter can be used to verify that the SIM card begins its ATR within the 400 to 40,000 clock cycle range.

1. Set General Purpose Counter Comparator to 0x9C40 using GPCNT register.
2. Enable General Purpose Counter Interrupt by clearing GPCNTM in INT_MASK register.
3. Enable General Purpose Counter by programming the GPCNT_CLKSEL[1:0] bits to 01 so the card clock is used for counting.

The ISO7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (Initial Waiting Time). The Character Wait Time Counter should be setup to detect any errors for this condition.

1. Set Character Wait Time Counter Comparator to 9600 using the CHAR_WAIT register
2. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register
3. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register

   The last step in preparing for ATR reception is to enable the receiver.

4. Set RCV_EN bit in ENABLE register

The SIM module will generate interrupts once a threshold number of characters is received. The software should react to these interrupts and read the characters from the receive FIFO (RCV_BUF) until the complete ATR has been received. If a General Purpose Counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec. Otherwise, once a valid ATR is received, the software will know from the ATR information the specific characteristics for this card (refer to the ISO 7816-3 spec for details).

11.2.4.4.2 Programming Considerations for Geldkarte Cards

There is at least one manufacturer of SIM cards (Geldkarte) that we know of that does not send the ATR in 12 ETU mode or support NACKs. This creates an issue with detecting a valid ATR from a SIM card. Since any kind of card can be attached to the SIM module, the software and hardware do not know how to begin communication. Basically, if the card fails to send a valid ATR on the first try, disable NACKs, configure the SIM module for 11 ETU and try again. The software should toggle between 12 and 11 ETU modes with and without NACKs enabled until a valid ATR is received, or the number of attempts to communicate passes a predetermined error threshold. The figure below shows the flow chart for the suggested Geldkarte Compliant SIM Initialization.

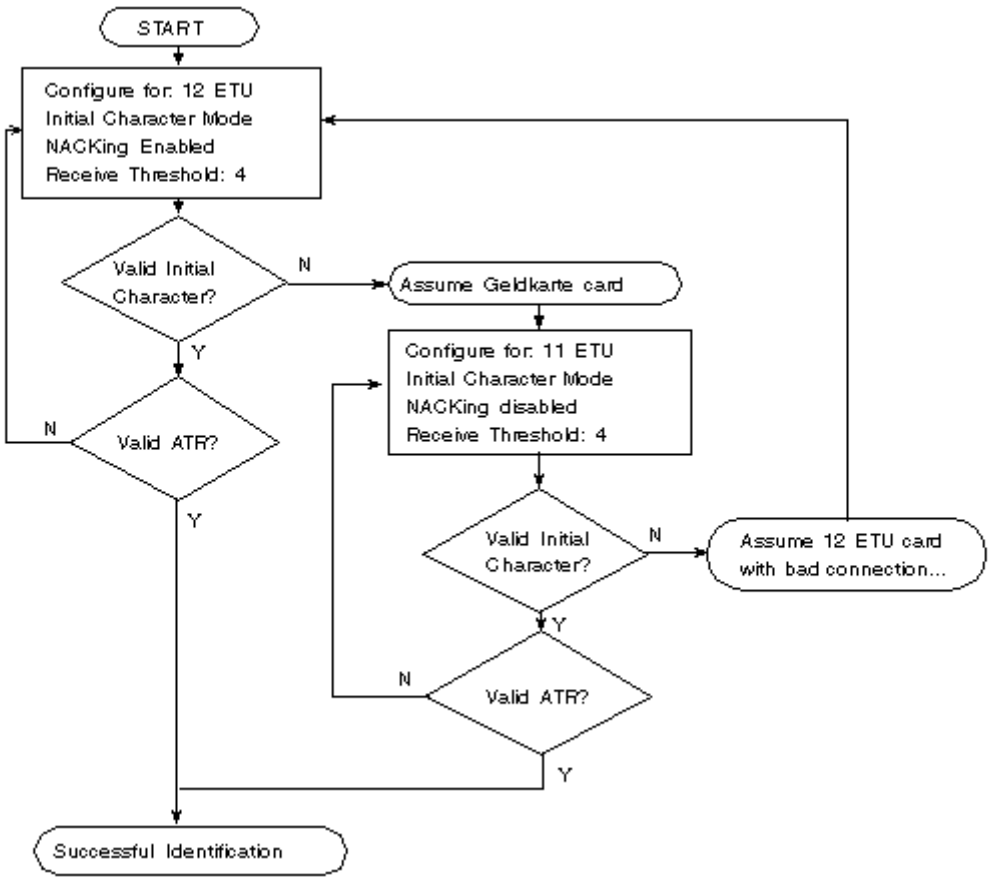

Figure 11-51. Suggested "T=1", EMV, Geldkarte Compliant SIM Initialization

11.2.4.4.3 Programming Considerations for T=0 SIM Cards

If the card is of type T=0, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register
3. Adjust NACK capability by modifying the values of the ONACK and ANACK bits in the CNTL register
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Adjust the level of transmit NACK re-transmissions allowed by modifying the value of the XTH[3:0] bits in the XMT_THRESHOLD register
6. Adjust the level for the Receive NACK threshold by modifying the RTH[3:0] bits in the RCV_THRESHOLD register.

If a negotiation with the SIM card is desired, the software sends a PPS response to the SIM card. To send the response, the following steps should be performed:

1. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
2. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
3. Clear all transmit interrupt flags in the XMT_STAT register by writing a one to them
4. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
5. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=0 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

11.2.4.4.4 Programming Considerations for T=1 SIM Cards

If the card is of type T=1, the software should adjust the following parameters according to the information in the ATR:

1. Adjust the baud rate by changing the values of BAUD_SEL[2:0] and SAMPLE12 in the CNTL register
2. Adjust the guard time between characters by changing the value of GETU[7:0] in the GUARD_CNTL register. Setting GETU[7:0] to 0xFF configures the SIM transmitter for 11 ETU transmissions
3. Disable NACK capability by clearing the ONACK and ANACK bits in the CNTL register. T=1 cards do not allow NACKs.
4. Adjust the stop clock polarity by modifying the values of the SCSP0 or SCSP1 bits in the PORTx_CNTL register
5. Set Character Wait Time Counter Comparator to value specified in the ATR by using the CHAR_WAIT register
6. Enable the Character Wait Time Counter Interrupt by clearing CWTM in INT_MASK register

7. Enable the Character Wait Time Counter by setting the CWTEN bit in the CNTL register
8. Enable CRC or LRC error checking according to the ATR information by setting either the CRCEN or LRCEN bit in the CNTL register. These bits will never be set at the same time!

   For T=1 cards, the ATR is sent using a T=0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the SIM card is desired, the software will send a PPS response to the SIM card. Otherwise, the protocol is initiated with a block transfer from the SIM module. In order to send the response or the first block, the following steps should be performed:

9. Set the desired transmit FIFO threshold level by writing the TDT[3:0] bits in the XMT_THRESHOLD register
10. Write the characters to be sent as response (max 16) to the transmit FIFO using the XMT_BUF register
11. Clear all transmit interrupt flags in the XMT_STAT register by writing a 1 to them
12. Enable the transmit interrupts desired by clearing the mask bits in the INT_MASK register. If more than 16 character are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the SIM card.
13. Enable the transmission of the error checking characters (LRC or CRC) by setting the XMT_CRC_LRC bit in the CNTL register.

NOTE

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is completed. If so, do not set the XMT_CRC_LRC bit during the PPS exchange.

14. Enable the transmitter by setting the XMT_EN bit in the ENABLE register

At this point, the SIM module will transmit the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt will be set when the threshold number of characters are remaining in the FIFO. The software can then write an additional number of characters to be sent without interrupting transmission to the SIM card.

Once the transmission is complete, the SIM module should be completely configured for standard operation with the T=1 SIM card. The software can continue to service RDRF interrupts for received characters, and TDTF interrupts for transmitted characters.

11.2.5 SIM Memory Map/Register Definition

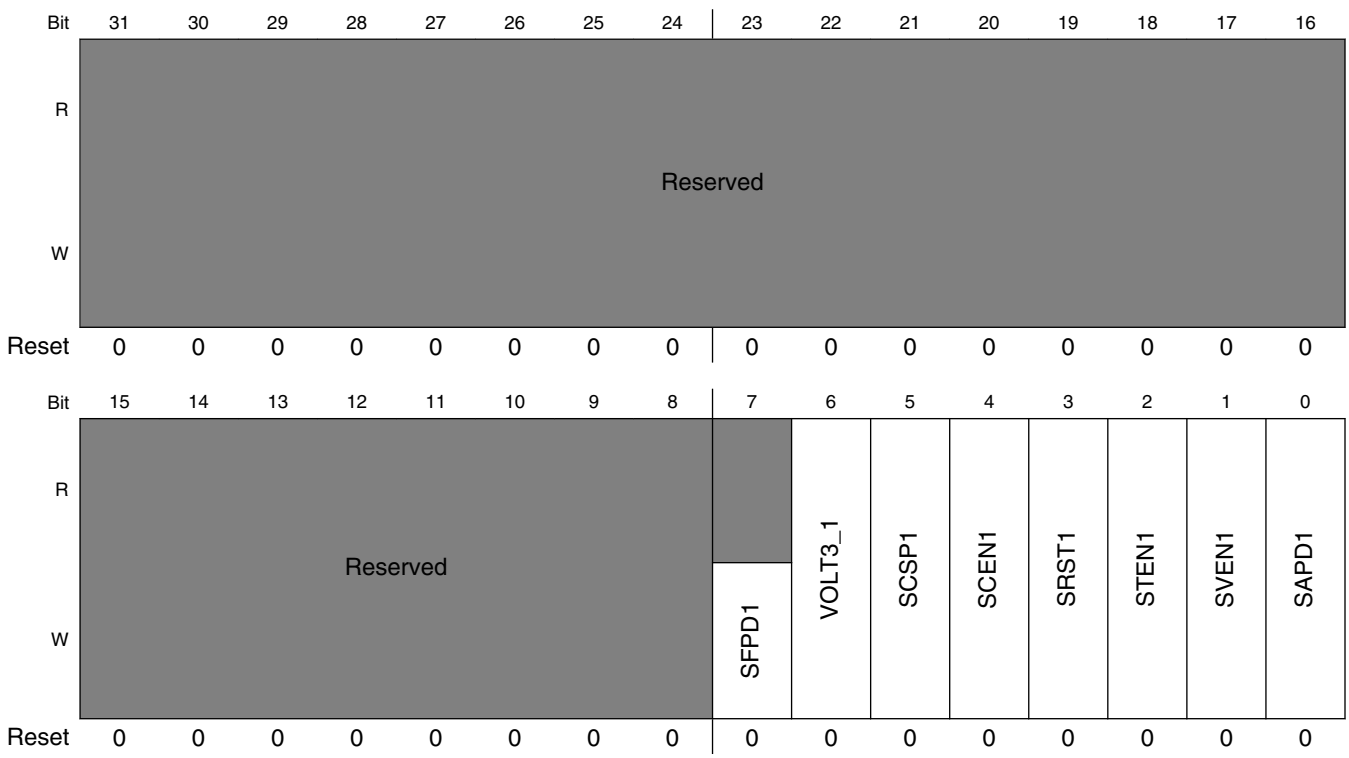
11.2.5.1 SIM Port1 Control Register (SIMx_PORT1_CNTL)

See the figure below for illustration of valid bits in the SIM Port1 Control Register and the table below for description of the bit fields.

Address: Base address + 0h offset



SIMx_PORT1_CNTL field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD1	Auto Power Down port1. Writing a "1" to this location will start the auto power down sequence for port 1. This bit will autoclear. A read of this bit will give a "0". 0 No effect 1 Start Auto Power down
6 VOLT3_1	External one wire interface for SIM Card port1. Used to configure the Port 1 transmit pin as bi-directional. This allows the Port 1 Receive pin to be re-used as General Purpose I/O. This operation is restricted to bi-directional data SIM cards only. This bit should not be changed while the receiver or transmitter is enabled! 0 Port1 uses both rcv and xmt pins 1 Port1 XMT pin bidirectional. Port1 RCV PIN unused

Table continues on the next page...

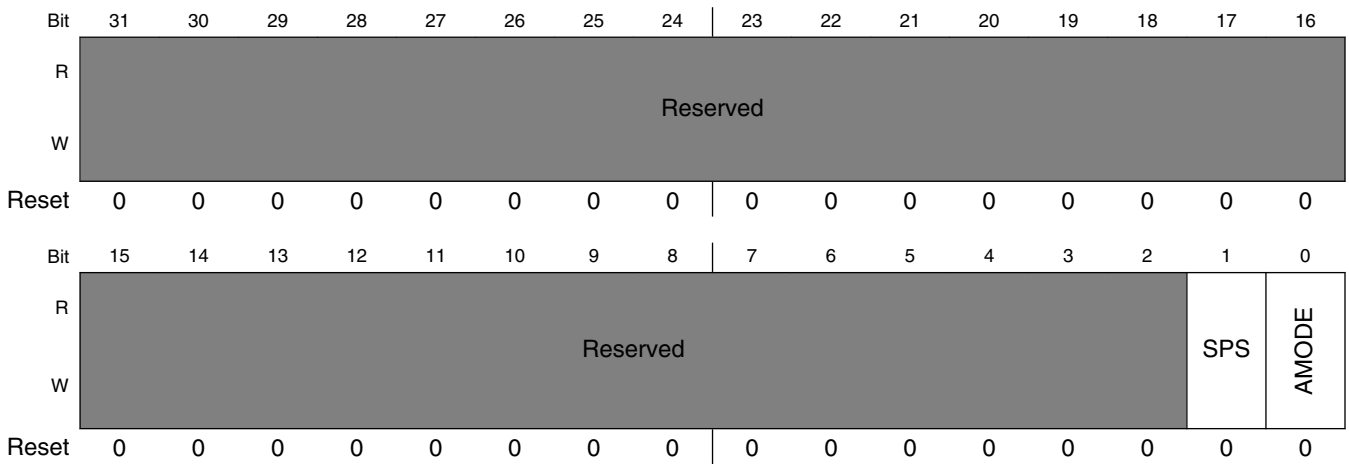
SIMx_PORT1_CNTL field descriptions (continued)

Field	Description
5 SCSP1	SIM Card Clock Stop Polarity Port1. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN1. It will be forced low by hardware during the auto power down sequence. This forces the clock be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by SCEN1 1 Clock is logic 1 when stopped by SCEN1
4 SCEN1	SIM card Clock Enable Port 1. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Disabled Port1 1 SIM Card Clock Enabled Port1
3 SRST1	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port1 inactive (default) 1 SIM Card reset Port1 active
2 STEN1	SIM card Transmit Enable Port 1. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port1 Transmit Data is forced to zero (default) 1 Port 1 Transmit Data controlled by SIM module
1 SVEN1	SIM card Vcc Enable Port 1. Used to control the state of the SVEN1 pin on SIM card port 1. The SVEN1 pin controls the SIM card V_{CC} enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 1 disabled (default) 1 SIM card Voltage Port 1 enabled
0 SAPD1	SIM card Auto Power Down Port 1. Used to enable/disable the auto power down function for port 1. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 1 disabled (default) 1 Auto power down Port 1 enabled

11.2.5.2 SIM Setup Register (SIMx_SETUP)

See the figure below for illustration of valid bits in the SIM Setup Register and the table below for description of the bit fields.

Address: Base address + 4h offset



SIMx_SETUP field descriptions

Field	Description
31–2 -	This field is reserved. Reserved
1 SPS	**SIM card Port Select.** Controls which port the SIM interface uses. **NOTE:** The AMODE bit must be zero when the SPS bit is set to 1. 0 Port 0 Enabled (default) 1 Port 1 Enabled
0 AMODE	**Alternate SIM Card Mode enable.** Enables an alternate SIM module to control SIM card Port 1. **NOTE:** The SPS bit must be 0 to give the alternate SIM module control. 0 Alternate Port Disabled (default) 1 Alternate Port Enabled

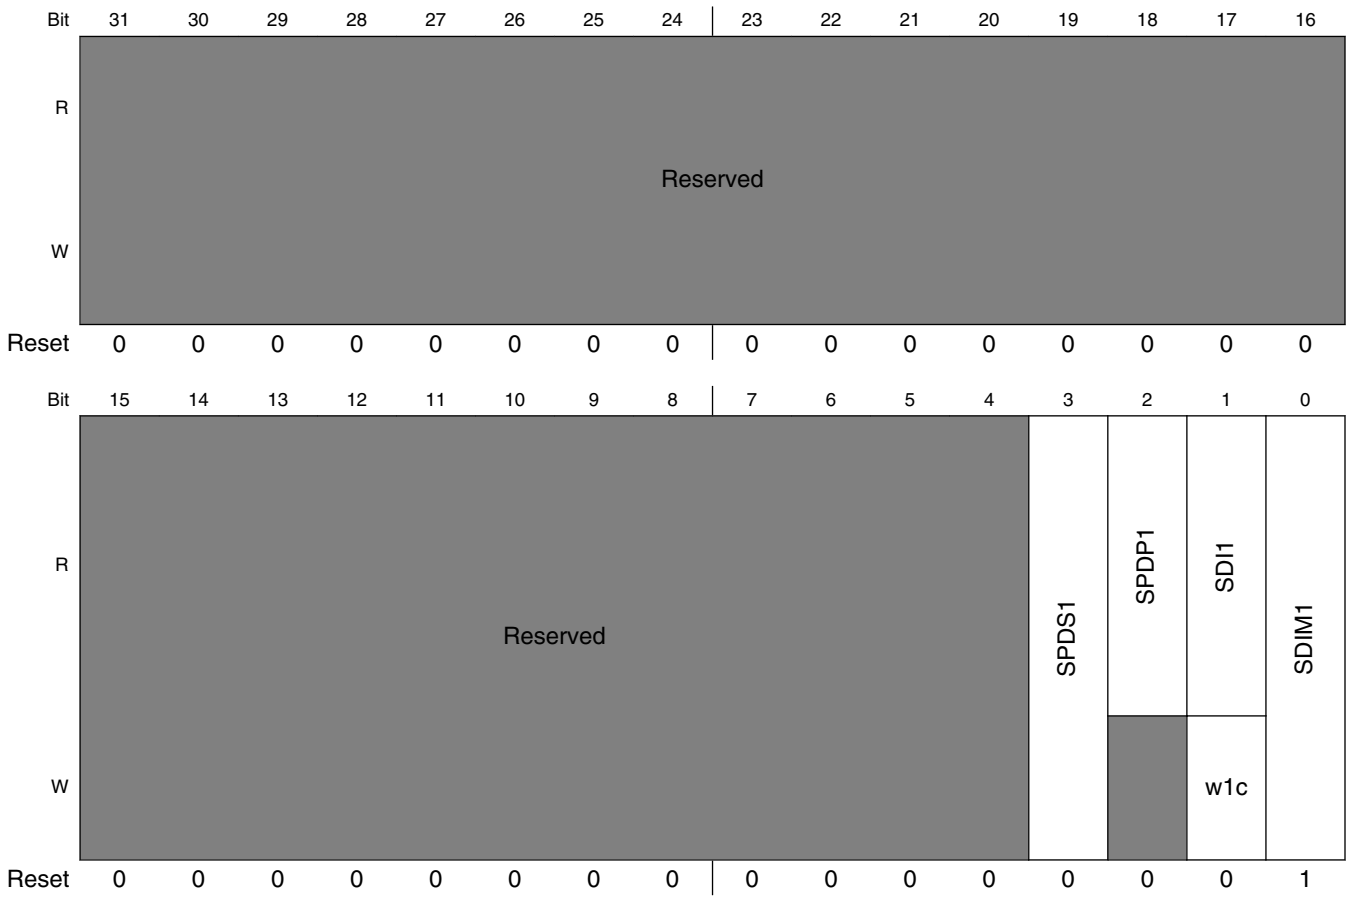
11.2.5.3 SIM Port 1 Detect Register (SIMx_PORT1_DETECT)

See the figure below for illustration of valid bits in the SIM Port1 Detect Register and the table below for description of the bit fields.

Summary:

spds1 determines which edge transition of the SIMPD1 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD1 edge specified by spds1 will cause the following: sdi1 to be set; if the sdim1 mask is clear, an interrupt on SIMIRQ_N; and if sapd1 in the PORT1_CNTL register is set, an auto power down sequence to begin. If SIM card insertion is expected, sapd1 can be set low to avoid the auto power down sequence. There is no auto power up sequence. The bit spdp1 can be used to determine the current state of the SIMPD1 pin.

Address: Base address + 8h offset



SIMx_PORT1_DETECT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3 SPDS1	SIM **Presence Detect Select Port 1.** Controls which edge of the SIMPD1 pin is used to detect the presence of the SIM card. 0 Falling edge of SIMPD1 Input (default) 1 Rising edge of SIMPD1 Input
2 SPDP1	**SIMPD1 input pin status.** This bit reflects the state of the SIMPD1 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD1 pin itself.

Table continues on the next page...

SIMx_PORT1_DETECT field descriptions (continued)

Field	Description
	0 SIMPD1 pin is logic low 1 SIMPD1 pin is logic high
1 SDI1	**SIM Detect Interrupt Flag Port 1.** Status flag to indicate the insertion or removal of a SIM card has been detected on port 1. Can create an interrupt to the MCU if SDIM1 is low. Write a "1" to this bit to clear. 0 No insertion or removal of SIM card detected on Port 1(default) 1 Insertion or removal of SIM card detected on Port 1
0 SDIM1	**SIM Detect Interrupt Mask Port 1.** Interrupt mask for the sdi1 interrupt flag. 0 SDI1 enabled 1 SDI1 masked (default)

11.2.5.4 SIM Transmit Buffer Register (SIMx_XMT_BUF)

See the figure below for illustration of valid bits in the SIM Transmit Buffer Register and the table below for description of the bit fields.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

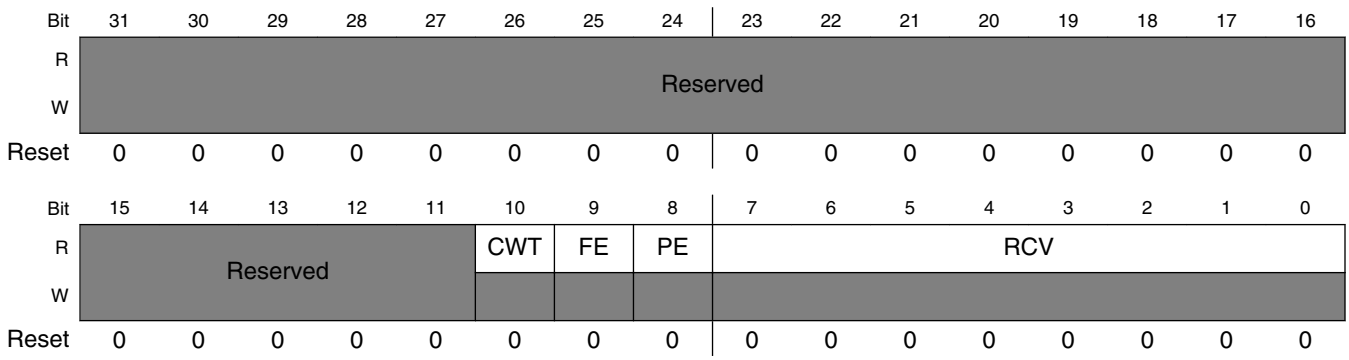
SIMx_XMT_BUF field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
XMT	**Transmit Buffer.** Write to the next available location in the transmit buffer.

11.2.5.5 SIM Receive Buffer Register (SIMx_RCV_BUF)

See the figure below for illustration of valid bits in the SIM Receive Buffer Register and the table below for description of the bit fields.

Address: Base address + 10h offset



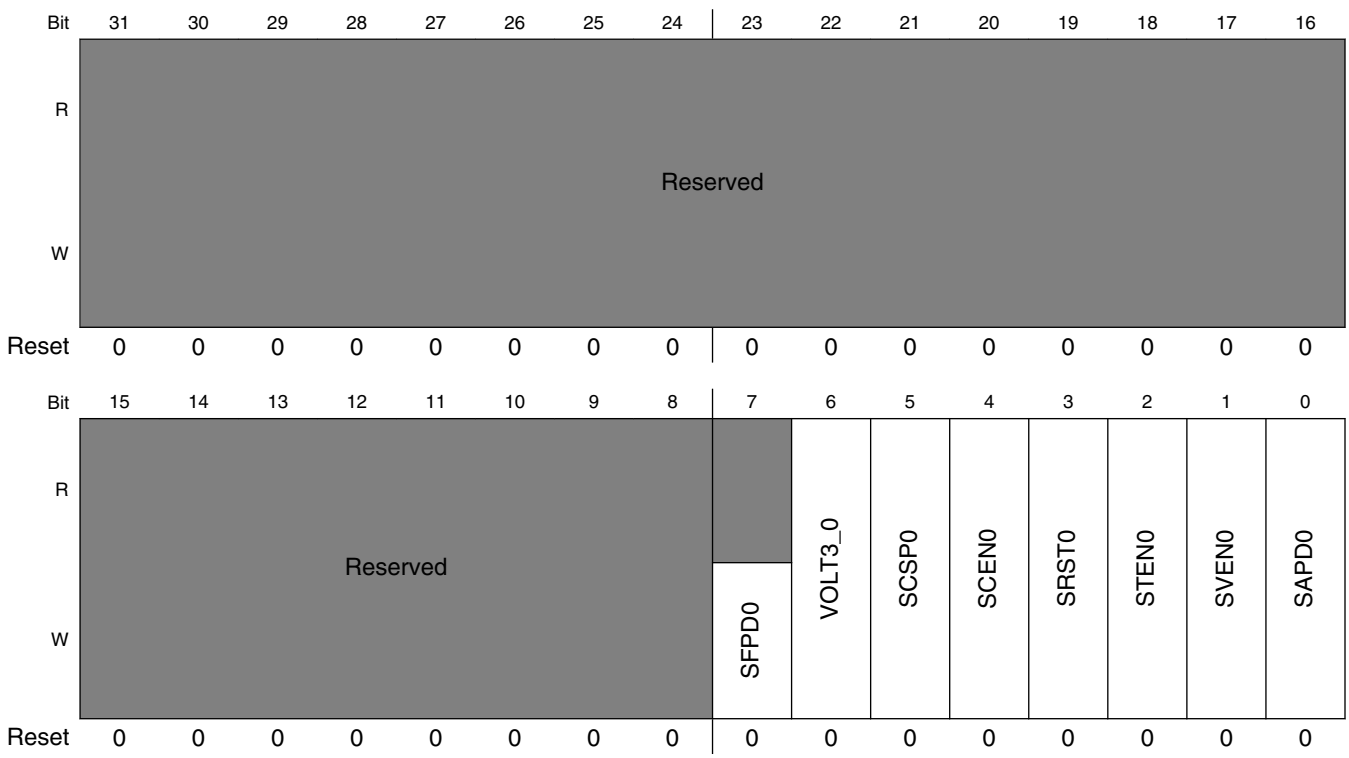
SIMx_RCV_BUF field descriptions

Field	Description
31–11 -	This field is reserved. Reserved
10 CWT	**CWT flag.** The CWT indicates that this byte was late. It is not necessary to clear the byte since it is overwritten by the next byte received into that location of the FIFO. 0 Byte was on time 1 Byte was late
9 FE	**Frame Error flag.** The FE flag indicates whether a frame error was detected during the reception of the corresponding byte read in the RCV field. The FE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. 0 Byte contains no framing error (default) 1 Byte contains a framing error
8 PE	**Parity Error flag.** The PE flag indicates whether a parity error was detected during the reception of the corresponding byte read in the RCV field. The PE flag cannot create an interrupt. It need not be cleared since it will be overwritten by the next byte received into that location of the FIFO. A parity error can create a NACK pulse. 0 Byte contains no parity error (default) 1 Byte contains a parity error
RCV	**Receive buffer.** Read from the next location in the receive buffer.

11.2.5.6 SIM Port0 Control Register (SIMx_PORT0_CNTL)

See the figure below for illustration of valid bits in the SIM Port0 Control Register and the table below for description of the bit fields.

Address: Base address + 14h offset



SIMx_PORT0_CNTL field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 SFPD0	Auto Power Down port0. Writing a "1" to this location will start the auto power down sequence for port 0. This bit will autoclear.A read of this bit will give a "0". 0 No effect 1 Start Auto Power down
6 VOLT3_0	External one wire interface for SIM Card port0. Used to configure the Port 0 transmit pin as bi-directional. Only bi-directional data SIM cards are supported. Hence user should program this bit to 1. This bit should not be changed while the receiver or transmitter is enabled! Port0 uses both RCV and XMT pins 1 Port0 XMT pin bidirectional. Port0 rcv pin unused

Table continues on the next page...

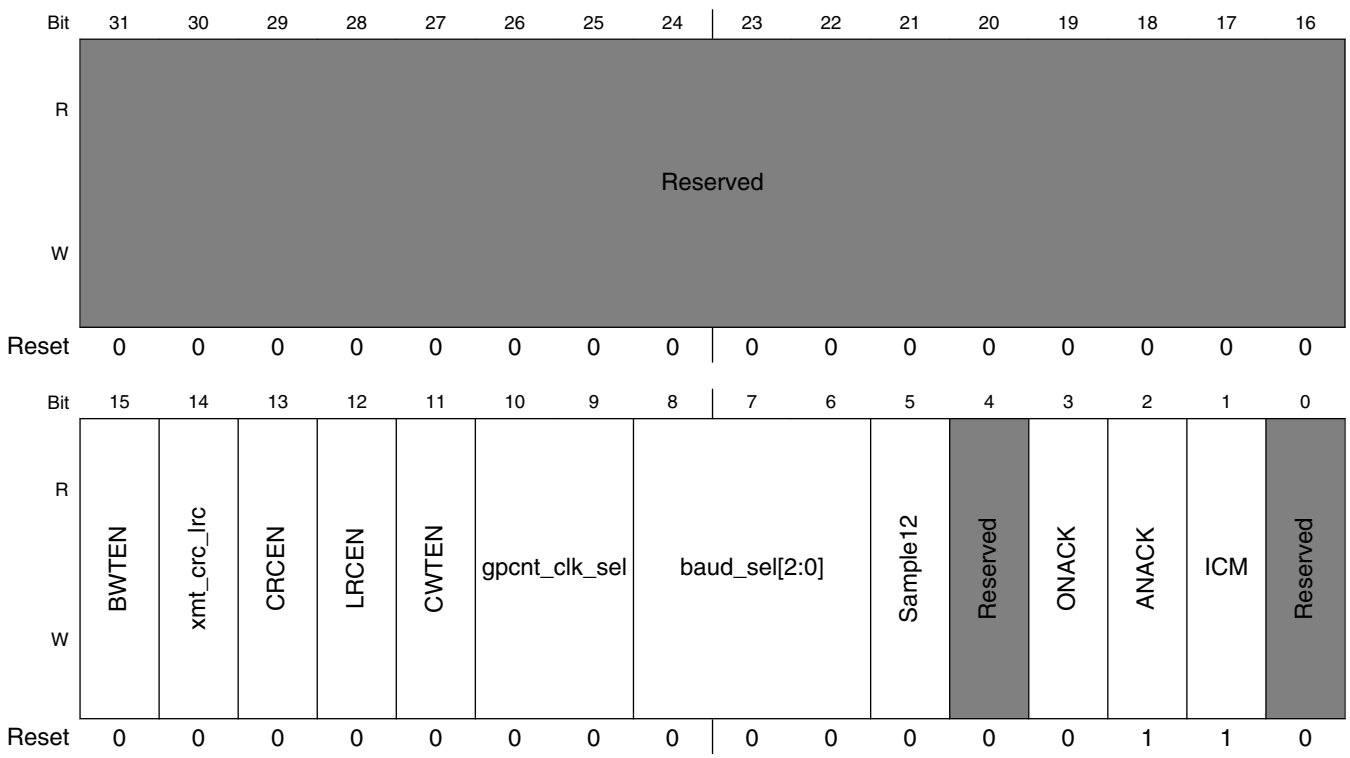
SIMx_PORT0_CNTL field descriptions (continued)

Field	Description
5 SCSP0	SIM Card Clock Stop Polarity port0. Used to control the polarity of the idle SIM clock when the clock is disabled by SCEN0. It will be forced low by hardware during the auto power down sequence. This forces the clock to be a logic 0 when stopped by auto power down as required by ISO 7816 spec. 0 Clock is logic 0 when stopped by scen0 1 Clock is logic 1 when stopped by scen0
4 SCEN0	SIM card Clock Enable Port 0. Used to enable/disable the clock to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 SIM Card Clock Disabled Port 0 1 SIM Card Clock Enabled Port 0
3 SRST0	SIM card Reset. Used to control state of reset line to the SIM card. It can be forced low by hardware during the auto power down sequence. SIM card reset signals are active low. 0 SIM Card reset Port0 inactive (default) 1 SIM Card reset Port0 active
2 STEN0	SIM card Transmit Enable Port 0. Used to enable/disable the XMT data to the SIM card. It can be forced low by hardware during the auto power down sequence. 0 Port0 Transmit Data is forced to zero (default) 1 Port 0 Transmit Data controlled by SIM module
1 SVEN0	SIM card V_{CC} Enable Port 0. Used to control the state of the SVEN0 pin on SIM card port 0. The SVEN0 pin controls the SIM card V_{CC} enable in the power management chip. It can be forced low by hardware during the auto power down sequence. 0 SIM card Voltage Port 0 disabled (default) 1 SIM card Voltage Port 0 enabled
0 SAPD0	SIM card Auto Power Down Port 0. Used to enable/disable the auto power down function for port 0. It will be forced low at the end of the auto power down sequence. 0 Auto power down Port 0 disabled (default) 1 Auto power down Port 0 enabled

11.2.5.7 SIM Control Register (SIMx_CNTL)

See the figure below for illustration of valid bits in the SIM Control Register and the table below for description of the bit fields.

Address: Base address + 18h offset



SIMx_CNTL field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 BWTEN	**Block wait time enable.** Writing a "1" to this bit will enable the bwt and bgt functions. The bwt and bgt functions can then be individually selected using the interrupt mask. 0 Disable BWT, BGT 1 Enable BWT, BGT
14 xmt_crc_lrc	**Transmit CRC or LRC.** This bit specifies whether or not to transmit the redundancy checking data at the end of a transmission (that is, when the FIFO becomes empty). 0 No Redundancy check info transmitted (default) 1 Transmit LRC or CRC info when FIFO empties (whichever is enabled)
13 CRCEN	**CRC Enable.** This bit enables the calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and reflected in the

Table continues on the next page...

SIMx_CNTL field descriptions (continued)

Field	Description
	crcok bit in the RCV_STAT register. Clearing this bit resets the current CRC residual value in the SIM hardware. 0 16-bit Cyclic Redundancy Checking disabled (default) 1 16-bit Cyclic Redundancy Checking enabled
12 LRCEN	**LRC Enable.** This bit enables the calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and reflected in the lrcok bit in the RCV_STAT register. Clearing this bit resets the current LRC value in the SIM hardware. 0 8-bit Linear Redundancy Checking disabled (default) 1 8-bit Linear Redundancy Checking enabled
11 CWTEN	**Character Wait Time Counter Enable.** Enables the character wait time counter. Clearing this bit resets the counter to zero. 0 Character Wait time Counter off (default) 1 Character Wait time counter on
10–9 gpcnt_clk_sel	**General Purpose Counter Clock Select.** Selects which clock source is used by SIM Module general purpose counter. The only way to reset the counter is to set these bits to zero. The counter will begin counting as soon as the clock input is selected and the clocks are enabled. These input clocks are enabled through other register bits of the SIM module (KILL_CLOCK, RCV_EN, and XMT_EN respectively). 00 Disabled / Reset 01 Card Clock 10 Receive Clock 11 ETU Clock (transmit clock)
8–6 baud_sel[2:0]	SIM **Baud Rate Select.** Selects the asynchronous baud rate divisor of the clock When set to "111", the divisor is set to the value programmed in the DIVISOR register. This allows for more flexible baud rate determination. 000 31 (512/1 Fi/Di) 001 32 (512/2 Fi/Di) 010 16 (512/4 Fi/Di) 011 8 (512/8 Fi/Di) 100 4 (512/16 Fi/Di) 101 2 (512/32 Fi/Di) 110 1 (512/64 Fi/Di) 111 DIVISOR Reg
5 Sample12	**Sample12.** Set the third stage divider. This sets the corresponding sample rate which is the number of times a bit being received is sampled. 0 divide by 8(default) 1 divide by 12
4 -	This field is reserved. Reserved
3 ONACK	**Overrun NACK Enable.** Enables overrun NACK generation. 0 NACK generation on overrun is disabled (default) 1 NACK generation on overrun is enabled

Table continues on the next page...

SIMx_CNTL field descriptions (continued)

Field	Description
2 ANACK	**Automatic NACK Enable.** Enables nack generation for parity errors or invalid initial characters when in ICM mode. 0 NACK generation on errors disabled 1 NACK generation on errors enabled (default)
1 ICM	**Initial Character Mode.** Enables initial character mode. Will be automatically cleared by hardware once a valid initial character is received. 0 Initial Character Mode disabled 1 Initial Character Mode enabled (default)
0 -	This field is reserved. Reserved

11.2.5.8 SIM Clock Prescaler Register (SIMx_CLK_PRESCALER)

See the figure below for illustration of valid bits in the SIM Clock Prescaler Register and the table below for description of the bit fields.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

SIMx_CLK_PRESCALER field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
CLK_ PRESCALER	**Clock prescaler divisor register.** The value written to this register will determine the first stage divider setting. If the ipg_perclk is 66Mhz, a typical setting would be 0x0e. This would set the SIM card clock to 66Mhz/14 = 4.7Mhz. The duty cycle of divided clock will be between 45% and 55% according to ISO7816 requirement. For the odd divider factor (2K+1), the duty cycle will be K/(2K+1) and (K+1)/(2k+1). So for 0x03, the duty cycle is 33%-66%. For 0x05, the duty cycle is 40%-60%. For 0x07, the duty cycle is 43%-57%, and for 0x09, the duty cycle is 44%-56%. For all other values, the clock duty cycle can meet the ISO7816 requirement. **NOTE:** Not all values are listed 0x00 ~0x02 ipg_perclk/ 2 0x03 ipg_perclk / 3 0x04 ipg_perclk / 4 0x05 ipg_perclk / 5 0x06 ipg_perclk / 6 0xFD ipg_perclk / 253

Table continues on the next page...

SIMx_CLK_PRESCALER field descriptions (continued)

Field	Description
	0xFE ipg_perclk / 254 0xFF ipg_perclk / 255

11.2.5.9 SIM Receive Threshold Register (SIMx_RCV_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Receive Threshold Register and the table below for description of the bit fields.

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																			RTH[3:0]				RDT[8:0]								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

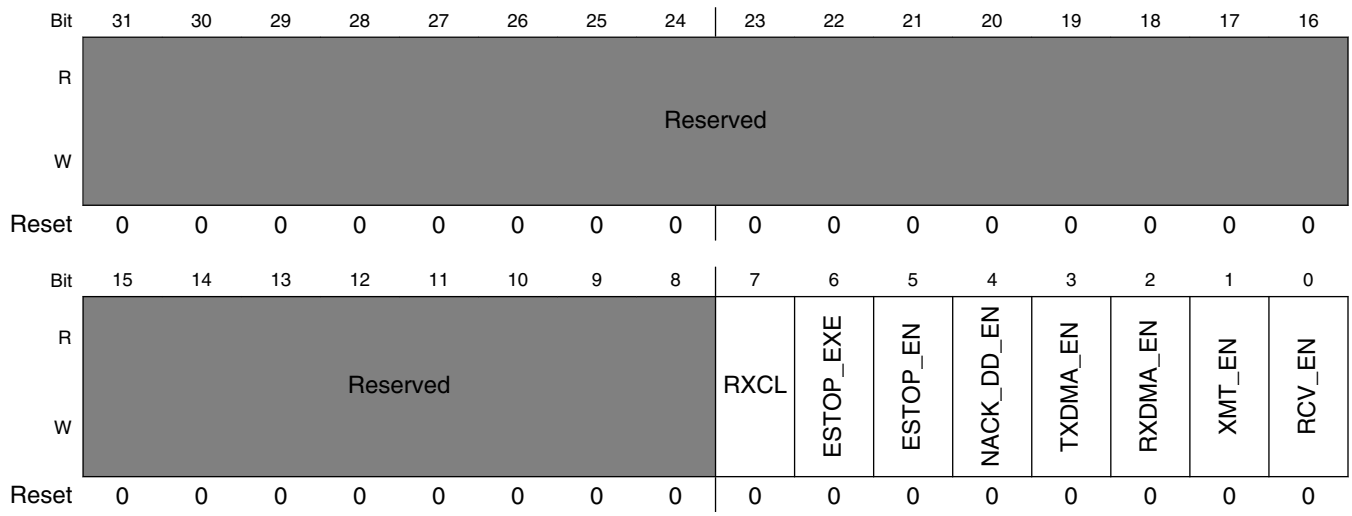
SIMx_RCV_THRESHOLD field descriptions

Field	Description
31–13 -	This field is reserved. Reserved
12–9 RTH[3:0]	**Receive Nack Threshold.** Used to specify the number of consecutive NACK's transmitted by the SIM module, for a given character, before the receive threshold error (RTE) flag is triggered. A value of 0 indicates that RTE is never set. When a valid character is received by the SIM, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If the ANACK bit is clear in the CNTL register, RTH has no effect.
RDT[8:0]	**Receive Data Threshold.** Determines the number of unread bytes that must exist in the FIFO to trigger the receive data register full (RDRF) interrupt flag. If the number of unread bytes in the receive FIFO is greater than or equal to the value in RDT, the RDRF flag in the RCV_STATUS register will be set. A value of zero indicates that there must be 288 unread bytes in the FIFO to trigger RDRF. If a value of more than 288 is entered in this register, the register value will remain 288.

11.2.5.10 SIM Enable Register (SIMx_ENABLE)

See the figure below for illustration of valid bits in the SIM Enable Register and the table below for description of the bit fields.

Address: Base address + 24h offset



SIMx_ENABLE field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 RXCL	Reception data latch disable. Used to disable/enable the cross clock domain synchronization operation of reception data in SIM receive state machine. 0 Enable the synchronization operation. 1 Disable the synchronization operation.
6 ESTOP_EXE	Enforce reception early stop execution. Used to execute the function of enforce reception early stop when ESTOP_EN bit set to 1. If this bit is 0 the early stop function can't be executed when NACK signal occur. 0 Enforce reception early stop function will be executed without NACK. 1 Enforce reception early stop function will be executed at all times.
5 ESTOP_EN	Enforce reception early stop enable. Used to early stop the SIM receive state machine. The state machine will stop earliey than 10.8 ETUs when 11 ETUs mode or earlier than 11.8 ETUs when non 11 ETUs mode, if enable this bit. This function is used for the test case tramsmission stop at 10.8 ETUs from the falling edge of start signal. **NOTE:** This bit should be set to 1 when receive data, and set to 0 when transmit data. 0 Disable the enforce reception early stop function. 1 Enable the enforce reception early stop function.
4 NACK_DD_EN	NACK delay detection enable. Used to enable/disable the function of NACK delay detection. The SIM receive state machine will detect the NACK signal at the 16th phase and use the values of12th, 14th and

Table continues on the next page...

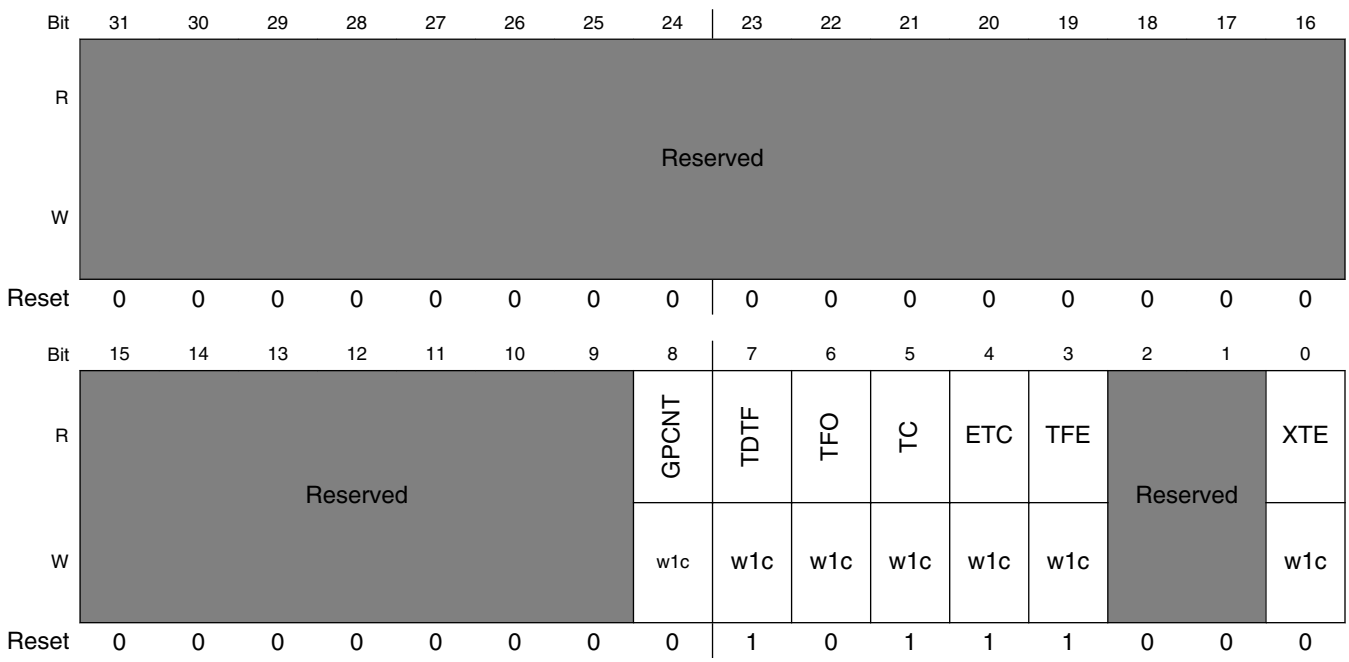
SIMx_ENABLE field descriptions (continued)

Field	Description
	15th sample point, if enable this bit. This function is used for the test case NACK signal send at 10.7 ETUs from the falling edge of start signal. 0 Disable the delay detection function. 1 Enable the delay detection function.
3 TXDMA_EN	Transmitter DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register and XMT_EN is set. 0 SIM Transmitter DMA requests disabled. 1 SIM Transmitter DMA requests enabled.
2 RXDMA_EN	Receiver DMA Enable. This bit allows SIM to request for DMA transfers. When enabled, DMA requests are generated when when the number of bytes in the receive FIFO is more than or equal to the value programed in the RDT[8:0] in the RCV_THRESHOLD register and RCV_EN is set 0 SIM Receiver DMA request disabled. 1 SIM Receiver DMA request enabled.
1 XMT_EN	SIM **Transmit Enable.** Used to enable/disable the SIM transmit state machine. When the SIM is being used to receive data, XMT_EN should be deasserted. This bit also enables the xmt_clk and rcv_clk inputs to the General Purpose Counter. **NOTE:** Setting this bit (transition from 0 to 1) will reset the CRC and LRC values. 0 SIM Transmitter disabled (default) 1 SIM Transmitter enabled
0 RCV_EN	SIM **Receiver Enable.** Used to enable/disable the SIM receive state machine. The RCV_EN bit should be left high whenever the SIM module is in use. The SIM module has an automatic receive mode operation that disables the reception of characters when the transmitter is operational. Once the transmitter has completed sending the last character, the receiver is automatically enabled. This bit also enables the RCV_CLK input to the General Purpose Counter. 0 SIM Receiver disabled (default) 1 SIM Receiver enabled

11.2.5.11 SIM Transmit Status Register (SIMx_XMT_STATUS)

See the figure below for illustration of valid bits in the SIM Transmit Status Register and the table below for description of the bit fields.

Address: Base address + 28h offset



SIMx_XMT_STATUS field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 GPCNT	**General purpose Counter Flag.** Used to indicate when the General purpose counter has reached the value in the GPCNT register. 0 GPCNT time not reached, or bit has been cleared. (default). 1 General Purpose counter has reached the GPCNT value.
7 TDTF	**Transmit Data Threshold Flag.** Used to indicate when the number of bytes in the transmit FIFO is less than or equal to the value programmed in the tdt[3:0] bits in the XMT_THRESHOLD register. 0 Number of bytes in FIFO is greater than tdt[3:0], or bit has been cleared. 1 Number of bytes in FIFO is less than or equal to tdt[3:0] (default)
6 TFO	**Transmit FIFO Overfill Error.** Used to indicate when the Transmit FIFO has been written with more than 16 bytes. The tfo bit can only be cleared by setting the flush_xmt or soft_reset bit in the RESET_CNTL register. 0 No transmit FIFO overfill error has occurred (default). 1 A Transmit FIFO overfill error has occurred.

Table continues on the next page...

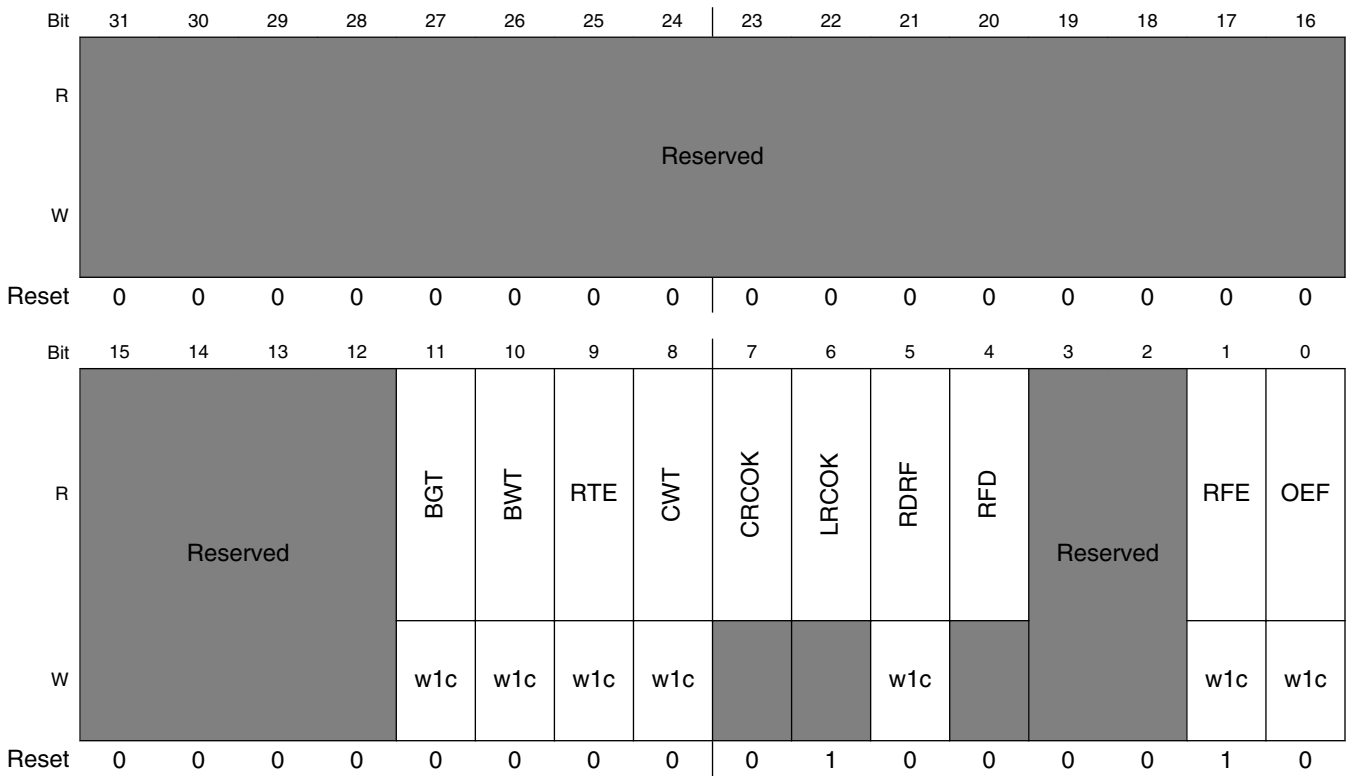
SIMx_XMT_STATUS field descriptions (continued)

Field	Description
5 TC	**Transmit Complete.** Used to indicate whether the SIM transmitter is ready for a new transmission. The tc flag becomes set after the guard time has expired for the last byte in the transmit FIFO. The tc flag will create an interrupt if tcim in the INT_MASK register is low. The tc bit is a write-one-to-clear bit. 0 Transmit pending or in progress 1 Transmit complete (default)
4 ETC	**Early Transmit Complete.** Used to indicate that the SIM transmitter has finished sending the current byte and the transmit FIFO is empty. This bit differs from the tc bit in that it is set before the guard time of the last byte has elapsed. The ETC flag will create an interrupt if ETCIM in the INT_MASK register is low. The ETC bit is a write-one-to-clear bit. 0 Transmit pending or in progress 1 Transmit complete (default)
3 TFE	**Transmit FIFO Empty.** Used to indicate that the SIM transmit FIFO has emptied. This bit will be set when the last byte in the transmit FIFO has been transferred to the SIM transmitter shift register. The TFE flag will create an interrupt if TFEIM in the INT_MASK register is low. The TFE bit is a write-one-to-clear bit. 0 Transmit FIFO is not empty 1 Transmit FIFO is empty (default)
2–1 -	This field is reserved. Reserved
0 XTE	**Transmit NACK Threshold Error.** Used to indicate the transmit NACK threshold has been reached. When XTE is high, no further transmissions will be done until the XTE flag is cleared. Any data transmissions still pending in the transmit FIFO will be aborted, and the TC, ETC, and TFE flags will be set. The XTE flag will create an interrupt if XTM in the IMT_MASK register is low. The XTE bit is a write-one-to-clear bit. 0 Transmit NACK threshold has not been reached (default) 1 Transmit NACK threshold reached; transmitter frozen

11.2.5.12 SIM Receive Status Register (SIMx_RCV_STATUS)

See the figure below for illustration of valid bits in the SIM Receive Status Register and the table below for description of the bit fields.

Address: Base address + 2Ch offset



SIMx_RCV_STATUS field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11 BGT	**Block guard time error flag.** Used to indicate if the block guard time was too small. The threshold is set by the block guard time register. 0 Block guard time was sufficient. 1 Block guard time was too small.
10 BWT	**Block wait time error flag.** Used to indicate if the block wait time has been exceeded. The threshold is set by the block wait time registers. 0 Block wait time not exceeded. 1 Block wait time was exceeded.
9 RTE	**Receive NACK threshold error flag.** Used to indicate whether the number of consecutive NACKs generated by the SIM module in response to receive parity errors, for the byte being received, equals the

Table continues on the next page...

SIMx_RCV_STATUS field descriptions (continued)

Field	Description
	value programmed in the RTH[3:0] in the RCV_THRESHOLD register. This bit would never be set unless the ANACK bit is set in the CNTL register. The SAPDx bit in the PORTx_CNTL resister must be set to enable the threshold error to trigger the auto power down sequence. RTE is a write-one-to-clear bit. Clearing this bit also resets the internal counter for consecutive NACKs being transmitted for a given byte. 0 Number of NACKs generated by the receiver is less than the value programmed in RTH[3:0] 1 Number of NACKs generated by the receiver is equal to the value programmed in RTH[3:0]
8 CWT	**Character Wait Time Counter Flag.** Used to indicate when the time between received characters is equal to or greater than the value programmed in the CHAR_WAIT register. 0 No CWT violation has occurred (default). 1 Time between two consecutive characters exceeded the value in CHAR_WAIT.
7 CRCOK	**Cyclic Redundancy Check Okay flag.** Used to indicate when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters from the point the CRCEN bit is set in the CNTL register. The current CRC residual can be reset by three mechanisms: Clear CRCEN bit in CNTL register Set XMT_EN bit in ENABLE register Automatically by hardware when ETC flag is set at the end of a transmission. 0 Current CRC value does not match remainder. 1 Current calculated CRC value matches the expected result.
6 LRCOK	Linear Redundancy Check Okay flag. Used to indicate when the calculated 8-bit LRC value is zero value for the current input data stream. The value is calculated across all received characters from the point the LRCEN bit is set in the CNTL register. The current LRC residual can be reset by three mechanisms: Clear LRCEN bit in CNTL register Set XMT_EN bit in ENABLE register Automatically by hardware when ETC flag is set at the end of a transmission. 0 Current LRC value does not match remainder. 1 Current calculated LRC value matches the expected result (that is, zero).
5 RDRF	Receive Data Register Full. Used to indicate when the number of bytes in the receive FIFO is more than or equal to the value programed in the RDT[8:0] in the RCV_THRESHOLD register. 0 Number of unread bytes in receive buffer < value set by RDT[8:0] (default), or bit has been cleared. 1 Number of unread bytes in receive buffer >= value set by RDT[8:0].
4 RFD	**Receive FIFO has unread Data.** Used to indicate that there is at least one unread byte in the receive data FIFO. Can only be cleared by reading all bytes out of the receive FIFO. The RFD bit cannot be used to create an interrupt. Normally, the SIM triggers the interrupt with RDRF and software uses rfd to read all of the bytes out of the receive FIFO. 0 There are no unread bytes in the receive FIFO (default). 1 There is at least one unread byte in the receiver FIFO.
3–2 -	This field is reserved. Reserved
1 RFE	**Receive FIFO Empty.** Used to indicate that the SIM receive FIFO has emptied. This bit will be set when the last byte in the receive FIFO has been transferred to the IPS bus. The RFE flag will create an interrupt if RFEIM in the INT_MASK register is low. The RFE bit is a write-one-to-clear bit.

Table continues on the next page...

SIMx_RCV_STATUS field descriptions (continued)

Field	Description
	0 Receive FIFO is not empty 1 Receive FIFO is empty (default)
0 OEF	**Overrun Error Flag.** Used to indicate that the SIM was unable to store received data due to already having 288 unread bytes in the FIFO. It does not necessarily indicate that data has been lost. If the ONACK control bit in the CNTL register is set, there will be a NACK pulse generated on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the SIM card which implies that no data has actually been lost. In this case, the OEF flag is just an indicator that this situation has occurred which may be helpful in system debug. For the case where ONACK is not set, a set OEF flag does indicate a loss of data since all bytes received with the OEF flag set will indeed be lost (including the byte that caused the bit to be set). The OEF flag will cause an interrupt if the oim bit in the INT_MASK register. The OEF flag is a write-one-to-clear bit. 0 No overrun error has occurred (default). 1 A byte was received when the received FIFO was already full.

11.2.5.13 SIM Interrupt Mask Register (SIMx_INT_MASK)

See the figure below for illustration of valid bits in the SIM Interrupt Mask Register and the table below for description of the bit fields.

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SIMx_INT_MASK field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 RFEM	**Receive fifo empty interrupt mask.** Used to enable/disable the ability of the RFE flag in the RCV_STATUS register to generate SIM interrupts.

Table continues on the next page...

SIMx_INT_MASK field descriptions (continued)

Field	Description
	0 RFE interrupt enabled 1 RFE interrupt masked (default)
12 BGTM	**Block guard time interrupt mask.** Used to enable/disable the ability of the bgt flag in the RCV_STATUS register to generate SIM interrupts. 0 BGT interrupt enabled 1 BGT interrupt masked (default)
11 BWTM	**Block wait time interrupt mask.** Used to enable/disable the ability of the bwt flag in the RCV_STATUS register to generate SIM interrupts. 0 BWT interrupt enabled 1 BWT interrupt masked (default)
10 RTM	**Receive Nack threshold interrupt mask.** Used to enable/disable the ability of the RTE flag in the RCV_STATUS register to generate SIM interrupts. 0 RTE interrupt enabled 1 RTE interrupt masked (default)
9 CWTM	**Character Wait Time Interrupt Mask.** Used to enable/disable the ability of the CWT flag in the RCV_STATUS register to generate SIM interrupts. 0 CWT interrupt enabled 1 CWT interrupt masked (default)
8 GPCNTM	**General Purpose Counter Interrupt Mask.** Used to enable/disable the ability of the GPCNT flag in the XMT_STATUS register to generate SIM interrupts. 0 GPCNT interrupt enabled 1 GPCNT interrupt masked (default)
7 TDTFM	**Transmit Data Threshold Interrupt Mask.** Used to enable/disable the ability of the TDTF flag in the XMT_STATUS register to generate SIM interrupts. 0 TDTF interrupt enabled 1 TDTF interrupt masked (default)
6 TFOM	**Transmit FIFO Overfill Error Interrupt Mask.** Used to enable/disable the ability of the TFO flag in the XMT_STATUS register to generate SIM interrupts. 0 TFO interrupt enabled 1 TFO interrupt masked (default)
5 XTM	**Transmit Threshold Interrupt Mask.** Used to enable/disable the ability of the XTE flag in the XMT_STATUS register to generate SIM interrupts 0 XTE interrupt enabled 1 XTE interrupt masked (default)
4 TFEIM	**Transmit FIFO Empty Interrupt Mask.** Used to enable/disable the ability of the TFE flag in the XMT_STATUS register to generate SIM interrupts. 0 TFE interrupt enabled 1 TFE interrupt masked (default)
3 ETCIM	**Early Transmit Complete Interrupt Mask.** Used to enable/disable the ability of the ETC flag in the XMT_STATUS register to generate SIM interrupts.

Table continues on the next page...

SIMx_INT_MASK field descriptions (continued)

Field	Description
	0 ETC interrupt enabled 1 ETC interrupt masked (default)
2 OIM	**Overrun Interrupt Mask.** Used to enable/disable the ability of the OEF flag in the RCV_STATUS register to generate SIM interrupts. 0 OEF interrupt enabled 1 OEF interrupt masked (default)
1 TCIM	**Transmit Complete Interrupt Mask.** Used to enable/disable the ability of the TC flag in the XMT_STATUS register to generate SIM interrupts. 0 TC interrupt enabled 1 TC interrupt masked (default)
0 RIM	**Receive Interrupt Mask.** Used to enable/disable the ability of the RDRF flag in the RCV_STATUS register to generate SIM interrupts. 0 RDRF interrupt enabled 1 RDRF interrupt masked (default)

11.2.5.14 SIM Port0 Detect Register (SIMx_PORT0_DETECT)

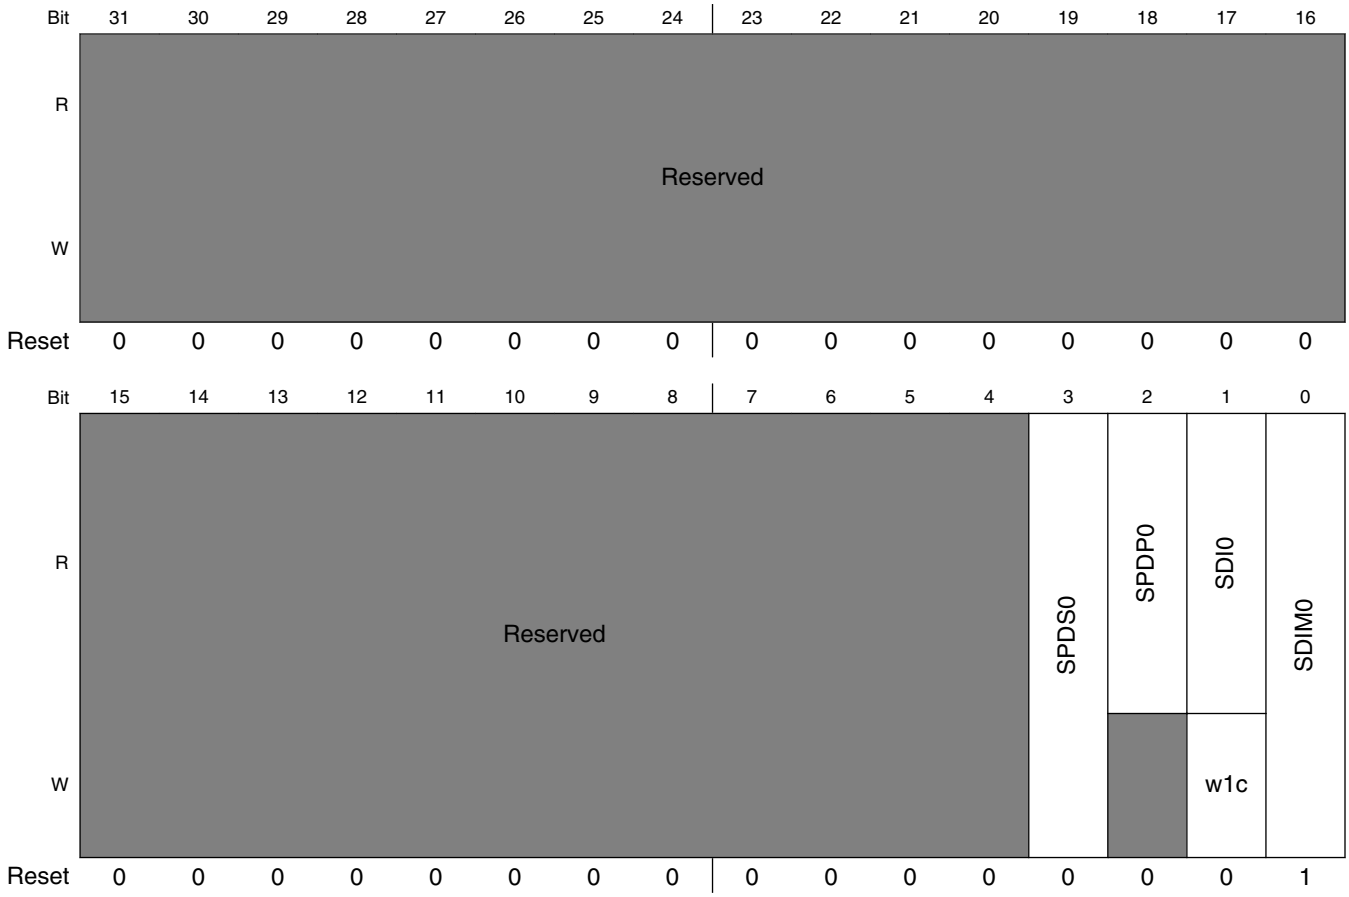
See the figure below for illustration of valid bits in the SIM Port0 Detect Register and the table below for description of the bit fields.

SPDS0 determines which edge transition of the SIMPD0 pin is used for SIM card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the SIMPD0 edge, specified by SPDS0, will cause the following:

- SDI0 to be set
- If the SDIM0 mask is clear, an interrupt to occur on SIMIRQ_N
- If SAPD0 in the PORT0_CNTL register is set, auto power down sequence will begin

If a SIM card insertion is expected, SAPD0 can be set low to avoid the auto power down sequence. There is no auto power up sequence. SPDP0 can be used to determine the current state of the SIMPD0 pin.

Address: Base address + 3Ch offset



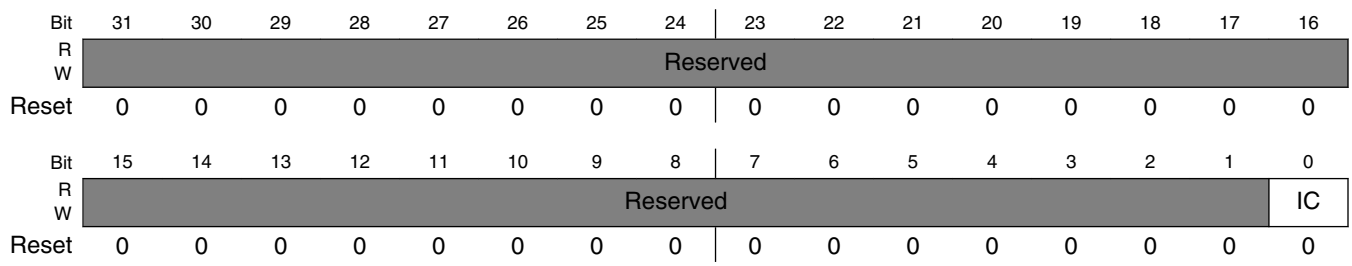
SIMx_PORT0_DETECT field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3 SPDS0	**SIM Presence Detect Select Port 0.** Controls which edge of the SIMPD0 pin is used to detect the presence of the SIM card. 0 Falling edge of SIMPD0 Input (default) 1 Rising edge of SIMPD0 Input
2 SPDP0	**SIMPD0 input pin status.** This bit reflects the state of the SIMPD0 pin. It is not a latched register bit, but instead a synchronized version of the state of the SIMPD0 pin itself. 0 SIMPD0 pin is logic low 1 SIMPD0 pin is logic high
1 SDI0	**SIM Detect Interrupt flag Port 0.** Status flag to indicate the insertion or removal of a SIM card has been detected on port 0. Can create an interrupt to the MCU if SDIM0 is low. Write a "1" to this bit to clear. 0 No insertion or removal of SIM card detected on Port 0 (default) 1 Insertion or removal of SIM card detected on Port 0
0 SDIM0	**SIM Detect Interrupt Mask Port 0.** Interrupt mask for the SDI0 interrupt flag. 0 sdi0 enabled 1 sdi0 masked (default)

11.2.5.15 SIM Data Format Register (SIMx_DATA_FORMAT)

See the figure below for illustration of valid bits in the SIM Data Format Register and the table below for description of the bit fields.

Address: Base address + 40h offset



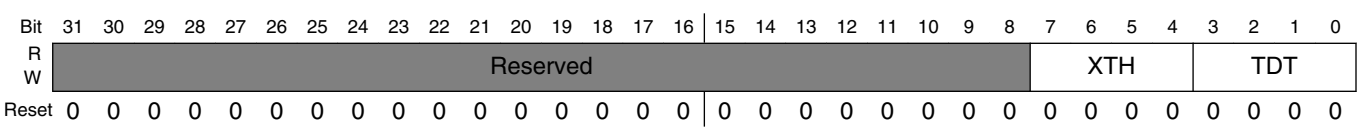
SIMx_DATA_FORMAT field descriptions

Field	Description
31–1 -	This field is reserved. Reserved
0 IC	**Inverse Convention.** Used to configure the SIM to use either inverse convention or direct convention for its data format. The IC bit can be controlled by software, but it is normally set by hardware as a result of the interpretation of the initial character when in ICM mode. 0 Direction convention transfers enabled (default). 1 Inverse convention transfers enabled.

11.2.5.16 SIM Transmit Threshold Register (SIMx_XMT_THRESHOLD)

See the figure below for illustration of valid bits in the SIM Transmit Threshold Register and the table below for description of the bit fields.

Address: Base address + 44h offset



SIMx_XMT_THRESHOLD field descriptions

Field	Description
31–8 -	This field is reserved. Reserved

Table continues on the next page...

SIMx_XMT_THRESHOLD field descriptions (continued)

Field	Description
7–4 XTH	XTH[3:0] **Transmit NACK Threshold.** Used to set the NACK threshold for the transmitter. Once the threshold number set by XTH has been reached for the current byte being transmitted, the error flag XTE in the XMT_STATUS register will be set. Setting of XTE causes the remaining transmissions queued in the transmit FIFO to be aborted and no more transmissions to occur until software clears XTE. To trigger XTE, a given byte being transmitted must reach the XTH threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next. 0x0 XTE will never be set; retransmission after NACK reception is disabled. 0x1 XTE will be set after 1 nack is received; 0 retransmissions occurs. 0x2 XTE will be set after 2 nacks are received; at most 1 retransmission occurs. 0x3 XTE will be set after 3 nacks are received; at most 2 retransmissions occurs. 0xX XTE will be set after X nacks are received; at most (X - 1) retransmissions occurs. 0xF XTE will be set after 15 nacks are received; at most 14 retransmissions occurs.
TDT	**Transmit Data Threshold.** Used to set the threshold value for the Transmit FIFO at which the TDTF bit in the XMT_STATUS register will be set. When the number of bytes in the Transmit FIFO is less than or equal to TDT[3:0], TDTF will be set.

11.2.5.17 SIM Transmit Guard Control Register (SIMx_GUARD_CNTL)

See the figure below for illustration of valid bits in the SIM Transmit Guard Control Register and the table below for description of the bit fields.

Address: Base address + 48h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIMx_GUARD_CNTL field descriptions

Field	Description
31–9 -	This field is reserved. Reserved

Table continues on the next page...

SIMx_GUARD_CNTL field descriptions (continued)

Field	Description
8 RCVR11	**Receiver use 11 ETUs.** Used to configure the SIM module receiver for 11 ETU operation (that is, 1 Stop bit). This bit is provided for support of T=1 cards. 0 Receiver configured for 12 ETU operation (default) 1 Receiver configured for 11 ETU operation
GETU	**Transmit Guard ETUs.** Used to control the number of additional Elementary Time Units (ETUs) inserted between bytes transmitted by the SIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a START bit). The guard time has no effect on the SIM receiver. A value of 0x00 inserts no additional ETUs, while a value of 0xFE inserts 254 additional ETUs. A value of 0xFF subtracts one ETU by reducing the number of STOP bits from two to one.

11.2.5.18 SIM Open Drain Configuration Control Register (SIMx_OD_CONFIG)

See the figure below for illustration of valid bits in the SIM Open Drain Configuration Control Register and the table below for description of the bit fields.

Address: Base address + 4Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIMx_OD_CONFIG field descriptions

Field	Description
31–2 -	This field is reserved. Reserved
1 OD_P1	**Open Drain control for Port 1.** Used to control whether the XMT data line on port 1 is open-drain. If AMODE bit in SETUP register is set, this bit will have no effect. 0 XMT pin on port 1 is push-pull (default). 1 XMT pin on port 1 is open-drain.

Table continues on the next page...

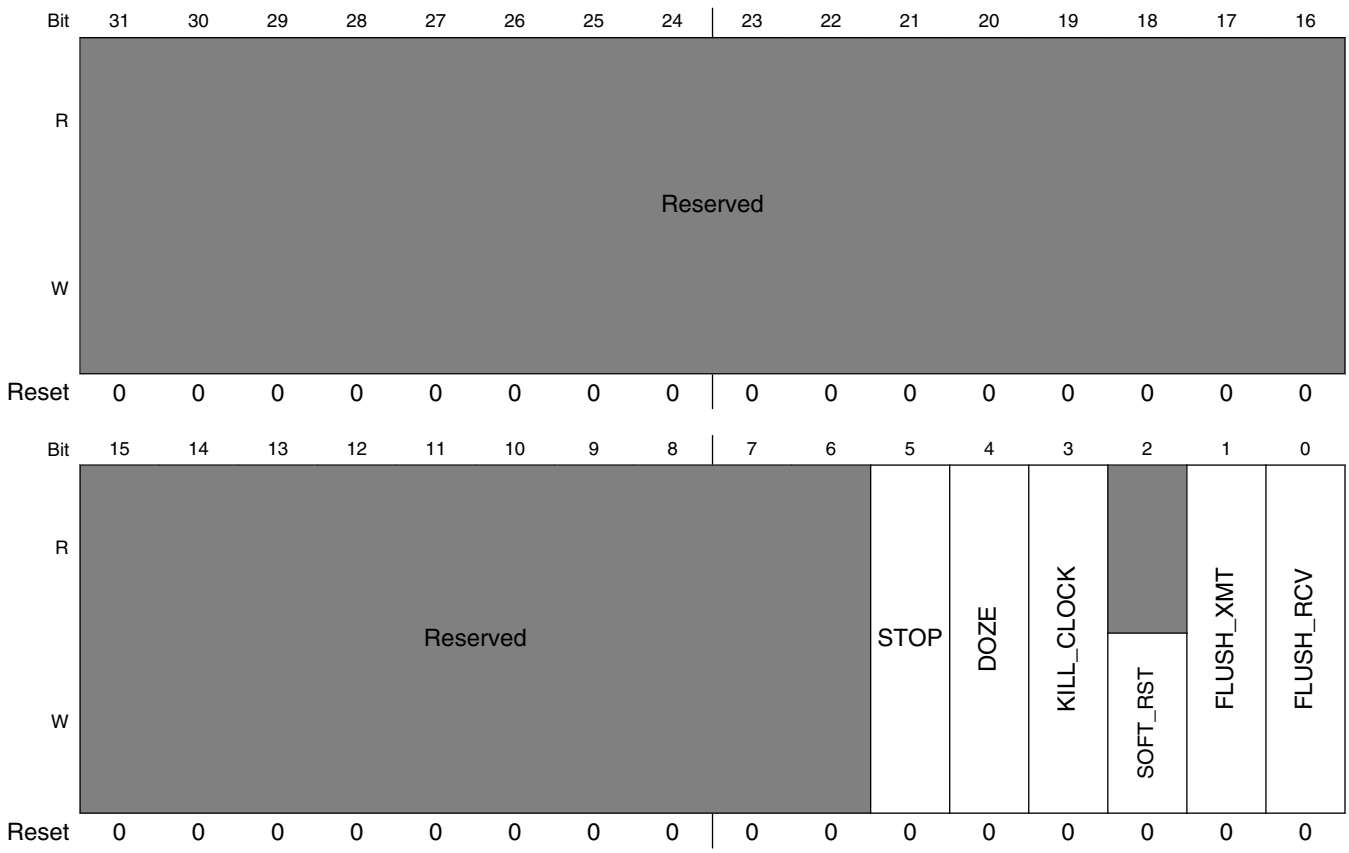
SIMx_OD_CONFIG field descriptions (continued)

Field	Description
0 OD_P0	**Open Drain control for Port 0.** Used to control whether the XMT data line on port 0 is open-drain. 0 XMT pin on port 0 is push-pull (default). 1 XMT pin on port 0 is open-drain.

11.2.5.19 SIM Reset Control Register (SIMx_RESET_CNTL)

See the figure below for illustration of valid bits in the SIM Reset Control Register and the table below for description of the bit fields.

Address: Base address + 50h offset



SIMx_RESET_CNTL field descriptions

Field	Description
31–6 -	This field is reserved. Reserved

Table continues on the next page...

SIMx_RESET_CNTL field descriptions (continued)

Field	Description
5 STOP	**STOP.** Used to configure the operation of the SIM module when a processor STOP instruction is executed. This bit is added to provide support for SIM cards that do not allow the SIM Card clock to be stopped while power is applied. 0 STOP instruction shuts down all SIM clocks (default). 1 STOP instruction shuts down all clocks except for the BAUD_CLK (clock provided to SIM Card).
4 DOZE	DOZE. Used to configure the operation of the SIM module when a processor DOZE instruction is executed. 0 DOZE instruction has no effect on SIM module (default). 1 DOZE instruction will cause SIM module to gate SIM clocks when the transmit FIFO is empty.
3 KILL_CLOCK	**Kill** SIM **Clock.** Used to enable/disable the SIM clock input to the SIM module. This bit will gate all SIM clocks including the SIM card clock regardless of the state of the STOP bit described above. 0 SIM input clock enabled (default). 1 SIM input clock disabled.
2 SOFT_RST	**Software Reset.** Used to reset the entire SIM module. This acts the same as a hardware reset for the SIM module. This bit is self-clearing. **NOTE:** Software should allow a minimum of 4 reference clock cycles (CKIH) before attempting to access the SIM module after a software reset. 0 SIM Normal operation (default). 1 SIM held in Reset.
1 FLUSH_XMT	**Flush Transmitter.** This bit operates as a SIM transmitter reset. The receive portion of the SIM module is not affected. The software must clear this bit before the SIM transmitter can operate. 0 SIM Transmitter normal operation (default). 1 SIM Transmitter held in Reset.
0 FLUSH_RCV	**Flush Receiver.** This bit operates as a SIM receiver reset. The transmit portion of the SIM module is not affected. The software must clear this bit before the SIM receiver can operate. 0 SIM Receiver normal operation (default). 1 SIM Receiver held in Reset.

11.2.5.20 SIM Character Wait Time Register (SIMx_CHAR_WAIT)

See the figure below for illustration of valid bits in the SIM Character Wait Time Register and the table below for description of the bit fields.

Address: Base address + 54h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																CWT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

SIMx_CHAR_WAIT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CWT	**Character Wait Time.** The value written to this register will specify the number of ETU times allowed between characters. Default is 0xFFFF

11.2.5.21 SIM General Purpose Counter Register (SIMx_GPCNT)

See the figure below for illustration of valid bits in the SIM General Purpose Counter Register and the table below for description of the bit fields.

Address: Base address + 58h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																GPCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

SIMx_GPCNT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
GPCNT	**General Purpose Counter.** The value written to this register will be used to compare to the general purpose counter in the SIM module. Once the General purpose counter reaches this value, the GPCNT flag in the XMT_STATUS register will be set. This counter is intended to be used for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration. Default is 0xFFFF

11.2.5.22 SIM Divisor Register (SIMx_DIVISOR)

See the figure below for illustration of valid bits in the SIM Divisor Register and the table below for description of the bit fields.

Address: Base address + 5Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																								DIVISOR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

SIMx_DIVISOR field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
DIVISOR	**DIVISOR Register.** The value written to this register will be used to generate the SIM Receive clock. The BAUD_SEL[2:0] bits in the CNTL register must be set to '111' in order to control the divisor value using the DIVISOR register. Default is 0xFF

11.2.5.23 SIM Block Wait Time Register (SIMx_BWT)

See the figure below for illustration of valid bits in the SIM Block Wait Time Register and the table below for description of the bit fields.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																BWT

11.3 Universal Serial Bus Controller (USB)

11.3.1 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision* 2.0 Specification (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of three independent USB controller cores: two On-The-Go (OTG) controller cores, and one Host-only controller core. Each controller core connects to its dedicated on-chip USB PHY instance using a UTMI interface. See Features for more details. All three controller cores are single-port cores.

The following figure is a block diagram of USB.

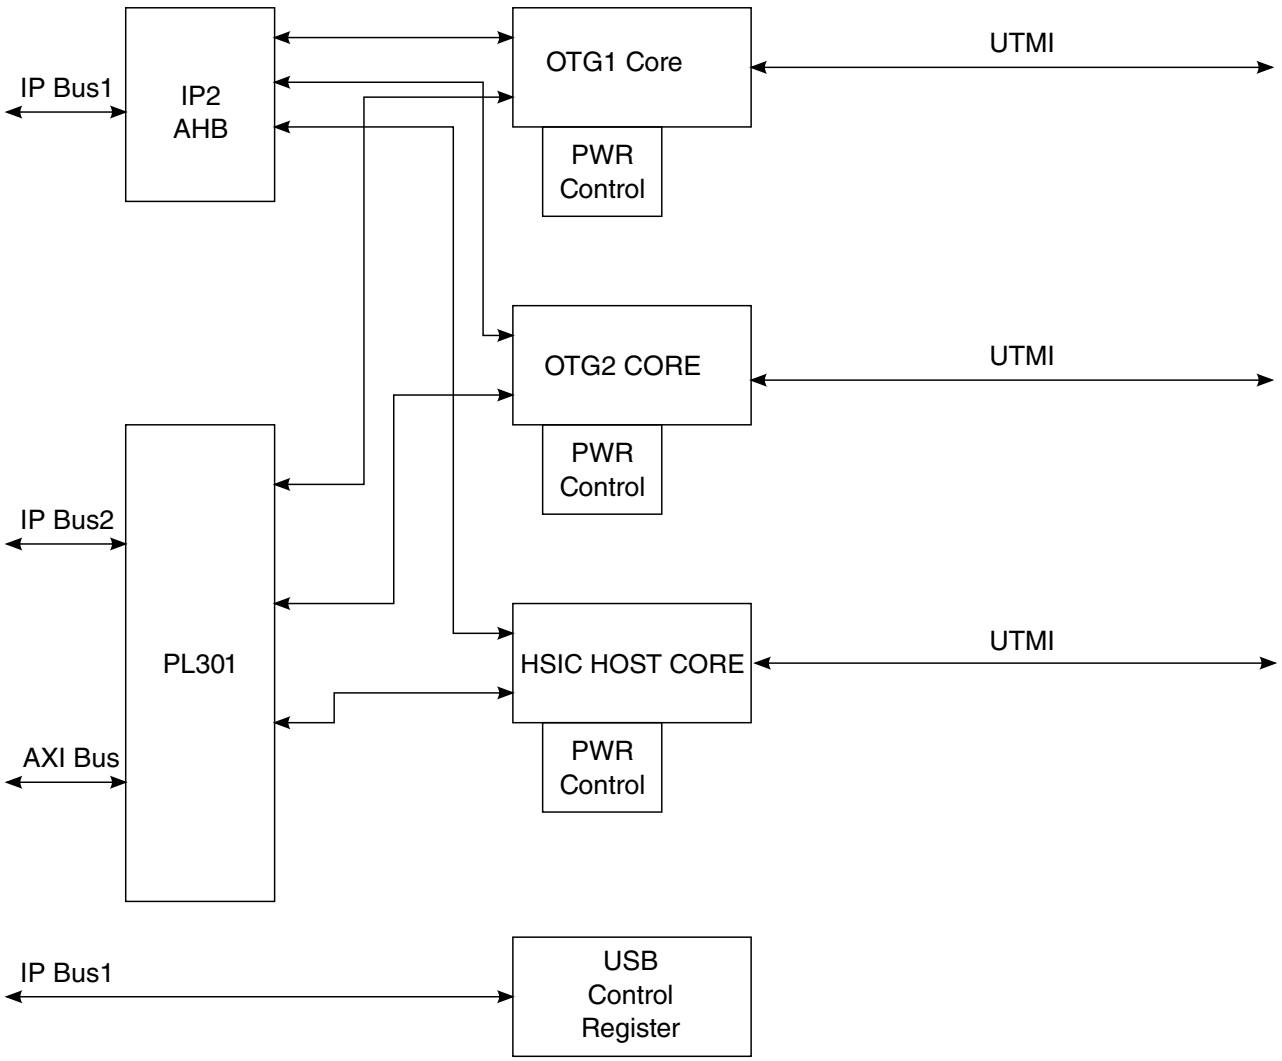

Figure 11-52. USB block diagram

11.3.1.1 Features

There are three USB 2.0 controller cores in this chip:

- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.
- Controller Core 2 is also named 'HSIC'.

The following list provides features of each of the controller cores.

- USB 2.0 Controller Core 0
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes dedicated timer hardware and register interface.
  - Up to 8 bidirectional endpoints
  - Supports charger detection with USB_OTG1_CHD_B pin and register interface
- USB 2.0 Controller Core 1
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface connected to on-chip UTMI PHY
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - High Speed, and Full Speed operation in Peripheral mode (with UTMI transceiver)
  - Hardware support for OTG signaling, Session Request Protocol (SRP), Host Negotiation Protocol (HNP), and Attach Detection Protocol (ADP). ADP support includes basic register interface only.
  - Up to 8 bidirectional endpoints
  - Supports charger detection with register interface only
- USB 2.0 Controller Core 2
  - High-Speed Host-Only core
  - HS UTMI interface connectes to on-chip HSIC PHY
- Low-power mode with local and remote wake-up capability
- Embedded DMA controller in each core

11.3.1.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.

Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps, Host mode only).

The HSIC controller core supports High Speed operation (other USB speeds are not defined for HSIC).

This chapter explains the operation modes.

11.3.1.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode. The Host-only HSIC controller core can operate in Host mode only.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

NOTE

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC.PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.
- Host1 Port
  - This port supports on-chip HSIC transceiver only.

    Interface for on-board HSIC compatible USB peripherals.

11.3.1.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local ARM platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see USB Power Control.

11.3.2 External Signals

The table found here describes the external signals of USB.

Table 11-54. USB External Signals

Signal	Description	Pad	Mode	Direction
USB_OTG1_ID	OTG1 ID Signal	GPIO1_IO02	ALT7	I
		GPIO1_IO12	ALT7	
		I2C4_SCL	ALT4	
		SD2_WP	ALT4	
USB_OTG1_OC	External Input for VBUS overcurrent detectoin	GPIO1_IO04	ALT1	I
		UART3_RXD	ALT1	
USB_OTG1_PWR	To control PMIC to supply VBUS voltage	GPIO1_IO05	ALT1	O
		UART3_TXD	ALT1	
USB_H_DATA	Data Signal	USB_H_DATA	No muxing	IO
USB_H_STROBE	Strobe Signal	USB_H_STROBE	No muxing	IO
USB_OTG1_CHD_B	Charge Detect Signal	USB_OTG1_CHD_B	No muxing	IO
USB_OTG1_DN	OTG1 DN Signal	USB_OTG1_DN	No muxing	O
USB_OTG1_DP	OTG1 DP Signal	USB_OTG1_DP	No muxing	IO
USB_OTG1_ID	OTG1 ID Signal	USB_OTG1_ID	No muxing	I
USB_OTG1_REXT	External reference resistor input.	USB_OTG1_REXT	No muxing	IO

11.3.3 Functional Description

These sections describe the functionality of the various building blocks of the USB.

11.3.3.1 USB 2.0 Controller Core 1

The USB 2.0 Controller 1 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

11.3.3.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

11.3.3.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP, ADP, and SRP
- Remote wake-up capability

11.3.3.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

11.3.3.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the ARM platform from core sleep mode by generating an interrupt.

11.3.3.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1.
3. Set the "PHCD" bit in USB_PORTSC1.

For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS).
2. Set the "PHCD" bit on USB_PORTSC1

11.3.3.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt (asynchronous) will be generated to ARM platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the ARM platform clocks if they were stopped during the suspend.

11.3.3.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect

If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see Port Status & Control (USB_PORTSC1).

11.3.3.3.2.2 USB OTG Power Domains

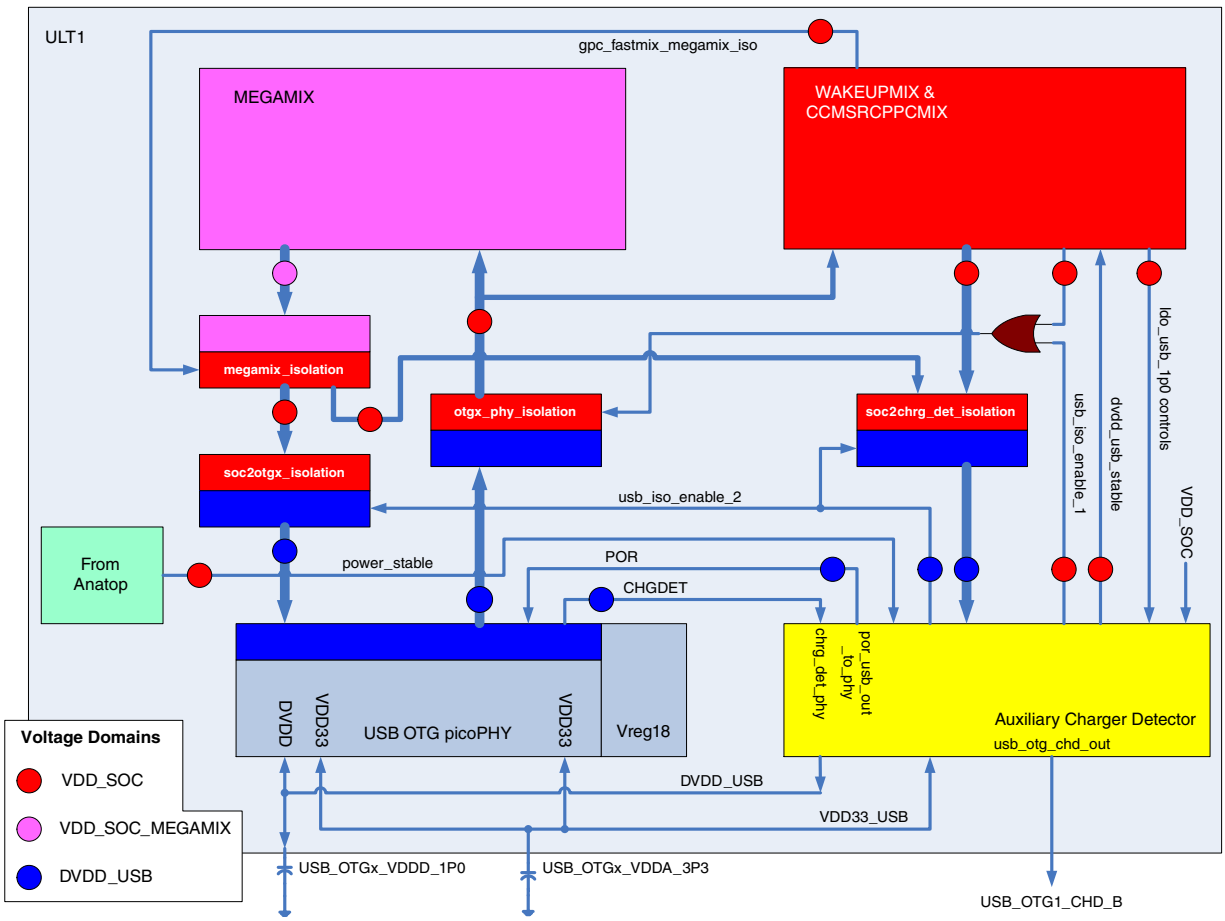

Figure 11-53. USB OTG Power Domains

11.3.3.3.2.2.1 Power Overview

USB controller and USB OTG PHY are in different power domains. USB controller locates in megamix power domain. USB OTG PHY has three powers: VDD33, VDD18, and DVDD (1.0 V).

- VDD33 comes from external of the chip, which may be from VBUS or 3.3 V power supply depend on the board design.
- VDD18 is generated by on-chip regulator vreg18 from VDD33.
- DVDD is generated by on-chip regulator inside the Auxiliary Charger Detector from VDD33.

All three OTG PHY power supplies turn on/off at same time.

Auxiliary Charger Detector can detect each power to control related power isolations and generate reset signal for the PHY.

11.3.3.3.2.2.2 Wake-up in Power Down Mode

NOTE

USB controller or OTG PHY can only power down during USB disconnect mode, power down any part when device/host is connected will cause unknown result.

11.3.3.3.2.2.2.1 Power Down USB Controller

When USB controller is power down, it can be wake-up by changes on PHY port. This is completed by the wake-up logic in the wakeupmix (it is always on power domain).

NOTE

This wake-up does not generate any interrupts, the wake-up event is only used to power up the system (includes USB controller), software re-initials the USB controller like a system power up event.

The wake-up source in the USB controller power down mode includes following:

- ID
- VBUS/SESS_VLD
- DP/DM

The related enable signals come from USB_x_CTRL1, software set related enable signals before USB controller is power down. The latch based isolation cells keep these enable values.

11.3.3.4 Interrupts

11.3.3.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the Interrupt Enable Register (USB_USBINTR) for details.

11.3.3.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and ARM platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the ARM platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the ARM platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

11.3.4 USB Operation Model

11.3.4.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

NOTE

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

Table 11-55. Interface Register Sets

Offset	Register Set	Explanation
000h-07Ch	Identification Registers	Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.
100h-124h	Capability Registers	Capability registers specify the limits, restrictions, and capabilities of a host/device controller implementation. These values are used as parameters to the host/device controller driver.
080h-0FCh 140h-1FCh	Operational Registers	Operational registers are used by the system software to control and monitor the operational state of the host/device controller.

11.3.4.1.1 Configuration, Control and Status Register Set

The following table describes the Device/Host capability registers.

.

Table 11-56. Device/Host Capability Registers

Offset	Size (Bytes)	Mnemonic	Register Name	Device Mode	Host Mode
000h	4	USB_*x*_ID	Identification Register	O	O

1C0 1C4 ... 1DCh	64	USB_*x*_ENDPTCTRL0 USB_*x*_ENDPTCTRL1 .... USB_*x*_ENDPTCTRL7	Endpoint Control Register 0-7	O	X

NOTE

"O" means the register is available in host/device operation mode;

"X" means the register is reserved in host/device operation mode

11.3.4.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

11.3.4.1.3 OTG Operations

11.3.4.1.3.1 Register Bits

In the previous section, the Register interface has behaviors described for device mode and behaviors described for host mode. However, for OTG operations it is necessary to perform tasks independent of the controller mode.

The following figure shows the controller mode.

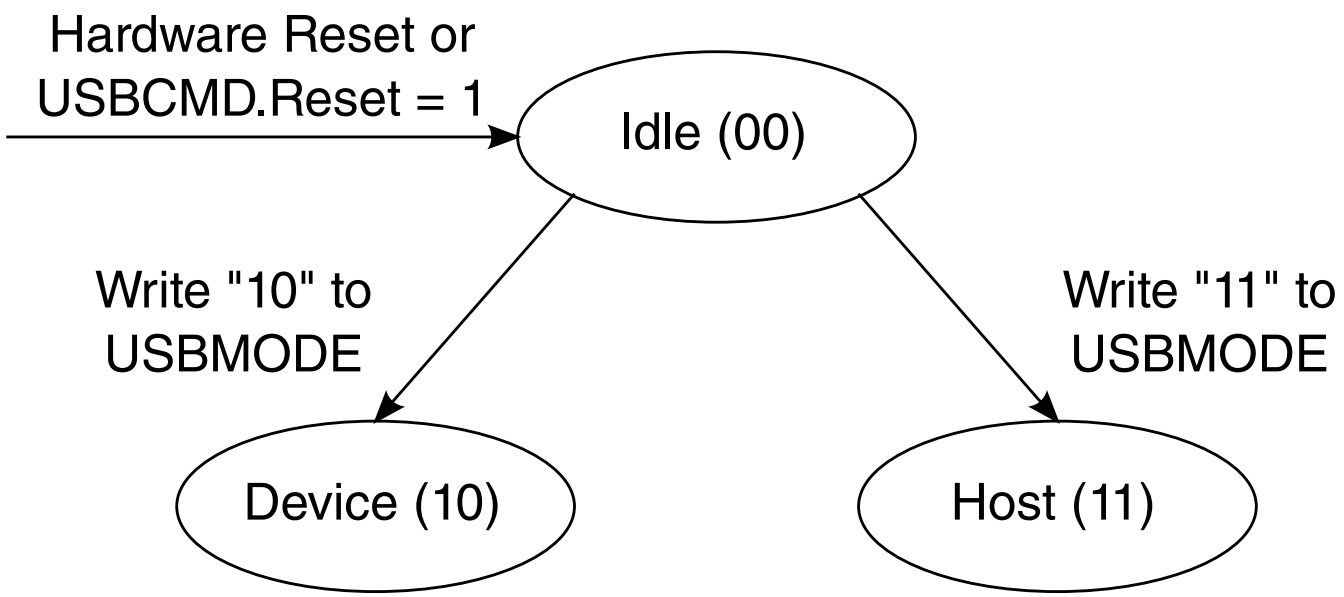

Figure 11-54. Controller Mode

To this end, listed below are the register bits that are used for OTG operations, which are independent of the controller mode and are also not affected by a write to the reset bit in the USBCMD register:

All Identification Registers

All Device/Host Capability Registers

OTGSC: All bits

Port Power

11.3.4.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

11.3.4.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASE address register and the USB_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.

The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

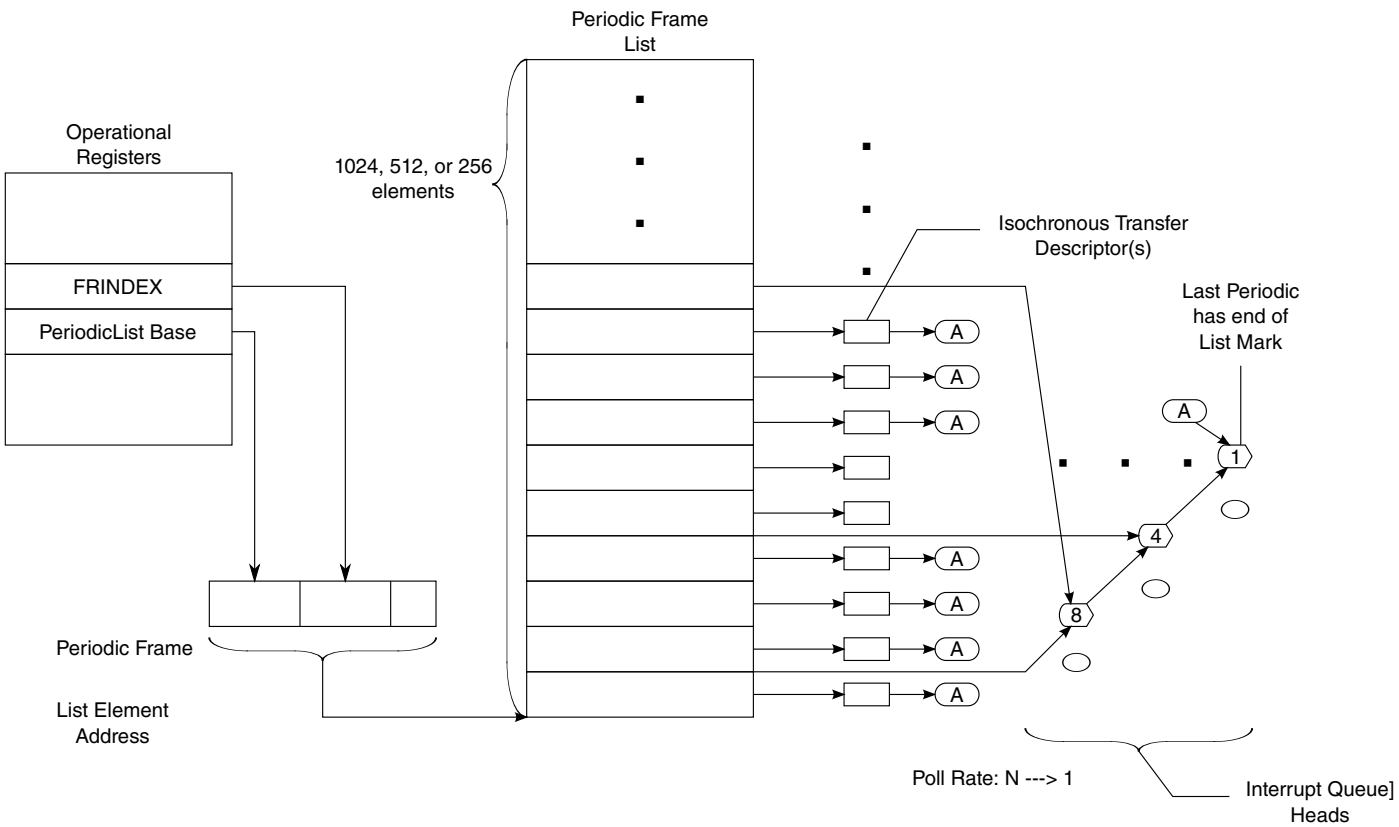

Figure 11-55. Periodic Schedule Organization

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must

support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.

The table below illustrates the format of the Frame list element pointer.

Table 11-57. Format of Frame List Element Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Frame List Link Pointer																											0		Typ			03-00H

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

Table 11-58. Typ Field Value Definitions

Value	Meaning
00b	Isochronous Transfer Descriptor
01b	Queue Head
10b	Split Transaction Isochronous Transfer Descriptor.
11b	Frame Span Traversal Node.

11.3.4.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.

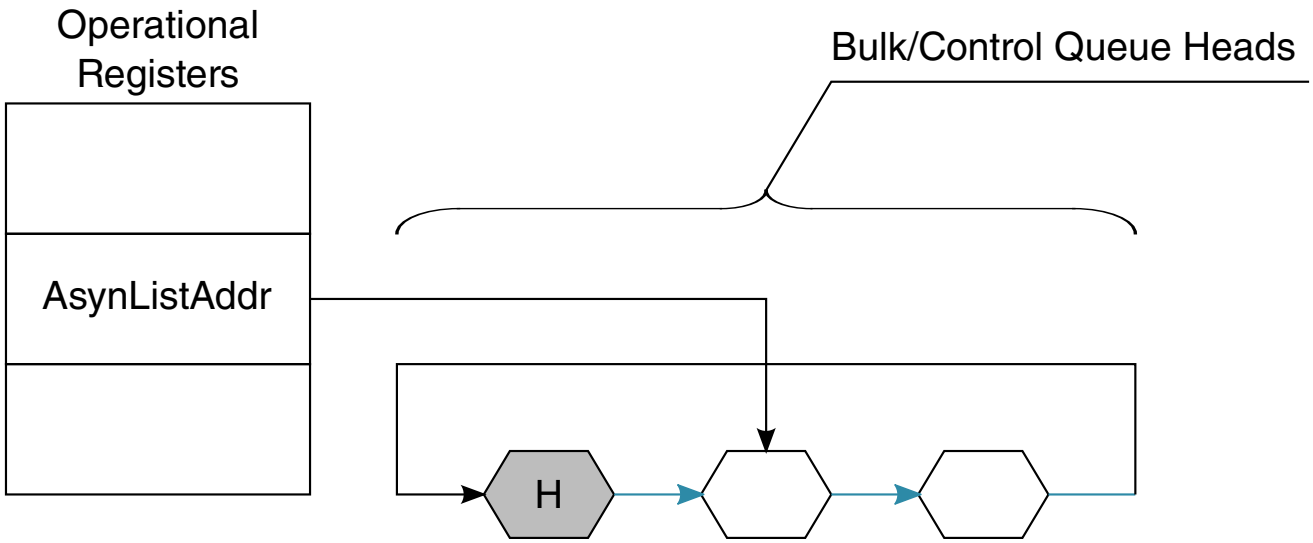

Figure 11-56. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

11.3.4.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below.

This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 11-59. Isochronous Transaction Descriptor (iTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host Controller Read/Write

Host Controller Read Only

These fields may be modified by the host controller if the I/O field indicates an OUT.

11.3.4.2.3.1 Next Link Pointer

The first DWord of an iTD is a pointer to the next schedule data structure.

The following table describes the Next Schedule Element pointer field.

Table 11-60. Next Schedule Element Pointer

Bit	Description
31-5 Link Pointer (LP)	These bits correspond to memory address signals [31:5], respectively. This field points to another Isochronous Transaction Descriptor (iTD/siTD) or Queue Head (QH).

Table continues on the next page...

Table 11-60. Next Schedule Element Pointer (continued)

4-3 Reserved	These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1 QH/(s)iTD Select (Typ)	This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0 Terminate (T)	1= Link Pointer field is not valid. 0= Link Pointer field is valid.

11.3.4.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 11-61. iTD Transaction Status and Control

Bit	Description	
31-28 Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
	Bit	Definition
	31	Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.
	30	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.
	29	Babble Detected. Set to one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 11-61. iTD Transaction Status and Control (continued)

Bit	Description	
	28	Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.
27-16 Transaction X Length	For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).	
15 Interrupt On Complete (IOC)	If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.	
14-12 Page Select (PG)	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.	
11-0 Transaction X Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent *PG* field to produce the starting buffer address for this transaction.	

11.3.4.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 11-62. iTD Buffer Pointer Page 0 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 0)	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-8	This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.

Table continues on the next page...

Table 11-62. iTD Buffer Pointer Page 0 (Plus) (continued)

Bit	Description
Endpoint Number (Endpt)	
7 Reserved	Bit reserved for future use and should be initialized by software to zero.
6-0 Device Address	This field selects the specific device serving as the data source or sink.

Table 11-63. iTD Buffer Pointer Page 1 (Plus)

Bit	Description
31-12 Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11 Direction (I/O)	0 = OUT; 1 = IN. This field encodes whether the high-speed transaction should use an IN or OUT PID.
10-0 Maximum Packet Size	This directly corresponds to the maximum packet size of the associated endpoint *(wMaxPacketSize)*. This field is used for high-bandwidth endpoints where more than one transaction is issued per transaction description (per micro-frame). This field is used with the *Multi* field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (400h). Any value larger yields undefined results.

Table 11-64. iTD Buffer Pointer Page 2 (Plus)

Bit	Description
31-12 Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits [31:12].
11-2 Reserved	This bit reserved for future use and should be set to zero.
1-0 Multi	This field is used to indicate to the host controller the number of transactions that should be executed per transaction description (per micro-frame). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro- frame. 10b Two transactions to be issued for this endpoint per micro- frame. 11b Three transactions to be issued for this endpoint per micro- frame.

Table 11-65. iTD Buffer Pointer Page 3-6

Bit	Description
31-12 Buffer Pointer	This is a 4 K aligned pointer to physical memory. Corresponds to memory address bits [31:12].

Table 11-65. iTD Buffer Pointer Page 3-6 (continued)

Bit	Description
11-0 Reserved	These bits reserved for future use and should be set to zero.

11.3.4.2.4 Split Transaction Isochronous Transfer Descriptor (siTD)

All Full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure. This data structure satisfies the operational requirements for managing the split transaction protocol.

The following table shows the Split Transaction Isochronous Transfer Descriptor (siTD).

Table 11-66. Split Transaction Isochronous Transfer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Host Controller Read/Write

Host Controller Read Only

11.3.4.2.4.1 Next Link Pointer

DWord0 of a siTD is a pointer to the next schedule data structure.

The following table describes the Next Link Pointer fields.

Table 11-67. Next Link Pointer

Bit	Description
31-5	Next Link Pointer (LP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved. These bits must be written as zeros.
2-1	QH/(s)iTD Select (Typ). This field indicates to the Host Controller whether the item referenced is an iTD/siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor 11b FSTN (frame span traversal node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

11.3.4.2.4.2 siTD Endpoint Capabilities/Characteristics

DWords 1 and 2 specify static information about the full-speed endpoint, the addressing of the parent Companion Controller, and micro-frame scheduling control.

The tables below describe the Endpoint and transaction translator characteristics and micro-frame schedule control fields.

Table 11-68. Endpoint and Transaction Translator Characteristics

Bit	Description
31	Direction (I/O).0 = OUT; 1 = IN. This field encodes whether the full-speed transaction should be an IN or OUT.
30-24	Port Number. This field is the port number of the recipient Transaction Translator.
23	Reserved. Bit reserved and should be set to zero.
22-16	Hub Address. This field holds the device address of the Companion Controllers' hub.
15-12	Reserved. Field reserved and should be set to zero.
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.
7	Reserved. Bit is reserved for future use. It should be set to zero.
6-0	Device Address. This field selects the specific device serving as the data source or sink.

Table 11-69. Micro-frame Schedule Control

Bit	Description
31-16	Reserved. This field reserved for future use. It should be set to zero.

Table continues on the next page...

Table 11-69. Micro-frame Schedule Control (continued)

Bit	Description
15-8	Split Completion Mask (mFrame C-Mask). This field (along with the *Active* and *SplitX- state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute complete-split transactions. When the criteria for using this field is met, an all zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame C-Mask* field is a one, then this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Split Start Mask (mFrame S-mask). This field (along with the *Active* and *SplitX-state* fields in the *Status* byte) is used to determine during which micro-frames the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the m*Frame S-mask* field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

11.3.4.2.4.3 siTD Transfer State

DWords 3-6 are used to manage the state of the transfer.

The following table describes siTD transfer state fields.

Table 11-70. siTD Transfer Status and Control

Bit	Description
31	Interrupt On Complete (ioc). 0 = Do not interrupt when transaction is complete. 1 = Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it asserts a hardware interrupt at the next interrupt threshold.
30	Page Select (P). Used to indicate which data page pointer should be concatenated with the *CurrentOffset* field to construct a data buffer pointer (0 selects *Page 0* pointer and 1 selects *Page 1*). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
29-26	Reserved. This field reserved for future use and should be set to zero.
25-16	Total Bytes To Transfer. This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)
15-8	µFrame Complete-split Progress Mask (C-prog-Mask). This field is used by the host controller to record which split-completes has been executed.
7-0: Status—This field records the status of the transaction executed by the host controller for this slot. It is a bit vector with the encoding shown in the following rows.	
7	Active. Set to one by software to enable the execution of an isochronous split transaction by the Host Controller.
6	ERR. Set to a one by the Host Controller when an ERR response is received from the Companion Controller.
5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the Host Controller transmits an incorrect CRC (thus invalidating the data at the endpoint). If an overrun condition occurs, no action is necessary.
4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 11-70. siTD Transfer Status and Control (continued)

Bit	Description
3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit is set only for IN transactions.
2	Missed Micro-Frame. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
1	Split Transaction State (SplitXstate). The bit encodings are: Value Meaning 00b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint when a match is encountered in the S-mask. 01b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint when a match is encountered in the C-mask.
0	Reserved. Bit reserved for future use and should be set to zero.

11.3.4.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 11-71. Buffer Page Pointer List (plus)

Bit	Description
31-12	Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field *P* (see siTD Transfer State) specifies the *current* active pointer.
Bits 11-0 (Page 0)	Current Offset—The 12 least significant bits of the Page 0 pointer are the current byte offset for the current page pointer (as selected with the page indicator bit (*P* field). The host controller is not required to write this field back when the siTD is retired (*Active* bit transitioned from a one to a zero).
Bits 11-0 (Page 1)—The least significant bits of the Page 1 pointer are split into three subfields as shown in the following rows.	
11-5 (Page 1)	Reserved
4-3 (Page 1)	Transaction position (TP). This field is used with T-count to determine whether to send *all*, *first*, *middle*, or *last* with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are: Value Meaning

Table continues on the next page...

Table 11-71. Buffer Page Pointer List (plus) (continued)

Bit	Description
	00b All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01b Begin. This is the first data payload for a full- speed that is greater than 188 bytes. 10B Mid. This is the *middle* payload for a full-speed OUT transaction that is larger than 188 bytes. 11b End. This is the *last* payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0 (Page 1)	Transaction count (T-Count). Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

11.3.4.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

Table 11-72. siTD Back Link Pointer

Bit	Description
31-5	siTD Back Pointer. This field is a physical memory pointer to a siTD.
4-1	Reserved. This field is reserved for future use. It should be set to zero.
0	Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.

11.3.4.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The following table shows the queue element transfer descriptor data structure.

Table 11-73. Queue element transfer descriptor data structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

1. 08-0F: Transfer Results

Host Controller Read/Write

Host Controller Read Only

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

11.3.4.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

Table 11-74. qTD Next Element Transfer Pointer (DWord 0)

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

11.3.4.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

Table 11-75. TD Alternate Next Element Transfer Pointer (DWord 1)

Bit	Description
31-5	Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved
0	Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.

11.3.4.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

NOTE

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

Table 11-76. TD Token (DWord 2)

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>31
Data Toggle</td><td>This is the data toggle sequence bit. The use of this bit depends on the setting of the Data Toggle Control bit in the queue head.</td></tr>
<tr><td>30-16
Total Bytes to Transfer</td><td>This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 * 4K (5000H). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that Total Bytes To Transfer be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.

Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</td></tr>
<tr><td>15
Interrupt On Complete (IOC)</td><td>If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.</td></tr>
<tr><td>14-12
Current Page (C_Page)</td><td>This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.</td></tr>
<tr><td>11-10
Error Counter (CERR)</td><td>This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the Halted bit to a one, and error status bit for the error that caused CERR to decrement to zero. An interrupt is generated if the USB Error Interrupt Enable bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.

Transaction Error - Decrement

Data Buffer Error - No Decrement[3]

Stalled - No Decrement[1]

Babble Detected - No Decrement[1]

No Error - No Decrement[2]
<table>
<tr><td>Error</td><td>Decrement Counter</td></tr>
<tr><td>1</td><td>Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented</td></tr>
<tr><td>2</td><td>If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset CERR to extend the total number of errors for this transaction. For example, CERR should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.</td></tr>
</table>
</td></tr>
</table>

Table continues on the next page...

Table 11-76. TD Token (DWord 2) (continued)

Bit	Description	
		See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the *PIDCode* indicates a SETUP.
	3	Data buffer errors are host problems. They don't count against the device's retries.
	NOTE: Software must not program CERR to a value of zero when the EPS field is programmed with a value indicating a Full- or Low-speed device. This combination could result in undefined behavior.	
9-8 PID Code	This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:	
	00b	OUT Token generates token (E1H)
	01b	IN Token generates token (69H)
	10b	SETUP Token generates token (2DH) (undefined if endpoint is an interrupt, the queue head is non-zero) transfer type, for example, µ*Frame S-mask* field in.
	11b	Reserved
7-0 Status	This field is used by the Host Controller to communicate individual command execution states back to HCD. This field contains the status of the last transaction performed on this qTD. The bit encodings are:	
	Bit	Status Field Description
	7	Active. Set to one by software to enable the execution of transactions by the Host Controller.
	6	Halted. Set to one by the Host Controller during status updates to indicate that a serious error has occurred at the device/endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set to a one, the Active bit is also set to zero.
	5	Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the Host Controller forces a timeout condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	4	Babble Detected. Set to a one by the Host Controller during status update when" babble" is detected during the transaction. In addition to setting this bit, the Host Controller also sets the *Halted* bit to a one. Because "babble" is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
	3	Transaction Error (XactErr). Set to a one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.

Table continues on the next page...

Table 11-76. TD Token (DWord 2) (continued)

Bit	Description	
	2	Missed Micro-Frame. This bit is ignored unless the *QH.EPS* field indicates a full- or low-speed endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
	1	Split Transaction State (SplitXstate). This bit is ignored by the host controller unless the *QH.EPS* field indicates a full- or low-speed endpoint. When a Full- or Low-speed device, the host controller uses this bit to track the state of the split-transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the endpoint is in the periodic or asynchronous schedule. The bit encodings are: Value Meaning 0b Do Start Split. This value directs the host controller to issue a Start split transaction to the endpoint. 1b Do Complete Split. This value directs the host controller to issue a Complete split transaction to the endpoint.
	0	Ping State (P)/ERR. If the *QH.EPS* field indicates a High-speed device and the *PID_Code* indicates an OUT endpoint, then this is the state bit for the Ping protocol. The bit encodings are: Value Meaning 0b Do OUT. This value directs the host controller to issue an OUT PID to the endpoint. 1b Do Ping. This value directs the host controller to issue a PING PID to the endpoint. If the *QH.EPS* field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.

11.3.4.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 11-77. qTD Buffer Pointer(s) (DWords 3-7)

Bit	Description
31-12	Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to

Table continues on the next page...

Table 11-77. qTD Buffer Pointer(s) (DWords 3-7) (continued)

	select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.
11-0	Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.

11.3.4.2.6 Queue Head

The following table shows the queue head structure layout.

Table 11-78. Queue Head Structure Layout

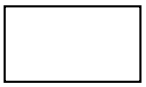
1. 04-0B: Static endpoint state.
2. These fields are used exclusively to support split transactions to USB 2.0 hubs
3. 10-2F: Transfer overlay.
4. 14-27: Transfer results.

Host Controller Read/Write



Host Controller Read Only

11.3.4.2.6.1 Queue Head Horizontal Link Pointer

The first DWord of a Queue Head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The following table describes the Queue head DWord 0 fields.

Table 11-79. Queue Head DWord 0

Bit	Description
31-5	Queue Head Horizontal Link Pointer (QHLP). This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD Select (Typ). This field indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)
0	Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

11.3.4.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.

- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

Table 11-80. Endpoint Characteristics: Queue Head DWord 1

Bit	Description	
31-28	Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.	
27	Control Endpoint Flag (C). If the *QH.EPS* field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.	
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (*wMaxPacketSize*). The maximum value this field may contain is 0x400 (1024).	
15	Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.	
14	Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition. 0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.	
13-12	Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:	
	Value	Meaning
	00b	Full-Speed (12 Mbits/sec)
	01b	Low-Speed (1.5 Mbits/sec)
	10b	High-Speed (480 Mbits/sec)
	11b	Reserved
	This field must not be modified by the host controller.	
11-8	Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink.	
7	Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule , for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the *EPS* field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the *EPS* field indicates a high-speed device yields undefined results.	
6-0	Device Address. This field selects the specific device serving as the data source or sink.	

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

Table 11-81. Endpoint Capabilities: Queue Head DWord 2

Bit	Description
31-30	High-Bandwidth Pipe Multiplier (Mult). This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). The valid values are: Value Meaning 00b Reserved. A zero in this field yields undefined results. 01b One transaction to be issued for this endpoint per micro-frame. 10b Two transactions to be issued for this endpoint per micro-frame. 11b Three transactions to be issued for this endpoint per micro-frame.
29-23	Port Number. This field is ignored by the host controller unless the *EPS* field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 Hub (for hub at device address *Hub Addr* below), below which the full- or low-speed device associated with this endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub Addr. This field is ignored by the host controller unless the *EPS* field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 Hub below which the full- or low-speed device associated with this endpoint is attached. This field is used in the split-transaction protocol.
15-8	Split Completion Mask (µFrame C-Mask). This field is ignored by the host controller unless the *EPS* field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the *Active* and *SplitX-state* fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the µ*Frame C- Mask* field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	Interrupt Schedule Mask (µFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µ*Frame S-mask* field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the *EPS* field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the *PID_Code* field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the *EPS* field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

11.3.4.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.

Table 11-82. Current qTD Link Pointer

Bit	Description
31-5	Current Element Transaction Descriptor Link Pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

Table 11-83. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)

DWord	Bit	Description
5	4-1	Nak Counter (NakCnt)µRW. This field is a counter the host controller decrements whenever a transaction for the endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from *RL* before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	31	Data Toggle. The *Data Toggle Control* controls whether the host controller preserves this bit when an overlay operation is performed.
6	15	Interrupt On Complete (IOC). The IOC control bit is always inherited from the source qTD when the overlay operation is performed.
6	11-10	Error Counter (C_ERR). This two-bit field is copied from the qTD during the overlay and written back during queue advancement.
6	0	Ping State (P)/ERR. If the *EPS* field indicates a high-speed endpoint, then this field should be preserved during the overlay operation.
8	7-0	Split-transaction Complete-split Progress (C-prog-mask). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	4-0	Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.
9	11-5	S-bytes. Software must ensure that the *S-bytes* field in a *qTD* is zero before activating the *qTD*. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.

11.3.4.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.

See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

Table 11-84. Frame Span Traversal Node Structure Layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Addr

Back Path Link Pointer																											0		Typ[1]		T	07-04

1. Must be set to indicate a queue head

Host Controller Read/Write

Host Controller Read Only

11.3.4.2.7.1 FSTN Normal Path Pointer

The first DWord of an FSTN contains a link pointer to the next schedule object. This object can be of any valid periodic schedule data type.

The following table describes the FSTN normal path pointer fields.

Table 11-85. FSTN Normal Path Pointer Field Descriptions

Bit	Description
31-5	Normal Path Link Pointer (NPLP). This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	QH/(s)iTD/FSTN Select (Typ). This field indicates to the Host Controller whether the item referenced is a iTD/siTD, a QH or an FSTN. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor)

Table continues on the next page...

Table 11-85. FSTN Normal Path Pointer Field Descriptions (continued)

	11b FSTN (Frame Span Traversal Node)
0	Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.

11.3.4.2.7.2 FSTN Back Path Link Pointer

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

Table 11-86. FSTN Back Path Link Pointer Field Descriptions

Bit	Description
31-5	Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.
4-3	Reserved
2-1	Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.
0	Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.

11.3.4.3 Host Operational Model

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

11.3.4.3.1 Host Controller Initialization

After initial power-on or HCReset (hardware or through HCReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.

.

Table 11-87. Default Values of Operational Register Space

Operational Register	Default Value (after Reset)
USB_USBCMD	00080000h (00080B00h, if *Asynchronous Schedule Park Capability is one*)
USB_USBSTS	00001000h
USB_USBINTR	00000000h
USB_FRINDEX	00000000h
USB_CTRLDSSEGMENT	00000000h
USB_PERIODICLISTBASE	Undefined
USB_ASYNCLISTADDR	Undefined
USB_CONFIGFLAG	00000000h
USB_PORTSC1	00002000h (w/*PPC* set to one); 00003000h (w/*PPC* set to zero)

To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLIST BASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

NOTE

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

11.3.4.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

NOTE

The USB controllers on i.MX parts do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to Embedded Transaction Translator Function for detail!

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.

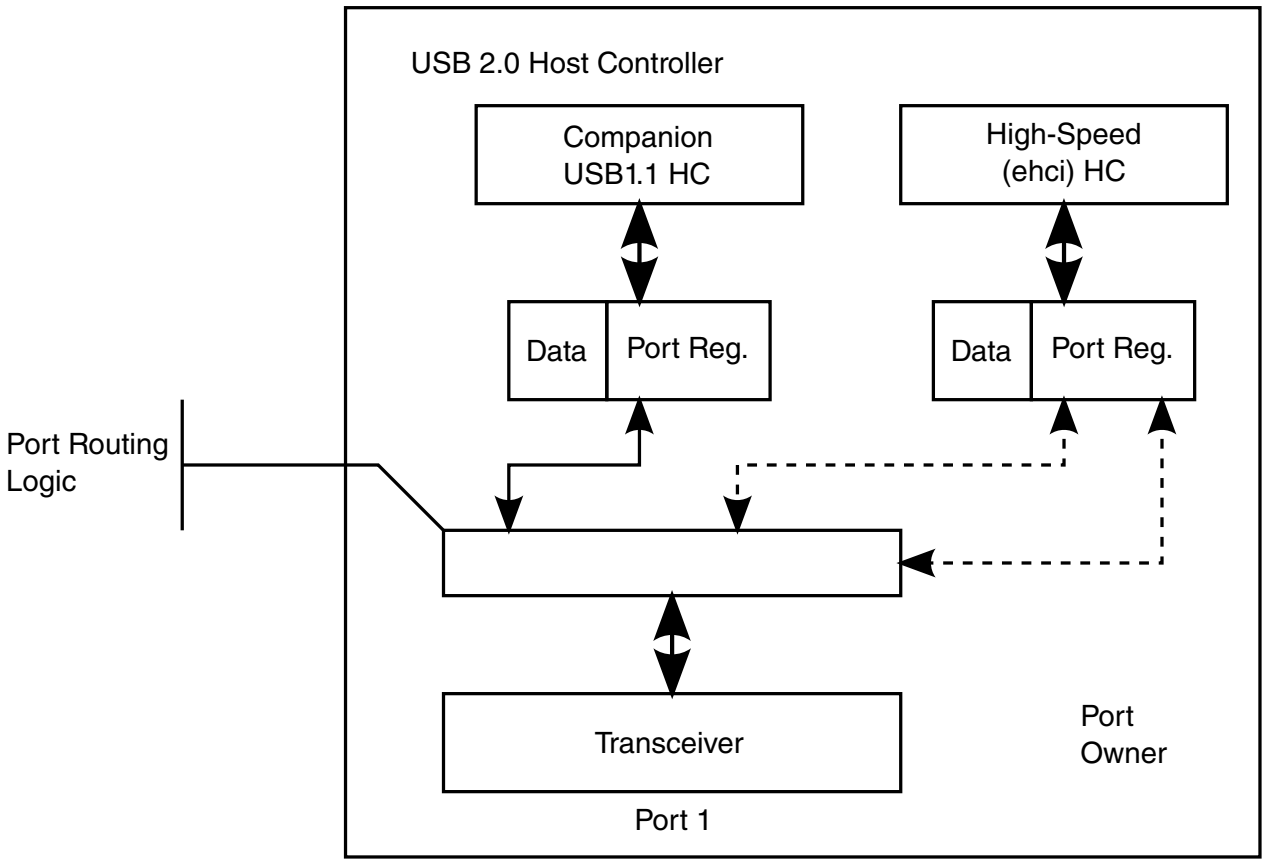

Figure 11-57. Example USB 2.0 Host Controller Port Routing Block Diagram

There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.[1]

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers' port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.

from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARAMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See .

11.3.4.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.

The *view* of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC's CF bit.

Table 11-88. Default Port Routing Depending on EHCI HC CF Bit

HS CF Bit	Default Port Ownership	Explanation
0B	Companion HCs	The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration
1B	EHCI HC	The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs' port status and control registers when the port owner is the EHCI HC.The EHCI HC has access to the additional port status and control bits defined in this specification (see). The EHCI HC can temporarily release control of the port to a companion HC by setting the *PortOwner* bit in the PORTSC1 register to one.

11.3.4.3.2.2 Port Routing Control through PortOwner and Disconnect Event

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI *CF-bit* is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and

identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.
- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.
- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.

11.3.4.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

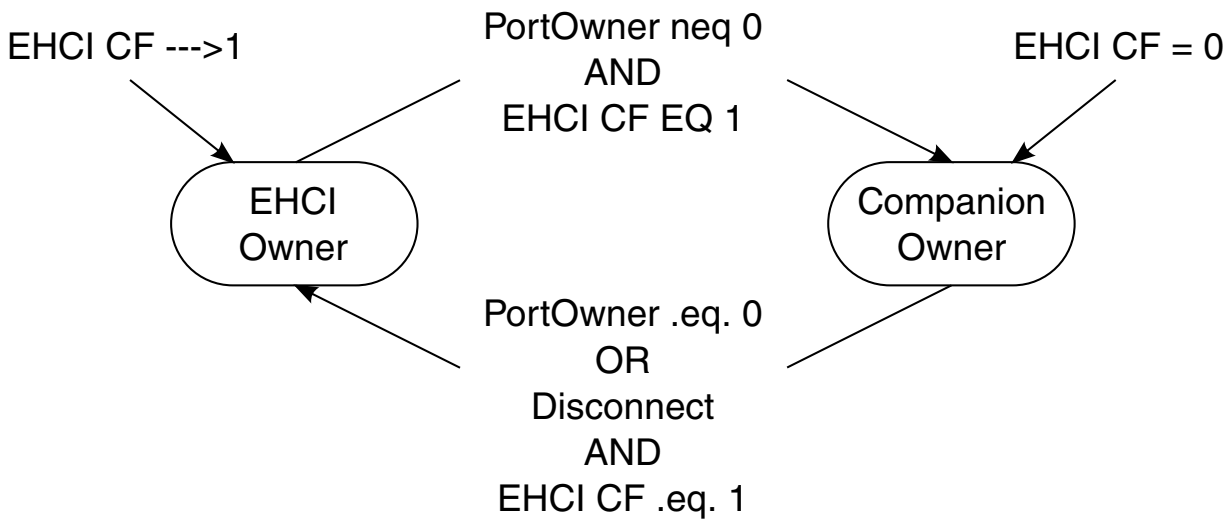

Figure 11-58. Port Owner Handoff State Machine

11.3.4.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.

11.3.4.3.2.3.2 Companion HC Owner

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

11.3.4.3.2.4 Port Power

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the *PPC* bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

Table 11-89. Port Power Enable Control Rules

CF	CHC[1] (PP)	EHC[2] (PP)	Owner	PPE[3]	Description
0	0	X	CHC	0	When the EHCI controller is not configured, the port is owned by the companion host controller. When the companion HC's port power select is off, then the port power is off.
0	1	X	CHC	1	Similar to previous entry. When the companion HC's port power select is on, then the port power is on.
1	0	0	CHC	0	Port owner has port power turned off, the power to port is off.
1	0	0	EHC	0	Port owner has port power turned off, the power to port is off.
1	0	1	EHC	1	Port owner has port power on, so power to port is on.
1	0	1	CHC	1	If either HC has port power turned on, the power to the port is on.

Table continues on the next page...

Table 11-89. Port Power Enable Control Rules (continued)

1	1	0	EHC	1	If either HC has port power turned on, the power to the port is on.
1	1	0	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	CHC	1	Port owner has port power on, so power to port is on.
1	1	1	EHC	1	Port owner has port power on, so power to port is on.

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

11.3.4.4.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- Over-current Active bits are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- Over-current Change bits are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- Port Enabled/Disabled bit is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- Port Power (PP) bits may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 11-90 for summary behavior for over-current detection

when the host controller is halted (suspended from a device component point of view).

11.3.4.4.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the ARM platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.

11.3.4.4.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a

port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

Table 11-90. Behavior During Wake-up Events

Port Status and Signaling Type	Signaled Port Response	Device State	
		D0	Not D0
Port disabled, resume K-State received	No Effect	N/A	N/A
Port suspended, resume K-State received	Resume reflected downstream on signaled port. Force Port Resume status bit in USB_PORTSC1 register is set to one. Port Change Detect bit in USB_USBSTS register set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is one. A disconnect is detected.	Depending in the initial port state, theUSB_ PORTSC1 Connected Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's WKDSCNNT_E bit is zero. A disconnect is detected.	Depending on the initial port state, the USB_PORTSC1 Connect and Enable status bits are set to zero, and the Connect Change status bit is set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is not connected and the port's WKCNNT_E bit is one. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [2]	[2]
Port is not connected and the port's WKCNNT_E bit is zero. A connect is detected.	USB_PORTSC1 Connect Status and Connect Status Change bits are set to one. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]
Port is connected and the port's WKOC_E bit is one. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one	[1], [2]	[2]
Port is connected and the port's WKOC_E bit is zero. An over-current condition occurs.	USB_PORTSC1 Over-current Active, Over-current Change bits are set to one. If Port Enable/Disable bit is one, it is set to zero. Port Change Detect bit in the USB_USBSTS register is set to one.	[1], [3]	[3]

[1] Hardware interrupt issued if Port Change Interrupt Enable bit in the USB_USBINTR register is one.

[2] PME# asserted if enabled (Note: PME Status must always be set to one).

[3] PME# not asserted.

11.3.4.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see)/ . The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structures. In each micro-frame, if the periodic schedule is enabled (see Periodic scheduling threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.

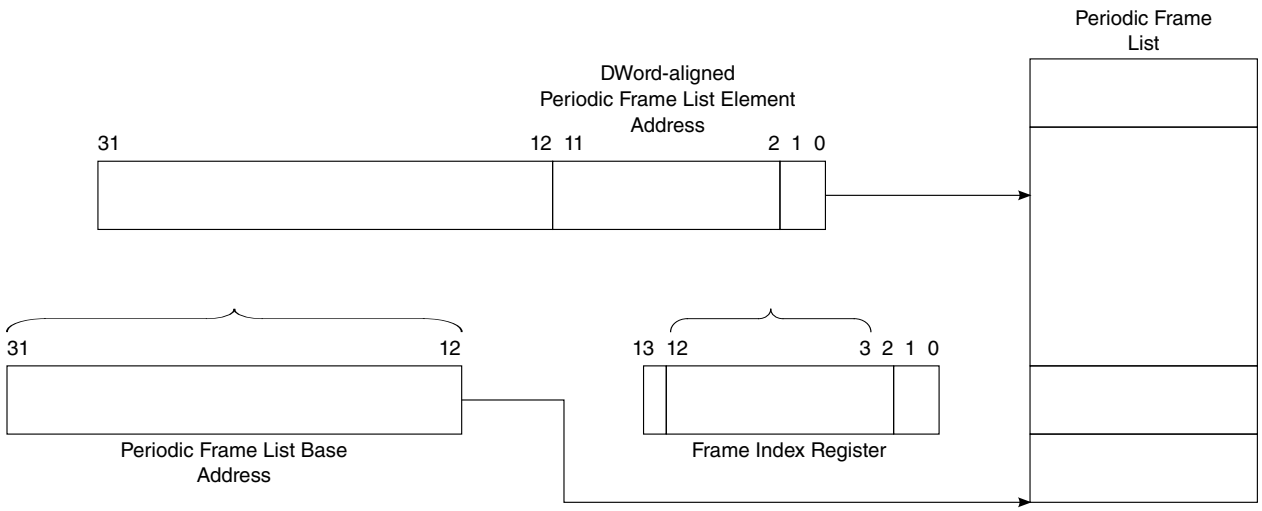

Figure 11-59. Derivation of Pointer into Frame List Array

When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

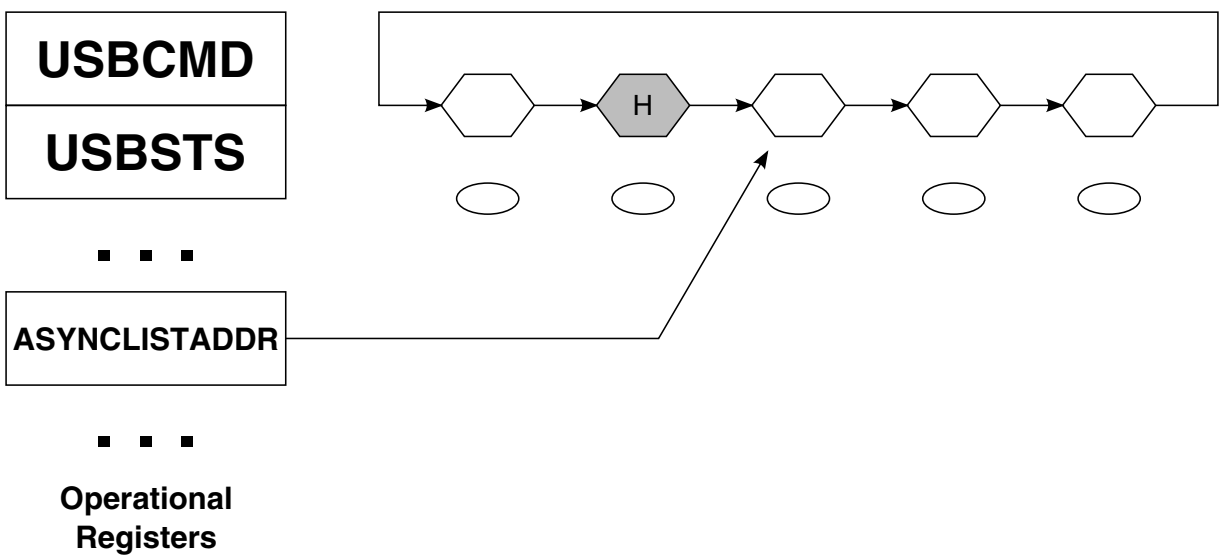

Figure 11-60. General Format of Asynchronous Schedule List

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

11.3.4.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

11.3.4.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.

This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 11-61. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function ($f(x)$) between the 80% and Last Start curves. The function $f(x)$ adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

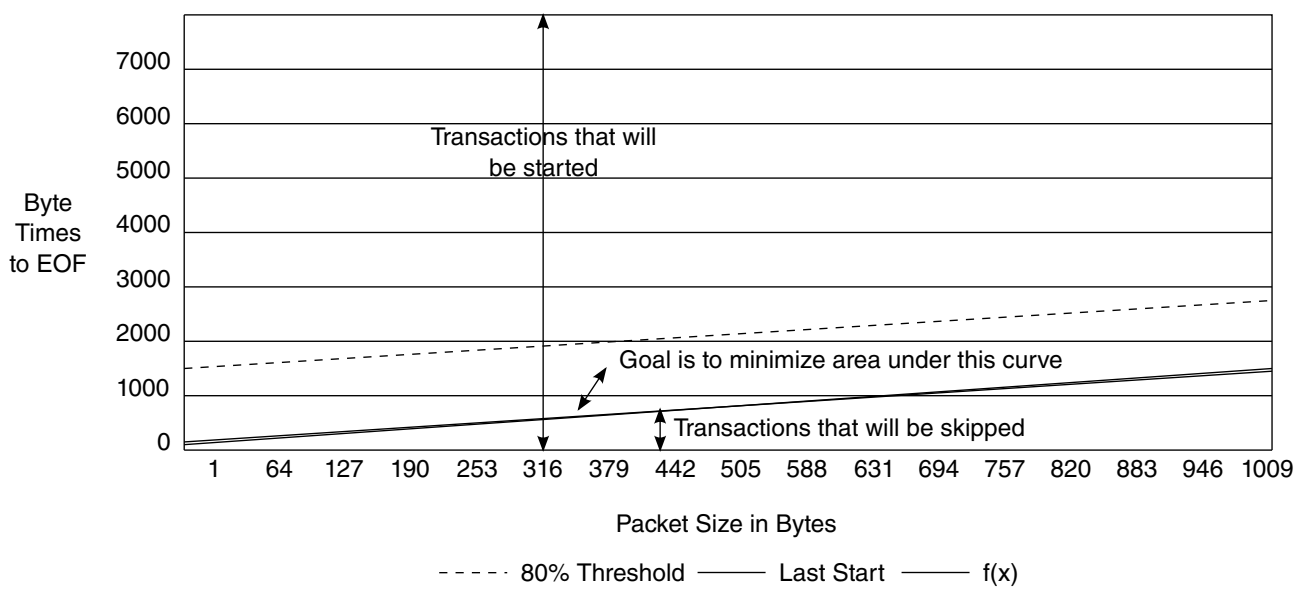

Figure 11-61. Best Fit Approximation

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

Table 11-91. Example Worse-case Transaction Timing Components

Component	Bit time	Byte Time	Explanation
Split Token	76	9.5	Split token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Number of bit times required between consecutive host packets.
Token	67	8.375	Token as defined in USB core specification. Includes sync, token, eop, and so on.
Host 2 Host IPG	88	11	Token as defined in USB core specification. Includessync, token, eop, and so on.
Data Packet (0 data bytes)	66.7	8.34	Zero-length data packet. Includes sync, PID, crc16, eop, and so on.
Turnaround time	721	90.125	Time for packet initiator (Host) to see the beginning of a response to a transmitted packet.
Handshake packet	48	6	Handshake packet as defined in USB core specification. Includes sync, PID, eop, and so on.
		144	Total

The exact details of the function (f(x)) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The f(x) in Figure 11-61 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Alorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
Local Temp = MaximumPacketSize + 192
Local rvalue = TRUE
If MaximumPacketSize >= 128 then
     Temp += 128
End If
If Temp > HC_BytesLeftInFrame then
     Rvalue = FALSE
End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the

running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the $f(x)$ plot was getting close to the LastStart line.

11.3.4.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

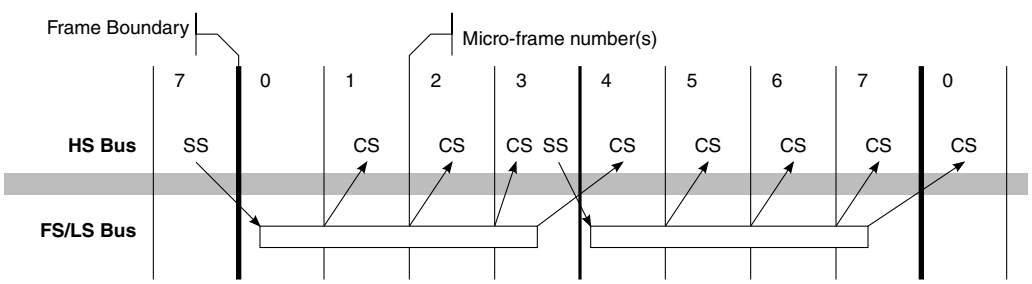

Figure 11-62. Frame Boundary Relationship between HS bus and FS/LS Bus

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in and initially illustrated in Schedule Traversal Rules . Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule

and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

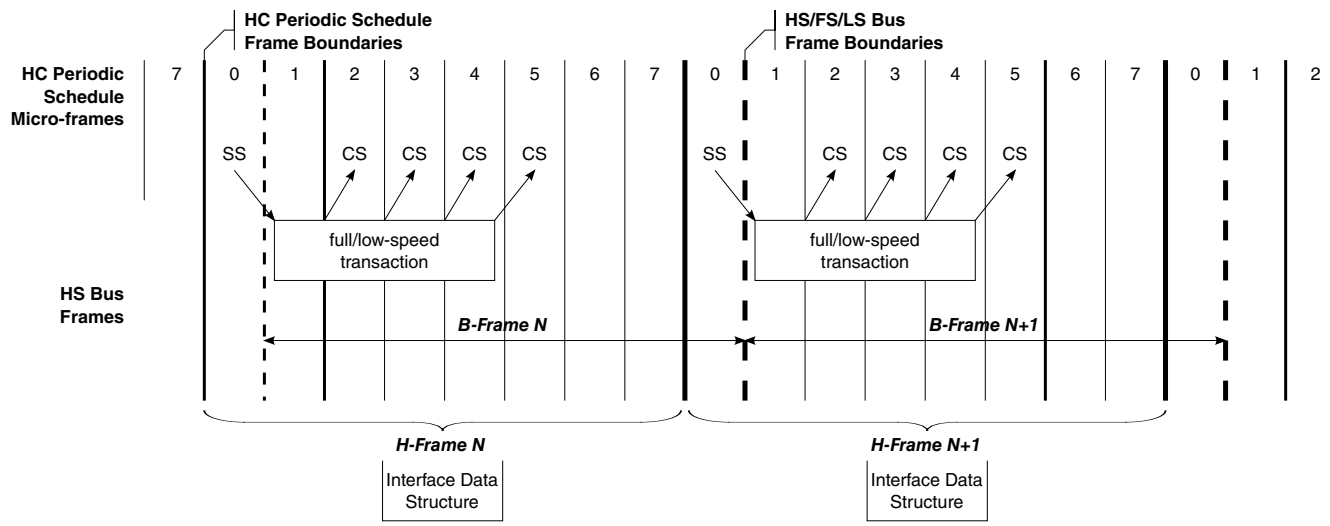

Figure 11-63. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in , the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].

Software is allowed to write to FRINDEX. provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

Table 11-92. Operation of FRINDEX and SOFV (SOF Value Register)

Current			Next		
FRINDEX[F]	SOFV	FRINDEX[mF]	FRINDEX[F]	SOFV	FRINDEX[mF]

11.3.4.3.6 Periodic Schedule

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register.

If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero. The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic schedule has

made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

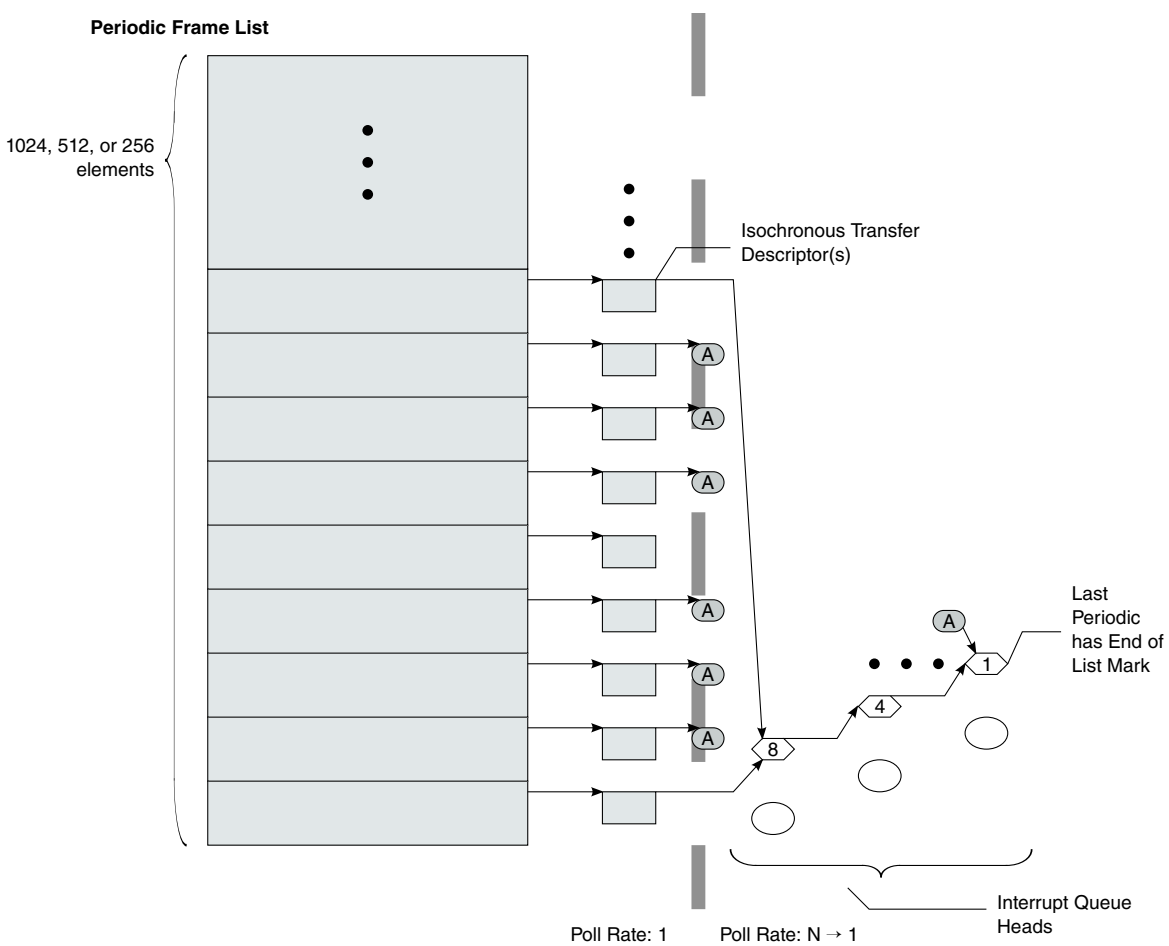

Figure 11-64. Example Periodic Schedule

11.3.4.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

11.3.4.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint.

When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Sixe. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the

iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

11.3.4.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

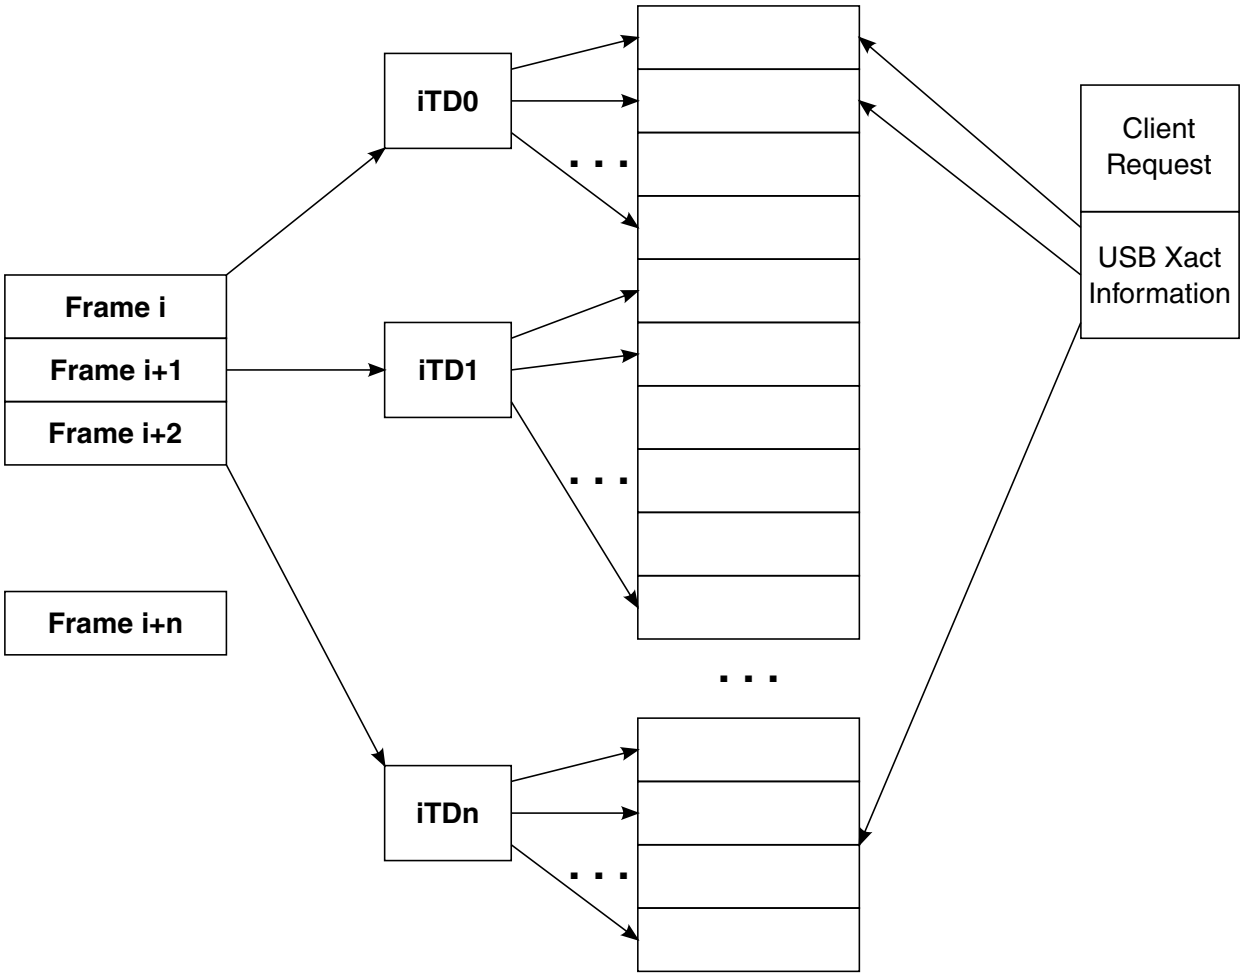

Figure 11-65. Example Association of iTDs to Client Request Buffer

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to 'alias' the page selector to Page zero. USB 2.0 isochronous

endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

11.3.4.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1

uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in adding the constant 1 to the micro-frame number). For any current frame N, if the current micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current micro-frame is 7, then software can add isochronous transactions to Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of the Isochronous Scheduling Threshold field. System software assumes the host controller caches one or more periodic data structures for the number of micro-frames indicated in the Isochronous Scheduling Threshold field. For example, if the count value were 2, then the host controller keeps a window of 2 micro-frames worth of state (current micro-frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases the current micro-frame state and begins accumulating the next micro-frame state.

11.3.4.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily immediate. Rather the new value of the bit is taken into consideration the next time the host controller needs to use the value of the USB_ASYNCLISTADDR register to get the next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to determine when the asynchronous schedule has made the desired transition. Software must not modify the Asynchronous Schedule Enable bit unless the value of the Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the USB_ASYNCLISTADDR register. The default value of the USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled when the Asynchronous Schedule Enable bit is zero.

Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 11-60. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

11.3.4.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadCurrent is a pointer to a queue head that is
          -- already in the active list
          -- pQHeadNew is a pointer to the queue head to be added
          --
          -- This algorithm links a new queue head into a existing
          -- list
          --
          pQueueHeadNew.HorizontalPointer  =  pQueueHeadCurrent.HorizontalPointer
          pQueueHeadCurrent.HorizontalPointer =  physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

11.3.4.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
          --
          -- Requirement: all inputs must be properly initialized.
          --
          -- pQHeadPrevious is a pointer to a queue head that
          -- references the queue head to remove
```

```
          -- pQHeadToUnlink is a pointer to the queue head to be
          -- removed
          -- pQheadNext is a pointer to a queue head still in the
          -- schedule. Software provides this pointer with the
          -- following strict rules:
          --          if the host software is one queue head, then
          --          pQHeadNext must be the same as
          --          QueueheadToUnlink.HorizontalPointer. If the host
          --          software is unlinking a consecutive series of
          --          queue heads, QHeadNext must be set by software to
          --          the  queue head remaining in the schedule.
          --
          -- This algorithm unlinks a queue head from a circular list
          --
          pQueueHeadPrevious.HorizontalPointer =  pQueueHeadToUnlink.HorizontalPointer
                                  pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

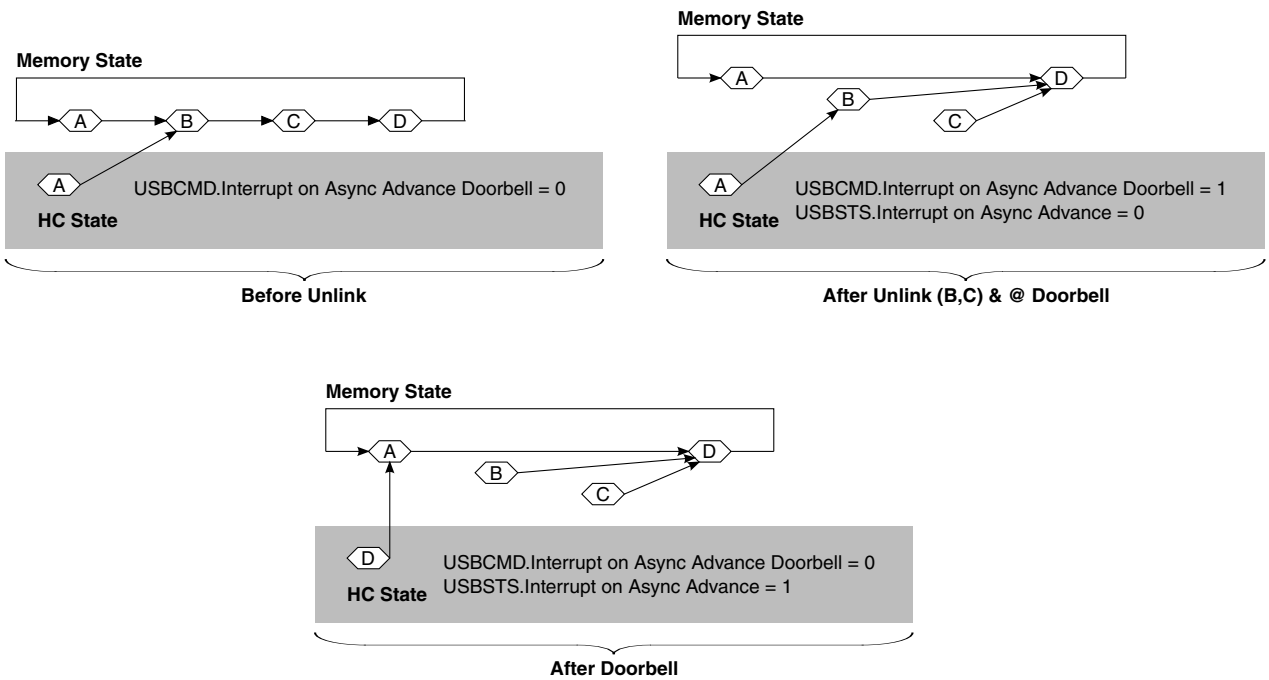

Figure 11-66. Generic Queue Head Unlink Scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

11.3.4.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Table 11-78) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

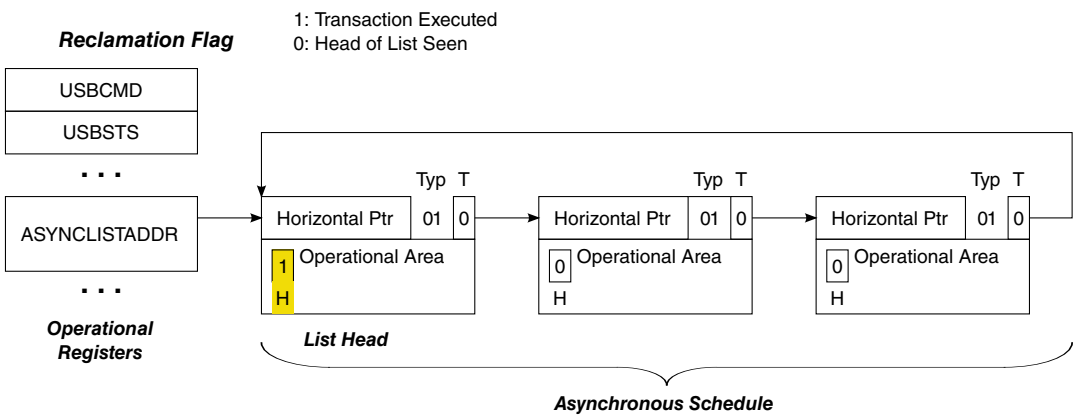

Figure 11-67. Asynchronous Schedule List w/Annotation to Mark Head of List

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

11.3.4.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

11.3.4.3.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: *how long should the host controller stay idle before restarting*?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called *AsyncSchedSleepTime*, and has a value of 10 µsec. The value is derived based on the analysis in Example Derivation for *AsyncSchedSleepTime*, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a *schedule sleep* state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to *schedule active* state. The start context allows the HC to reload *Nakcnt* fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.

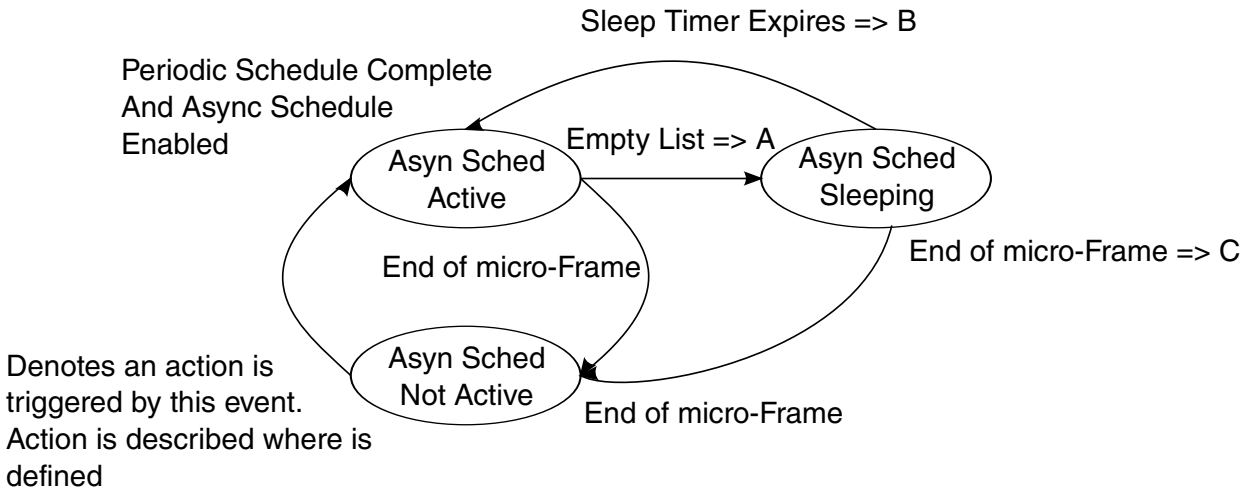

Figure 11-68. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 11-93. Asynchronous Schedule SM Transition Actions

Action	Action Description Label
A	On detection of the empty list, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.
B	When the *AsynchronousTraversalSleepTimer* expires, the host controller sets the *Reclamation* bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).
C	The host controller cancels the sleep timer (*AsynchronousTraversalSleepTimer*).

11.3.4.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the *Asynchronous Schedule Enable* bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

11.3.4.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the *AsyncrhonousTraversalSleepTimer* expires. On every transition into this state, the host controller sets the *Reclamation* bit in the USB_USBSTS register to one.

While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

11.3.4.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the *AsynchronousTraversalSleepTimer* to *AsyncSchedSleepTime*.

11.3.4.3.8.4.5 Example Derivation for AsyncSchedSleepTime

The derivation is based on analysis of what work the host controller could be doing next.

It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example *footprint*, or *wall clock*) the transaction takes to complete.

Table 11-94. Typical Low-/Full-speed Transaction Times

Transaction Attributes		Footprint (time)	Description
Speed	HS	11.9 ms	Maximum foot print for a worst-case, full-sized bulk data transaction.
Size	512	9.45 ms	Maximum footprint for an approximate best-case, full-sized bulk data transaction.
Type	Bulk		
Speed	FS	~50 ms	Approximate typical for full-sized bulk data. An 8-byte low-speed is about 2x, or between 90 and 100 ms.
Size	64		
Type	Bulk		
Speed	FS	~12 ms	Approximate typical for 8-byte bulk/control (that is setup)
Size	8		
Type	Cntrl		

A *AsyncSchedSleepTime* value of 10 µs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 µs sleep period would allow the host controller to get the NAK results on the first complete-split.

11.3.4.3.8.5 Asynchronous schedule traversal: *Start Event*

Once the HC has *idled* itself through the empty schedule detection (Section 0), it will naturally *activate* and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally *re-activate* during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF . Asynchronous schedule *Start Event*s are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

11.3.4.3.8.6 Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the *Reclamation* bit in the USB_USBSTS register.

The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

It is required that the host controller sets the *Reclamation* bit to one whenever an asynchronous schedule traversal *Start Event*, as documented inAsynchronous schedule traversal: *Start Event*, occurs. The *Reclamation* bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the *Reclamation* bit to zero whenever it finds a queue head with its *H-bit* set to one. Software should only set a queue head's *H-bit* if the queue head is in the asynchronous schedule. If software sets the *H-bit* in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the *Reclamation* bit to zero when executing from the periodic schedule.

11.3.4.3.9 Operational Model for Nak Counter

This section describes the operational model for the *NakCnt* field defined in a queue head.

See Queue Head Initialization for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the *Start-split* transaction and the first *Complete-split* transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the *Complete-split* transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (*NakCnt*), and a counter reload field (*RL*). *NakCnt* is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- Not Used- This mode is set when the *RL* field is zero. The host controller ignores the *NakCnt* field for any execution of transactions through a queue head with an *RL* field of zero. Software must use this selection for interrupt endpoints.
- Nak Throttle Mode- This mode is selected when the *RL* field is non-zero. In this mode, the value in the *NakCnt* field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the *NakCnt* field based on the token/handshake criteria listed in the table below. The host controller must reload *NakCnt* when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

Table 11-95. NakCnt Field Adjustment Rules

Token	Handshake	
	Handshake NAK	NYET
IN/PING	decrement *NakCnt*	N/A (protocol error)
OUT	decrement *NakCnt*	No Action[1] Start
Split	decrement *NakCnt*	N/A (protocol error)
Complete Split	No Action	Decrement *NakCnt*

1. Recommended behavior on this response is to reload *NakCnt*

In summary, system software enables the counter by setting the reload field (*RL*) to a non-zero value. The host controller may execute a transaction if *NakCnt* is non-zero. The host controller does not execute a transaction if *NakCnt* is zero. The reload mechanism is described in detail in Nak Count Reload Control .

NOTE

When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see Empty Asynchronous Schedule Detection).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a *Start Event* is assumed, see Asynchronous schedule traversal: *Start Event*. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

11.3.4.3.9.1 Nak Count Reload Control

When the host controller reaches the *Execute Transaction* state for a queue head (meaning that it has an active operational state), it checks to determine whether the *NakCnt* field should be reloaded from *RL* (see Execute Transaction). If the answer is yes, then *RL* is copied into *NakCnt*. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (*NakCnt* see Table 11-78) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see Asynchronous schedule traversal: *Start Event* for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see Figure 11-67).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see Table 11-78) is set to zero.

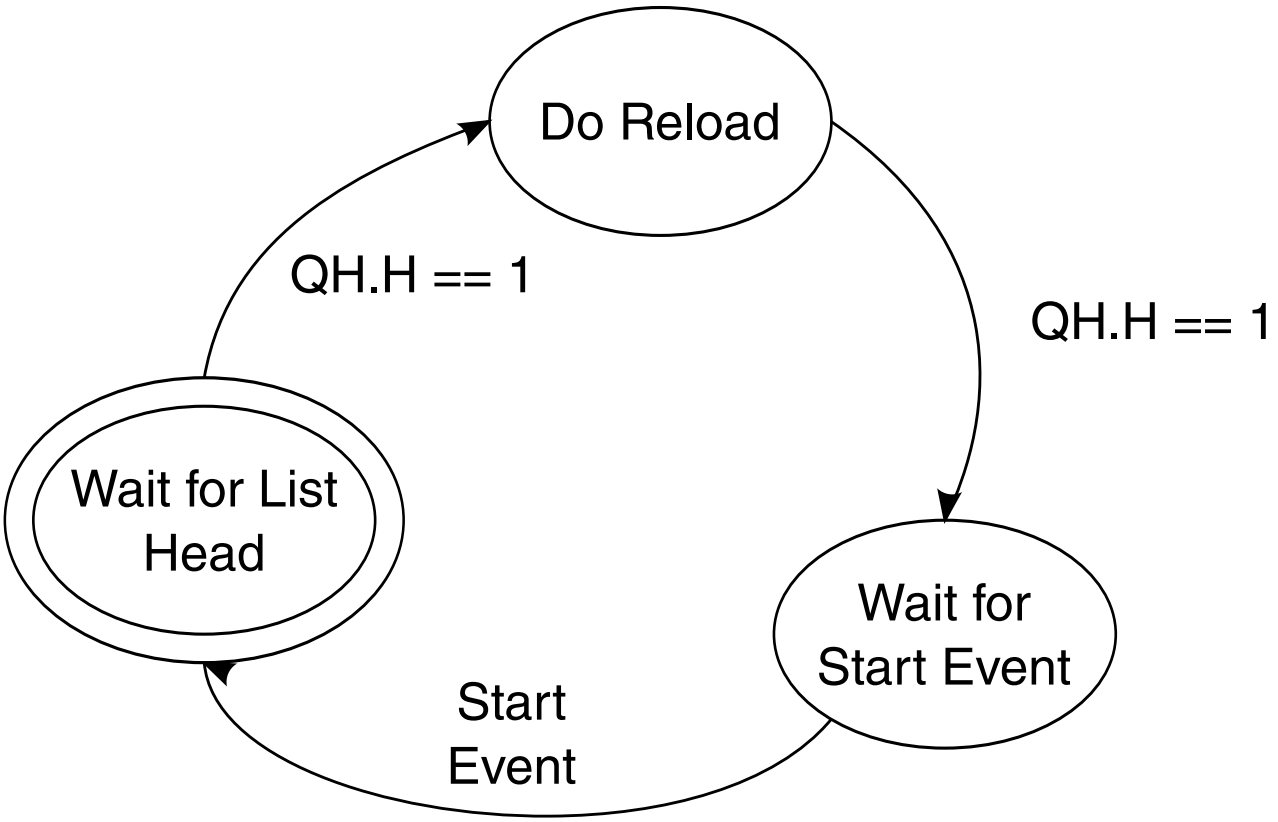

Figure 11-69. Example HC State Machine for Controlling Nak Counter Reloads

11.3.4.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous schedule traversal: *Start Event*occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose *H-bit* is set to one.

11.3.4.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the *H-bit* set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (*RL*) field.

11.3.4.3.9.1.3 Wait for Start Event

This state is entered from the *Do Reload* state when a queue head with the *H-bit* set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

11.3.4.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 11-78). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a *transfer*.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's *Status* field. The *Status* field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head *Status* field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the *Fetch QH* state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and *activate* them, then the host controller always *find* them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.

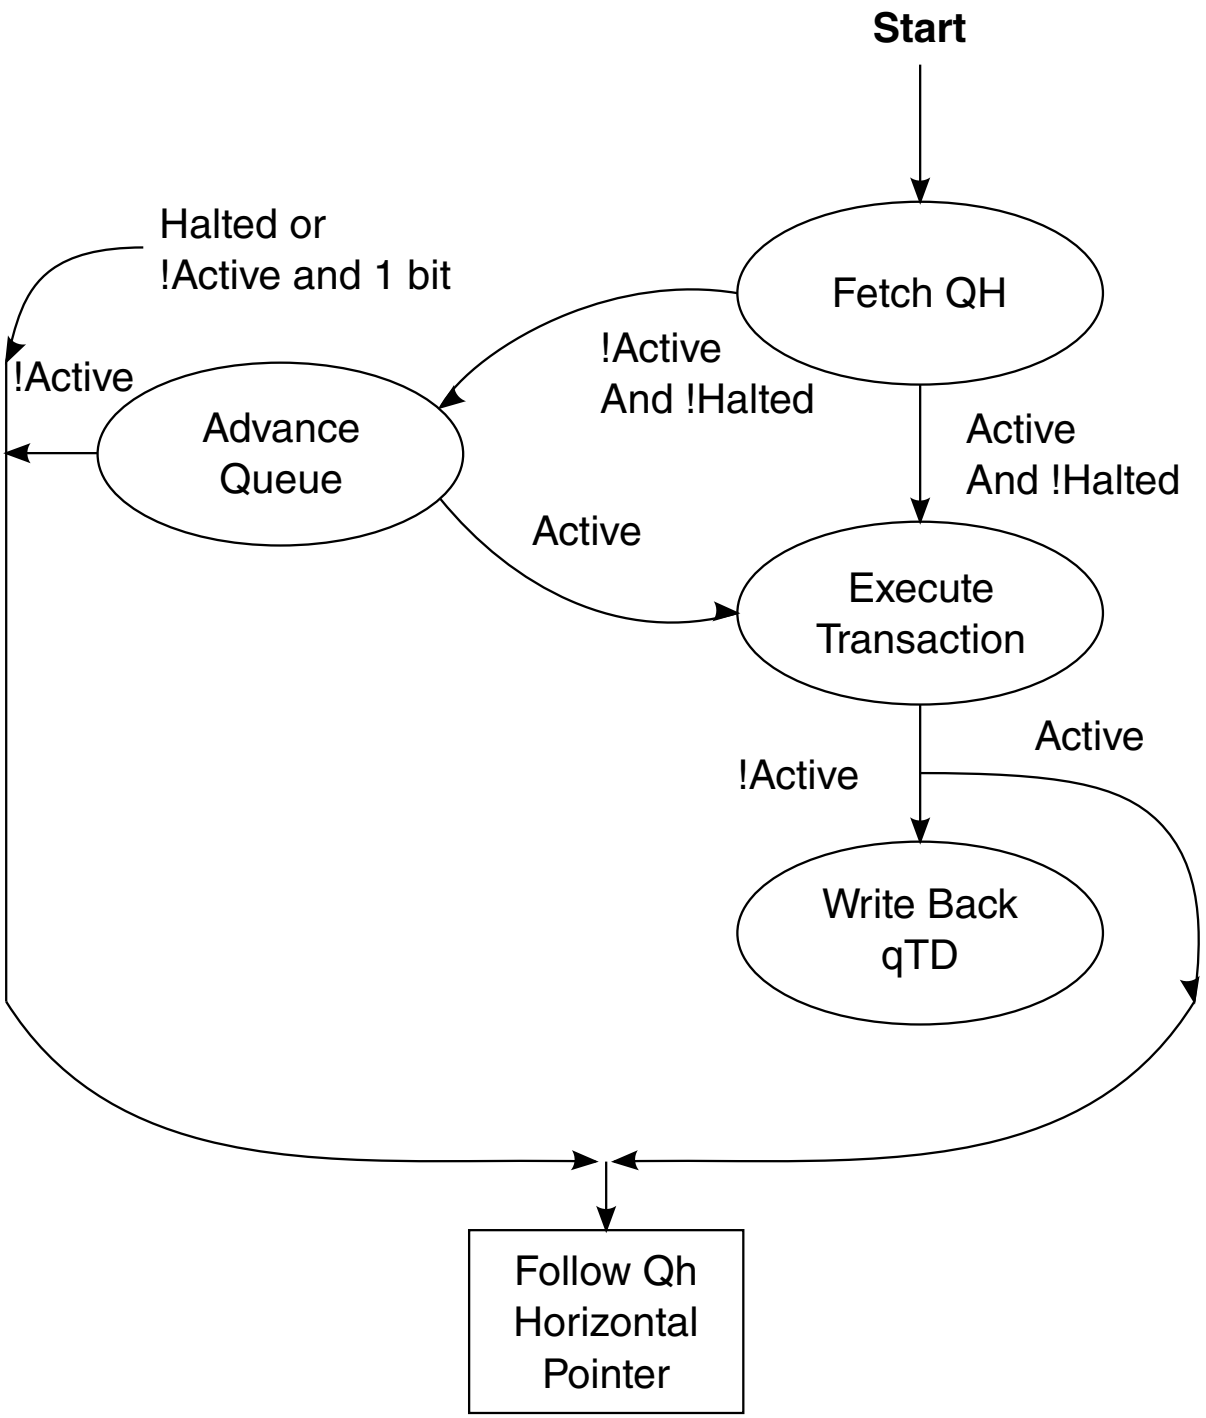

Figure 11-70. Host Controller Queue Head Traversal State Machine

This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute

Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

NOTE

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the *Next qTD Pointer* field value to reference a valid qTD.

11.3.4.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see Next Asynch. Address (USB_ASYNCLISTADDR))/ Endpoint List Address (USB_ENDPTLISTADDR) Additionally, it may be referenced from the *Next LinkPointer* field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the *Typ* field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Table 11-78.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is *S-mask* is zero), and
- The *H-bit* is one, and
- The *Reclamation* bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the *H-bit* is one and the *Reclamation* bit is one, then the host controller sets the *Reclamation* bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.

11.3.4.3.10.2 Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay *Active* and *Halt* bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

NOTE

If the *I-bit* is one and the *Active* bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field *Bytes to Transfer* is not zero and the *T-bit* in the *Alternate Next qTD Pointer* is set to zero, then the host controller uses the *Alternate Next qTD Pointer*. Otherwise, the host controller uses the *NextqTD Pointer*. If *NextqTD Pointer's T-bit* is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its *Active* bit set to one, the host controller moves the pointer value used to reach the qTD (*Next* or *Alternate Next*) to the *Current qTD Pointer* field, then performs the overlay. If the fetched qTD has its *Active* bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (*dt*) field in the overlay area depends on the value of the *data toggle control* (*dtc*) bit (see Table 11-80).
- If the *EPS* field indicates the endpoint is a high-speed endpoint, the *Ping* state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- *C-prog-mask* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *Frame Tag* field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- *NakCnt* field in the overlay area is loaded from the *RL* field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.

11.3.4.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the *Active* bit in *Status* field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's *S-mask* field contains a non-zero value. It is the responsibility of software to ensure the *S-mask* field is appropriately initialized based on the transfer type. There are other criteria that must be met if the *EPS* field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt .

11.3.4.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero *S-mask* field), then the FRINDEX[2:0] field must identify a bit in the *S-mask* field that has one in it.

For example, an *S-mask* value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

11.3.4.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero *S-mask* field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the *NakCnt* field has been reloaded, the host controller checks the value of the *NakCnt* field in the queue head. If *NakCnt* is non-zero, or if the *Reload Nak Counter* field is zero, then the host controller considers this queue head for a transaction.

11.3.4.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter *qHTransactionCounter* is loaded from the queue head's *Mult* field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the *Mult* field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of *qHTransactionCounter* for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the *Reclamation* bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates *qHTransactionCounter* times in this state executing transactions. After each transaction is executed, *qHTransactionCounter* is decremented by one. The host controller exits this state when one of the following events occurs:

- The *qHTransactionCounter* decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,[4] or
- The transaction experiences a transaction error, or
- The *Active* bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction(see Transaction Fit - A Best-Fit Approximation Algorithm) for example method for implementing the frame boundary test).

NOTE

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the *Total Bytes to Transfer* field is decremented by the number of bytes moved in the transaction, the data toggle bit (*dt*) is toggled, the current page offset is advanced to the next appropriate value (for example,

advanced by the number of bytes successfully moved), and the *C_Page* field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs .

NOTE

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the *PID_Code* field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement *qHTransactionCounter*). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of *qHTransactionCounter* is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and *RL* is non-zero, *NakCnt* is decremented by one. If *RL* is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of *CErr* did not change). Software should set the *RL* field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly *NakCnt*, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The *CErr* field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in Transaction Error .

The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

11.3.4.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:

- An endpoint may return a STALL handshake during a transaction,
- A transaction had three consecutive error conditions, or
- A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the *Active* bit is set to zero and the *Halted* bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a *Halt* condition (for example no updates necessary for *Total Bytes to Transfer*, *C_Page*, *Current Offset,* and *dt*). The host controller must update *CErr* as appropriate. When a queue head is halted, the *USB Error Interrupt* bit in the USB_n_USBSTS register is set to one. If the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

11.3.4.3.10.3.5 Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the *Mult* feature that is used in the Periodic schedule. Where-as the *Mult* feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the *Asynchronous Schedule Park Capability* bit in the USB_n_HCCPARAMs register to one. This information keys system software that the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the *Asynchronous Schedule Park Mode Enable* bit.

When park-mode is not enabled (for example *Asynchronous Schedule Park Mode Enable* bit in the USB_n_USBCMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose *EPS* field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose *EPS* field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose *EPS* field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the *Asynchronous Schedule Park Mode Count* field in the USB_n_USBCMD register. Software must not set *Asynchronous Schedule Park Mode Enable* bit to one and also set *Asynchronous Schedule Park Mode Count* field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction . It only effects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the *Mult* field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter *PM-Count* from *Asynchronous Schedule Park Mode Count* when *Asyncrhonous Schedule Park Mode Enable* bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, *PM-Count* is decremented. The host controller may continue to execute bus transactions from the current queue head until *PM-Count* goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

Table 11-96. Actions for Park Mode, based on Endpoint Response and Residual Transfer State

PID	Endpoint Response	Transfer State after Transaction		Action
		PM-Count	Bytes to Transfer	
IN	DATA[0,1] w/Maximum Packet sized data	Not zero	Not Zero	Allowed to perform another bus transaction.[1, 2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't care	Move to next QH.

Table continues on the next page...

Table 11-96. Actions for Park Mode, based on Endpoint Response and Residual Transfer State (continued)

	DATA[0,1] w/short packet	Don't care	Don't care	Retire qTD and move to next QH.
	NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH.
OUT	ACK	Not zero	Not Zero	Allowed to perform another bus transaction.[2]
		Not zero	Zero	Retire qTD and move to next QH
		Zero	Don't' care	Move to next QH.
	NYET, NAK	Don't care	Don't care	Move to next QH.
	STALL, XactErr	Don't care	Don't care	Move to next QH
PING	ACK	Not Zero	Not Zero	Allowed to perform another bus transaction. [2]
	NAK	Don't care	Don't care	Move to next QH
	STALL, XactErr	Don't care	Don't care	Move to next QH

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if *PM-Count* is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not *require* that the host controller execute another bus transaction when *PM-Count* is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

11.3.4.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the *Active* bit is set to zero.

The source data for the write-back is the transfer results area of the queue head overlay area (see Table 11-96).

The host controller uses the *Current qTD Pointer* field as the target address for the qTD.

The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include *Total Bytes to Transfer*, *Cerr*, and *Status*.

The duration of this state depends on when the qTD write-back is committed.

11.3.4.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the *Active* bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or

- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the *Halted* bit is one on exit from the Fetch QH state.

There is no functional requirement that the host controller wait until the current transaction is complete before using the horizontal pointer to read the next linked data structure. However, it must wait until the current transaction is complete before executing the next data structure.

11.3.4.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer. This specification requires that the buffer associated with the transfer be *virtually contiguous*.

This means: if the buffer spans more than one physical page, it must obey the following rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20 K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field *C_Page* field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing *C_Page* and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the *Bytes to Transfer* field.

The following figure illustrates a nominal example of how System software would initialize the buffer pointers list and the *C_Page* field for a transfer size of 16383 bytes. *C_Page* is set to zero. The upper 20-bits of Page 0 references the start of the physical

page. *Current Offset* (the lower 12-bits of queue head Dword 7) holds the offset in the page for example 2049 (for example 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4 K page.

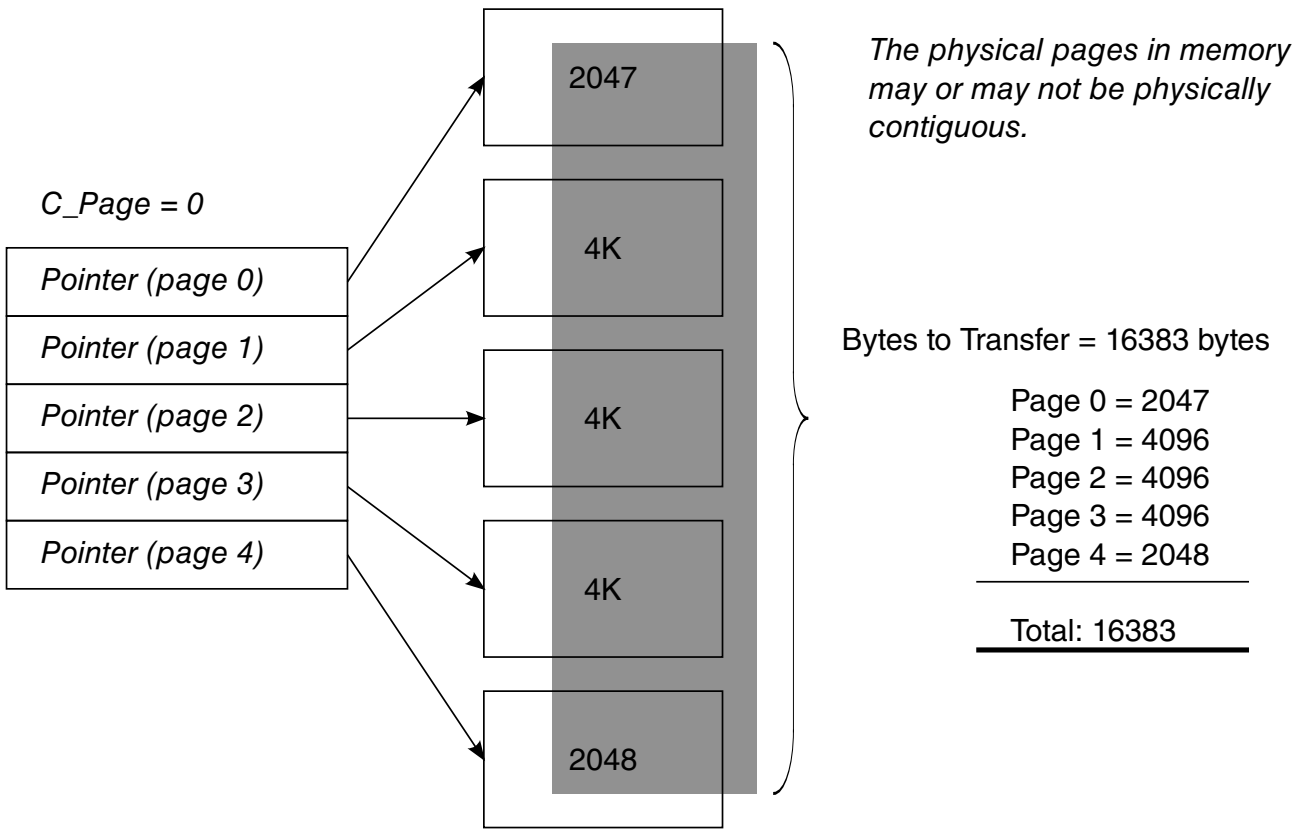

Figure 11-71. Example Mapping of qTD Buffer Pointers to Buffer Pages

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because *C_Page* is set to zero) and concatenates the *Current Offset* field. The 512 bytes are moved during the transaction, the *Current Offset* and *Total Bytes to Transfer* are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments *C_Page* (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and *Current Offset* has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is *C_Page*) when necessary. The three conditions for how the host controller handles *C_Page*:

- The current transaction does not span a page boundary. The value of *C_Page* is not adjusted by the host controller.

- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment *C_Page* before writing back status for the transaction.

NOTE

The only valid adjustment the host controller may make to *C_Page* is to increment by one.

11.3.4.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's *S-Mask* to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have *S-Mask* set to a non-zero value. An *S-mask* with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and *S-Mask* values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

Table 11-97. Example Periodic Reference Patterns for Interrupt Transfers with 2ms Poll Rate

Frame # Reference Sequence	Description
0, 2, 4, 6, 8, and so on *S-Mask* = 01h	A queue head for the *bInterval* of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the *S-Mask* field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.
0, 2, 4, 6, 8, and so on *S-Mask* = 02h	Another example of a queue head with a *bInterval* of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the *S-Mask* is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.

11.3.4.3.10.8 Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an *Interrupt on Complete* (*IOC*) bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

11.3.4.3.11 Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The *Status* field has a *Ping State* bit, which the host controller uses to determine the *next* actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- *EPS* field equals High-Speed and
- *PIDCode* field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

Table 11-98. Ping Control State Transition Table

Event			
Current	Host	Device	Next
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr [1]	Do Ping
Do Ping	PING	Stall	N/C [2] Do
OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping
Do OUT	OUT	Ack	Do OUT

Table continues on the next page...

Table 11-98. Ping Control State Transition Table (continued)

Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C [2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 11-99. Ping State bit Encoding

Value	Meaning
0B	Do OUT The host controller uses an OUT PID during the next bus transaction to this endpoint.
1B	Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don't know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

11.3.4.3.12 Split Transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.

The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the

Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

11.3.4.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an *EPS* field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit (*SplitXState*) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the *Control Transfer Type* (*C*) bit in the queue head to one. If this is not a control transfer type endpoint, the *C* bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the *C* bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the *C* bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

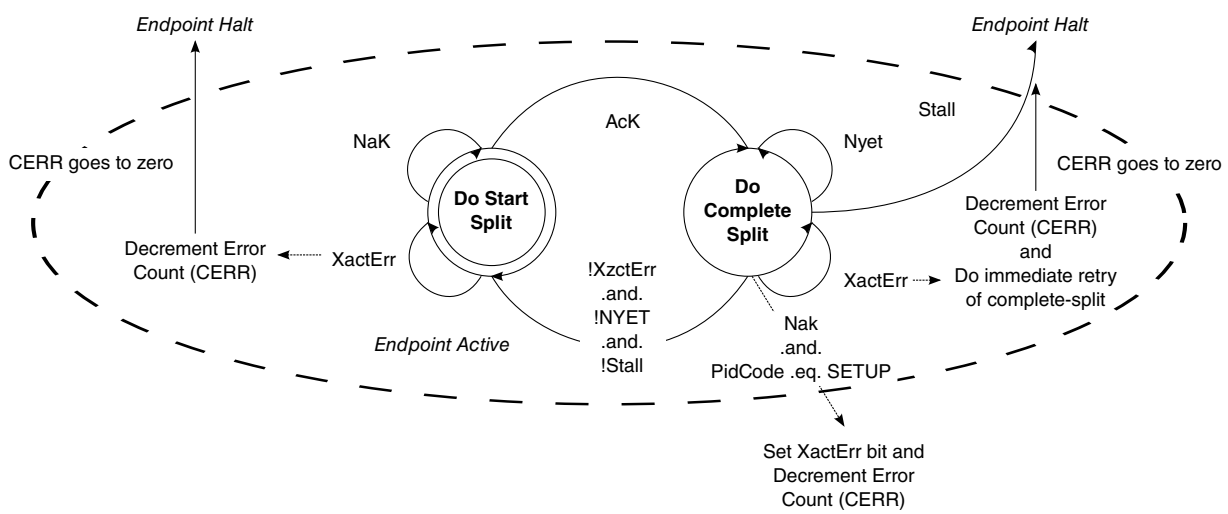

Figure 11-72. Host Controller Asynchronous Schedule Split-Transaction State Machine

11.3.4.3.12.1.1 Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and *PidCode* indicates an IN or OUT transaction, then the host controller reloads the error counter (*CErr*). If it is a successful bus transaction and the *PidCode* indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements *Cerr* and proceeds to the next queue head in the asynchronous schedule.

11.3.4.3.12.1.2 Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's *PidCode* indicates an IN or OUT, the host controller reloads the error counter (*CErr*). When a Nyet handshake is received for a complete-split bus transaction where the queue head's *PidCode* indicates a SETUP, the host controller must not adjust the value of *CErr*.

Independent of *PIDCode*, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (*Cerr*) is decremented by one and the complete split transaction is *immediately* retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to accomplish this behavior is to not advance the asynchronous schedule. When the host

controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If *Cerr* went to zero, the host controller must halt the queue.

- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the *PidCode* is a SETUP, then the Nak response is a protocol error. The *XactErr* status bit is set to one and the *CErr* field is decremented.
- STALL. The target endpoint responded with a STALL handshake. The host controller sets the *halt* bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the *PidCode* indicates an IN, then any of following responses are expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is *good*, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement *BytesToTransfer* field by the number of bytes received, and toggle the *dt* bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the *PidCode* indicates an OUT/SETUP, then any of following responses are expected:

- ACK. The target endpoint accepted the data, so the host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount and the data toggle bit (*dt*) is toggled. The host controller then exit this state.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

11.3.4.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.

Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the *execution* phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

11.3.4.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an *EPS* field indicating full- or low-speed and have a non-zero *S-mask* field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and ^{C}X labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).

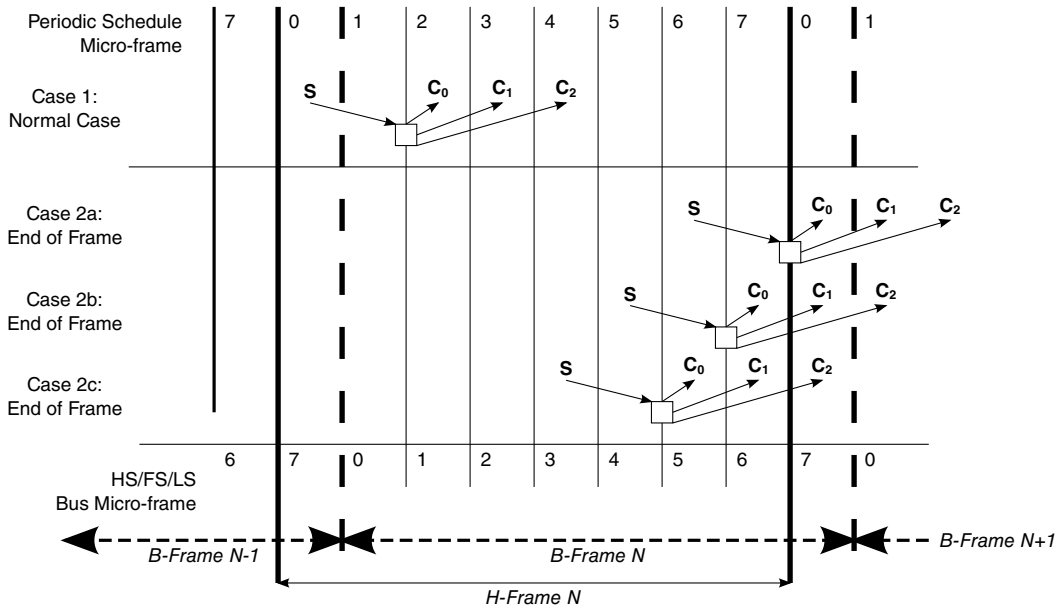

Figure 11-73. Split Transaction, Interrupt Scheduling Boundary Conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

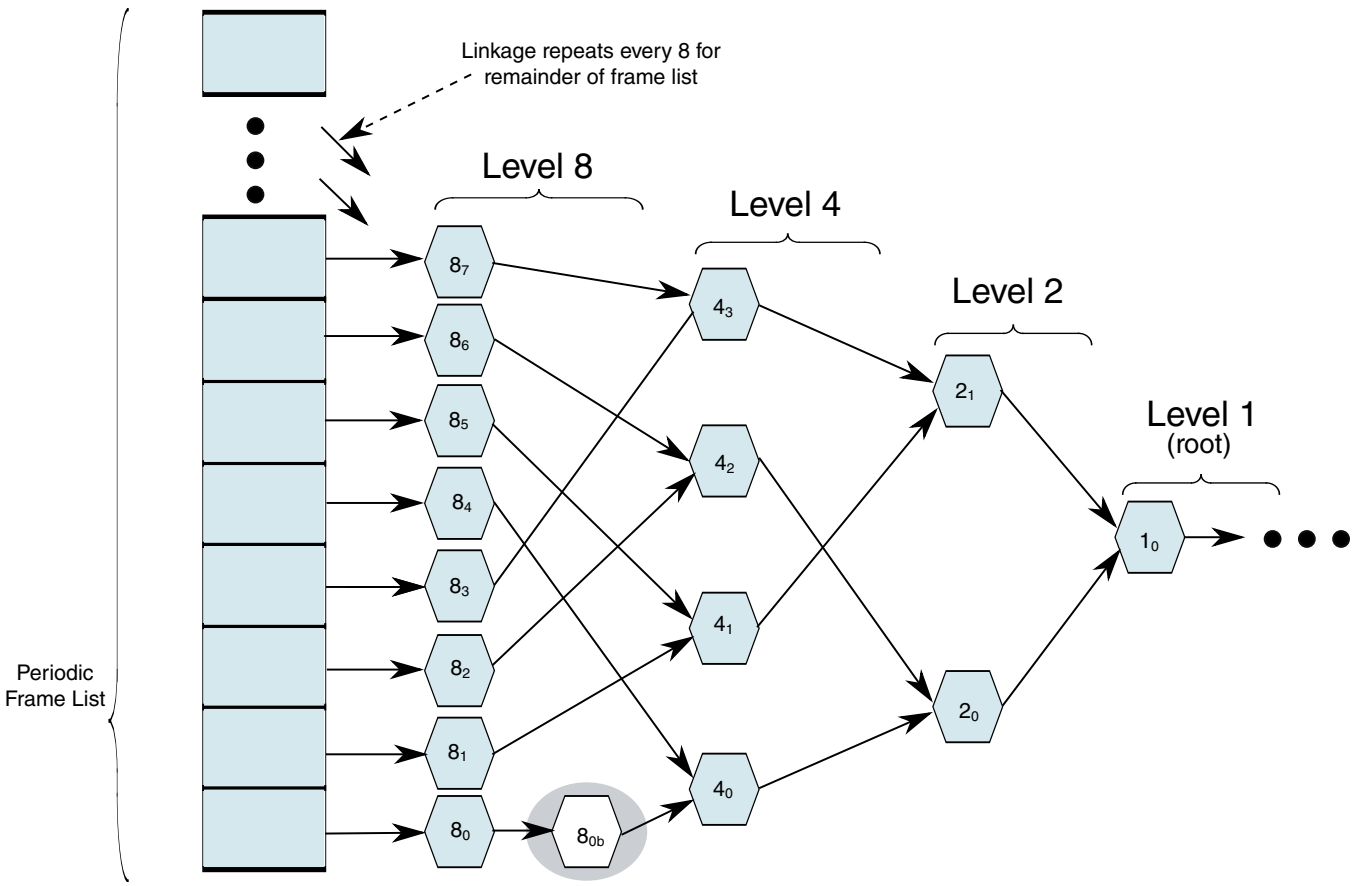

Figure 11-74. General Structure of EHCI Periodic Schedule Utilizing Interrupt Spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} where such an endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- *SplitXState*. This is single bit residing in the *Status* field of a queue head (see Table 11-76). This bit is used to track the current state of the split transaction.
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 11-73, case one, the *S-mask* would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit in the *Status* field of the queue head. For example, referring to Figure 11-73, case one, the *C-mask* would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the *SplitXState* indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between *H-Frames* and *B-Frames* is correctly performed when setting bits in *S-mask* and *C-mask*

11.3.4.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to zero.

- A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer.T-bit* set to one.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

NOTE

The FSTN's *Normal Path Link Pointer.T-bit* may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

- Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
- Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
- Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
- When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See Execute Transaction and Tracking Split Transaction Progress for Interrupt Transfers for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  - The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See Periodic Isochronous - Do Complete Split for special handling when in *Recovery Path* mode.
- Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The

host controller must clear the context of executing a *Recovery Path* when it restores schedule traversal to the *Save-Place* FSTN's *Normal Path Link Pointer*.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

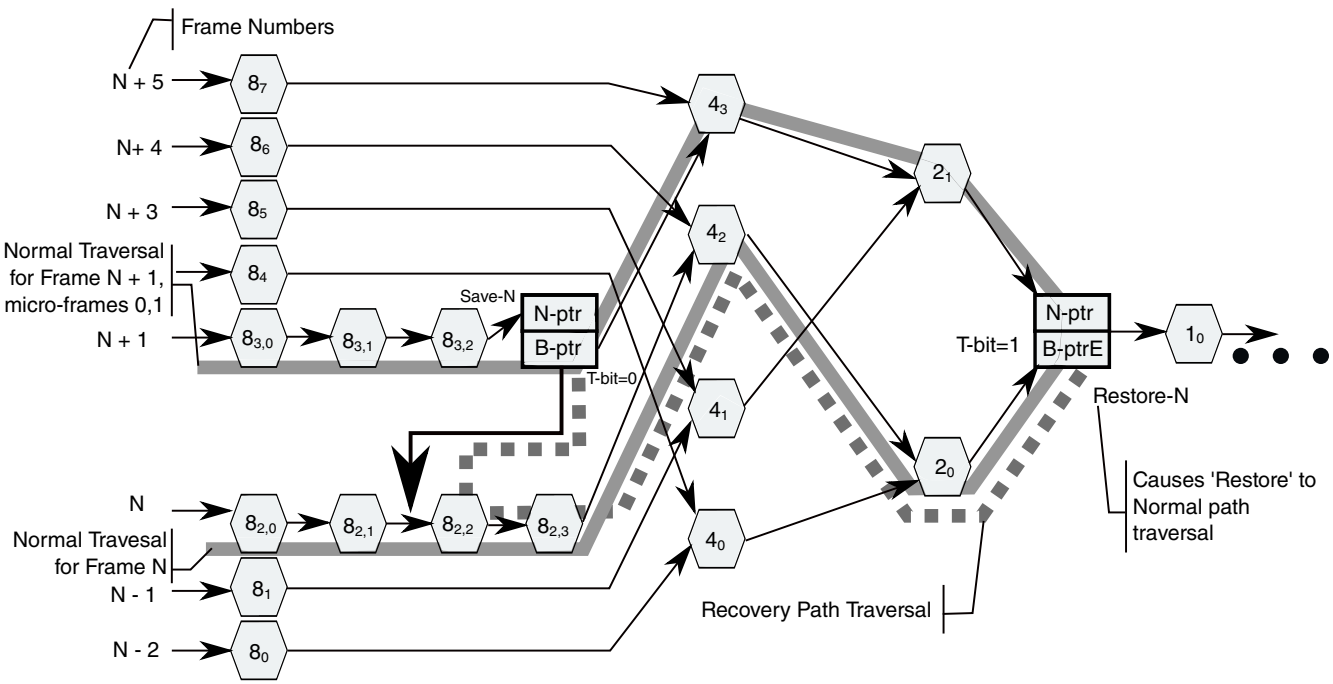

Figure 11-75. Example Host Controller Traversal of Recovery Path via FSTNs

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in *Recovery Path* mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits *Recovery Path* mode by clearing the internal *Recovery Path* mode flag and commences (restores) schedule traversal using the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2,

2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 …}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the *Normal Path Link Pointers* in any FSTNs it encounters. This is because the host controller has not yet encountered a *Save-Place* FSTN so it not executing in *Recovery Path* mode. When it encounters the *Restore* FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's *Normal Path Link Pointer* when not executing in a *Recovery-Path* mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 …}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 …}.

11.3.4.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each *Save-Place* indicator requires a matching *Restore* indicator.
  - The *Save-Place* indicator is an FSTN with a valid *Back Path Link Pointer and T-bit* equal to zero.
    - *Back Path Link Pointer.Typ* field must be set to indicate the referenced data structure is a queue head. The *Restore* indicator is an FSTN with its *Back Path Link Pointer.T-bit* set to one.
  - A *Restore* FSTN may be matched to one or more *Save-Place* FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a *Restore* FSTN at the beginning of this list in order to match all possible *Save-Place* FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more *Save-Place* FSTNs are used, then System Software must ensure the *Restore* FSTN's *Normal Path Link Pointer*'s *T-bit* is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a *Restore* FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that *Recovery Path* mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A *Save-Place* FSTN's *Back Path Link Pointer* must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list

location. In other words, if the *Save-Place* FSTN is reachable from frame list offset N, then the FSTN's *Back Path Link Pointer* must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one *Save-Place* FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the *Save-Place* FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

11.3.4.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets one of the *C-prog*-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a

complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- *FrameTag*. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame* number) when the next complete split must be executed.
- *S-bytes*. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

11.3.4.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

>As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- *cMicroFrameBit*. This is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, *cMicroFrameBit* = (1 shifted-left(*FRINDEX*[2:0])). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-splt transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each

encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

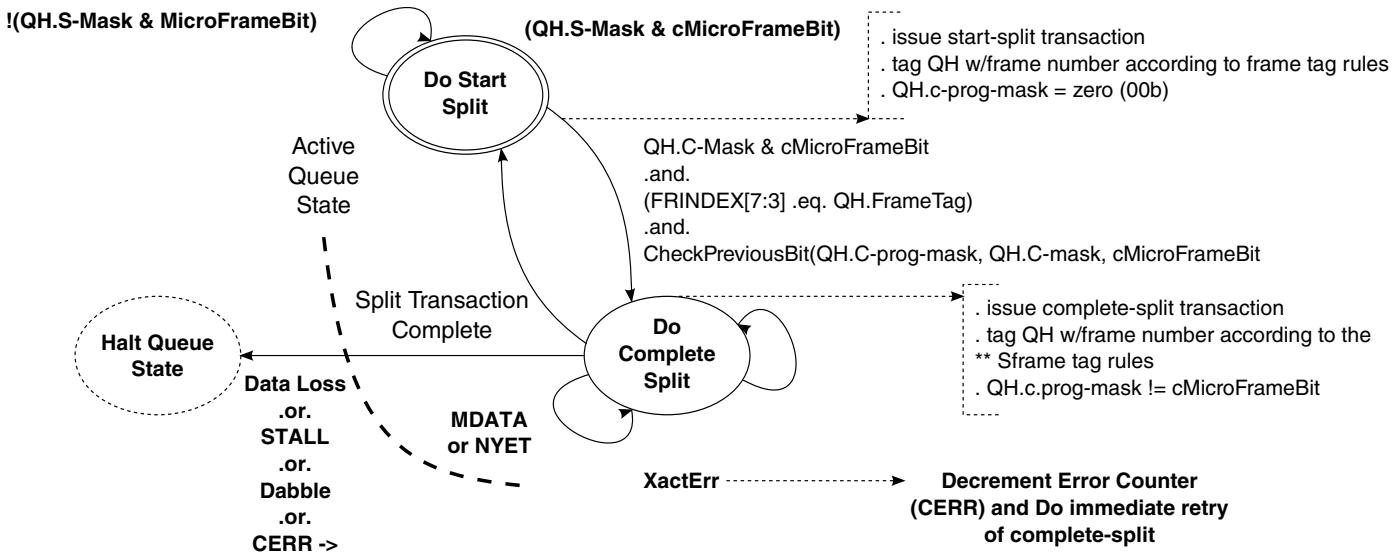

Figure 11-76. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head *StartXState* bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- *QH.S-mask* is bit-wise anded with *cMicroFrameBit*.

If the result is non-zero, then the host controller will issue a start-split transaction. If the *PIDCode* field indicates an IN transaction, the host controller must zero-out the *QH.S-bytes* field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into *QH.FrameTag* field (see Section), set *C-prog-mask* to zero (00h), and exits this state. Note that the host controller must not adjust the value of *CErr* as a result of completion of a start-split transaction.

Periodic Interrupt - Do Complete Split

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. *cMicroFrameBit* is bit-wise anded with *QH.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- Test B. *QH.FrameTag* is compared with the current contents of *FRINDEX*[7:3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
-- Return values:
-- TRUE - no error
-- FALSE - error
--
Boolean rvalue = TRUE;
previousBit = cMicroframeBit logical-rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates
-- whether there was an intent
-- to send a complete split in the previous micro-frame. So,
-- if the

```

- Test D. Check to see if a start-split should be executed in this micro-frame. Note this is the same test performed in the Do Start Split state (see Section Periodic Isochronous - Do Start Split). Whenever it evaluates to TRUE and the controller is NOT processing in the context of a *Recovery Path* mode, it means a start-split should occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets *QH.FrameTag* to the expected *H-Frame* number (see Section). The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the *CErr* will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last). On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction translator must have responded to all the clompete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.
- The test for whether this is the Last complete split can be performed by XOR *QH.C-mask* with *QH.C-prog-mask*. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the *XactErr* status bit is set to a one and the *CErr* field is decremented.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask* and *FrameTag*) and stay in this state. The host controller must not adjust *CErr* on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, etc. The *CErr* field is decremented and the *XactErr* bit in the *Status* field is set to a one. The complete split transaction is *immediately* retried (if *Cerr* is non-zero).If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or *CErr* is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and *CErr* is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.
- ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The *Current Offset* field is incremented by *Maximum Packet Length* or *Bytes to Transfer*, whichever is less. The field *Bytes To Transfer* is decremented by the same amount. And the data toggle bit (*dt*) is toggled. The host controller will then exit this state for this queue head. The host controller must reload *CErr* with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in *QH.S-bytes*. The host controller must not adjust *CErr* on this response.
- DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in *QH.S-bytes*. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.
- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).
- If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.
- NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload *CErr* with maximum value on this response.

- ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, *Cerr* is decremented, the state of the transfer is not advanced, and this state is exited.
- STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: *Active* bit is set to zero and the *Halted* bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 11-100. Interrupt IN/OUT Do Complete Split State Execution Criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current micro-frame.Host controller should continue walking the schedule.
A not(C)	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	*QH.FrameTag* test failed. This means that exactly one or more *H-Frames* have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If *PIDCode* is an IN, then the Queue head must be halted. If *PIDCode* is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect *CER*R. In either case, set the *Missed Micro-frame* bit in the status field to a one. Note: When executing in the context of a *Recovery Path* mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 11-100. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a *Recovery Path* mode.

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see Figure 11-73).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 11-73).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases (Figure 11-73).

11.3.4.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction* (*I*) bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

11.3.4.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

11.3.4.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^{S}X and ^{C}X labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

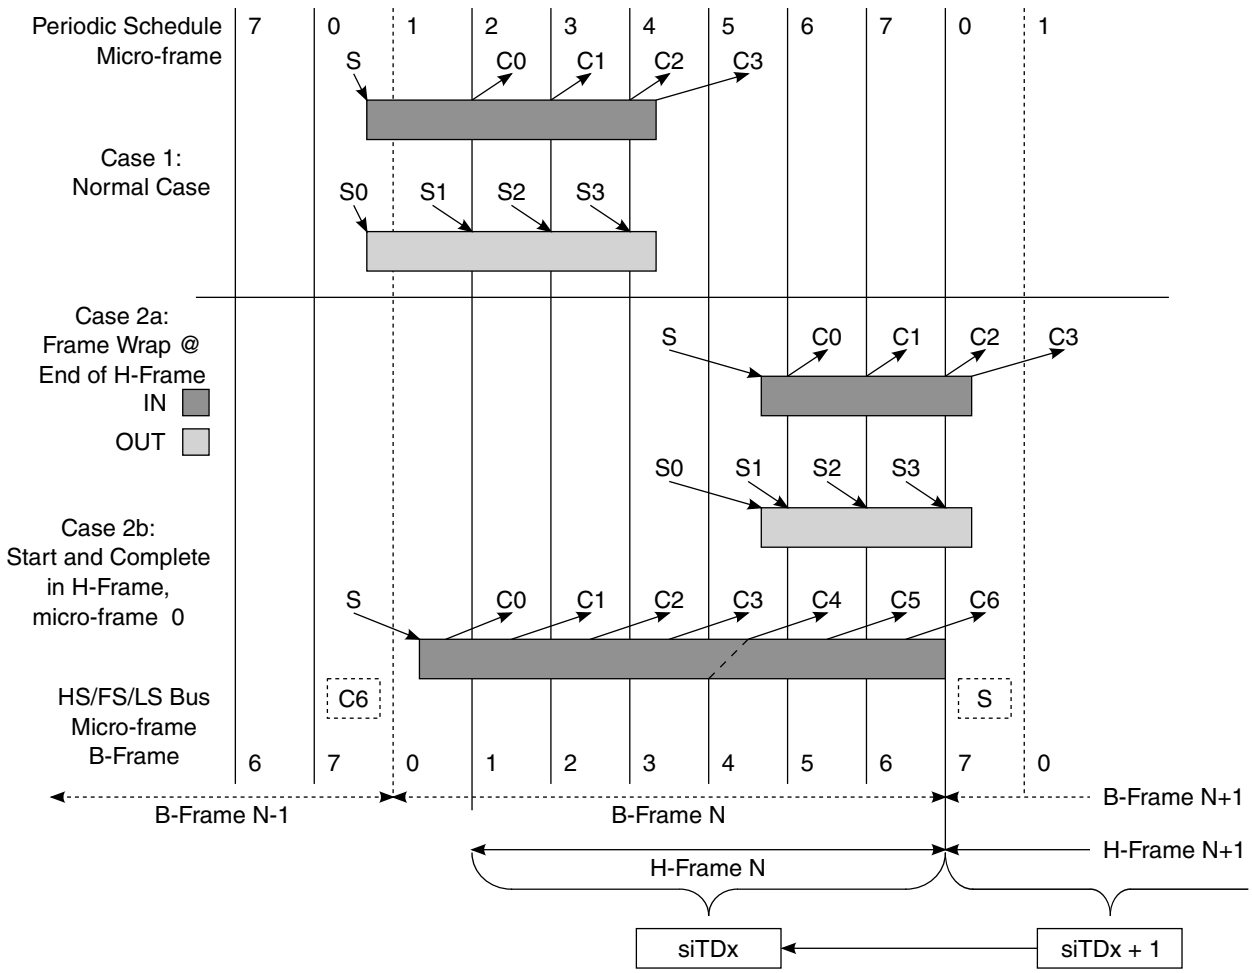

Figure 11-77. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame,* micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see Figure 11-78). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt .
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 11-77, case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by USB_n_FRINDEX[2:0] is 0, then execute a start-split transaction.
- *Frame C-mask.* This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in Figure 11-77, case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

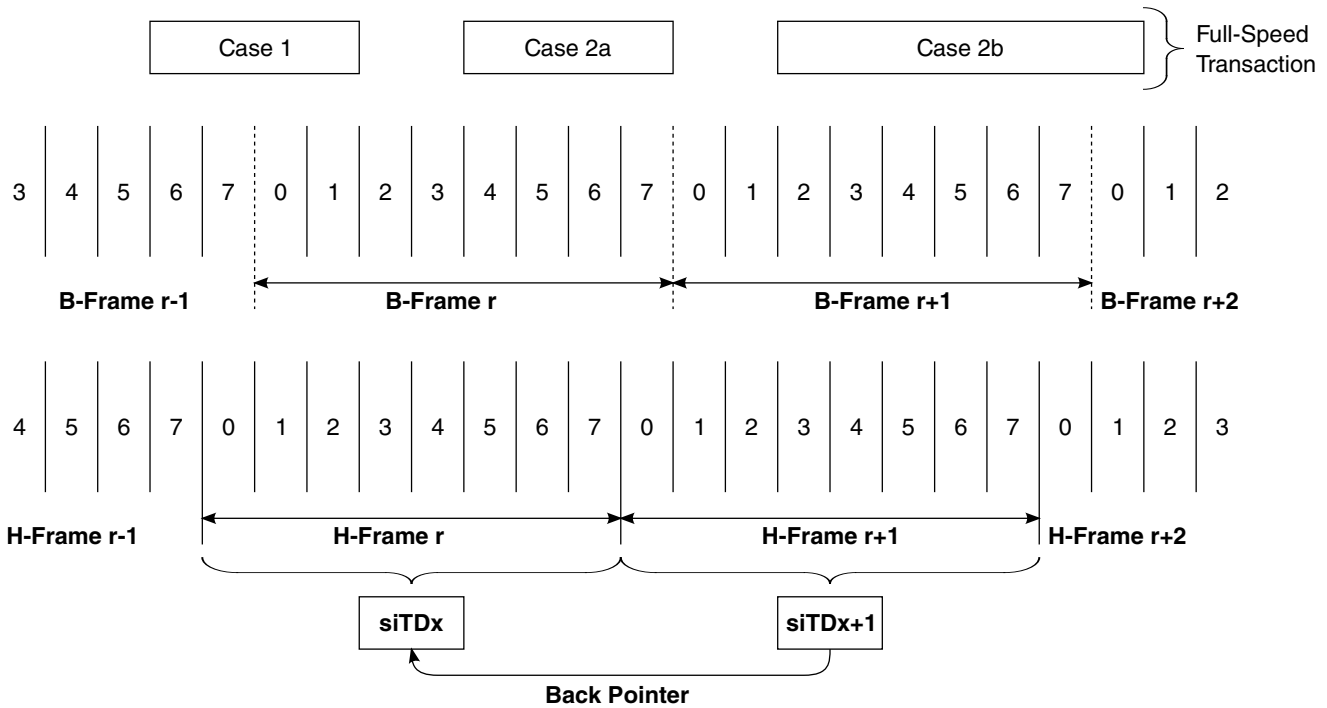

Figure 11-78. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1*: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b*: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H\text{-}Frame_{Y+1}$, or micro-frame 0 of $H\text{-}Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H\text{-}Frame_{Y+2}$is to use $siTD_{X+2}$'s back pointer. The host controller rules for when to use the back pointer are described is Section Periodic Isochronous - Do Complete Split .

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame* N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

11.3.4.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position* (*TP*) and *Transaction Count* (*T-count*). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

11.3.4.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame.*

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers , plus the variable *cMicroFrameBit* defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

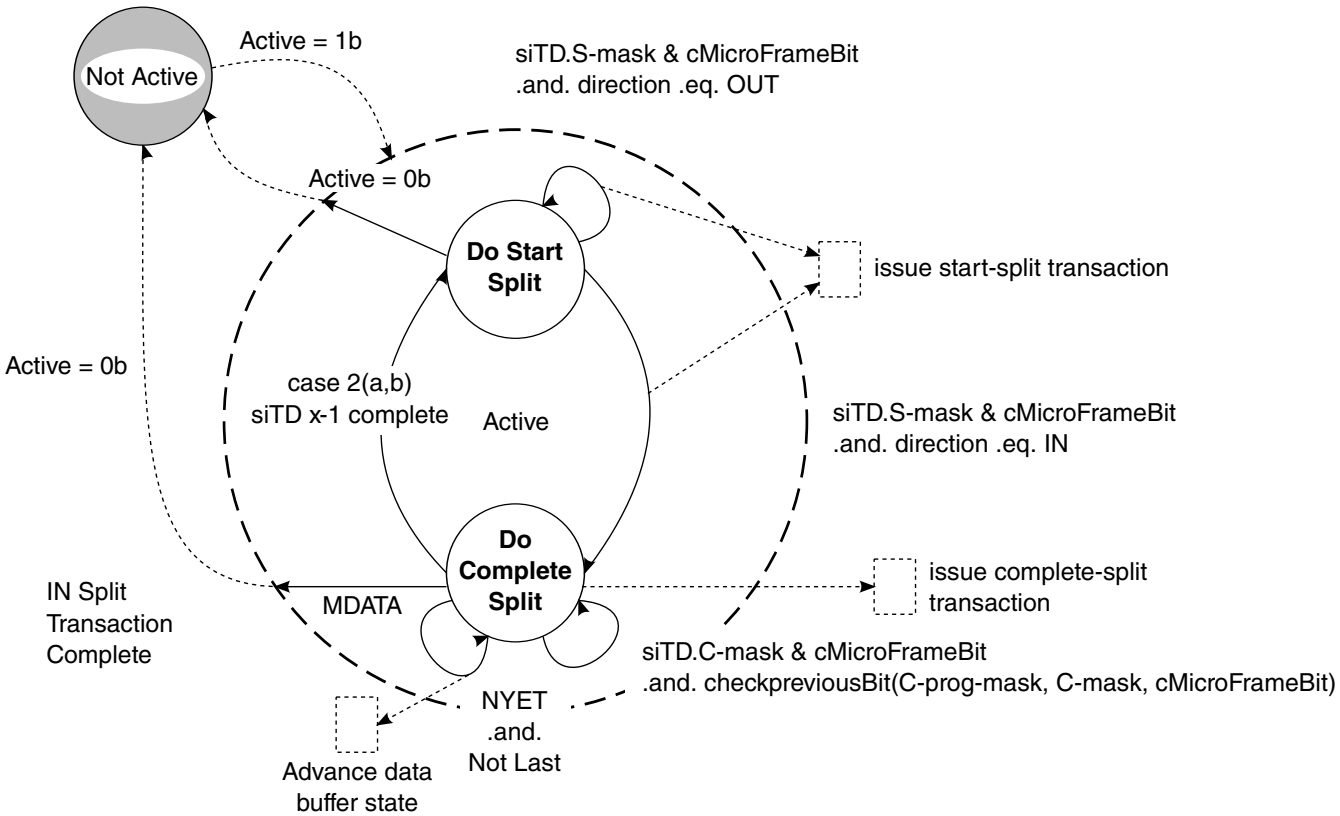

Figure 11-79. Split Transaction State Machine for Isochronous

11.3.4.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 11-78) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 11-101. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

.

Table 11-102. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when *T-count* starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when *T-count* starts at greater than 2.
MID	!=1	MID	*TP* stays at MID while *T-count* is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the *T-count* starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in Table 11-102.

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section Split Transaction for Isochronous - Processing Examples .

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit*() algorithm defined in Periodic Isochronous - Do Complete Split can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

11.3.4.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Complete Split). The sequence in which this test is applied depends on the current value of USB_n_FRINDEX[2:0]. If USB_n_FRINDEX[2:0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
          Boolean rvalue = TRUE;
          previousBit = cMicroFrameBit rotate-right(1)
          -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
          -- to send a complete split in the previous micro-frame. So, if the
          -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
          -- happened.
          if previousBit bitAND siTD.C-mask then
                    if not (previousBit bitAND siTD.C-prog-mask) then
                              rvalue = FALSE
                    End if
          End if
          Return rvalue
End Algorithm
```

If Test A is true and USB_n_FRINDEX[2:0] is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 11-77). See Section Periodic Isochronous - Do Complete Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer,*
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last). See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-mask*s incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- NYET (and not Last). See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- MDATA (and not Last). The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

11.3.4.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 11-77) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 11-103. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$.*Back Pointer*.

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 11-103) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s *Active* bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If $siTD_{X-1}$*'sActive* bit is a zero, (because it was zero when the host controller first visited $siTD_{X-1}$ via $siTD_X$*'s* back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$*'s* complete-split transaction transitioned it to zero), then the host controller returns to the context of $siTD_X$ and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and $siTD_X$.*S-mask*[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$.*Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$.*Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

11.3.4.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 11-70).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 11-104. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, sofware ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that $siTD_{X+1}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's *Active* bit is set to zero and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the *SplitXState* in the $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section Periodic Isochronous - Do Complete Split), that is, before all the scheduled complete-splits have been executed, the host controller will transition $siTD_X$.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame X+2,* micro-frame 0, the host controller detects that $siTD_{X+2}$'s *Back Pointer.T-bit* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of $siTD_{X+2}$, and traverses its next pointer without any state change updates to $siTD_{X+2}$. S

During *H-Frame X+2*, micro-frame 1, the host controller detects $siTD_{X+2}$'s *S-mask[0]* is a zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of $siTD_{X+2}$ and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it

reaches micro-frame 4. <TBD… describe how software detects that there was missing micro-frames (don't think we care about missing out micro-frames. There is enough residual state to identify than not all transactions were executed.).

11.3.4.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create ARM platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the ARM platform, based on recent history usage. In the more aggressive power saving modes, the ARM platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the ARM platform power management software can detect this activity over time and inhibit the transition of the ARM platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the ARM platform power management software from placing the ARM platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the ARM platform power management to get the ARM platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the ARM platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the ARM platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

11.3.4.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCReset* to a one.

11.3.4.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, ARM platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section) from a one to a zero.

11.3.4.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

11.3.4.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 11-105. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1[1]
Timeout	-1	XactErr set to a one.	1[1]
Bad PID[2]	-1	XactErr set to a one.	1[1]
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head.
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

11.3.4.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see Halting a Queue Head). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

11.3.4.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

11.3.4.3.15.1.4 USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

11.3.4.3.15.1.5 Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

11.3.4.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

11.3.4.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

11.3.4.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

11.3.4.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupton Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule .

11.3.4.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion.In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - *Host System Error* bit is to a one.
  - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 11-106. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCReset* in the USB.USBCMD register before re-initializing and restarting the host controller.

11.3.4.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

11.3.4.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

11.3.4.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

11.3.4.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the register.

11.3.4.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 11-107. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

11.3.4.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)
       - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

11.3.4.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

11.3.4.4.1.5.1 Micro- frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

11.3.4.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 11-108. Summary of the Conditons of Handshakes[1]

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

11.3.4.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

11.3.4.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

11.3.4.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

11.3.4.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

11.3.4.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames

11.3.4.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

11.3.4.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the register.

11.3.4.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

11.3.4.4.2.1 USB_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode (USB_USBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

11.3.4.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

11.3.4.4.2.3 SOF Interrupt

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See and registers.

11.3.4.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

11.3.4.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

11.3.4.4.4 Miscellaneous variations from EHCI

11.3.4.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes.

Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase.

The control bits for selecting the Physical Interface operating mode have been added to the register providing a capability that is not defined by EHCI.

11.3.4.4.4.2 Discovery

11.3.4.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.
  - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

11.3.4.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

11.3.4.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

11.3.4.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

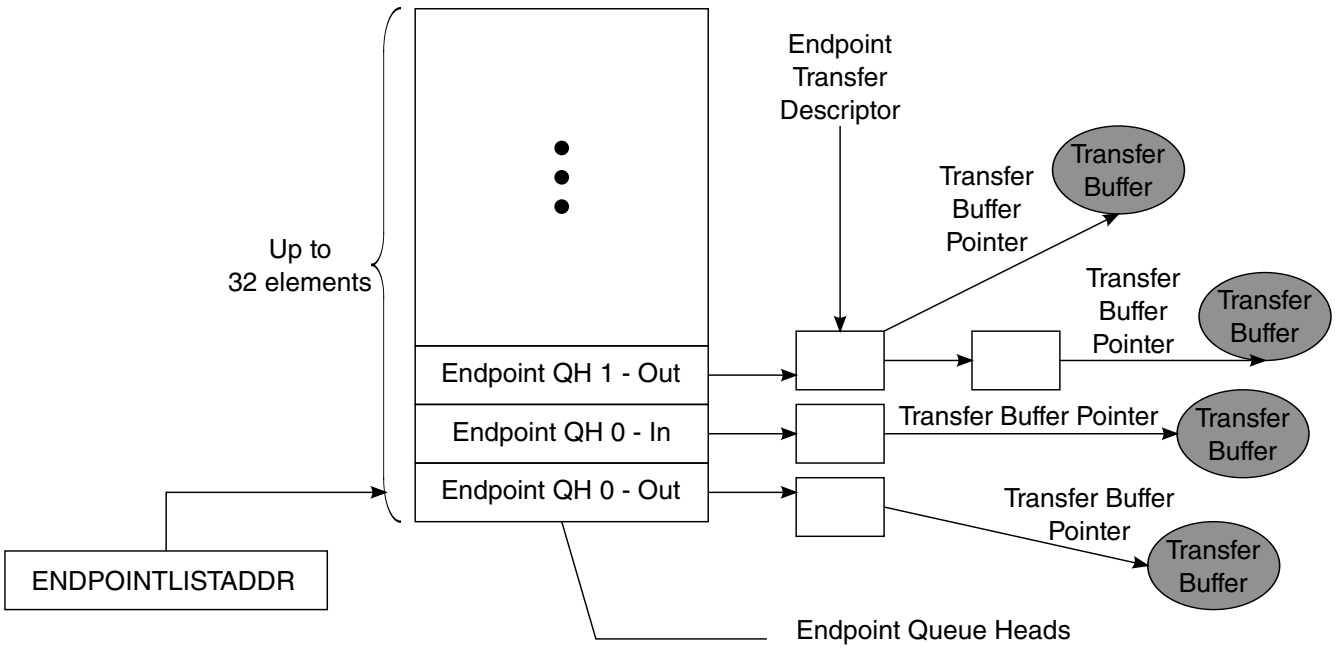

Figure 11-80. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

11.3.4.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD

status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 11-109. Endpoint Queue Head (dQH)

Host Controller Read/Write

Host Controller Read Only

11.3.4.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

Table 11-110 describes the endpoint capabilities.

Table 11-110. Endpoint Capabilities/Characteristics

Bit	Description

Table continues on the next page...

Table 11-110. Endpoint Capabilities/Characteristics (continued)

31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where to total transfer length is a multiple . This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bit reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

11.3.4.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

11.3.4.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 11-111. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

11.3.4.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 11-112. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

11.3.4.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/ received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 11-113. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

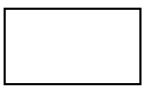
Host Controller Read/Write



Host Controller Read Only

The following table describes the dTD Pointer.

Table 11-114. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 11-115. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of *Maximum Packet Length*. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that *Maximum Packet Length*.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example:

Table continues on the next page...

Table 11-115. dTD Token (continued)

	if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO = "00".
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.

The table below describes the dTD Buffer Page Pointer List.

Table 11-116. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

11.3.4.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

11.3.4.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device Data Structures.
- Configure USB.ENDPOINTLISTADDR Pointer.
  - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
  - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
  - For a list of available interrupts refer to the and the register tables.
- Set Run/Stop bit to Run Mode.
  - After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

11.3.4.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS or defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

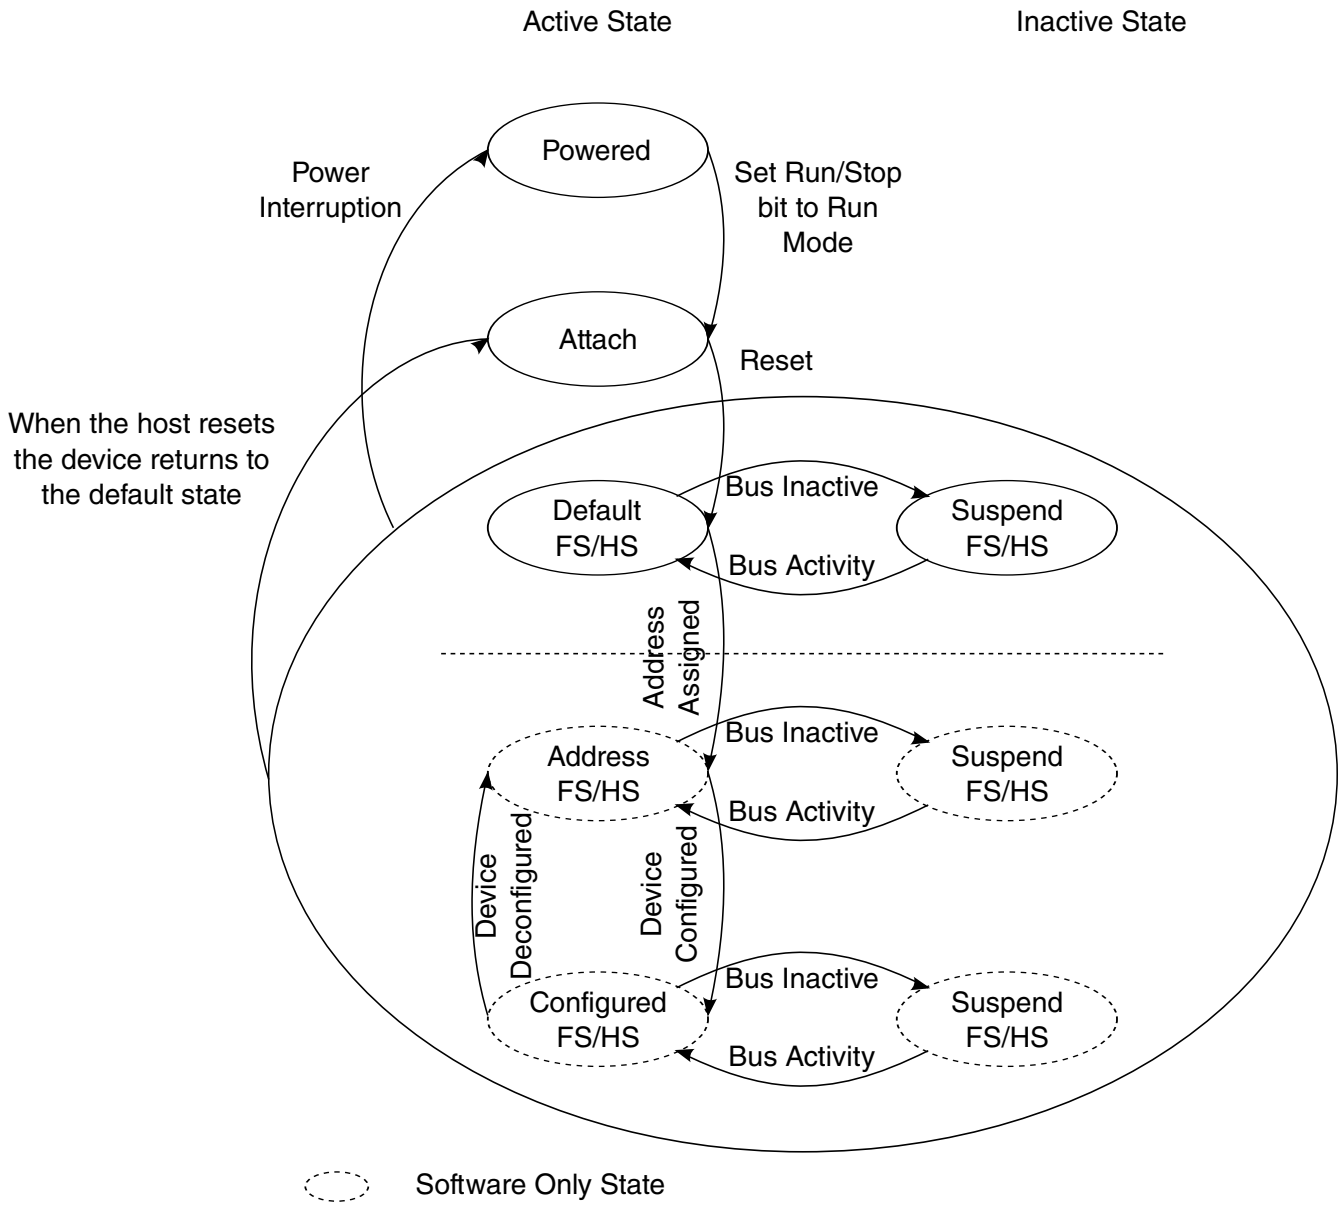


Figure 11-81. Device State Diagram

States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 11-117. Device Controller State Information Bits

Bit	Register
DCSuspend	
USB Reset Received	
Port Change Detect	
High-Speed Port	

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

11.3.4.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the register and writing the same value back to the register.

Clear all the endpoint complete status bits by reading the register and writing the same value back to the register.

Cancel all primed status by waiting until all bits in the are 0 and then writing 0xFFFFFFFF to Endpoint Flush (USB_ENDPTFLUSH).

Read the reset bit in the register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

11.3.4.6.2.2 Suspend/Resume

11.3.4.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

11.3.4.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the Port Status & Control (USB_PORTSC1) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

11.3.4.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk, interrupt*, and

isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

11.3.4.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 11-118. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

11.3.4.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 11-119. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

11.3.4.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

11.3.4.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

11.3.4.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

11.3.4.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

11.3.4.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

11.3.4.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN

requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

11.3.4.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(Number Of Bytes/Max. Packet Length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(Number Of Bytes/Max. Packet Length)

Table 11-120. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 11-121. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

11.3.4.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrput/Bulk Endpoint Bus.

Table 11-122. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.3.4.6.4.2 Control Endpoint Operation Model

11.3.4.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted be an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in . (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit .
  b. Write 1 to Setup Tripwire (SUTW) in register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in register.
  f. Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

11.3.4.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the register is zero and the associated bit in the register is a one. If a prime fails, ie. The bit goes to zero and the Endpoint Status (USB_ENDPTSTAT) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status () to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.3.4.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.3.4.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 11-123. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.3.4.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [*Transaction Error* bit is set]

- # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [*Buffer Error* bit is set]
    - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
  - Fulfillment Error [*Transaction Error* bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

11.3.4.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does

not have enough time to complete the prime before the SOF for packet N is received.

11.3.4.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 11-124. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

   NULL Packet = Zero Length Packet

11.3.4.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

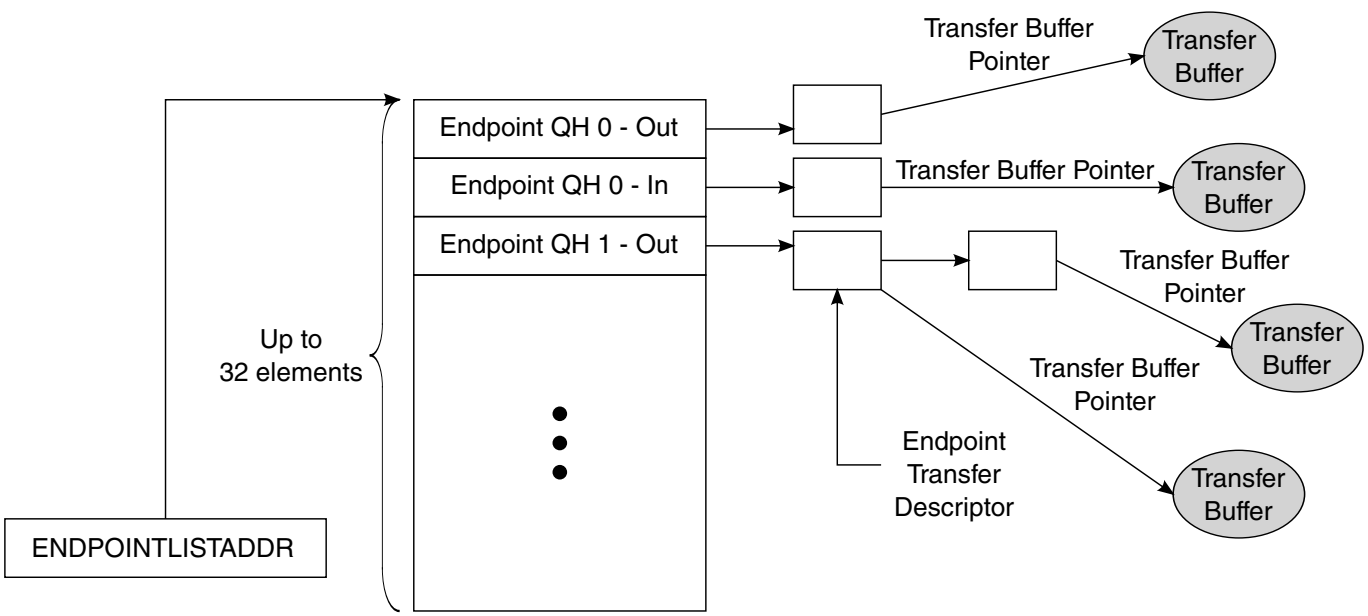

Figure 11-82. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 11-82. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

11.3.4.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

11.3.4.6.5.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
- After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

11.3.4.6.6 Managing Transfers with Transfer Descriptors

11.3.4.6.6.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

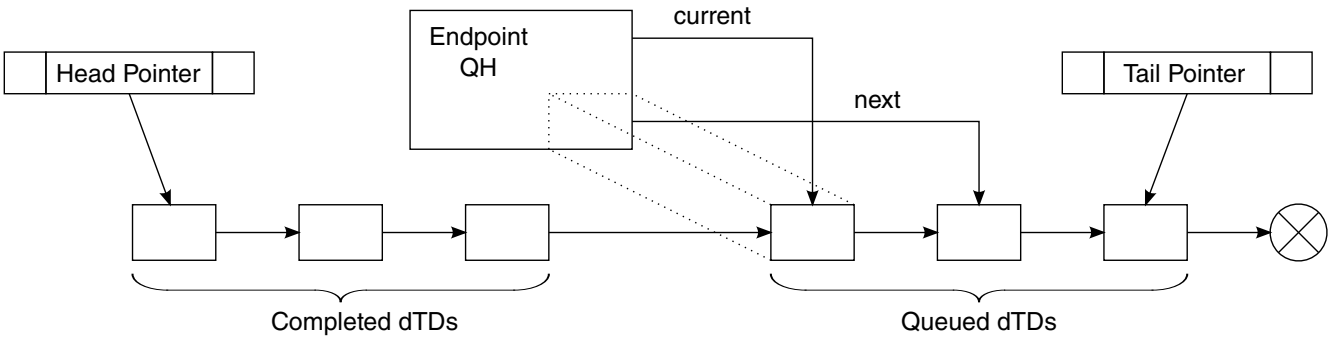

Figure 11-83. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

11.3.4.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

11.3.4.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  b. Clear active & halt bit in dQH (in case set from a previous error).
  c. Prime endpoint by writing 1 to correct bit position in .
- Case 2: Link list is not empty
  a. Add dTD to end of linked list.
  b. Read correct prime bit in - if 1 DONE.
  c. Set ATDTW bit in USBCMD register to 1.
  d. Read correct status bit in . (store in tmp. variable for later)
  e. Read ATDTW bit in USBCMD register.
     - If 0 goto 3.
     - If 1 continue to 6.
  f. Write ATDTW bit in USBCMD register to 0.
  g. If status bit read in (3) is 1 DONE.
  h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

11.3.4.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

11.3.4.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in .
2. Wait until all bits in are '0'.
   - Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
   - Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using . A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

11.3.4.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 11-125. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 11-126. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

11.3.4.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

11.3.4.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 11-127. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 11-82 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.

Table continues on the next page...

Table 11-127. High Frequency Interrupt Events (continued)

1b	USB Interrupt[1] - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 11-82 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

11.3.4.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 11-128. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

11.3.4.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrput events.

Table 11-129. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

11.3.5 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registera are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to Register Interface .

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

USBNC_*n*_CTRL1 field descriptions

Field	Description
31 WIR	Wake-up Interrupt Request This bit indicates that a wake-up interrupt request is received on the OTG1 port. This bit is cleared by disabling the wake-up interrupt (clearing bit "OWIE"). 1 Wake-up Interrupt Request received 0 No wake-up interrupt request received
30 Reserved	This field is reserved.
29 WKUP_DPDM_EN	Wake-up on DPDM change enable 1 (Default) DPDM changes wake-up to be enabled, it is for device only. 0 DPDM changes wake-up to be disabled only when VBUS is 0.
28–18 Reserved	This field is reserved.
17 WKUP_VBUS_EN	Wake-up on VBUS change enable 1 Enable 0 Disable
16 WKUP_ID_EN	Wake-up on ID change enable 1 Enable 0 Disable
15 WKUP_SW	Software Wake-up 1 Force wake-up 0 Inactive
14 WKUP_SW_EN	Software Wake-up Enable 1 Enable 0 Disable
13–11 Reserved	This field is reserved. Reserved. Do not write to.
10 WIE	Wake-up Interrupt Enable This bit enables or disables the OTG1 wake-up interrupt. Disabling the interrupt also clears the Interrupt request bit. Wake-up interrupt enable should be turned off after receiving a wake-up interrupt and turned on again prior to going in suspend mode 1 Interrupt Enabled 0 Interrupt Disabled
9 PWR_POL	Power Polarity This bit should be set according to PMIC Power Pin polarity. 1 PMIC Power Pin is High active. 0 PMIC Power Pin is Low active.
8 OVER_CUR_POL	Polarity of Overcurrent The polarity of OTG1/OTG2 port overcurrent event

Table continues on the next page...

USBNC_*n*_CTRL1 field descriptions (continued)

Field	Description
	1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
Reserved	This field is reserved.

11.3.5.2 USBNC_*n*_CTRL2

The USB_OTGx_PHY_CTRL2 register allows observation of the UTMI Clock Valid status along with control of selected inputs to the USB OTG PHY transceiver.

Some of these input signals may be used for USB out-of-band signaling. Customers should use caution when overriding any UTMI signals since that will interfere with normal USB data communication.

Address: 30B1_0200h base + 204h offset + (65536d × i), where i=0d to 2d

USBNC_*n*_CTRL2 field descriptions

Field	Description
31 UTMI_CLK_VLD	Indicate whether PHY clock is valid. Write 1 to clear 0 UTMI clock to USB PHY is not toggling (Default) 1 UTMI clock to USB PHY has toggled several times
30–28 Reserved	This field is reserved.
27–23 Reserved	This field is reserved. 0B11110 Default
22–21 Reserved	This field is reserved. Customers should not change the value of this bit field.
20 DIG_ID_SEL	Selects whether the USB OTG ID pin function is connected to the PHY's USB_OTG*_ID pin or a GPIO pin. The ID pin state is observed on USBNC_n_PHY_STATUS[ID_DIG]. 0 Use the USB_OTG*_ID pin for the USB OTG ID pin detection function(default) 1 Use the pin configured by the IOMUXC_USB_OTG*_ID_SELECT_INPUT register for the USB OTG ID pin detection function
19–16 Reserved	This field is reserved. Customers should not change the value of this bit field.
15 DMPULLDOWN_ OVERRIDEEN	Enables override of control of the DM pulldown resistor instead of the state set by the USB controller. 0 USB controller enables/disables the DM pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DMPULLDOWN_OVERRIDE] bit field to enable/disable the DM pulldown resistor in the USB PHY.
14 DMPULLDOWN_ OVERRIDE	Controls state of DM pulldown resistor if USBNC_n_CTRL2[DMPULLDOWN_OVERRIDEEN] is set to 1'b1. 0 DM pulldown resistor disabled 1 DM pulldown resistor enabled

Table continues on the next page...

USBNC_*n*_CTRL2 field descriptions (continued)

Field	Description
13 DPPULLDOWN_ OVERRIDEEN	Enables override of control of the DP pulldown resistor instead of using the state set by the USB controller. 0 USB controller enables/disables the DP pulldown resistor in the USB PHY. 1 Use the value set by the USBNC_n_CTRL2[DPPULLDOWN_OVERRIDE] bit field to enable/disable the DP pulldown resistor in the USB PHY.
12 DPPULLDOWN_ OVERRIDE	Controls state of DP pulldown resistor if USBNC_n_CTRL2[DPPULLDOWN_OVERRIDEEN] is set to 1'b1. 0 DP pulldown resistor disabled 1 DP pulldown resistor enabled
11 XCVRSEL_ OVERRIDEEN	Enables override of control of the UTMI XcvrSelect signals to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI XcvrSelect signals to the USB PHY is set by the USB controller. 1 The state of the UTMI XcvrSelect signals to the USB PHY is set by the values in the USBNC_x_CTRL2[XCVRSEL_OVERRIDE] bit field.
10–9 XCVRSEL_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[XCVRSEL_OVERRIDEEN] is set to 1'b1. See the *UTMI+ Specification* for descriptions of the functions of the XcvrSelect signals.
8 OPMODE_ OVERRIDEEN	Enables override of control of the UTMI OpMode signals to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI OpMode signals to the USB PHY is set by the USB controller. 1 The state of the UTMI OpMode signals to the USB PHY is set by the values in the USBNC_x_CTRL2[OPMODE_OVERRIDE] bit field.
7–6 OPMODE_ OVERRIDE	Controls the state of the UTMI XcvrSelect signals to the USB OTG PHY if the value of USBNC_x_CTRL2[OPMODE_OVERRIDEEN] is set to 1'b1. See the *UTMI+ Specification* for descriptions of the functions of the OpMode signals.
5 TERMSEL_ OVERRIDEEN	Enables override of control of the UTMI TermSelect signal to the USB OTG PHY instead of using the state normally set by the USB controller. 0 The state of the UTMI TermSelect signal to the USB PHY is set by the USB controller. 1 The state of the UTMI TermSelect signal to the USB PHY is set by the value in the USBNC_x_CTRL2[TERMSEL_OVERRIDE] bit field.
4 TERMSEL_ OVERRIDE	Controls the state of the UTMI TermSelect signal to the USB OTG PHY if the value of USBNC_x_CTRL2[TERMSEL_OVERRIDEEN] is set to 1'b1. See the *UTMI+ Specification* for descriptions of the function of the TermSelect signal.
3 LOWSPEED_EN	Set if AUTURESUME_EN is set and works on low speed. 0 Default
2 AUTURESUME_ EN	Auto Resume Enable This bit field is for UTMI OTG PHY host mode only (UH core does not have this feature since HSIC PHY does not support auto resume). To set USB, it will send resume with 32 KHz clock when it detects remote wakeup from device. This feature is useful if device drives a very short remote wakeup (minimal value is 1 ms for USB2 spec) and system 24 MHz is off during suspend mode. 0 Default

Table continues on the next page...

USBNC_*n*_CTRL2 field descriptions (continued)

Field	Description
VBUS_SOURCE_SEL	VBUS source select used to detect a VBUS wakeup event. This bit field is for UTMI OTG PHY only (UH core and HSIC PHY have no such feature). 2'b00 vbus_valid others sess_valid

11.3.5.3 USB OTG PHY Configuration Register 1 (USBNC_*n*_PHY_CFG1)

The USB_OTGx_PHY_CFG1 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for parametric tuning of the USB transceiver functions.

One signal is used to allow persistent control of the USB_OTG1_CHD_B external pin.

Address: 30B1_0200h base + 230h offset + (65536d × i), where i=0d to 1d

USBNC_*n*_PHY_CFG1 field descriptions

Field	Description
31 CHRGDET_Megamix	USB_OTG1_CHD_B output control This signal controls the state of the USB_OTG1_CHD_B external pin together with the CHRGDET (USBNC_USB_OTG1_PHY_STATUS[29] signal during periods when the SOC is fully powered. If either CHRGDET_Megamix or CHRGDET are set to 1'b1, then USB_OTG1_CHD_B will be pulled low. If both CHRGDET_Megamix and CHRGDET are set to 1'b0, then USB_OTG1_CHD_B will be pulled high by its external open-drain pull-up resistor.

Table continues on the next page...

USBNC_*n*_PHY_CFG1 field descriptions (continued)

Field	Description
	Note: The instance of this bit field for the USB OTG2 PHY does not produce results on an external pin. The R/W register bit may still be used as a memory location to store results of Battery Charger detection tests for USB OTG2 PHY. 0 The external state of USB_OTG1_CHD_B is only controlled by the state of the CHRGDET signal 1 The external state of USB_OTG1_CHD_B is forced low
30 TXPREEMPPULSETUNE0	HS Transmitter Pre-Emphasis Duration Control This signal controls the duration for which the HS pre-emphais current is sourced on the the USB_OTG*_DP and USB_OTG*DN pins. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580ps and is defined as 1X pre-emphasis duration. This signal is valid only if TXPREEMPAMPTUNE (USBNC_USB_OTGx_PHY_CFG1[29:28]) is NOT set to 2'b00. 0 2X, long pre-emphasis current duration (design default) 1 1X, short pre-emphasis current duration
29–28 TXPREEMPAMPTUNE0	HS Treansmitter Pre-Emphasis Current Control This signal controls the amount of current sourced to the USB_OTG*_DP and USB_OTG*_DN pins after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600uA and is defined as 1X pre-emphasis current. 00 HS Transmitter pre-emphasis is disabled 01 HS Transmitter pre-emphasis circuit sources 1X pre-emphasis current (design default) 10 HS Transmitter pre-emphasis circuit sources 2X pre-emphasis current 11 HS Transmitter pre-emphasis circuit sources 3X pre-emphasis current
27–26 TXRESTUNE0	USB Source Impedance Adjustment In some applications, there can be significant series resistance on the USB DP/DN path between the USB_OTG*_DP/USB_OTG*_DN pins tns and the USB cable. This bus adjusts the driver source impedance to compensate for that added resistance. **Note:** Any setting other than the design default can cause HS/FS signal integrity changes along with variation across process, voltage, and temperature conditions that affect compliance with USB 2.0 specification limits. 00 Source impedance is increased by approximately 1.5 Ω 01 Design default 10 Source impedance is decreased by approximately 2 Ω 11 Source impedance is decreased by approximately 4 Ω
25–24 TXRISETUNE0	HS Transmitter Rise/Fall Time Adjustment This bus adjust the rise/fall times of the high-speed transmitter waveform. 00 -10% 01 Design default 10 +15% 11 +20%
23–20 TXVREFTUNE0	HS DC Voltage Level Adjustment This bus adjust the high-speed transmitter DC level voltage.

0 COMMONONN	Common Block Power-Down Control This signal controls the power-down signals in the Bias and PLL blocks when the USB OTG PHY is in Suspend or Sleep modes. 0 In Suspend or Sleep modes, the Bias and PLL blocks remain powered 1 In Suspend or Sleep modes, the Bias and PLL blocks are powered down 0

11.3.5.4 USB OTG PHY Configuration Register 2 (USBNC_*n*_PHY_CFG2)

The USB_OTGx_PHY_CFG2 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for configuration of VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accesory Charging Adaptor) functions.

Address: 30B1_0200h base + 234h offset + (65536d × i), where i=0d to 1d

USBNC_*n*_PHY_CFG2 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DRVVBUS0	VBUS Valid Comparator Enable This signal controls the USB OTG PHY VBUS Valid comparator which indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The VBUS Valid threshold is nominally 4.75V on this USB PHY. The VBUS Valid threshold can be adjusted using the USBNC_OTGn_PHY_CFG1[OTGTUNE0] bit field. Status of the VBUS Valid comparator, when it is enabled, is reported on the USBNC_OTGn_PHY_STATUS[VBUS_VLD] bit. When OTGDISABLE0 (USBNC_USB_OTGx_PHY_CFG2[10])is set to 1'b0 and DRVVBUS0 is set to 1'b1, the Bandgap circuitry and VBUS Valid comparator are powered, even in Suspend or Sleep mode. DRVVBUS0 should be reset to 1'b0 when the internal VBUS Valid comparator is not required, to reduce quiescent current in Suspend or Sleep mode. 0 The VBUS Valid comparator is disabled 1 The VBUS Valid comparator is enabled
15 VBUSVLDEXT	External VBUS Valid Indicator

Table continues on the next page...

USBNC_*n*_PHY_CFG2 field descriptions (continued)

Field	Description
	This signal is used if a VBUS Valid signal generated from a circuit outside the USB OTG PHY is desired. If the USB OTG PHY is configured for Device mode and VBUSVLDEXTSEL0 (USBNC_USB_OTGx_PHY_CFG2[14] is set to 1'b1, VBUSVLD indicated whether the VBUS signal on the USB cable is valid and enables the pull-up resistor on USB_OTG1_DP. This signal has no effect when the USB OTG PHY is configured for Host mode. 0 The VBUS signal sensed outside the USB OTG PHY is not valid, and the pull-up resistor on USB_OTG*_DP is disabled 1 The VBUS signal sensed outside the USB OTG PHY is valid, and the pull-up resistor on USB_OTG*_DP is enabled
14 VBUSVLDEXTSEL0	External VBUS Valid Select This signal selects whether the VBUSVLDEXT input (USBNC_USB_OTGx_PHY_CFG2[15]) or the internal Session Valid comparator in the USB OTG PHY is used to check if the VBUS signal on USB_OTG*_VBUS is valid and to enable the pull-up resistor on the USB_OTG*_DP pin. The activation of the pull-up resistor on the USB_OTG*_DP pin also depends on the state of the XCVRSEL, OPMODE, TERMSEL, DPPULLDOWN, and DMPULLDOWN signals in the UTMI bus per the UTMI+ specification. 0 The USB OTG PHY internal Session Valid comparator is used to enable the pull-up resistor on the USB_OTG*_DP pin 1 The VBUSVLDEXT signal is used to enable the pull-up resistor on the USB_OTG*_DP pin
13 ADPPRBENB0	ADP Probe Enable This signal determines whether the ADP (Attach Detection Protocol) Probe comparator on the USB_OTG*_VBUS pin is enabled. The ADP Probe threshold is > 0.6V and < 0.75V on this USB PHY. 0 ADP Probe comparator is disabled 1 ADP Probe comparator is enabled
12 ADPDISCHRG0	VBUS Input ADP Discharge Enable This signal controls discharging the USB_OTG*_VBUS pin during ADP. The I_{ADP_SINK} current is >1.1mA and <2.0mA. 0 Disables discharging USB_OTG*_VBUS during ADP 1 Enables discharging USB_OTG*_VBUS during ADP
11 ADPCHRG0	VBUS Input ADP Charge Enable This signal controls charging the USB_OTG*_VBUS pin during ADP. The I_{ADP_SRC} current is >1.1mA and <1.65mA. 0 Disables charging USB_OTG*_VBUS during ADP 1 Disables charging USB_OTG*_VBUS during ADP
10 OTGDISABLE0	OTG Block Disable This signal powers down the VBUS Valid comparator. It does not control power to the Session Valid comparator, ADP Probe and Sense comparators, or the ID detection circuitry.

Table continues on the next page...

USBNC_*n*_PHY_CFG2 field descriptions (continued)

Field	Description
	0 The OTG block is powered up 1 The OTG block is powered down
9 TXBITSTUFFENH0	High-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAINH[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
8 TXBITSTUFFEN0	Low-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAIN[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 LOOPBACKENB0	Loopback Test Enable This signal places the USB OTG PHY in Loopback mode, which enables the receive and transmit logic concurrently. Loopback mode is for test purposes only; it cannot be used for normal operation. 0 During data transmission, the receive logic is disabled 1 During data transmission, the receive logic is enabled
5 SLEEPM0	Sleep Mode Assertion Asserting this signal places the USB OTG PHY in Sleep mode accourding to the USB 2.0 Link Power Management (LPM) addendum to the USB 2.0 specification. In Sleep mode, the transmitter is tri-stated and the USB OTG PHY circuits used in this SOC are powered down. **Note:**The USB controller used in this SOC does not support LPM operation. Leave this bit set to 1'b1 for normal operation. 0 Sleep mode 1 Normal operating mode
4 ACAENB0	ACA USB_OTG*_ID Pin Resistance Detection Enable This signal enables the circuitry to detect resistance on the USB_OTG*_ID pin if the USB cable is connected to an ACA (Acessory Charger Adaptor). When ACAENB0 is set to 1'b1, IDPULLUP0 (USB_OTGSC[26]) is overridden and set to 1'b0 internally to the USB OTG PHY. The RID* results are reported in USBNC_USB_OTGx_PHY_STATUS[28:24]. 0 Disables detection of resistance on the USB_OTG*_ID pin 1 Enables detection of resistance on the USB_OTG*_ID pin
3 DCDENB	Data Contact Detection Enable This signal enables current sourcing on the USB_OTG*_DP pin and pull-down resistaince on the USB_OTG*_DN pin for Data Contact Detect (DCD) per the USB Battery Charging Specification revision 1.2.

Table continues on the next page...

USBNC_*n*_PHY_CFG2 field descriptions (continued)

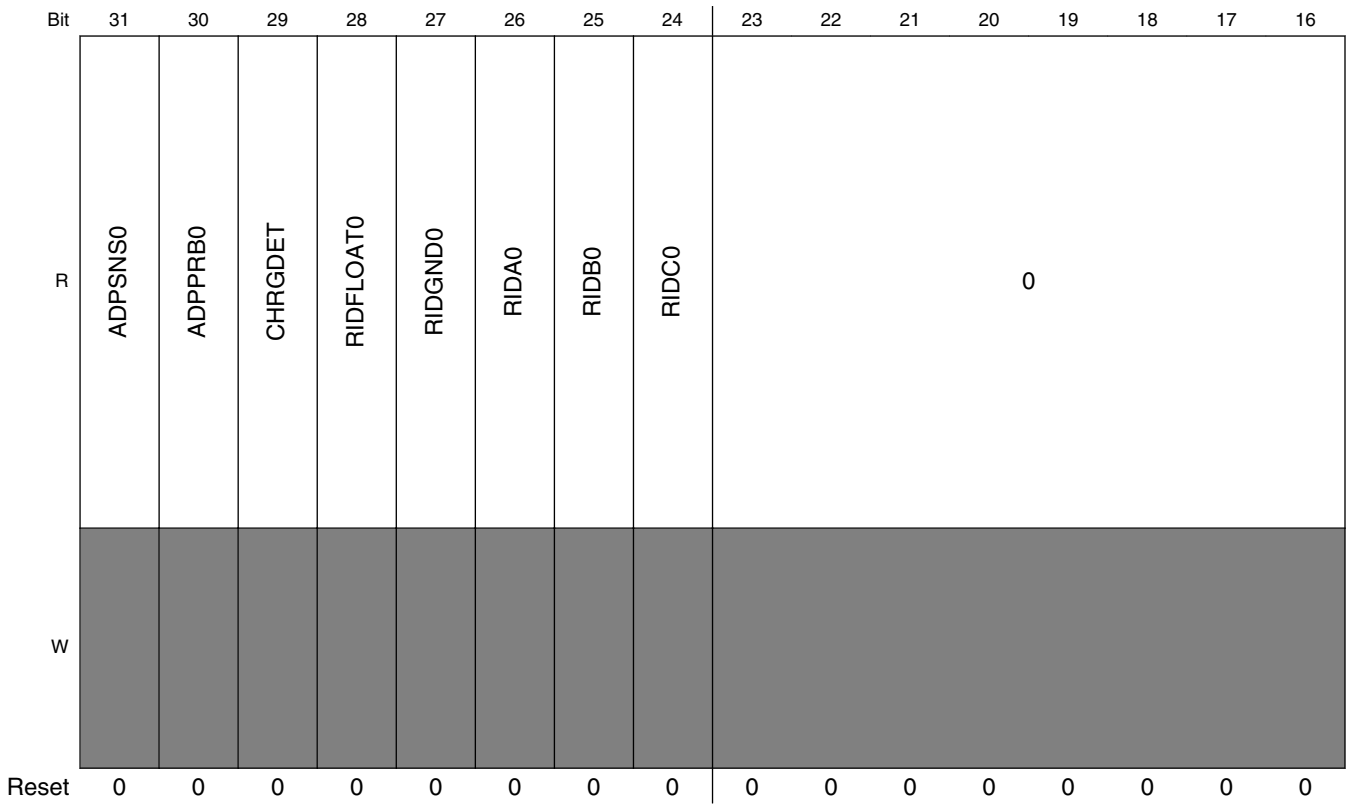
Field	Description
	Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0. 0 I_{DP_SRC} current and R_{DM_DWN} pull-down resistance are disabled 1 I_{DP_SRC} current and R_{DM_DWN} pull-down resistance are enabled
2 VDATSRCENB0	Battery Charging Source Select This signal is used to enable the VD*_SRC voltage source and ID*SINK current sink per the USB Battery Charging Specification revision 1.2. Pin selection for the voltage source and the current sink are controlled by USBNC_USB_OTGx_PHY_CFG2[0]. **Note:** During normal USB operation of the USB OTG PHY, set this signal to 1'b0. 0 VD*_SRC and ID*_SINK are disabled 1 VD*_SRC and ID*_SINK are enabled
1 VDATDETENB0	Battery Charging Attach / Connect Detection Enable This signal is used to enable attach/connect detection per the USB Battery Charging Specification revision 1.2. Results are reported by using the single-ended receiver status in USBNC_USB_OTGx_PHY_STATUS[1:0]. **Note:** During normal USB operation of the USB OTG PHY, set this signal to 1'b0. 0 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is disabled 1 IDP_SRC current source compliant to VLGC_HI connected to USB_OTG*_DP pin is enabled
0 CHRGSEL	Battery Charging Source Select This signal is used to select the Battery Charging detection connections per the USB Battery Charging Specification revision 1.2. It determines which of USB_OTG*_DP / USB_OTG*_DN has the VD*_SRC voltage source and which has the ID*_SINK current sink. Results are reported in USBNC_USB_OTGx_PHY_STATUS[29]. **Note:** During normal USB operation of the USB OTG PHY, set this signal to 1'b0. 0 VDP_SRC is connected to USB_OTG*_DP and IDM_SINK is connected to USB_OTG*_DN. Used for Primary Detection. 1 VDM_SRC is connected to USB_OTG*_DN and IDP_SINK is connected to USB_OTG*_DP. Used for Secondary Detection.

11.3.5.5 USB OTG PHY Status Register (USBNC_*n*_PHY_STATUS)

The USB_OTGx_PHY_STATUS register allows visibility of selected outputs of the USB OTG PHY.

These signals are used for some VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accesory Charging Adaptor) functions.

Address: 30B1_0200h base + 23Ch offset + (65536d × i), where i=0d to 1d



USBNC_*n*_PHY_STATUS field descriptions

Field	Description
31 ADPSNS0	ADP Sense Indicator This signal is output from the USB OTG PHY ADP Sense comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the ADP sensing voltage. 0 The voltage on USB_OTG*_VBUS is below the ADP sensing voltage 1 The voltage on USB_OTG*_VBUS is above the ADP sensing voltage
30 ADPPRB0	ADP Probe Indicator This signal is output from the USB OTG PHY ADP Probe comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the ADP probing voltage. 0 The voltage on USB_OTG*_VBUS is below the ADP probing voltage 1 The voltage on USB_OTG*_VBUS is above the ADP probing voltage
29 CHRGDET	Battery Charger Detection Output This signal indicates whether the voltage level on USB_OTG*_DP or USB_OTG*_DN is greater than VDAT_REF as defined in the USB Battery Charger, Revision 1.2 Specification. The selection of which USB data pins have the VD*_SRC and the ID*_SINK sources is controlled by register bit USBNC_USB_OTGx_CFG2[0]. The CHRGDET register bit is only valid when USBNC_USB_OTGx_CFG2[2:1] is set to 2'b11. 0 VD* < VDAT_REF 1 VD* > VDAT_REF
28 RIDFLOAT0	ACA USB_OTG*_ID Pin Resistance Indicator For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is floating (has resistance > R_{ID_FLOAT}). 0 ACA OTG_ID pin resistance is ≤ R_{ID_A} (max) 1 ACA OTG_ID pin resistance is ≥ R_{ID_FLOAT} (min)
27 RIDGND0	ACA USB_OTG*_ID Pin Resistance Indicator For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is grounded (has resistance < R_{ID_GND}). 0 ACA OTG_ID pin resistance is ≥ R_{ID_C} (min) 1 ACA OTG_ID pin resistance is ≤ R_{ID_GND} (max)
26 RIDA0	ACA USB_OTG*_ID Pin Resistance Indicator For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R_{ID_A}) range. 0 ACA OTG_ID pin resistance is ≥ R_{ID_FLOAT} (min) and ≤ R_{ID_B} max 1 ACA OTG_ID pin resistance is ≥ R_{ID_A} (min) and ≤ R_{ID_A} max
25 RIDB0	ACA USB_OTG*_ID Pin Resistance Indicator For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R_{ID_B}) range. 0 ACA OTG_ID pin resistance is ≥ R_{ID_A} (min) and ≤ R_{ID_C} max 1 ACA OTG_ID pin resistance is ≥ R_{ID_B} (min) and ≤ R_{ID_B} max

Table continues on the next page...

USBNC_*n*_PHY_STATUS field descriptions (continued)

Field	Description
24 RIDC0	ACA USB_OTG*_ID Pin Resistance Indicator For USB Charger Detection, indicates whether the USB_OTG*_ID pin connected to an ACA is within the R_{ID_C}) range. 0 ACA OTG_ID pin resistance is ≥ R_{ID_B} (min) and ≤ R_{ID_GND} max 1 ACA OTG_ID pin resistance is ≥ R_{ID_C} (min) and ≤ R_{ID_C} max
23–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 HOST_ DISCONNECT	Peripheral Disconnect Indicator This signal indicates to the USB_OTGx controller that a peripheral has been disconnected from or connected to the USB cable. In high-speed host operation, HOST_DISCONNECT is updated only at the end of SOF packet transmission. In FS and LS host operations, HOST_DISCONNECT is updated according to UTMI+ Specification, Section 2.2.1.10. This output is valid only when the USB OTG PHY and associated USB controller are configured to Host mode by setting USBC_n_USBMODE[1:0] to 2'b11. 0 Peripheral is connected 1 No peripheral is connected
4 ID_DIG	Micro- or Mini- A/B Plug Indicator This signal is the output from the ID pin A/B detector, which determines whether the resistance from the USB_OTG*_ID pin to VSS is grounded (10 Ω maximum for a Micro- or Mini-A plug) or floating (1 MegΩ minimum for a Micro- or Mini- B plug). The USB OTG PHY internal ID pin A/B detector circuit is enabled or disabled depending on the states of register bits USBC_n_OTGSC[5] and USBNC_USB_OTGx_PHY_CFG2[4]. Selection of whether to use the USB OTG PHY ID pin A/B detector or a GPIO pin ID detector is determined by the state of the USBNC_n_CTRL2[DIG_ID_SEL] bit field. 0 The connnected plug is a Micro- or Mini-A plug 1 The connnected plug is a Micro- or Mini-B plug
3 VBUS_VLD	VBUS Valid Indicator from USB OTG PHY This signal is the output from the USB OTG PHY VBUS Valid comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The threshold is 4.75V but can be adjusted with OTGTUNE0 (USBNC_USB_PHY_CFG1[12:10]). The USB OTG PHY VBUS Valid comparator is enabled or disabled depending on the states of register bits USBNC_USB_OTGx_PHY_CFG2[10] and USBNC_USB_OTGx_PHY_CFG2[16]. 0 The voltage on USB_OTG*_VBUS is below the VBUS Valid threshold 1 The voltage on USB_OTG*_VBUS is above the VBUS Valid threshold
2 SESS_VLD	OTG Device Session Valid Indicator from USB OTG PHY This signal is the output from the USB OTG PHY Session Valid comparator and indicates whether the voltage on the USB_OTG*_VBUS pin is below the OTG Device Session Valid threshold. The Session Valid threshold is > 0.8V and < 2.0V on this USB PHY. 0 The voltage on USB_OTG*_VBUS is below the OTG Device Session Valid threshold 1 The voltage on USB_OTG*_VBUS is above the OTG Device Session Valid threshold

Table continues on the next page...

USBNC_*n*_PHY_STATUS field descriptions (continued)

Field	Description
LINE_STATE	Line State Indicator outputs from USB OTG PHY These signals reflect the state of the single-ended receivers as defined by the UTMI+ Specification. In Suspend or Sleep mode, this bus is a combinatatorial output (directly reflecting the current state of DN and DP, respectively. During normal high-speed packet transfers, the line indicates a high-speed J state. 00 SE0 (DP low, DN low) 01 J state for high-speed and full-speed USB traffic; K state for low-speed USB traffic (DP high, DN low) 10 K state for high-speed and full-speed USB traffic; J state for low-speed USB traffic (DP low, DN high) 11 SE1 (DP high, DN high)

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 REFCLKSEL	Reference clock select. Leave this field set to 2'b10. Operation with other settings is undefined.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–16 REFCLKDIV	Reference clock frequency select. This bus selects the HSIC PHY reference clock frequency. The value must remain static during normal operation. 0100100 12 MHz (Default) 0011100 15 MHz 0011010 16 MHz 0010101 19.2 MHz 0010100 20 MHz
15–12 TXSRTUNE	Driver slew rate adjustment for USB_H_DATA and USB_H_STROBE pins. 0000 -20% 0001 -10% 0011 Design default 0111 +10% 1111 +20%
11–10 TXRPDTUNE	Driver pull-down single-ended source impedance adjustment for USB_H_DATA and USB_H_STROBE pins when driving low. 00 +11% 01 +5% 10 Design default 11 -5%
9–8 TXRPUTUNE	Driver pull-up single-ended source impedance adjustment for USB_H_DATA and USB_H_STROBE pins when driving high. 00 +11% 01 +5% 10 Design default 11 -5%
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

USBNC_UH_HSICPHY_CFG1 field descriptions (continued)

Field	Description
6 TXBITSTUFFENH	High-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAINH[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
5 TXBITSTUFFEN	Low-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAIN[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
4 SLEEPM	Sleeep mode assertion. Reseting this signal laces the USB UH HSIC PHY in Sleep mode. Since the controller used for the HSB UH HSIC port does not support USB 2.0 Link Power Management (LPM) this bit field should remain at 1'b1. 0 Sleep mode 1 Normal operating mode
3 DMPULLDOWN	Bus keeper resistors enable. If both DPPULLDOWN and DMPULLDOWN are set to 1'b1, the HSIC PHY is configured to operate as a Host. Otherwise, the HSIC PHY is configured to operate as a Device. Since the controller for the USB UH HSIC port only operates as a USB Host, these signals should not be reset to 1'b0 . 0 Disable bus keeper resistors 1 Enable bus keeper resistors
2 DPPULLDOWN	Bus keeper resistors enable. If both DPPULLDOWN and DMPULLDOWN are set to 1'b1, the HSIC PHY is configured to operate as a Host. Otherwise, the HSIC PHY is configured to operate as a Device. Since the controller for the USB UH HSIC port only operates as a USB Host, these signals should not be reset to 1'b0 . 0 Disable bus keeper resistors 1 Enable bus keeper resistors
1 LOOPBACKENB	Loopback test enable. This controller signal places the HSIC PHY in Loopback mode, which enables the receive and transmit logic concurrently. **Note:** Loopback mode is for test purposes only; it cannot be used for normal operation. 0 During data transmission, the receive logic is disabled 1 During data transmission, the receive logic is enabled
0 COMMONONN	This clock configuration setting should not be changed and must remain at 1'b1.

11.3.6 USB Core Memory Map/Register Definition

* Notes:
- x = Undefined at reset.

USBx_HWGENERAL field descriptions

Field	Description
31–12 -	This field is reserved.
11–10 SM	Serial interface mode capability SM bit reset value is '00b' 00 No Serial Engine, always use parallel signalling.
9–6 PHYM	Transceiver type PHYM bit reset value: '0000b' for OTG1/OTG2 controller core, and '1011b' for Host-only HSIC controller core.

Table continues on the next page...

USBx_HWGENERAL field descriptions (continued)

Field	Description
	0000 UTMI/UMTI+ 1011 Software programmable - reset to HSIC
5–4 PHYW	Data width of the transciever connected to the controller core. PHYW bit reset value is PHYW bit reset value is '11b'. 11 Reset to 16 bit wide data bus Software programmable
-	This field is reserved. Reserved

11.3.6.3 Host Hardware Parameters (USBx_HWHOST)

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												NPORT			HC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

USBx_HWHOST field descriptions

Field	Description
31–4 -	This field is reserved. Reserved
3–1 NPORT	The Nmber of downstream ports supported by the host controller is (NPORT+1). **NOTE:** When these bits value is '000', it indicates a single-port host controller.
0 HC	Host Capable. Indicating whether host operation mode is supported or not. 1 Supported 0 Not supported

11.3.6.4 Device Hardware Parameters (USBx_HWDEVICE)

NOTE

This register is only available in OTG core.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBx_HWTXBUF field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 TXCHANADD	TX FIFO Buffer size is: (2^TXCHANADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers. For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer
15–8 -	This field is reserved. Reserved
TXBURST	Default burst size for memory to TX buffer transfer. This is reset value of TXPBURST bits in USB core regsiter USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_BURSTSIZE) .

11.3.6.6 RX Buffer Hardware Parameters (USBx_HWRXBUF)

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

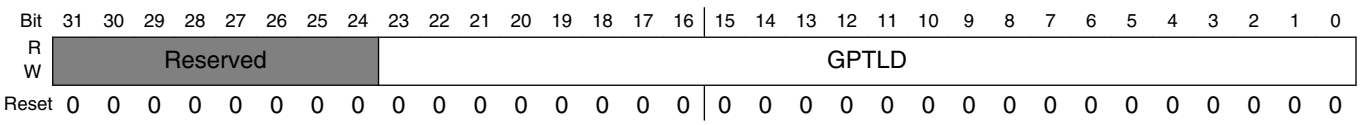
Field	Description
31–16 -	This field is reserved. Reserved
15–8 RXADD	Buffer total size for all receive endpoints is (2^RXADD). RX Buffer size is: (2^RXADD) * 4 Bytes. These bits are set to '08h', so buffer size is 256*4 Bytes. There is a single Receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in device mode.
RXBURST	Default burst size for memory to RX buffer transfer. This is reset value of RXPBURST bits in USB core regsiter USB_n_BURSTSIZE. Please see Programmable Burst Size (USB_BURSTSIZE) .

11.3.6.7 General Purpose Timer #0 Load (USBx_GPTIMER0LD)

This register controls load value of the count timer in register n_GPTIMER0CTRL. Please see General Purpose Timer #0 Controller (USB_GPTIMER0CTRL) .

Address: Base address + 80h offset



USBx_GPTIMER0LD field descriptions

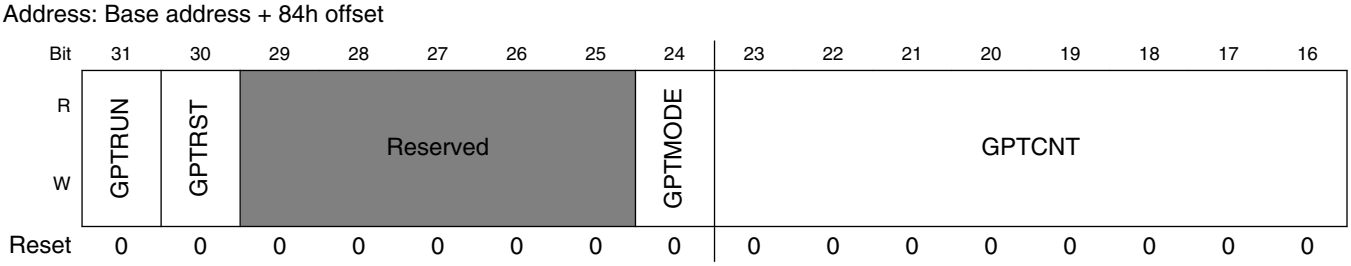
Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

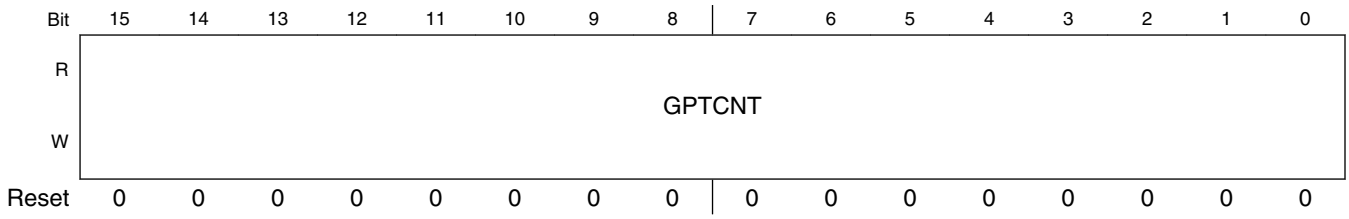
11.3.6.8 General Purpose Timer #0 Controller (USBx_GPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See USB Status Register (USB_USBSTS)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See Interrupt Enable Register (USB_USBINTR) .)

Address: Base address + 84h offset





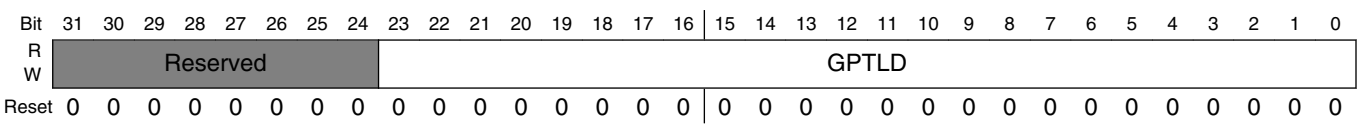
USBx_GPTIMER0CTRL field descriptions

Field	Description
31 GPTRUN	General Purpose Timer Run GPTCNT bits are not effected when setting or clearing this bit. 0 Stop counting 1 Run
30 GPTRST	General Purpose Timer Reset 0 No action 1 Load counter value from GPTLD bits in n_GPTIMER0LD
29–25 -	This field is reserved. Reserved
24 GPTMODE	General Purpose Timer Mode In one shot mode, the timer will count down to zero, generate an interrupt, and stop until the counter is reset by software; In repeat mode, the timer will count down to zero, generate an interrupt and automatically reload the counter value from GPTLD bits to start again. 0 One Shot Mode 1 Repeat Mode
GPTCNT	General Purpose Timer Counter. This field is the count value of the countdown timer.

11.3.6.9 General Purpose Timer #1 Load (USBx_GPTIMER1LD)

This register controls load value of the count timer in register n_GPTIMER1CTRL. Please see General Purpose Timer #1 Controller (USB_GPTIMER1CTRL) .

Address: Base address + 88h offset



USBx_GPTIMER1LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration. Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. **NOTE:** Max value is 0xFFFFFF or 16.777215 seconds.

11.3.6.10 General Purpose Timer #1 Controller (USBx_GPTIMER1CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in USB_n_USBSTS register (See USB Status Register (USB_USBSTS)), interrupt enable bit is TIE1 bit in n_USBINTR register (See Interrupt Enable Register (USB_USBINTR)).

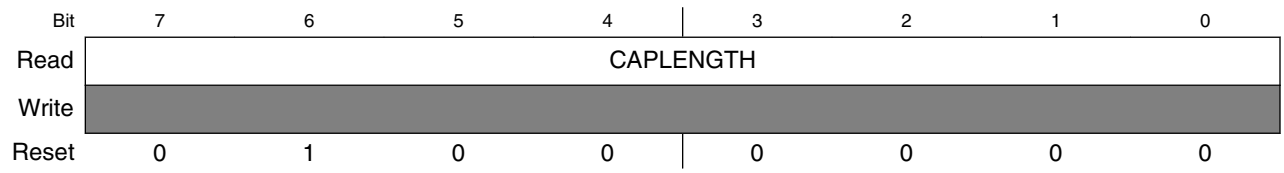
AHBBRST	AHB master interface Burst configuration These bits control AHB master transfer type sequence (or priority). **NOTE:** This register overrides n_BURSTSIZE register when its value is not zero. 000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

11.3.6.12 Capability Registers Length (USBx_CAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: Base address + 100h offset



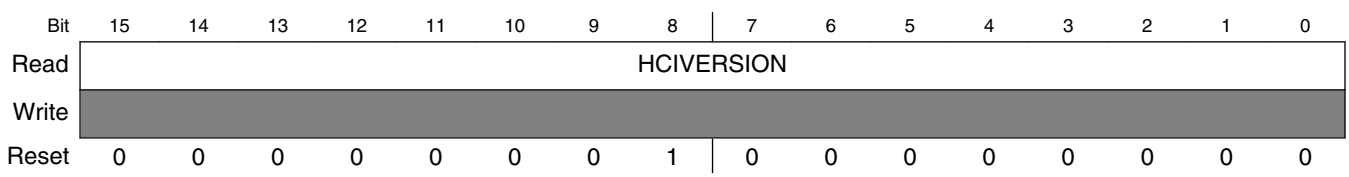
USBx_CAPLENGTH field descriptions

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

11.3.6.13 Host Controller Interface Version (USBx_HCIVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: Base address + 102h offset



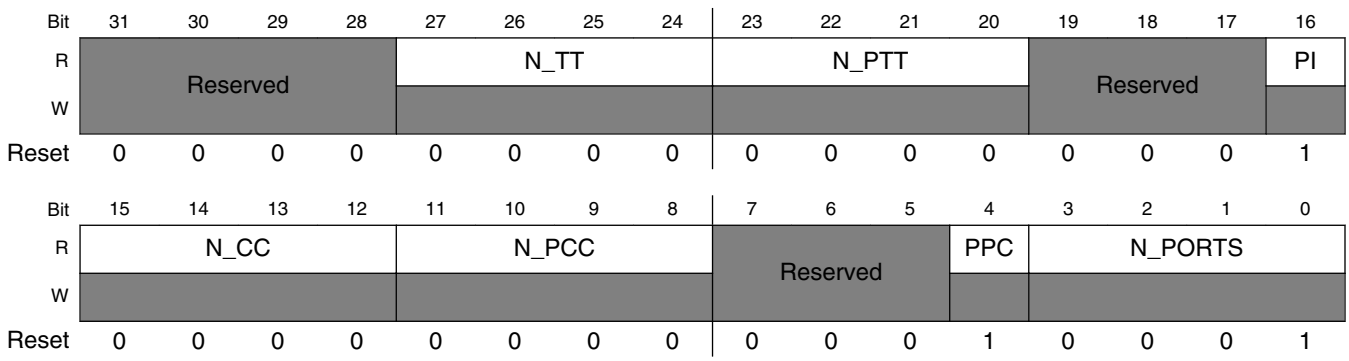
USBx_HCIVERSION field descriptions

Field	Description
HCIVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

11.3.6.14 Host Controller Structural Parameters (USBx_HCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Address: Base address + 104h offset



USBx_HCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.

Table continues on the next page...

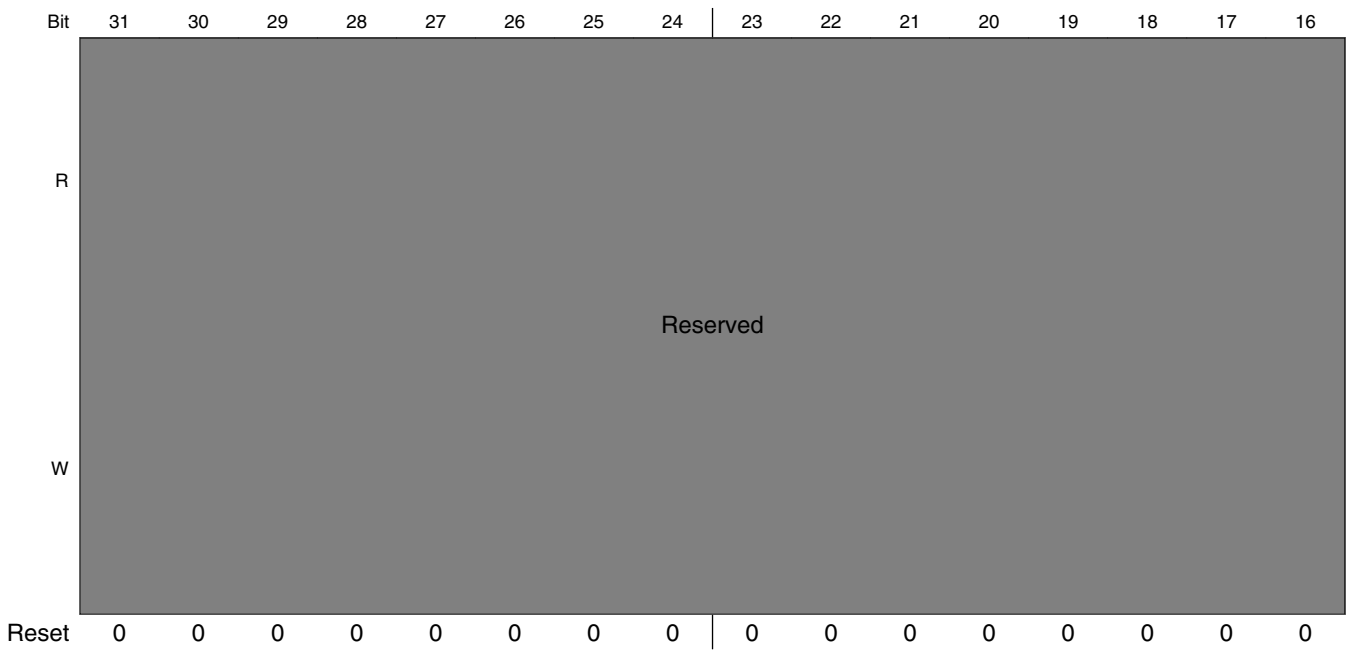
USBx_HCSPARAMS field descriptions (continued)

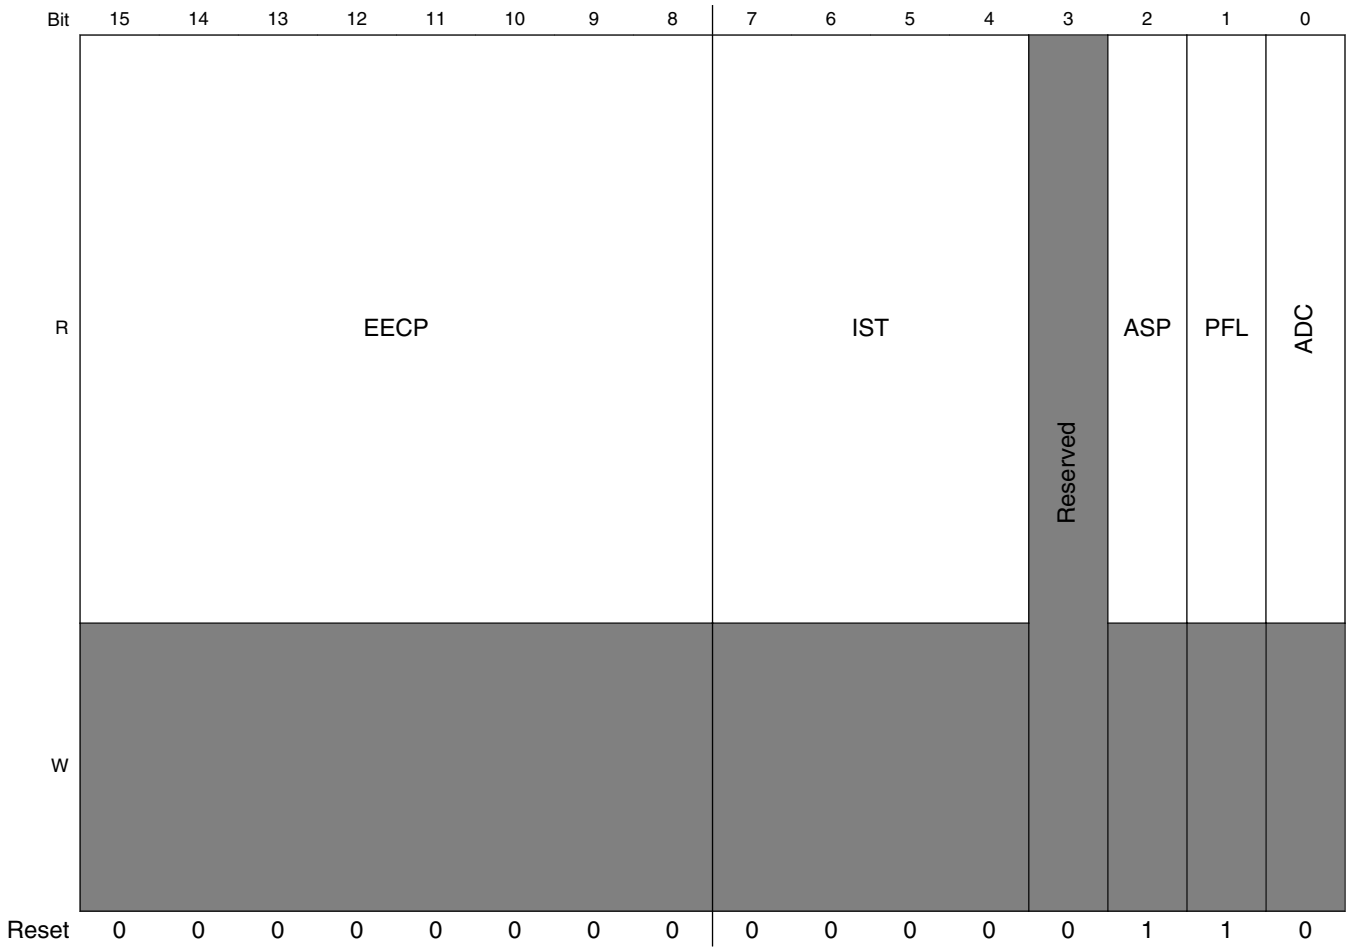
Field	Description
11–8 N_PCC	Number of Ports per Companion Controller This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.
7–5 -	This field is reserved. Reserved
4 PPC	Port Power Control This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register
N_PORTS	Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.

11.3.6.15 Host Controller Capability Parameters (USBx_HCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: Base address + 108h offset





USBx_HCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. **NOTE:** These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

USBx_HCCPARAMS field descriptions (continued)

Field	Description
2 ASP	Asynchronous Schedule Park Capability If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the *Asynchronous Schedule Park Mode Enable* and *Asynchronous Schedule Park Mode Count* fields in the USBCMD register. **NOTE:** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.
1 PFL	Programmable Frame List Flag If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This bit is set '1b' in all controller core.
0 ADC	64-bit Addressing Capability This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.

11.3.6.16 Device Controller Interface Version (USBx_DCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: Base address + 120h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

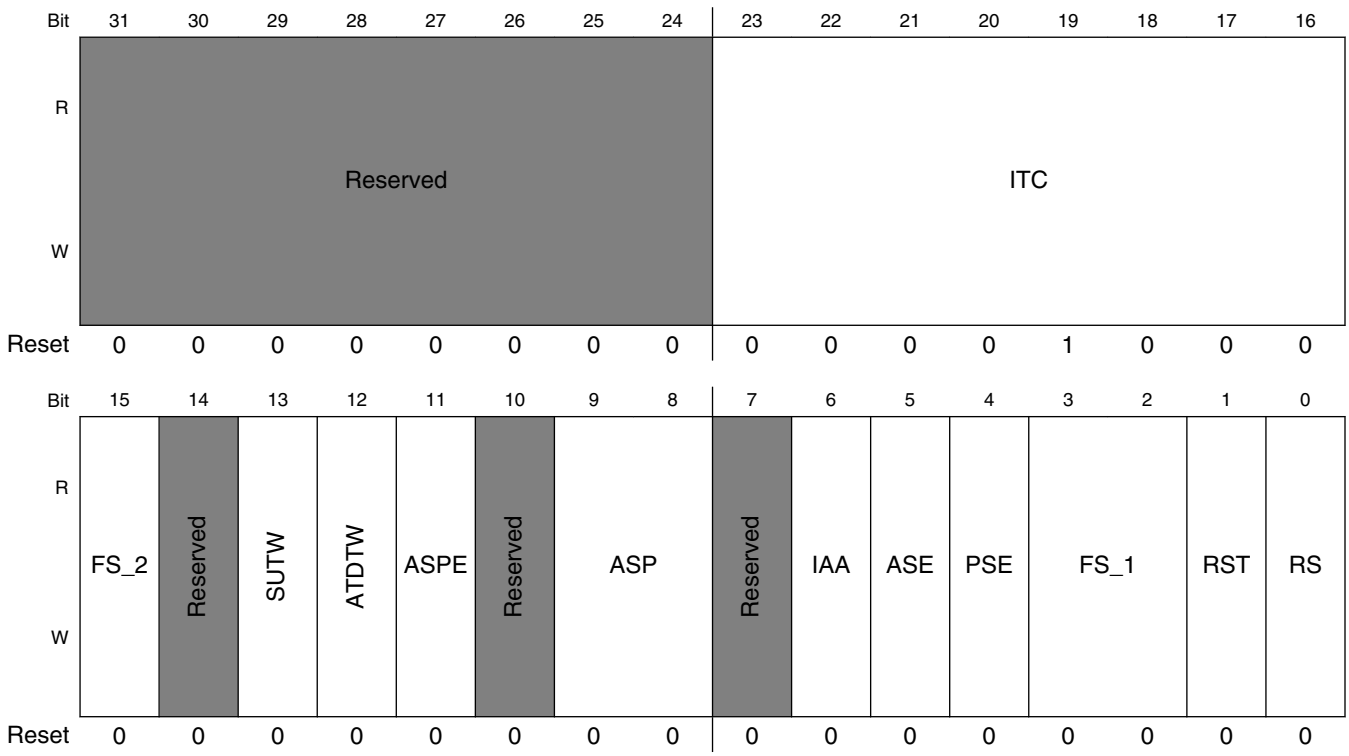
USBx_DCCPARAMS field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 HC	Host Capable When this bit is 1, this controller is capable of operating as an EHCI compatible USB 2.0 host controller.
7 DC	Device Capable When this bit is 1, this controller is capable of operating as a USB 2.0 device.
6–5 -	This field is reserved. Reserved
DEN	Device Endpoint Number This field indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field will be zero. Valid values are 0 - 15.

11.3.6.18 USB Command Register (USB*x*_USBCMD)

The Command Register indicates the command to be executed by the serial bus host/device controller. Writing to the register causes a command to be executed.

Address: Base address + 140h offset



USB*x*_USBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 ITC	Interrupt Threshold Control -Read/Write. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 0x00 Immediate (no threshold) 0x01 1 micro-frame 0x02 2 micro-frames 0x04 4 micro-frames 0x08 8 micro-frames 0x10 16 micro-frames

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	See also bits 3-2 Frame List Size - (Read/Write or Read Only). [host mode only] This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. **NOTE:** This field is made up from USBCMD bits 15, 3 and 2. Value Meaning 000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
14 -	This field is reserved. Reserved
13 SUTW	Setup TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB_USBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software. This bit would also be cleared by hardware when a hazard detected.
12 ATDTW	Add dTD TripWire - Read/Write. [device mode only] This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software. This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.
11 ASPE	Asynchronous Schedule Park Mode Enable - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. **NOTE:** ASPE bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.
10 -	This field is reserved. Reserved
9–8 ASP	Asynchronous Schedule Park Mode Count - Read/Write. If the *Asynchronous Park Capability* bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when *Park Mode Enable* is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3–2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode:

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

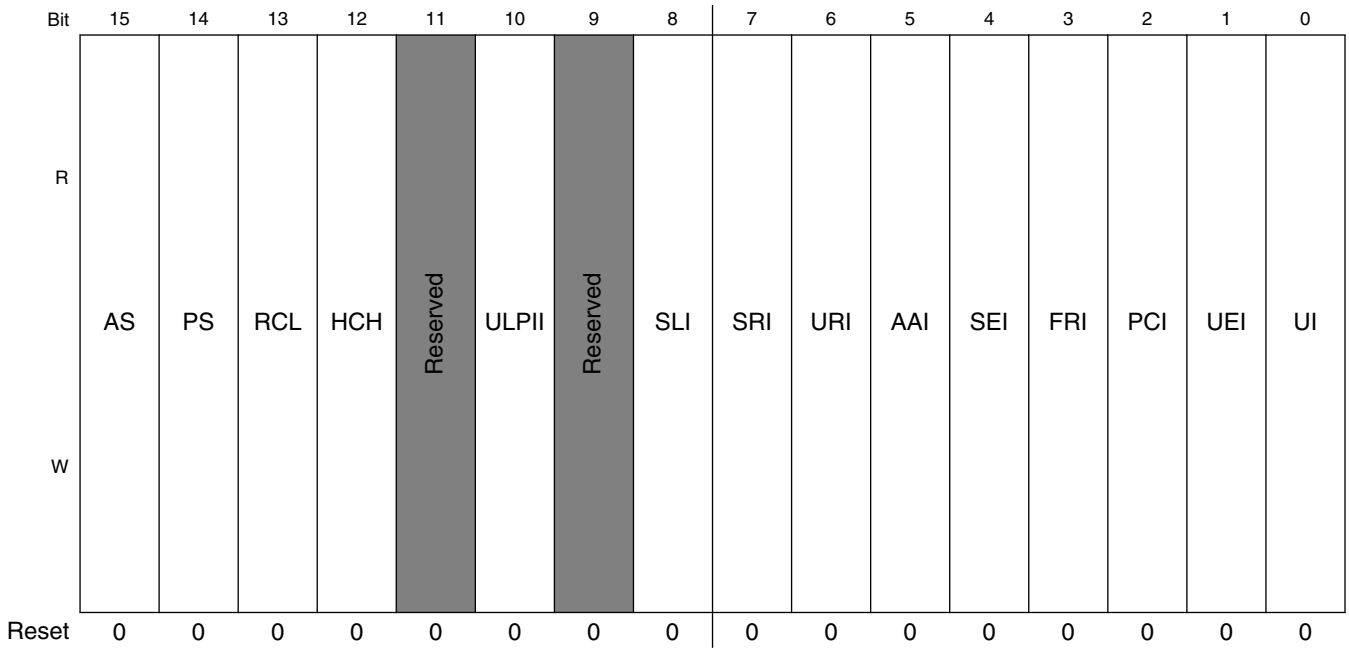
Field	Description
	When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop. Host operation mode: When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one). Device operation mode: Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.

11.3.6.19 USB Status Register (USB*x*_USBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: Base address + 144h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved						TI1	TI0	Reserved							NAKI
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



USBx_USBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

USBx_USBSTS field descriptions (continued)

Field	Description
	This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
13 RCL	Reclamation - Read Only. This is a read-only status bit used to detect an empty asynchronous schedule. Only used in the host operation mode.
12 HCH	HCHalted - Read Only. This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error). Only used in the host operation mode. Default value is '0b' for OTG core, and '1b' for Host1/Host2/Host3 core. This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register. **NOTE:** HCH bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.
11 -	This field is reserved. Reserved
10 ULPII	ULPI Interrupt - R/WC. This bit will be set '1b' by hardware when there is an event completion in ULPI viewport. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLI	DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.
7 SRI	SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.
6 URI	USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.

Table continues on the next page...

USBx_USBSTS field descriptions (continued)

Field	Description
5 AAI	Interrupt on Async Advance - R/WC. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source. Only used in host operation mode.
4 SEI	System Error- R/WC. This bit is will be set to '1b' when an Error response is seen to a read on the system interface.
3 FRI	Frame List Rollover - R/WC. The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles. Only used in host operation mode.
2 PCI	Port Change Detect - R/WC. The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/ Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.
1 UEI	USB Error Interrupt (USBERRINT) - R/WC. When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. The device controller detects resume signaling only.
0 UI	USB Interrupt (USBINT) - R/WC. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

11.3.6.20 Interrupt Enable Register (USBx_USBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Address: Base address + 148h offset

Table continues on the next page...

USBx_USBINTR field descriptions (continued)

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLII bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

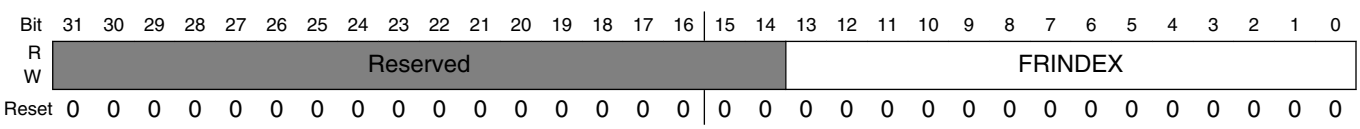
11.3.6.21 USB Frame Index (USBx_FRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: Base address + 14Ch offset



USBx_FRINDEX field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
FRINDEX	Frame Index. The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe. 000 (1024) 12 001 (512) 11

Table continues on the next page...

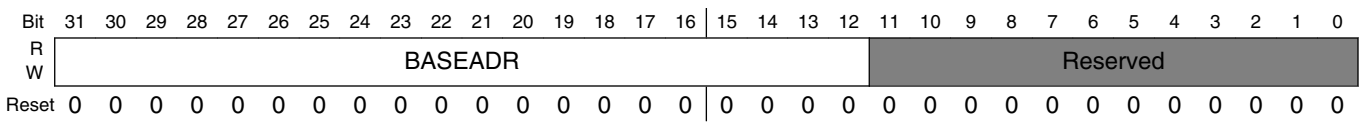
11.3.6.22 Frame List Base Address (USBx_PERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: Base address + 154h offset



USBx_PERIODICLISTBASE field descriptions

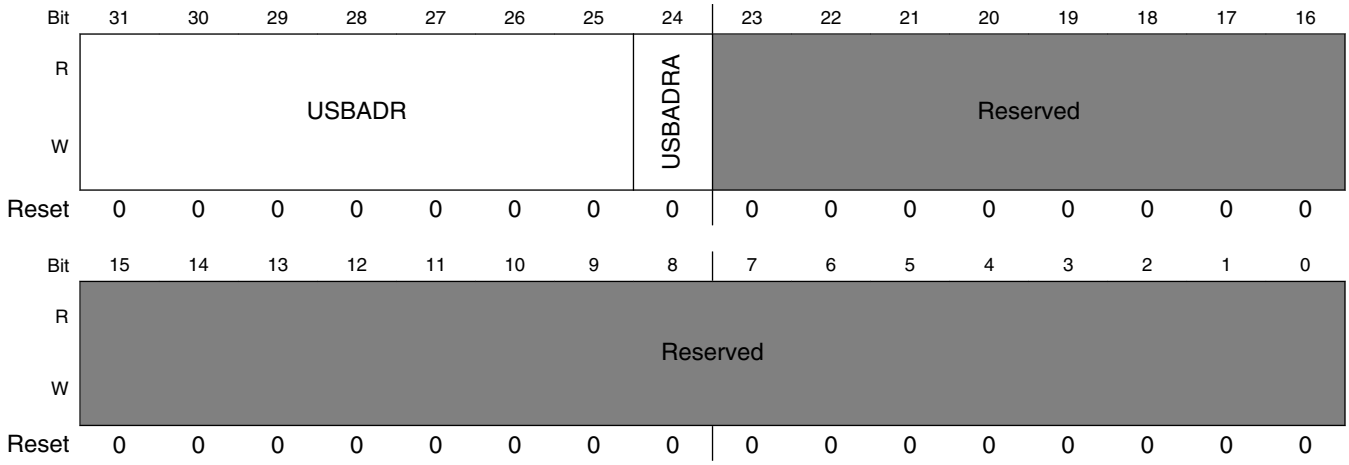
Field	Description
31–12 BASEADR	Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.
-	This field is reserved. Reserved

11.3.6.23 Device Address (USBx_DEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.

Address: Base address + 154h offset



USBx_DEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). **NOTE:** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

11.3.6.24 Next Asynch. Address (USBx_ASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: Base address + 158h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

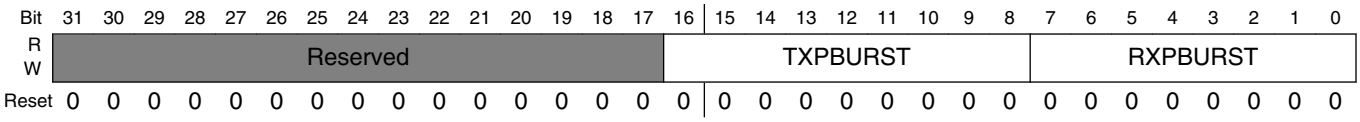
11.3.6.26 Programmable Burst Size (USBx_BURSTSIZE)

This register is used to control the burst size used during data movement on the AHB master interface. This register is ignored if AHBBRST bits in SBUSCFG register is non-zero value.

Address: Base address + 160h offset



USBx_BURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

11.3.6.27 TX FIFO Fill Tuning (USBx_TXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

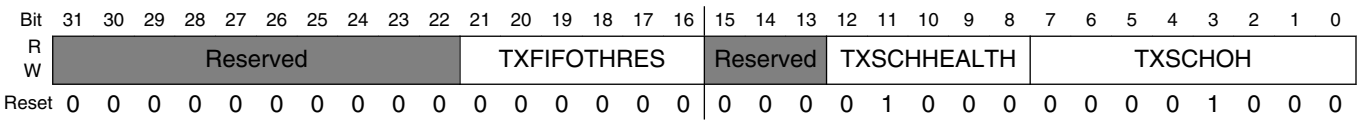
Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: Base address + 164h offset



USBx_TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set. Default value is '00h' for OTG controller core, and '02h' for Host-only controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.

11.3.6.28 Endpoint NAK (USBx_ENDPTNAK)

0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

11.3.6.31 Port Status & Control (USBx_PORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see Host Controller Structural Parameters (USB_HCSPARAMS)). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

For OTG core, it is Read-Only. Reset value is 000b. **NOTE:** All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see Features . The behaviour is unknown when unsupported interface mode is selected.
29 STS	Serial Transceiver Select - Read Only Serial Transceiver Select 1 Serial Interface Engine is selected 0 Parallel Interface signals is selected Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals. When this bit is set '1b', serial interface engine will be used instead of parallel interface signals. This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface. The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value.
28 PTW	Parallel Transceiver Width This bit has no effect if serial interface engine is used. For OTG1/OTG2/Host1 core, it is Read-Only. Reset value is '1b'. 0 Select the 8-bit UTMI interface [60MHz] 1 Select the 16-bit UTMI interface [30MHz]
27–26 PSPD	Port Speed - Read Only. This register field indicates the speed at which the port is operating. 00 Full Speed 01 Low Speed 10 High Speed 11 Undefined
25 PTS_2	See description at bits 31-30
24 PFSC	Port Force Full Speed Connect - Read/Write. Default = 0b. When this bit is set to '1b', the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed. 1 Forced to full speed 0 Normal operation

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
23 PHCD	PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b. When this bit is set to '1b', the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock. **NOTE:** The PHY clock cannot be disabled if it is being used as the system clock. In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. 1 Disable PHY clock 0 Enable PHY clock
22 WKOC	Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero or in device mode.
20 WKCN	Wake on Connect Enable (WKCNNT_E) - Read/Write. Default=0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero or in device mode.
19–16 PTC	Port Test Control - Read/Write. Default = 0000b. Refer to Port Test Mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** *Low speed operations are not supported as a peripheral device.* Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000 TEST_MODE_DISABLE 0001 J_STATE 0010 K_STATE 0011 SE0 (host) / NAK (device) 0100 Packet 0101 FORCE_ENABLE_HS 0110 FORCE_ENABLE_FS 0111 FORCE_ENABLE_LS 1000-1111 Reserved

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
15–14 PIC	Port Indicator Control - Read/Write. Default = Ob. Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero. Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used. This field is zero if *Port Power* is zero. Bit Value Meaning 00 Port indicators are off 01 Amber 10 Green 11 Undefined
13 PO	Port Owner-Read/Write. Default = 0. This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.
12 PP	Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1b *Read Only - Host controller does not have port power control switches. Each port is hard-wired to power.* 1 1b/0b - *Read/Write. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.* When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).
11–10 LS	Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 SE0 10 J-state

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. **NOTE:** HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. *This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.* In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the *Force Port Resume* bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, *Port enabled* bit is a zero) the results are undefined. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the *Port Change Detect* bit in the USBSTS register is also set to one. *This bit*

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
	will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit wil be cleared because a K-to-J transition detected, the *Port Change Detect* bit in the USBSTS register is also set to one.
5 OCC	Over-current Change-R/WC. Default=0. This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.
4 OCA	Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.
3 PEC	Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero. In Device mode: The device port is always enabled, so this bit is always '0b'.
2 PE	Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always '1b'.

Table continues on the next page...

USBx_PORTSC1 field descriptions (continued)

Field	Description
1 CSC	Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: This bit is undefined in device controller mode.
0 CCS	Current Connect Status-Read Only. In Host Mode: 1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the *Connect Status Change* bit (Bit 1) to be set. This field is zero if *Port Power(*Port Status & Control (USB_PORTSC1)*)* is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.

11.3.6.32 On-The-Go Status & control (USBx_OTGSC)

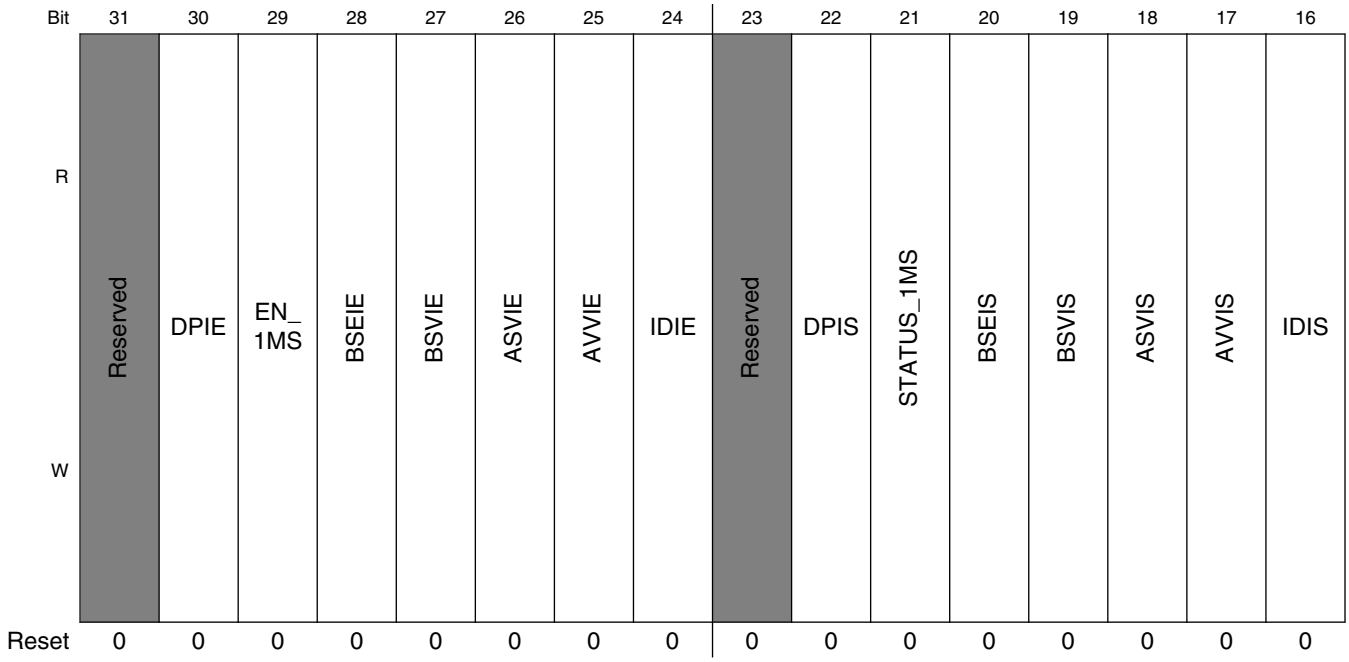
This register is availabe only in OTG controller core. It has four sections:

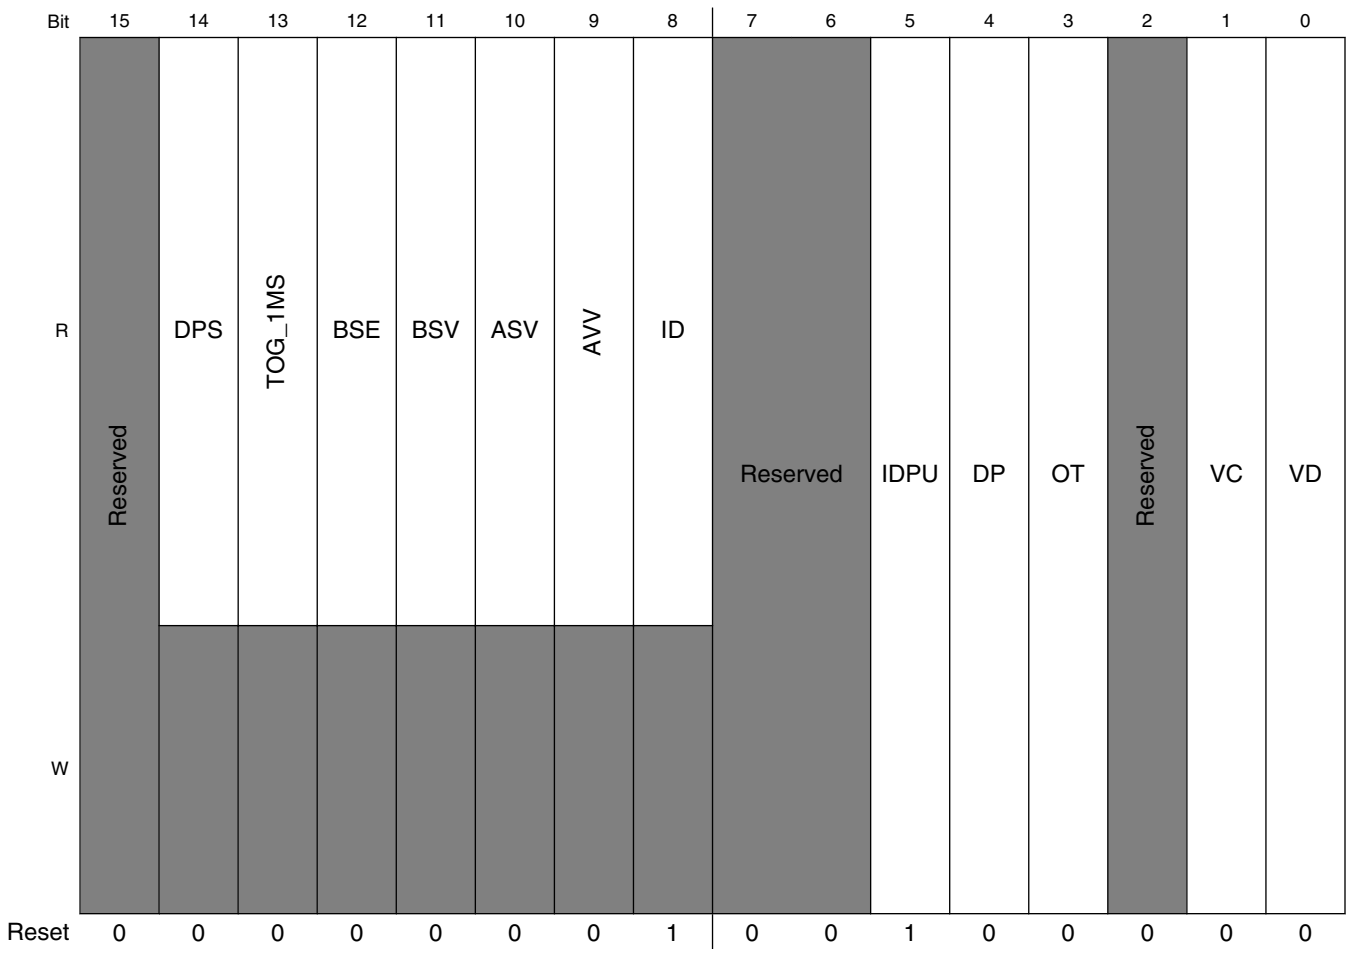
- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also USB Device Mode (USB_USBMODE) register.

Address: Base address + 1A4h offset





USBx_OTGSC field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 EN_1MS	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

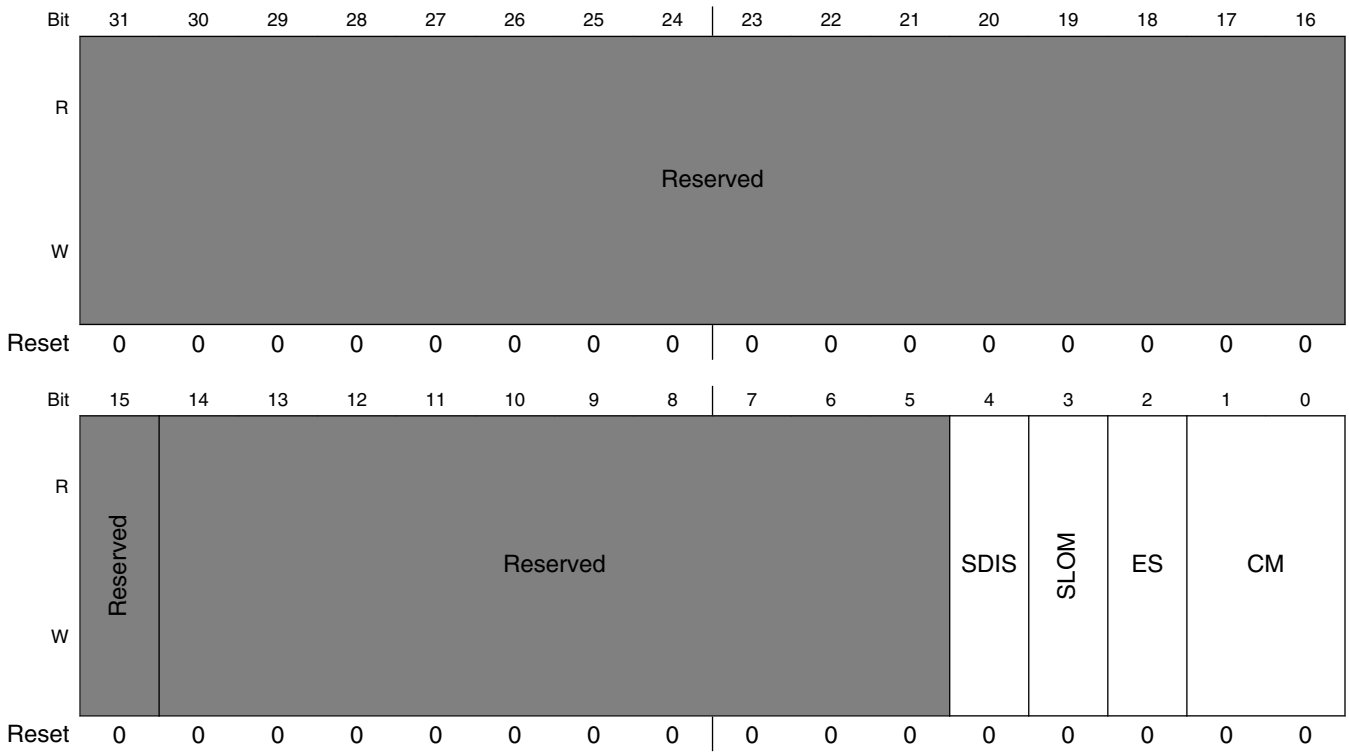
Table continues on the next page...

USBx_OTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7–6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

11.3.6.33 USB Device Mode (USBx_USBMODE)

Address: Base address + 1A8h offset



USBx_USBMODE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	Stream Disable Mode. (0 - Inactive [default]; 1 - Active) Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active. Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_TXFILLTUNING) and TXTTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.

Table continues on the next page...

USBx_USBMODE field descriptions (continued)

Field	Description
	NOTE: The use of this feature substantially limits of the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB_USBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the *RESET* bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. For Host-only controller core, reset value is '11b'. 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

11.3.6.34 Endpoint Setup Status (USBx_ENDPTSETUPSTAT)

Address: Base address + 1ACh offset

USBx_ENDPTSETUPSTAT field descriptions

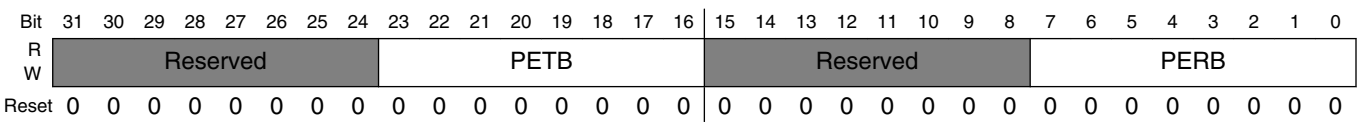
Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

11.3.6.35 Endpoint Prime (USBx_ENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: Base address + 1B0h offset



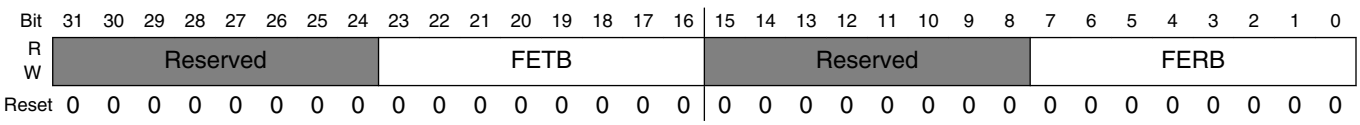
USBx_ENDPTPRIME field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 PETB	Prime Endpoint Transmit Buffer - R/WS. For each endpoint a corresponding bit is used to request that a buffer is prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
PERB	Prime Endpoint Receive Buffer - R/WS. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation for when a USB host initiates a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware clears this bit when the associated endpoint(s) is (are) successfully primed. **NOTE:** These bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated. PERB[N] - Endpoint #N, N is in 0..7

11.3.6.36 Endpoint Flush (USBx_ENDPTFLUSH)

This register is only used in device mode.

Address: Base address + 1B4h offset



USBx_ENDPTFLUSH field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
23–16 FETB	Flush Endpoint Transmit Buffer - R/WS. Writing one to a bit(s) in this register causes the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[N] - Endpoint #N, N is in 0..7
15–8 -	This field is reserved. Reserved
FERB	Flush Endpoint Receive Buffer - R/WS. Writing one to a bit(s) causes the assocUOGiated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[N] - Endpoint #N, N is in 0..7\

11.3.6.37 Endpoint Status (USBx_ENDPTSTAT)

This register is only used in device mode.

Address: Base address + 1B8h offset

It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.

Table continues on the next page...

USBx_ENDPTCTRL0 field descriptions (continued)

Field	Description
	NOTE: There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the dcd software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.

11.3.6.40 Endpoint Control 1 (USBx_ENDPTCTRL1)

This is endpoint control register for endpoint 1 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: Base address + 1C4h offset

USBx_ENDPTCTRL1 field descriptions (continued)

Field	Description
7 RXE	RX Endpoint Enable 0 Disabled [Default] 1 Enabled An Endpoint should be enabled only after it has been configured.
6 RXR	RX Data Toggle Reset (WS) Write 1 - Reset PID Sequence Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID's between the host and device.
5 RXI	RX Data Toggle Inhibit 0 Disabled [Default] 1 Enabled This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID.
4 -	This field is reserved. Reserved.
3–2 RXT	RX Endpoint Type - Read/Write 00 Control 01 Isochronous 10 Bulk 11 Reserved
1 RXD	RX Endpoint Data Sink - Read/Write - TBD 0 Dual Port Memory Buffer/DMA Engine [Default] Should always be written as zero.
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpointand this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints. **NOTE:** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

11.3.6.41 Endpoint Control 2 (USBx_ENDPTCTRL2)

This is endpoint control register for endpoint 2 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

11.4 Universal Serial Bus 2.0 Integrated PHY (USB-PHY)

11.4.1 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

The integrated PHY provides a standard UTM interface. The USB_*n*_DN and USB_*n*_DP pins connect directly to a USB connector.

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.

11.4.2 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in Figure 11-84.

11.4.2.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, transceiver termination selection, and clock generation logic for the clocks derived from the PHY's 480 MHz USB PLL.

11.4.2.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section's transmitter block.

11.4.2.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and multiphase 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).

11.4.2.4 Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module

, as shown in the figure below and described further in this section.

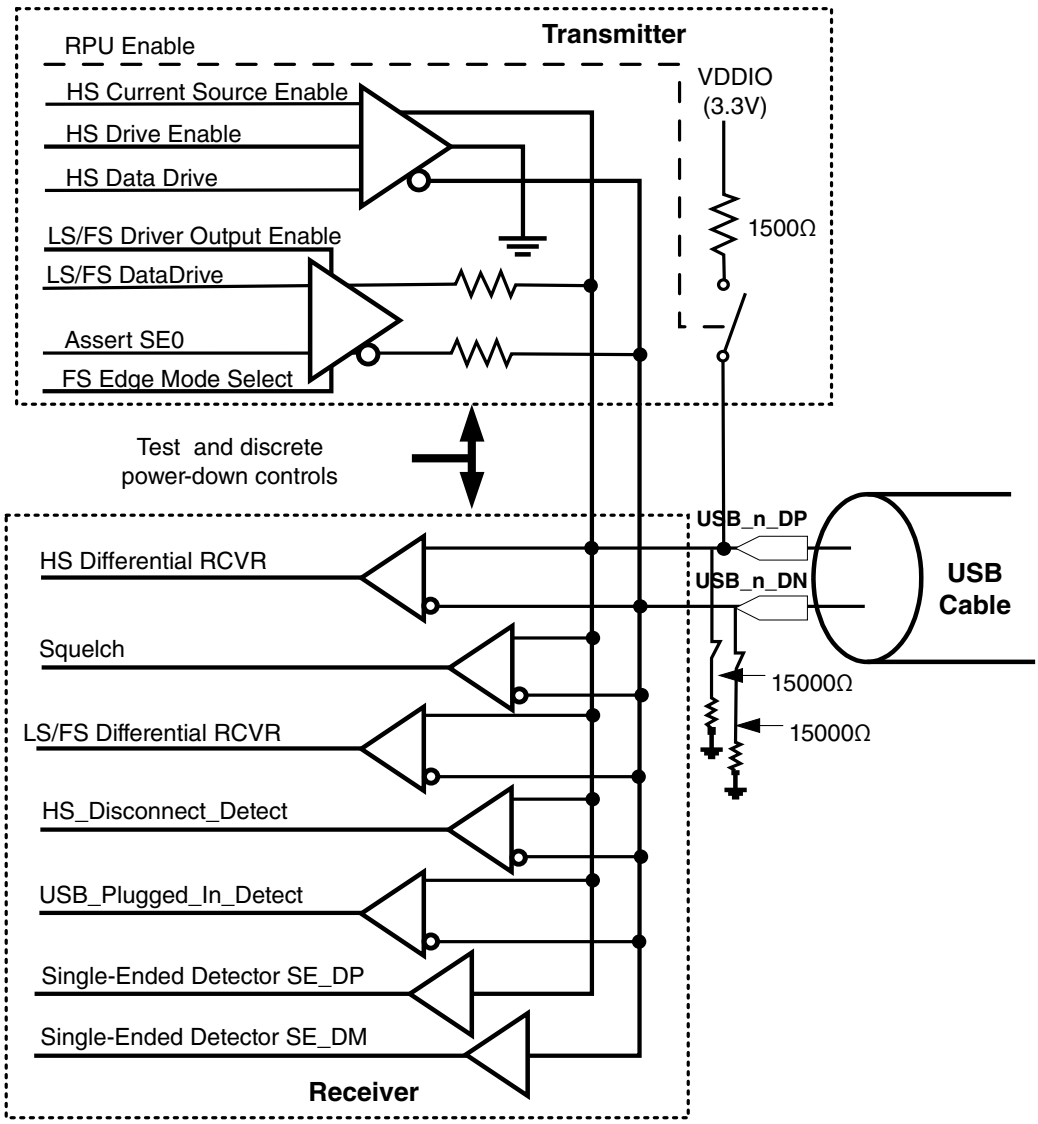

Figure 11-84. USB 2.0 PHY Analog Transceiver Block Diagram

11.4.2.4.1 HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.

Otherwise, its output is 0. Its purpose is to discriminate the ± 400-mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

11.4.2.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

11.4.2.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB_*n*_DP line is above the crossover point and the USB_*n*_DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

11.4.2.4.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

11.4.2.4.5 Single-Ended USB_DP Receiver

The single-ended USB_*n*_DP receiver output is high whenever the USB_*n*_DP input is above its nominal 1.8 V threshold.

11.4.2.4.6 Single-Ended USB_DN Receiver

The single-ended USB_*n*_DN receiver output is high whenever the USB_*n*_DN input is above its nominal 1.8 V threshold.

11.4.2.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 KΩ pullup resistor.

See Figure 11-84.

11.4.2.5.1 Switchable High-Speed 45Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in Figure 11-85. The HW_USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45Ω terminator on the USB_*n*_DP signal.

11.4.2.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

11.4.2.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or the USB_DN signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit. The Iref, Ibias, and V to I circuits are shared with the integrated battery charger.

11.4.2.5.4 Switchable 1.5KΩ USB_DP Pullup Resistor

This product contains a switchable 1.5 KΩ pullup resistor on the USB_*n*_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.

11.4.2.5.5 Switchable 15KΩ USB_DP Pulldown Resistor

This product contains a switchable 15 KΩ pulldown resistor on both USB_*n*_DP and USB_*n*_DN signals. This is used in host mode to indicate to the device controller that a host is present.

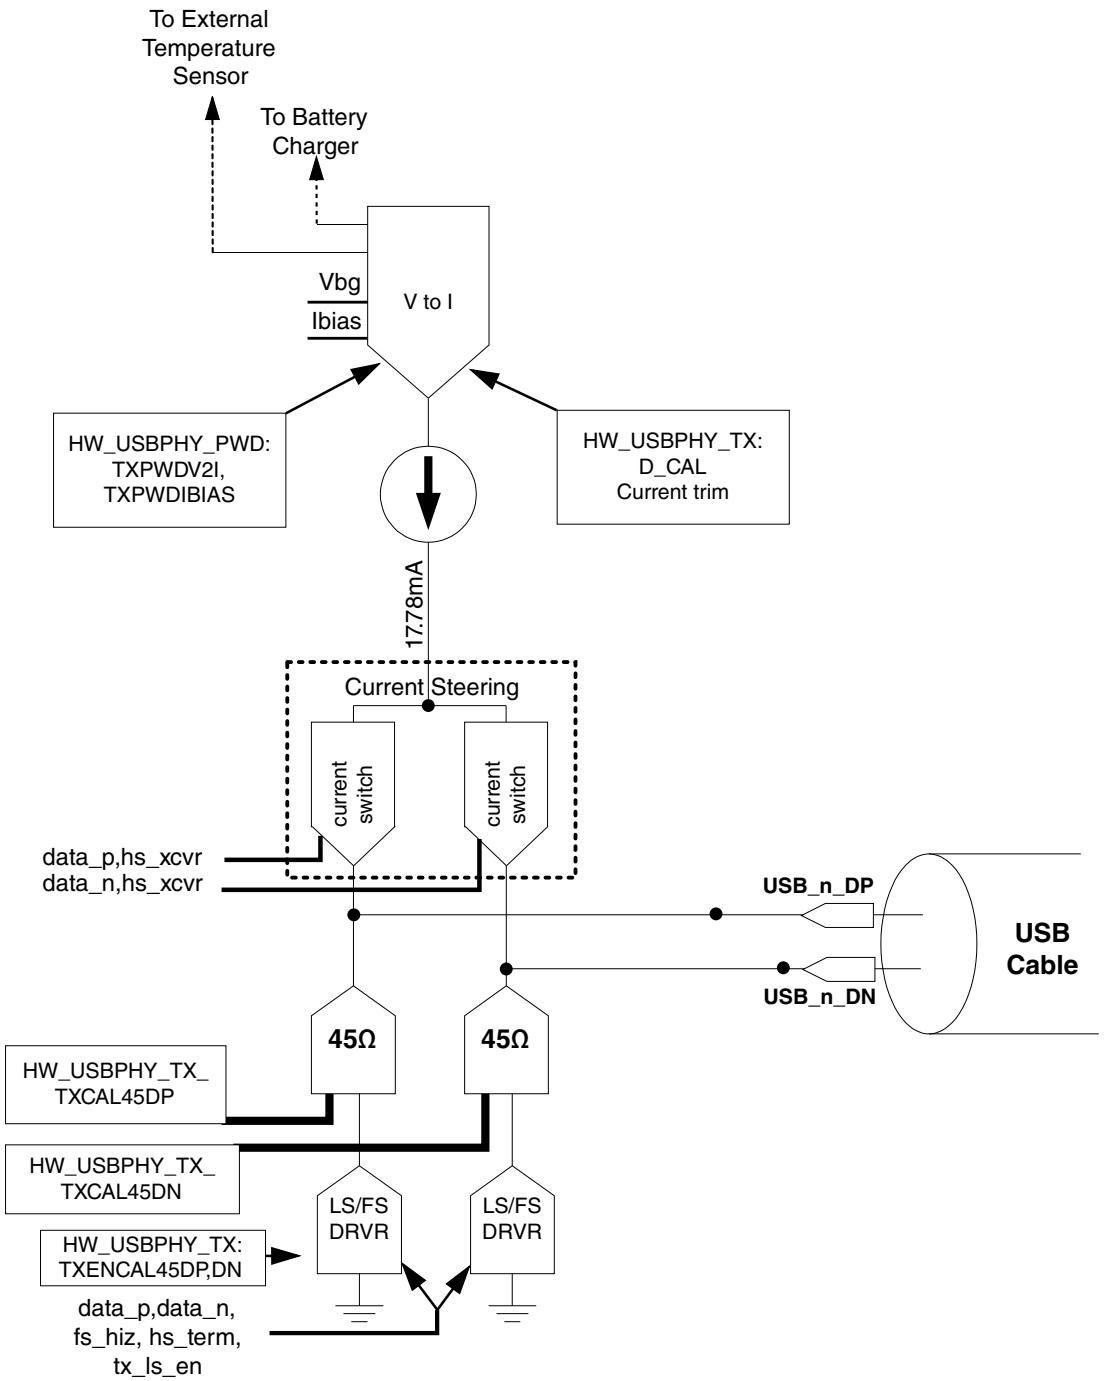

Figure 11-85. USB 2.0 PHY Transmitter Block Diagram

11.4.2.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

HW_USBPHY_TX_TXCAL45DP = 0x0
HW_USBPHY_TX_TXCAL45DN = 0x0
HW_USBPHY_TX_D_CAL = 0x7

Chapter 12
Timers

12.1 General Purpose Timer (GPT)

12.1.1 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming.

The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the DO_CMPOUT*n* pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.

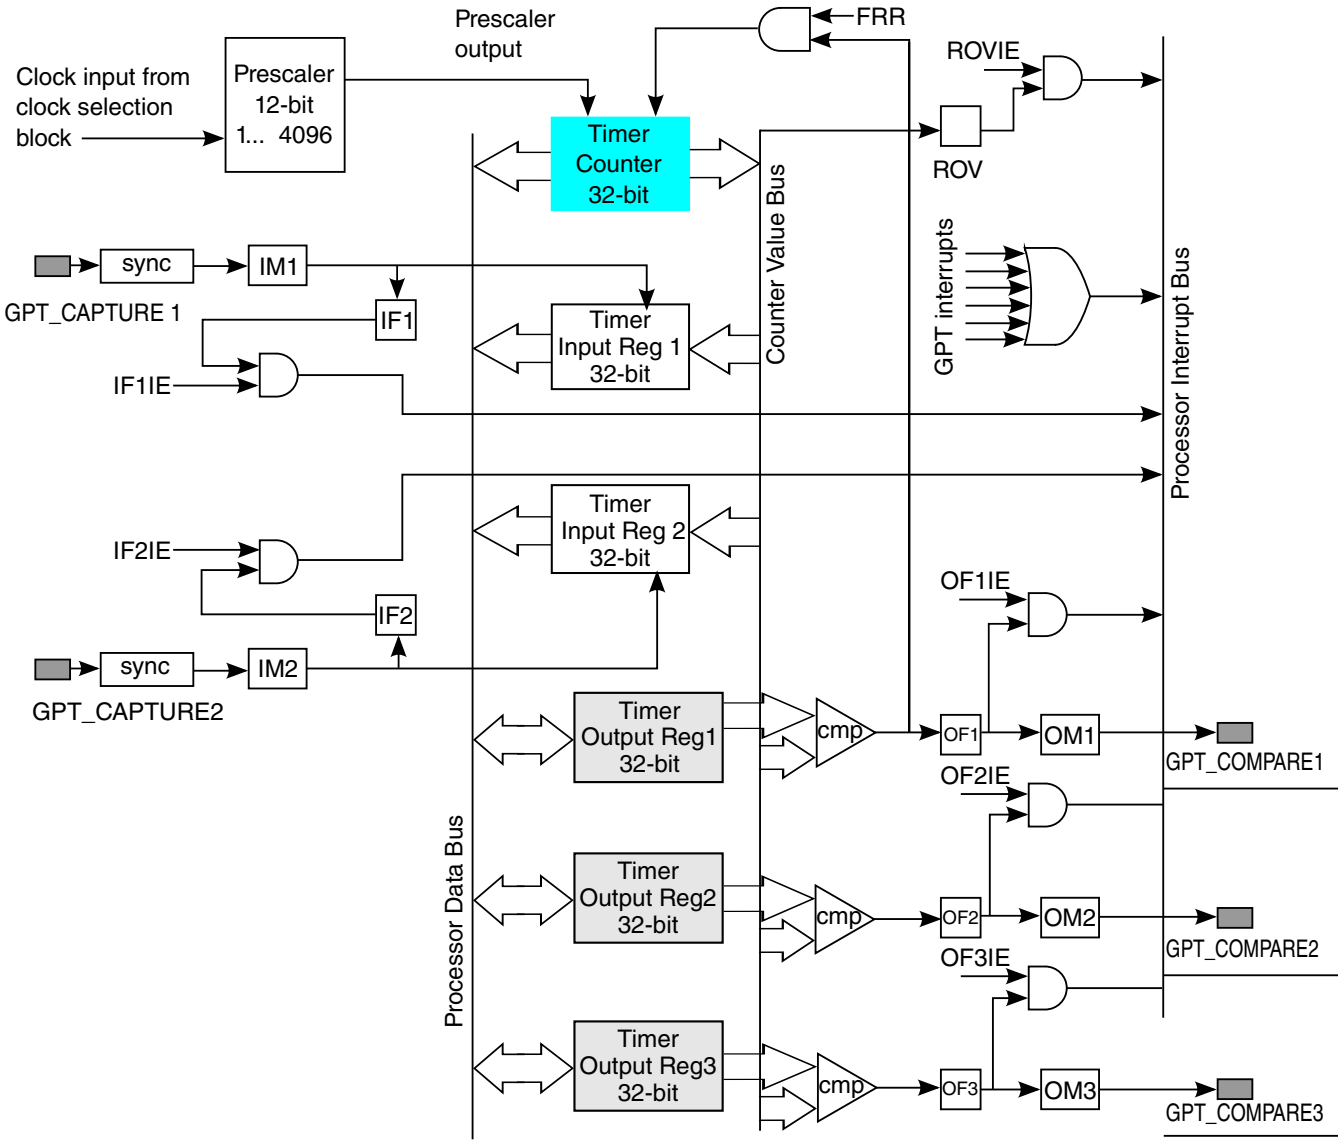

Figure 12-1. GPT Block Diagram

The following figure shows the GPT functional clocking scheme.

12.1.1.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

12.1.1.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- Operating Modes
  - Restart Mode
  - Free-Run Mode

12.1.2 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip,* except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip.

Table 12-1. GPT External Signals

Signal	Description	Pad	Mode	Direction
GPT1_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	LCD1_DATA03	ALT1	I
GPT1_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	LCD1_DATA04	ALT1	I
GPT1_CLK	Input pin for an external clock that the counter can be operated at.	LCD1_DATA02	ALT1	I
GPT1_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	LCD1_RESET	ALT1	O
GPT1_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	LCD1_DATA00	ALT1	O
GPT1_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	LCD1_DATA01	ALT1	O
GPT2_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	ENET1_CRS	ALT3	I
GPT2_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	ENET1_COL	ALT3	I
GPT2_CLK	Input pin for an external clock that the counter can be operated at.	ENET1_RX_CLK	ALT3	I
GPT2_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	ENET1_TX_CTL	ALT3	O

Table continues on the next page...

Table 12-1. GPT External Signals (continued)

Signal	Description	Pad	Mode	Direction
GPT2_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	ENET1_TXC	ALT3	O
GPT2_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	ENET1_TX_CLK	ALT3	O
GPT3_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	SD3_CMD	ALT4	I
GPT3_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	SD3_DATA0	ALT4	I
GPT3_CLK	Input pin for an external clock that the counter can be operated at.	SD3_CLK	ALT4	I
GPT3_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	SD3_DATA1	ALT4	O
GPT3_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	SD3_DATA2	ALT4	O
GPT3_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	SD3_DATA3	ALT4	O
GPT4_CAPTURE1	Input pin for a capture event for Input Capture Channel 1.	SD2_CMD	ALT3	I
GPT4_CAPTURE2	Input pin for a capture event for Input Capture Channel 2.	SD2_DATA0	ALT3	I
GPT4_CLK	Input pin for an external clock that the counter can be operated at.	SD2_CLK	ALT3	I
GPT4_COMPARE1	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	SD2_DATA1	ALT3	O
GPT4_COMPARE2	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	SD2_DATA2	ALT3	O
GPT4_COMPARE3	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	SD2_DATA3	ALT3	O

There are six signals (three input, three output) in the GPT module that *can be* connected to the chip pads.

12.1.2.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose.

The external clock input GPT_CLK is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

12.1.2.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*.

A positive or/and negative edge on these signals GPT_CAPTURE1 , GPT_CAPTURE2 can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

12.1.2.3 Output Compare Signals

The output compare signals: GPT_COMPARE1, GPT_COMPARE2, GPT_COMPARE3, indicate that output compare events have gone through a specified transition.

12.1.3 Signals

12.1.3.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose.

The external clock input GPT_CLK is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

12.1.3.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from *outside the device*.

A positive or/and negative edge on these signals GPT_CAPTURE1 , GPT_CAPTURE2 can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

12.1.3.3 Output Compare Signals

The output compare signals: GPT_COMPARE1, GPT_COMPARE2, GPT_COMPARE3, indicate that output compare events have gone through a specified transition.

12.1.4 Clocks

The clock that is input to the prescaler can be selected from 4 clock sources:

The following table describes the clock sources for GPT. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 12-2. GPT Clocks

Clock name	Clock Root	Description
ipg_clk	GPT_CLK_ROOT	Peripheral clock
ipg_clk_32k	CKIL_SYNC_CLK_ROOT	Low-frequency reference clock (32 kHz)
ipg_clk_highfreq	GPT_CLK_ROOT	High-frequency reference clock
ipg_clk_s	GPT_CLK_ROOT	Peripheral access clock

- High-Frequency Clock (ipg_clk_highfreq)

  Provided by the Clock Controller Module (CCM), the High Frequency Clock is intended to be ON in Normal Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock *in Normal Power mode*. The CCM is expected to provide this clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the High Frequency Clock in a Low Power mode.

- Low-Reference Clock (ipg_clk_32k)

  This 32 kHz Low Reference Clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode. The CCM

is expected to provide the Low Reference Clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the Low Reference Clock in a Low Power mode.

- Peripheral Clock (ipg_clk)

  If the Peripheral Clock or the External Clock is selected(CLKSRC=001 or 011) as Clock Source, then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock can be switched OFF.

- External Clock

  The External Clock comes from *outside the device* and can be selected to run the GPT counter. The External Clock is treated as *asynchronous to the Peripheral Clock,* and is synchronized to the Peripheral Clock, *inside* the module. Therefore, the External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock, for proper GPT operations. Note that in Low Power modes, *if* the Peripheral Clock is not available, then the External Clock *cannot be used* to run the counter.

- Crystal Oscillator Clock

  This 24 MHz Crystal Oscillator Clock (provided by the CCM) is intended to be used against frequency change of Peripheral Clock changes to provide a more accurate timer clock for operation system. The CCM is expected to provide the 24 MHz Crystal Oscillator Clock *without* synchronizing it to the System Bus Clock in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24 MHz Crystal Oscillator Clock is divided by a 24 MHz clock prescaler, to make sure the clock frequency less than half of System Bus Clock .

The clock input source is configured using the clock source field (CLKSRC, in the GPT_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT_CR control register) to 000. **The CLKSRC field value should be changed** *only after disabling the GPT* (by setting the EN bit in the GPT_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

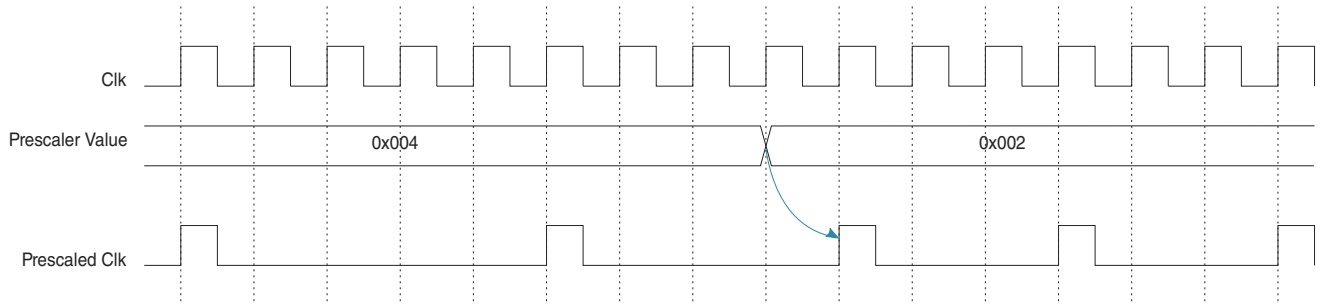

Figure 12-2. Prescaler Value Change Timing Diagram

12.1.5 Functional Description

This section provides a complete functional description of the GPT.

12.1.5.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

12.1.5.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

12.1.5.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

12.1.5.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running *up-counter,* which starts counting *after it is enabled by software* (EN=1).

The counter's clock source is the output of the prescaler labelled "Prescaler output" in Figure 12-1.

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xffffffff.
- The software reset (SWR bit in the GPT_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

12.1.5.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock

cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

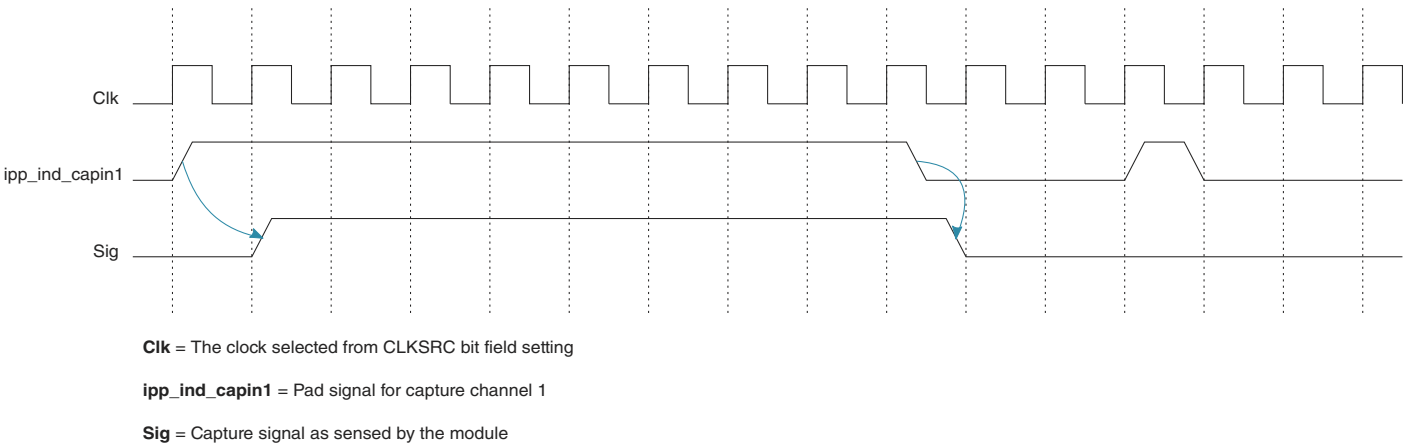

Figure 12-3. Input Capture Event Timing

12.1.5.2.2 Output Compare

The three Output Compare Channels *use the same counter* (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

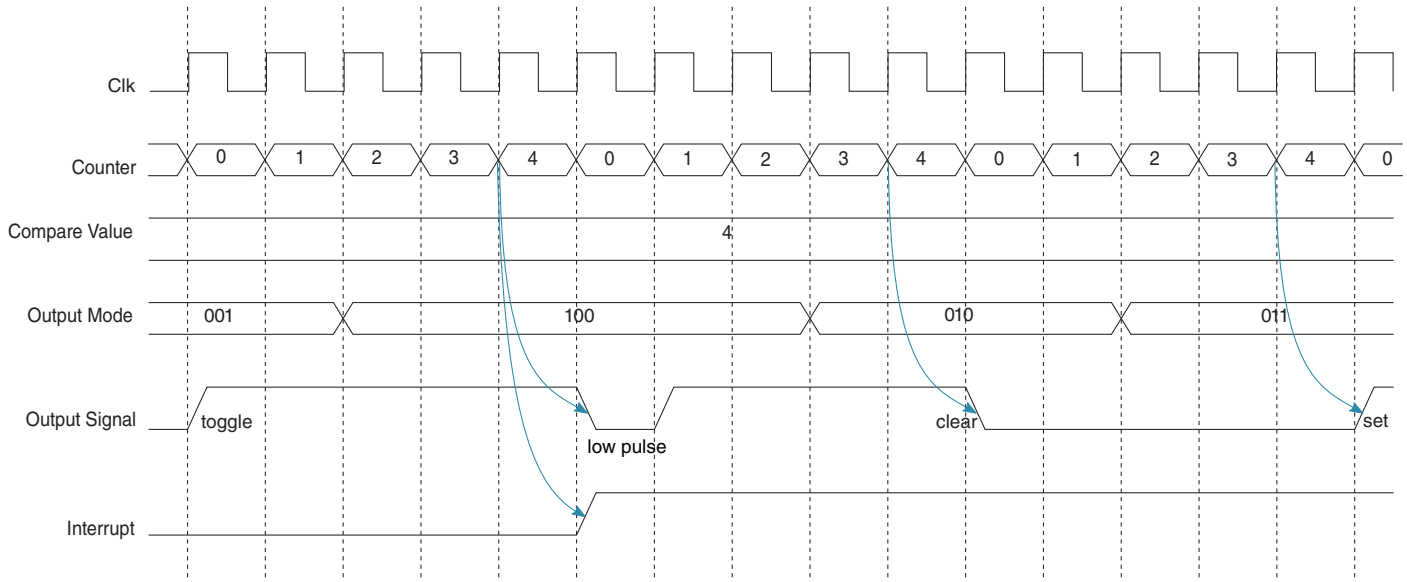

Figure 12-4. Output Compare and Interrupt Timing

12.1.5.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

  The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

  After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is *not affected by a pending capture interrupt*. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

12.1.5.2.4 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock, which can be used *only if* the Peripheral Clock is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

12.1.5.2.5 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

12.1.6 Initialization/ Application Information

12.1.6.1 Selecting the Clock Source

The CLKSRC field in the GPT_CR register selects the clock source. The CLKSRC field value should be changed only after disabling the GPT (EN=0).

The software sequence to be followed while changing clock source is:

1. Disable GPT by setting EN=0 in GPT_CR register.
2. Disable GPT interrupt register (GPT_IR).
3. Configure Output Mode to unconnected/ disconnected—Write zeros in OM3, OM2, and OM1 in GPT_CR
4. Disable Input Capture Modes—Write zeros in IM1 and IM2 in GPT_CR

5. Change clock source CLKSRC to the desired value in GPT_CR register.
6. Assert the SWR bit in GPT_CR register.
7. Clear GPT status register (GPT_SR) (i.e., w1c).
8. Set ENMOD=1 in GPT_CR register, to bring GPT counter to 0x00000000.
9. Enable GPT (EN=1) in GPT_CR register.
10. Enable GPT interrupt register (GPT_IR).

12.1.7 GPT Memory Map/Register Definition

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT_CR) and the GPT Output Compare Register1 (GPT_OCR1) results in *one cycle of wait state*, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT_ICR1, GPT_ICR2, GPT_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the *unimplemented* address space of GPT (*ips_addr* is greater than or equal to $BASE + $028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will *not* generate any error response (like a bus exception).

GPT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
302D_0000	GPT Control Register (GPT1_CR)	32	R/W	0000_0000h	12.1.7.1/ 3392

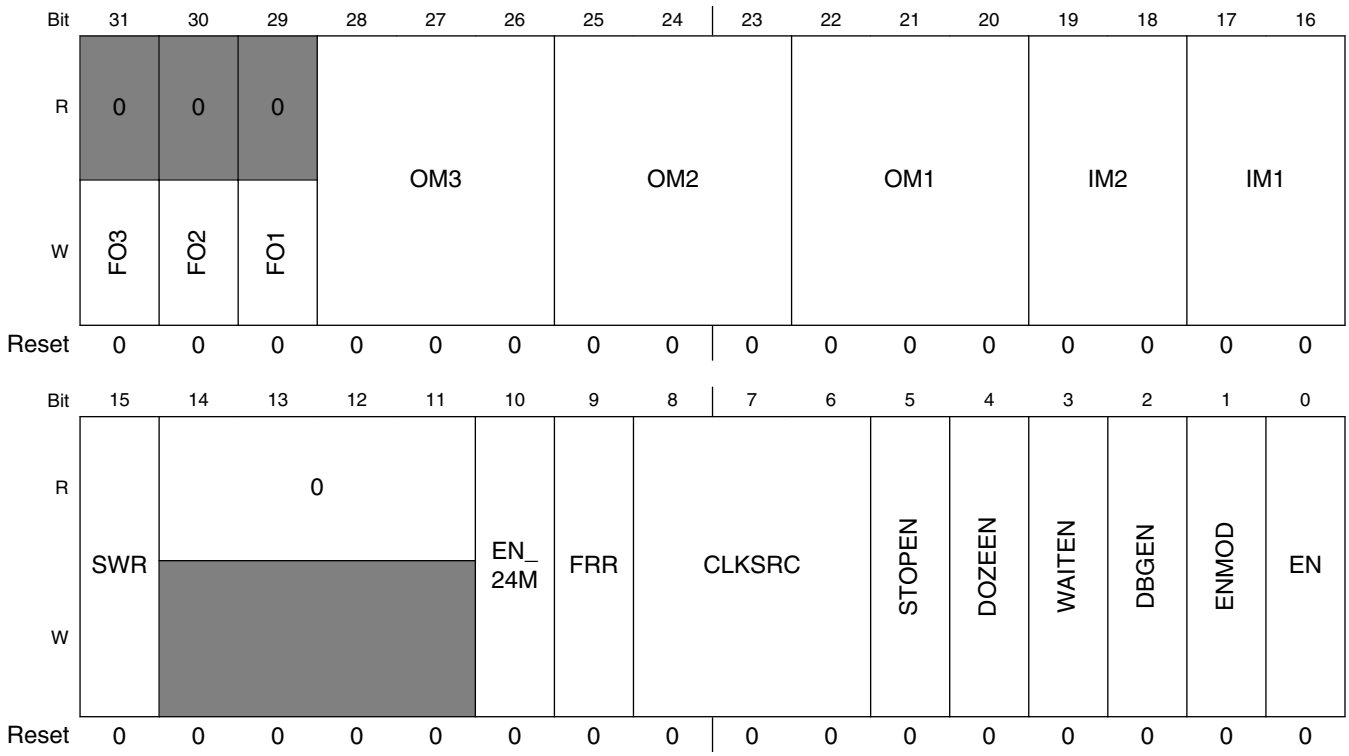
12.1.7.1 GPT Control Register (GPTx_CR)

The GPT Control Register (GPT_CR) is used to program and configure GPT operations. An IP Bus Write to the GPT Control Register occurs after one cycle of wait state, while an IP Bus Read occurs after 0 wait states.

Address: Base address + 0h offset



GPTx_CR field descriptions

Field	Description
31 FO3	FO3 Force Output Compare Channel 3 FO2 Force Output Compare Channel 2 FO1 Force Output Compare Channel 1 The FO*n* bit causes the pin action *programmed* for the timer Output Compare *n* pin (according to the OM*n* bits in this register). • The OF*n* flag (OF3, OF2, OF1) in the status register is **not affected**. • This bit is self-negating and always read as zero. 0 Writing a 0 has no effect. 1 Causes the programmed pin action on the timer Output Compare *n* pin; the OF*n* flag is not set.
30 FO2	See F03

Table continues on the next page...

GPTx_CR field descriptions (continued)

Field	Description
29 FO1	See F03
28–26 OM3	OM3 (bits 28-26) controls the Output Compare Channel 3 operating mode. OM2 (bits 25-23) controls the Output Compare Channel 2 operating mode. OM1 (bits 22-20) controls the Output Compare Channel 1 operating mode. The OM*n* bits specify the response that a compare event will generate on the output pin of Output Compare Channel *n*. • The toggle, clear, and set options cause a change on the output pin *only* if a compare event occurs. • When OM*n* is programmed as 1xx (active low pulse), the output pin is set to one immediately on the next input clock; a low pulse (that is an input clock in width) occurs when there is a compare event. Note that here, "input clock" refers to the clock selected by the CLKSRC bits of the GPT Control Register. 000 Output disconnected. No response on pin. 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate an active low pulse (that is one input clock wide) on the output pin.
25–23 OM2	See OM3
22–20 OM1	See OM3
19–18 IM2	IM2 (bits 19-18, Input Capture Channel 2 operating mode) IM1 (bits 17-16, Input Capture Channel 1 operating mode) The IM*n* bit field determines the transition on the input pin (for Input capture channel *n*), which will trigger a capture event. 00 capture disabled 01 capture on rising edge only 10 capture on falling edge only 11 capture on both edges
17–16 IM1	See IM2
15 SWR	Software reset. This is the software reset of the GPT module. It is a self-clearing bit. • The SWR bit is set when the module is in reset state. • The SWR bit is cleared when the reset procedure finishes. • Setting the SWR bit resets **all of the registers** to their default reset values, except for the CLKSRC, EN, ENMOD, STOPEN, WAITEN, and DBGEN bits in the GPT Control Register (this control register). 0 GPT is not in reset state 1 GPT is in reset state
14–11 Reserved	This read-only field is reserved and always has the value 0.
10 EN_24M	Enable 24 MHz clock input from crystal.

Table continues on the next page...

GPTx_CR field descriptions (continued)

Field	Description
	• A hardware reset resets the EN_24M bit. • A software reset *does not affect* the EN_24M bit. 0 24M clock disabled 1 24M clock enabled
9 FRR	Free-Run or Restart mode. The FFR bit determines the behavior of the GPT when a compare event in channel 1 occurs. • In Restart mode, after a compare event, the counter resets to 0x00000000 and resumes counting (after the occurrence of a compare event). • In Free-Run mode, after a compare event, the counter continues counting until 0xFFFFFFFF and then rolls over to 0. 0 Restart mode 1 Free-Run mode
8–6 CLKSRC	Clock Source select. The CLKSRC bits select which clock will go to the prescaler (and subsequently be used to run the GPT counter). • The CLKSRC bit field value should only be changed after disabling the GPT by clearing the EN bit in this register (GPT_CR). • A software reset does not affect the CLKSRC bit. 000 No clock 001 Peripheral Clock 010 High Frequency Reference Clock 011 External Clock (CLKIN) 100 Low Frequency Reference Clock 101 Crystal oscillator as Reference Clock others Reserved
5 STOPEN	GPT Stop Mode enable. The STOPEN read/write control bit enables GPT operation *during Stop mode*. • A hardware reset resets the STOPEN bit. • A software reset *does not affect* the STOPEN bit. 0 GPT is disabled in Stop mode. 1 GPT is enabled in Stop mode.
4 DOZEEN	GPT Doze Mode Enable. • A hardware reset resets the DOZEEN bit. • A software reset *does not affect* the DOZEEN bit. 0 GPT is disabled in doze mode. 1 GPT is enabled in doze mode.
3 WAITEN	GPT Wait Mode enable. The WAITEN read/write control bit enables GPT operation *during Wait mode*. • A hardware reset resets the WAITEN bit. • A software reset *does not affect* the WAITEN bit. 0 GPT is disabled in wait mode. 1 GPT is enabled in wait mode.

Table continues on the next page...

GPTx_CR field descriptions (continued)

Field	Description
2 DBGEN	GPT debug mode enable. The DBGEN read/write control bit enables GPT operation *during Debug mode*. • A hardware reset resets the DBGEN bit. • A software reset *does not affect* the DBGEN bit. 0 GPT is disabled in debug mode. 1 GPT is enabled in debug mode.
1 ENMOD	GPT Enable mode. When the GPT is disabled (EN=0), then both the Main Counter and Prescaler Counter *freeze their current count values*. The ENMOD bit determines the value of the GPT counter when Counter is enabled again (if the EN bit is set). • If the ENMOD bit is 1, then the Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1). • If the ENMOD bit is 0, then the Main Counter and Prescaler Counter restart counting *from their frozen values* after GPT is enabled (EN=1). • If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter *freeze at their current count values* when the GPT enters low power mode. • When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value. • Setting the SWR bit will clear the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits. • A hardware reset resets the ENMOD bit. • A software reset *does not affect* the ENMOD bit. 0 GPT counter will retain its value when it is disabled. 1 GPT counter value is reset to 0 when it is disabled.
0 EN	GPT Enable. The EN bit is the GPT module enable bit. **Before setting the EN bit**, we recommend that *all registers be properly programmed*. • A hardware reset resets the EN bit. • A software reset *does not affect* the EN bit. 0 GPT is disabled. 1 GPT is enabled.

12.1.7.2 GPT Prescaler Register (GPTx_PR)

The GPT Prescaler Register (GPT_PR) contains bits that determine the *divide value* of the clock that runs the counter.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	PRESCALER24M				PRESCALER											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPTx_PR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–12 PRESCALER24M	Prescaler bits. 24M crystal clock is divided by [PRESCALER24M + 1] before selected by the CLKSRC field. If 24M crystal clock is not selected, this feild takes no effect. 0x0 Divide by 1 0x1 Divide by 2 ... ... 0xF Divide by 16
PRESCALER	Prescaler bits. The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter. • A change in the value of the PRESCALER bits cause the Prescaler counter to reset and a new count period to start immediately. • See Figure 12-2 for the timing diagram. 0x000 Divide by 1 0x001 Divide by 2 ... ... 0xFFF Divide by 4096

12.1.7.3 GPT Status Register (GPTx_SR)

The GPT Status Register (GPT_SR) contains bits that indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The bits are cleared by writing a 1 to them.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

2 OF3IE	OF3IE Output Compare 3 Interrupt Enable OF2IE Output Compare 2 Interrupt Enable OF1IE Output Compare 1 Interrupt Enable The OF*n*IE bit controls the Output Compare Channel *n* interrupt. 0 Output Compare Channel *n* interrupt is disabled. 1 Output Compare Channel *n* interrupt is enabled.
1 OF2IE	See OF3IE
0 OF1IE	See OF3IE

12.1.7.5 GPT Output Compare Register 1 (GPTx_OCR1)

The GPT Compare Register 1 (GPT_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT_OCR1) occurs *after* one cycle of wait state; an IP Bus Read access occurs *immediately* (0 wait states).

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPTx_OCR2 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 2.

12.1.7.7 GPT Output Compare Register 3 (GPTx_OCR3)

The GPT Compare Register 3 (GPT_OCR3) holds the value that determines when a compare event will be generated on Output Compare Channel 3.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COMP																															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

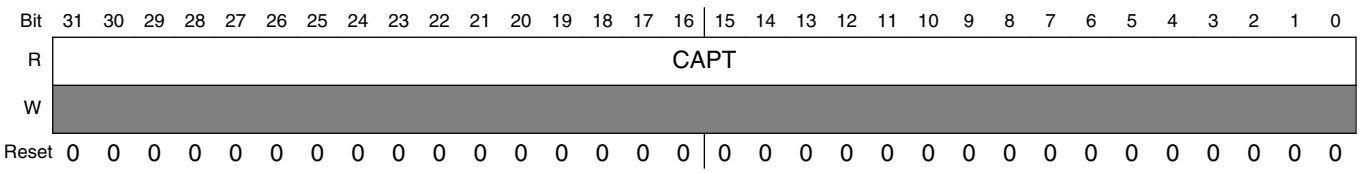
GPTx_OCR3 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 3.

12.1.7.8 GPT Input Capture Register 1 (GPTx_ICR1)

The GPT Input Capture Register 1 (GPT_ICR1) is a read-only register that holds the value *that was in the counter during the last capture event* on Input Capture Channel 1.

Address: Base address + 1Ch offset



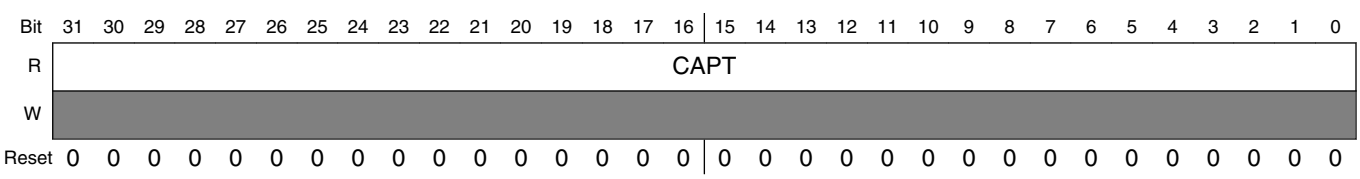
GPTx_ICR1 field descriptions

Field	Description
CAPT	Capture Value. After a capture event on Input Capture Channel 1 occurs, the current value of the counter is loaded into GPT Input Capture Register 1.

12.1.7.9 GPT Input Capture Register 2 (GPTx_ICR2)

The GPT Input capture Register 2 (GPT_ICR2) is a read-only register which holds the value that was in the counter during the last capture event on input capture channel 2.

Address: Base address + 20h offset



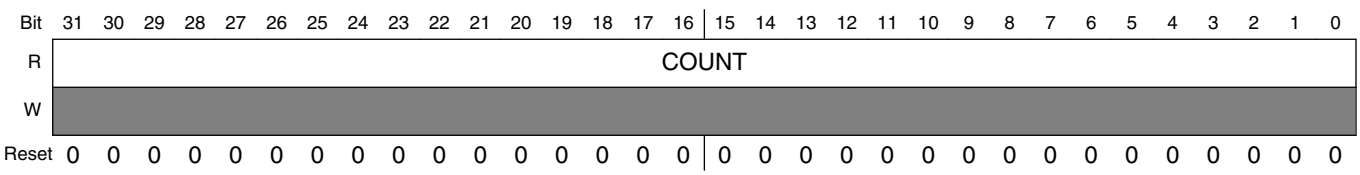
GPTx_ICR2 field descriptions

Field	Description
CAPT	Capture Value. After a capture event on Input Capture Channel 2 occurs, the current value of the counter is loaded into GPT Input Capture Register 2.

12.1.7.10 GPT Counter Register (GPTx_CNT)

The GPT Counter Register (GPT_CNT) is the main counter's register. GPT_CNT is a read-only register and can be read *without affecting the counting process* of the GPT.

Address: Base address + 24h offset



GPTx_CNT field descriptions

Field	Description
COUNT	Counter Value. The COUNT bits show the current count value of the GPT counter.

12.2 Flextimer (FTM)

12.2.1 Introduction

The FlexTimer module (FTM) is a two-to-eight channel timer that supports input capture, output compare, and the generation of PWM signals to control electric motor and power management applications. The FTM time reference is a 16-bit counter that can be used as an unsigned or signed counter.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

12.2.1.1 FlexTimer philosophy

The FlexTimer is built upon a simple timer, the HCS08 Timer PWM Module – TPM, used for many years on Freescale's 8-bit microcontrollers. The FlexTimer extends the functionality to meet the demands of motor control, digital lighting solutions, and power conversion, while providing low cost and backwards compatibility with the TPM module.

Several key enhancements are made:

- Signed up counter
- Deadtime insertion hardware
- Enhanced triggering functionality
- Initialization and polarity control

All of the features common with the TPM have fully backwards compatible register assignments. The FlexTimer can also use code on the same core platform without change to perform the same functions.

Motor control and power conversion features have been added through a dedicated set of registers and defaults turn off all new features. The new features, such as hardware deadtime insertion, polarity, and output forcing and masking, greatly reduce loading on the execution software and are usually each controlled by a group of registers.

FlexTimer input triggers can be from comparators, ADC, or other submodules to initiate timer functions automatically. These triggers can be linked in a variety of ways during integration of the sub modules so please note the options available for used FlexTimer configuration.

More than one FlexTimers may be synchronized to provide a larger timer with their counters incrementing in unison, assuming the initialization, the input clocks, the initial and final counting values are the same in each FlexTimer.

All main user access registers are buffered to ease the load on the executing software. A number of trigger options exist to determine which registers are updated with this user defined data.

12.2.1.2 Features

The FTM features include:

- FTM source clock is the system clock.
- Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
- 16-bit counter

    - It can be a free-running counter or a counter with initial and final value
    - The counting can be up or up-down
- Each channel can be configured for input capture, output compare, or edge-aligned PWM mode
- In Input Capture mode:
    - The capture can occur on rising edges, falling edges or both edges
    - An input filter can be selected for some channels
- In Output Compare mode the output signal can be set, cleared, or toggled on match
- All channels can be configured for center-aligned PWM mode
- Each pair of channels can be combined to generate a PWM signal with independent control of both edges of PWM signal
- The FTM channels can operate as pairs with equal outputs, pairs with complementary outputs, or independent channels with independent outputs
- The deadtime insertion is available for each complementary pair
- Generation of match triggers
- Initialization trigger
- Software control of PWM outputs
- The polarity of each channel is configurable
- The generation of an interrupt per channel
- The generation of an interrupt when the counter overflows
- Synchronized loading of write buffered FTM registers
- Write protection for critical registers
- Backwards compatible with TPM
- Testing of input captures for a stuck at zero and one conditions
- Dual edge capture for pulse and period width measurement
- Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event

12.2.1.3 Modes of operation

When the chip is in an active BDM mode, the FTM temporarily suspends all counting until the chip returns to normal user operating mode. During Stop mode, all FTM input clocks are stopped, so the FTM is effectively disabled until clocks resume. During Wait mode, the FTM continues to operate normally. If the FTM does not need to produce a real time reference or provide the interrupt sources needed to wake the chip from Wait mode, the power can then be saved by disabling FTM functions before entering Wait mode.

12.2.1.4 Block diagram

The FTM uses one input/output (I/O) pin per channel, CHn (FTM channel (n)) where n is the channel number (0–7).

The following figure shows the FTM structure. The central component of the FTM is the 16-bit counter with programmable initial and final values and its counting can be up or up-down.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

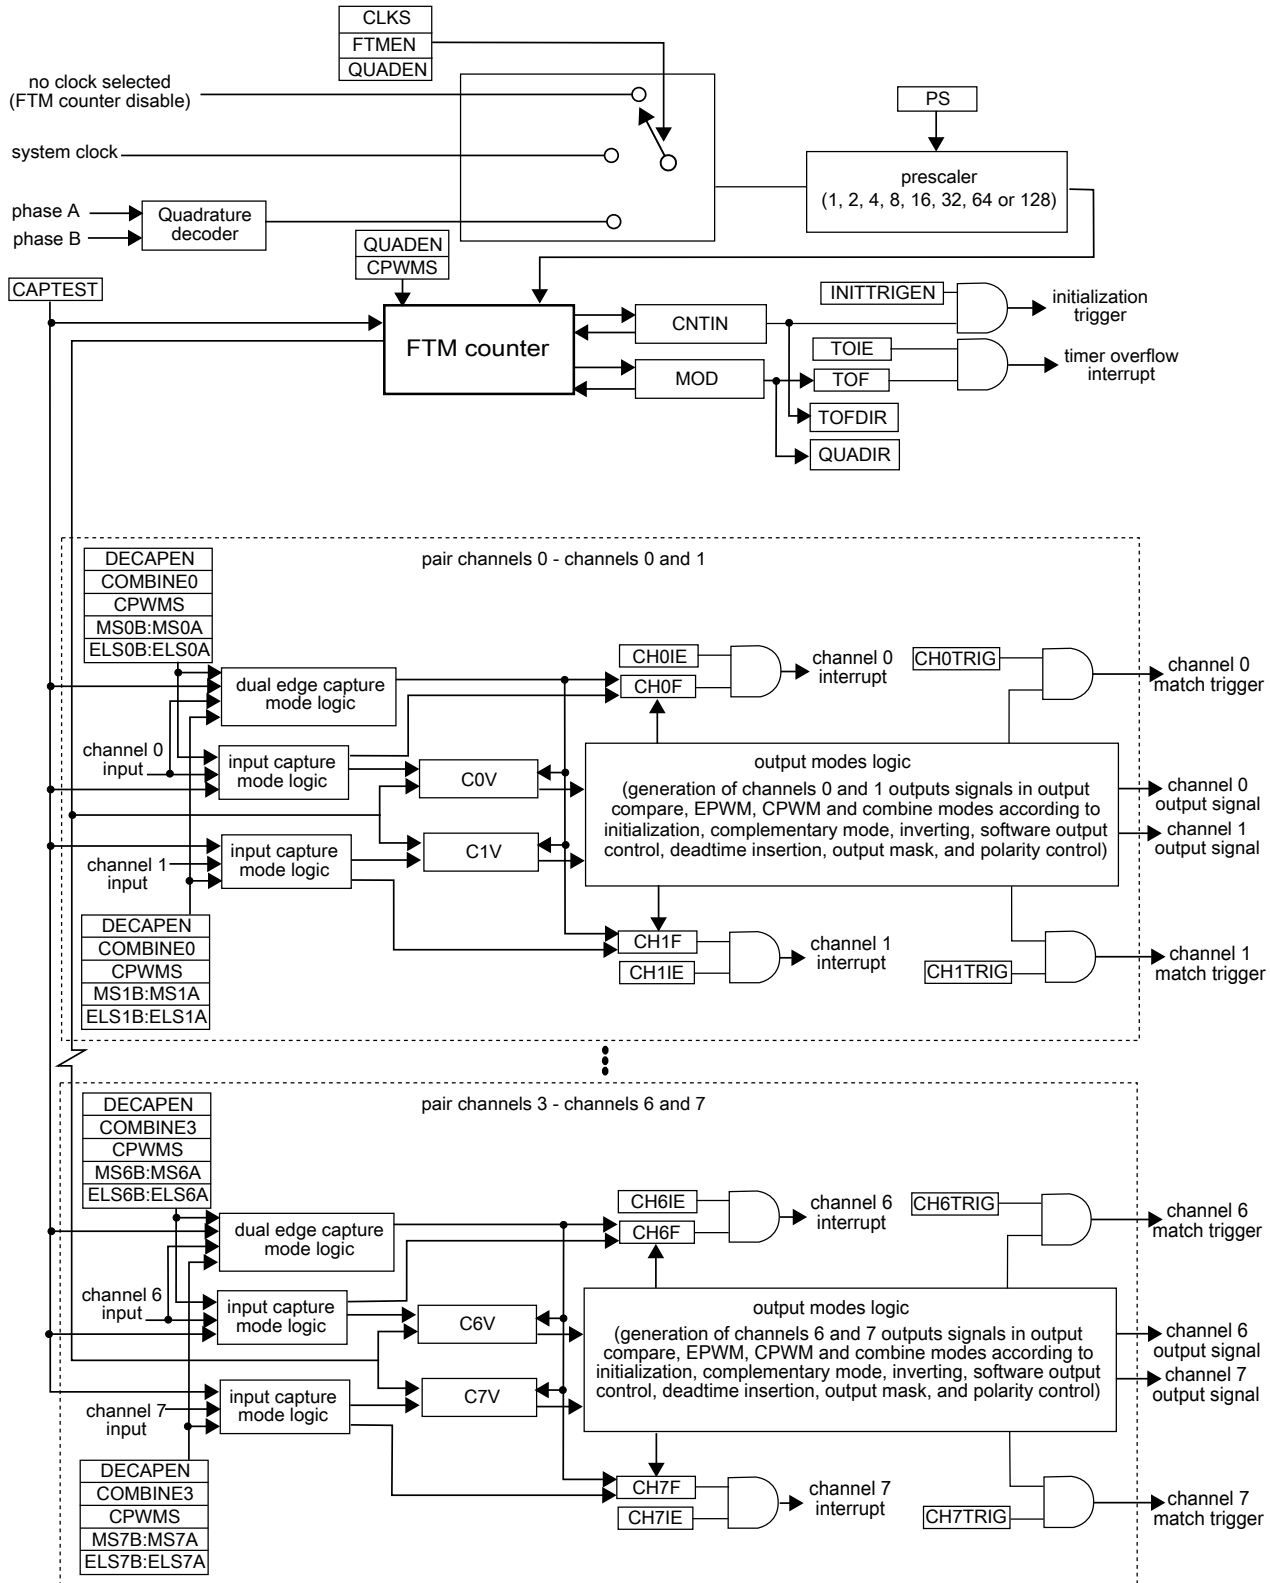


Figure 12-5. FTM block diagram

12.2.2 FTM signal descriptions

Table 12-3 shows the user-accessible signals for the FTM.

Table 12-3. FTM signal descriptions

Signal	Description	I/O	Function
CHn	FTM channel (n), where n can be 7-0	I/O	Each FTM channel can be configured to operate either as input or output. The direction associated with each channel, input or output, is selected according to the mode assigned for that channel.
PHA	Quadrature decoder phase A input. Input pin associated with quadrature decoder phase A.	I	The quadrature decoder phase A input is used as the Quadrature Decoder mode is selected. The phase A input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode.
PHB	Quadrature decoder phase B input. Input pin associated with quadrature decoder phase B.	I	The quadrature decoder phase B input is used as the Quadrature Decoder mode is selected. The phase B input signal is one of the signals that control the FTM counter increment or decrement in the Quadrature Decoder mode.

12.2.3 Memory map and register definition

12.2.3.1 Memory map

This section presents a high-level summary of the FTM registers and how they are mapped.

The registers and bits of an unavailable function in the FTM remain in the memory map and in the reset value, but they have no active function.

Note

Do not write in the region from the CNTIN register through the PWMLOAD register when FTMEN = 0.

NOTE

The number of channels supported can vary for each instance of the FTM module on a chip. See the chip-specific FTM information to see how many channels are supported for each module instance. For example, if a module instance supports only six channels, references to channel numbers 6 and 7 do not apply for that instance.

12.2.3.2 Register descriptions

Accesses to reserved addresses result in transfer errors. Registers for absent channels are considered reserved.

FTM memory map

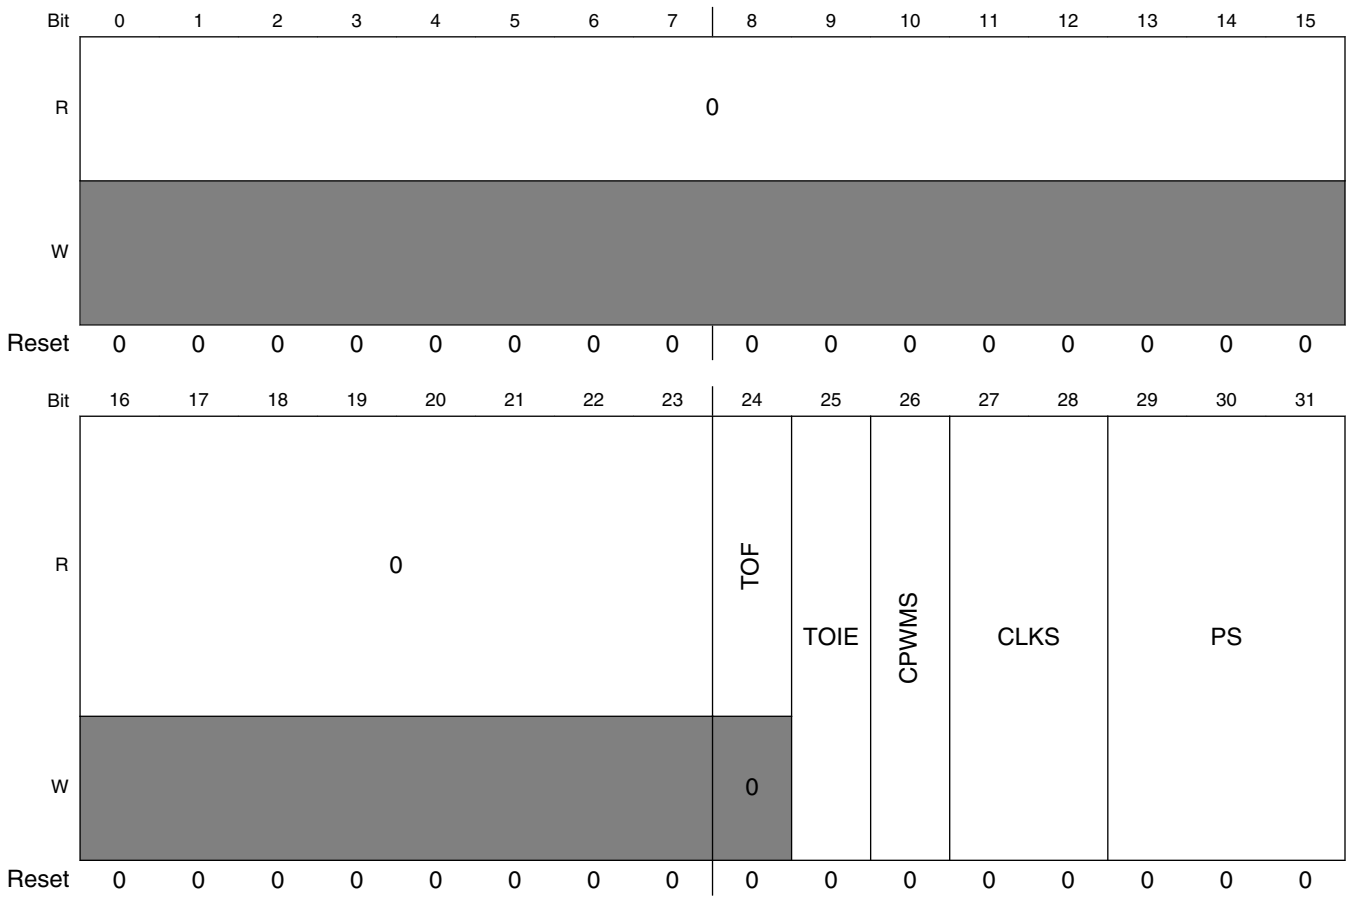
12.2.3.3 Status And Control (FTMx_SC)

SC contains the overflow status flag and control bits used to configure the interrupt enable, FTM configuration, clock source, and prescaler factor. These controls relate to all channels within this module.

Address: Base address + 0h offset



FTMx_SC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TOF	Timer Overflow Flag Set by hardware when the FTM counter passes the value in the MOD register. The TOF bit is cleared by reading the SC register while TOF is set and then writing a 0 to TOF bit. Writing a 1 to TOF has no effect. If another FTM overflow occurs between the read and write operations, the write operation has no effect; therefore, TOF remains set indicating an overflow has occurred. In this case, a TOF interrupt request is not lost due to the clearing sequence for a previous TOF. 0 FTM counter has not overflowed. 1 FTM counter has overflowed.

Table continues on the next page...

FTMx_SC field descriptions (continued)

Field	Description
25 TOIE	Timer Overflow Interrupt Enable Enables FTM overflow interrupts. 0 Disable TOF interrupts. Use software polling. 1 Enable TOF interrupts. An interrupt is generated when TOF equals one.
26 CPWMS	Center-Aligned PWM Select Selects CPWM mode. This mode configures the FTM to operate in Up-Down Counting mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 FTM counter operates in Up Counting mode. 1 FTM counter operates in Up-Down Counting mode.
27–28 CLKS	Clock Source Selection Selects FTM counter clock sources. This field is write protected. It can be written only when MODE[WPDIS] = 1. 00 No clock selected. This in effect disables the FTM counter. 01 System clock 10 Reserved
29–31 PS	Prescale Factor Selection Selects one of 8 division factors for the clock source selected by CLKS. The new prescaler factor affects the clock source on the next system clock cycle after the new value is updated into the register bits. This field is write protected. It can be written only when MODE[WPDIS] = 1. 000 Divide by 1 001 Divide by 2 010 Divide by 4 011 Divide by 8 100 Divide by 16 101 Divide by 32 110 Divide by 64 111 Divide by 128

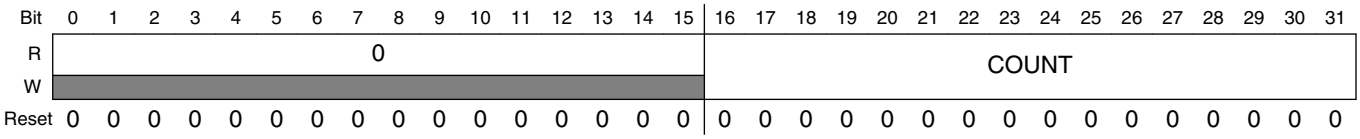
12.2.3.4 Counter (FTMx_CNT)

The CNT register contains the FTM counter value.

Reset clears the CNT register. Writing any value to COUNT updates the counter with its initial value, CNTIN.

When BDM is active, the FTM counter is frozen. This is the value that you may read.

Address: Base address + 4h offset



FTMx_CNT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Counter Value

12.2.3.5 Modulo (FTMx_MOD)

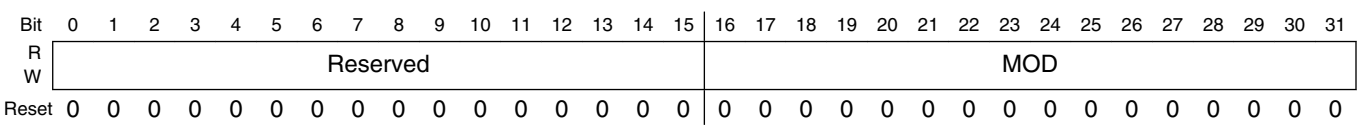
The Modulo register contains the modulo value for the FTM counter. After the FTM counter reaches the modulo value, the overflow flag (TOF) becomes set at the next clock, and the next value of FTM counter depends on the selected counting method; see Counter.

Writing to the MOD register latches the value into a buffer. The MOD register is updated with the value of its write buffer according to Registers updated from write buffers.

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the SC register whether BDM is active or not.

Initialize the FTM counter, by writing to CNT, before writing to the MOD register to avoid confusion about when the first counter overflow will occur.

Address: Base address + 8h offset



FTMx_MOD field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16–31 MOD	Modulo Value

12.2.3.6 Channel (n) Status And Control (FTM*x*_C*n*SC)

CnSC contains the channel-interrupt-status flag and control bits used to configure the interrupt enable, channel configuration, and pin function.

Table 12-4. Mode, edge, and level selection

DECAPEN	COMBINE	CPWMS	MSnB:MSnA	ELSnB:ELSnA	Mode	Configuration
X	X	X	XX	00	Pin not used for FTM—revert the channel pin to general purpose I/O or other peripheral control	
0	0	0	00	01	Input Capture	Capture on Rising Edge Only
				10		Capture on Falling Edge Only
				11		Capture on Rising or Falling Edge
			01	01	Output Compare	Toggle Output on match
				10		Clear Output on match
				11		Set Output on match
			1X	10	Edge-Aligned PWM	High-true pulses (clear Output on match)
				X1		Low-true pulses (set Output on match)
		1	XX	10	Center-Aligned PWM	High-true pulses (clear Output on match-up)
				X1		Low-true pulses (set Output on match-up)
	1	0	XX	10	Combine PWM	High-true pulses (set on channel (n) match, and clear on channel (n+1) match)
				X1		Low-true pulses (clear on channel (n) match, and set on channel (n +1) match)

Table continues on the next page...

FTMx_C*n*SC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CHF	Channel Flag Set by hardware when an event occurs on the channel. CHF is cleared by reading the CSC register while CHnF is set and then writing a 0 to the CHF bit. Writing a 1 to CHF has no effect. If another event occurs between the read and write operations, the write operation has no effect; therefore, CHF remains set indicating an event has occurred. In this case a CHF interrupt request is not lost due to the clearing sequence for a previous CHF. 0 No channel event has occurred. 1 A channel event has occurred.
25 CHIE	Channel Interrupt Enable Enables channel interrupts. 0 Disable channel interrupts. Use software polling. 1 Enable channel interrupts.
26 MSB	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See Table 12-4 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
27 MSA	Channel Mode Select Used for further selections in the channel logic. Its functionality is dependent on the channel mode. See Table 12-4 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
28 ELSB	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. See Table 12-4 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
29 ELSA	Edge or Level Select The functionality of ELSB and ELSA depends on the channel mode. See Table 12-4 . This field is write protected. It can be written only when MODE[WPDIS] = 1.
30 ICRST	FTM counter reset by the selected input capture event. FTM counter reset is driven by the selected event of the channel (n) in the Input Capture mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 FTM counter is not reset when the selected channel (n) input event is detected. 1 FTM counter is reset when the selected channel (n) input event is detected.
31 DMA	DMA Enable Enables DMA transfers for the channel. 0 Disable DMA transfers. 1 Enable DMA transfers.

12.2.3.7 Channel (n) Value (FTM*x*_C*n*V)

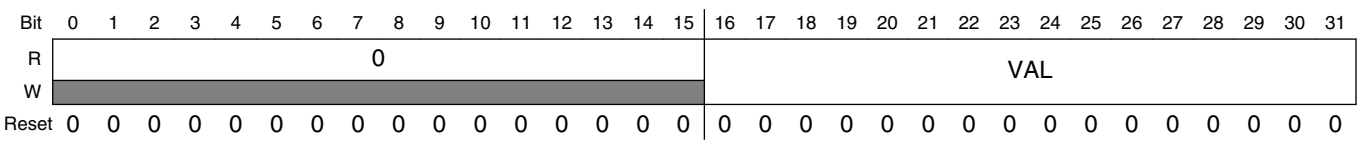
These registers contain the captured FTM counter value for the input modes or the match value for the output modes.

In Input Capture, Capture Test, and Dual Edge Capture modes, any write to a CnV register is ignored.

In output modes, writing to a CnV register latches the value into a buffer. A CnV register is updated with the value of its write buffer according to Registers updated from write buffers.

If FTMEN = 0, this write coherency mechanism may be manually reset by writing to the CnSC register whether BDM mode is active or not.

Address: Base address + 10h offset + (8d × i), where i=0d to 7d



FTM*x*_C*n*V field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 VAL	Channel Value Captured FTM counter value of the input modes or the match value for the output modes

12.2.3.8 Counter Initial Value (FTM*x*_CNTIN)

The Counter Initial Value register contains the initial value for the FTM counter.

Writing to the CNTIN register latches the value into a buffer. The CNTIN register is updated with the value of its write buffer according to Registers updated from write buffers.

When the FTM clock is initially selected, by writing a non-zero value to the CLKS bits, the FTM counter starts with the value 0x0000. To avoid this behavior, before the first write to select the FTM clock, write the new value to the the CNTIN register and then initialize the FTM counter by writing any value to the CNT register.

Address: Base address + 4Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FTMx_CNTIN field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16–31 INIT	Initial Value Of The FTM Counter

12.2.3.9 Capture And Compare Status (FTMx_STATUS)

The STATUS register contains a copy of the status flag CHnF bit in CnSC for each FTM channel for software convenience.

Each CHnF bit in STATUS is a mirror of CHnF bit in CnSC. All CHnF bits can be checked using only one read of STATUS. All CHnF bits can be cleared by reading STATUS followed by writing 0x00 to STATUS.

Hardware sets the individual channel flags when an event occurs on the channel. CHnF is cleared by reading STATUS while CHnF is set and then writing a 0 to the CHnF bit. Writing a 1 to CHnF has no effect.

If another event occurs between the read and write operations, the write operation has no effect; therefore, CHnF remains set indicating an event has occurred. In this case, a CHnF interrupt request is not lost due to the clearing sequence for a previous CHnF.

31 CH0F	Channel 0 Flag See the register description. 0 No channel event has occurred. 1 A channel event has occurred.

12.2.3.10 Features Mode Selection (FTMx_MODE)

This register contains the global enable bit for FTM-specific features and the control bits used to configure:

- Capture Test mode
- PWM synchronization
- Write protection
- Channel output initialization

These controls relate to all channels within this module.

Address: Base address + 54h offset

FTMx_MODE field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 CAPTEST	Capture Test Mode Enable Enables the capture test mode. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Capture test mode is disabled. 1 Capture test mode is enabled.
28 PWMSYNC	PWM Synchronization Mode Selects which triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. See PWM synchronization. The PWMSYNC bit configures the synchronization when SYNCMODE is 0. 0 No restrictions. Software and hardware triggers can be used by MOD, CnV, OUTMASK, and FTM counter synchronization. 1 Software trigger can only be used by MOD and CnV synchronization, and hardware triggers can only be used by OUTMASK and FTM counter synchronization.
29 WPDIS	Write Protection Disable When write protection is enabled (WPDIS = 0), write protected bits cannot be written. When write protection is disabled (WPDIS = 1), write protected bits can be written. The WPDIS bit is the negation of the WPEN bit. WPDIS is cleared when 1 is written to WPEN. WPDIS is set when WPEN bit is read as a 1 and then 1 is written to WPDIS. Writing 0 to WPDIS has no effect. 0 Write protection is enabled. 1 Write protection is disabled.
30 INIT	Initialize The Channels Output When a 1 is written to INIT bit the channels output is initialized according to the state of their corresponding bit in the OUTINIT register. Writing a 0 to INIT bit has no effect. The INIT bit is always read as 0.
31 FTMEN	FTM Enable This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 TPM compatibility. Free running counter and synchronization compatible with TPM. 1 Free running counter and synchronization are different from TPM behavior.

12.2.3.11 Synchronization (FTMx_SYNC)

This register configures the PWM synchronization.

A synchronization event can perform the synchronized update of MOD, CV, and OUTMASK registers with the value of their write buffer and the FTM counter initialization.

NOTE

The software trigger, SWSYNC bit, and hardware triggers TRIG0, TRIG1, and TRIG2 bits have a potential conflict if used together when SYNCMODE = 0. Use only hardware or software triggers but not both at the same time, otherwise unpredictable behavior is likely to happen.

The selection of the loading point, CNTMAX and CNTMIN bits, is intended to provide the update of MOD, CNTIN, and CnV registers across all enabled channels simultaneously. The use of the loading point selection together with SYNCMODE = 0 and hardware trigger selection, TRIG0, TRIG1, or TRIG2 bits, is likely to result in unpredictable behavior.

The synchronization event selection also depends on the PWMSYNC (MODE register) and SYNCMODE (SYNCONF register) bits. See PWM synchronization.

FTMx_SYNC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 SWSYNC	PWM Synchronization Software Trigger Selects the software trigger as the PWM synchronization trigger. The software trigger happens when a 1 is written to SWSYNC bit. 0 Software trigger is not selected. 1 Software trigger is selected.
25 TRIG2	PWM Synchronization Hardware Trigger 2

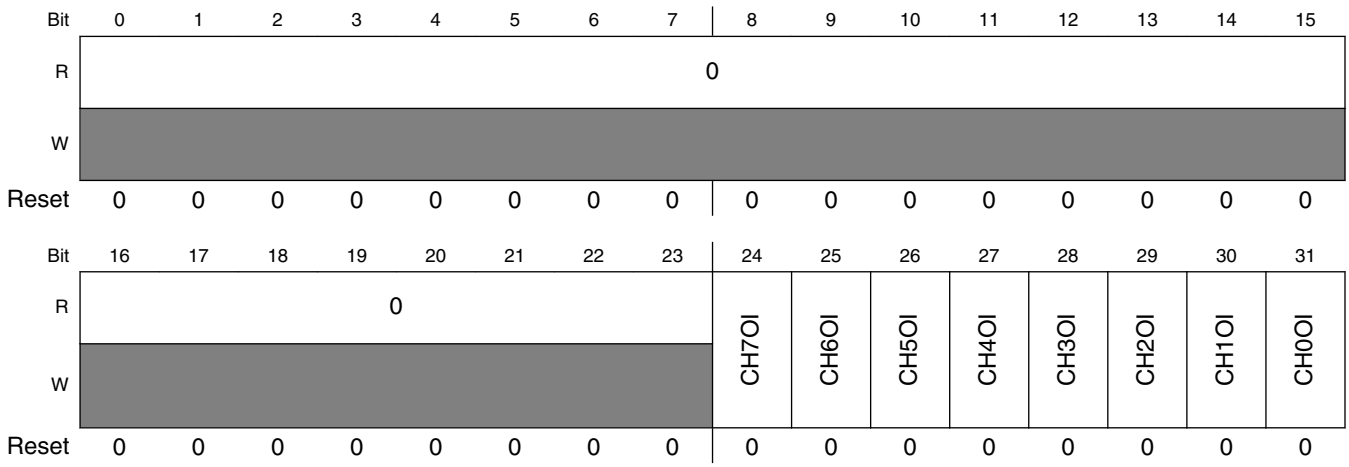
Table continues on the next page...

FTMx_SYNC field descriptions (continued)

Field	Description
	Enables hardware trigger 2 to the PWM synchronization. Hardware trigger 2 happens when a rising edge is detected at the trigger 2 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
26 TRIG1	PWM Synchronization Hardware Trigger 1 Enables hardware trigger 1 to the PWM synchronization. Hardware trigger 1 happens when a rising edge is detected at the trigger 1 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
27 TRIG0	PWM Synchronization Hardware Trigger 0 Enables hardware trigger 0 to the PWM synchronization. Hardware trigger 0 occurs when a rising edge is detected at the trigger 0 input signal. 0 Trigger is disabled. 1 Trigger is enabled.
28 SYNCHOM	Output Mask Synchronization Selects when the OUTMASK register is updated with the value of its buffer. 0 OUTMASK register is updated with the value of its buffer in all rising edges of the system clock. 1 OUTMASK register is updated with the value of its buffer only by the PWM synchronization.
29 REINIT	FTM Counter Reinitialization By Synchronization (FTM counter synchronization) Determines if the FTM counter is reinitialized when the selected trigger for the synchronization is detected. The REINIT bit configures the synchronization when SYNCMODE is zero. 0 FTM counter continues to count normally. 1 FTM counter is updated with its initial value when the selected trigger is detected.
30 CNTMAX	Maximum Loading Point Enable Selects the maximum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMAX is 1, the selected loading point is when the FTM counter reaches its maximum value (MOD register). 0 The maximum loading point is disabled. 1 The maximum loading point is enabled.
31 CNTMIN	Minimum Loading Point Enable Selects the minimum loading point to PWM synchronization. See Boundary cycle and loading points. If CNTMIN is one, the selected loading point is when the FTM counter reaches its minimum value (CNTIN register). 0 The minimum loading point is disabled. 1 The minimum loading point is enabled.

12.2.3.12 Initial State For Channels Output (FTMx_OUTINIT)

Address: Base address + 5Ch offset



FTMx_OUTINIT field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CH7OI	Channel 7 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
25 CH6OI	Channel 6 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
26 CH5OI	Channel 5 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
27 CH4OI	Channel 4 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
28 CH3OI	Channel 3 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs.

Table continues on the next page...

FTMx_OUTINIT field descriptions (continued)

Field	Description
	0 The initialization value is 0. 1 The initialization value is 1.
29 CH2OI	Channel 2 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
30 CH1OI	Channel 1 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.
31 CH0OI	Channel 0 Output Initialization Value Selects the value that is forced into the channel output when the initialization occurs. 0 The initialization value is 0. 1 The initialization value is 1.

12.2.3.13 Output Mask (FTMx_OUTMASK)

This register provides a mask for each FTM channel. The mask of a channel determines if its output responds, that is, it is masked or not, when a match occurs. This feature is used for BLDC control where the PWM signal is presented to an electric motor at specific times to provide electronic commutation.

Any write to the OUTMASK register, stores the value in its write buffer. The register is updated with the value of its write buffer according to PWM synchronization.

FTMx_OUTMASK field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CH7OM	Channel 7 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
25 CH6OM	Channel 6 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
26 CH5OM	Channel 5 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
27 CH4OM	Channel 4 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
28 CH3OM	Channel 3 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
29 CH2OM	Channel 2 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
30 CH1OM	Channel 1 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.
31 CH0OM	Channel 0 Output Mask Defines if the channel output is masked or unmasked. 0 Channel output is not masked. It continues to operate normally. 1 Channel output is masked. It is forced to its inactive state.

12.2.3.14 Function For Linked Channels (FTMx_COMBINE)

This register contains the control bits used to configure the synchronization, deadtime insertion, Dual Edge Capture mode, Complementary, and Combine mode for each pair of channels (n) and (n+1), where n equals 0, 2, 4, and 6.

Address: Base address + 64h offset

FTMx_COMBINE field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 SYNCEN3	Synchronization Enable For n = 6 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
3 DTEN3	Deadtime Enable For n = 6 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
4 DECAP3	Dual Edge Capture Mode Captures For n = 6 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
5 DECAPEN3	Dual Edge Capture Mode Enable For n = 6 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 12-4. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
6 COMP3	Complement Of Channel (n) for n = 6 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
7 COMBINE3	Combine Channels For n = 6 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SYNCEN2	Synchronization Enable For n = 4 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
11 DTEN2	Deadtime Enable For n = 4 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
12 DECAP2	Dual Edge Capture Mode Captures For n = 4 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
13 DECAPEN2	Dual Edge Capture Mode Enable For n = 4 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 12-4. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
14 COMP2	Complement Of Channel (n) For n = 4 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
15 COMBINE2	Combine Channels For n = 4 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SYNCEN1	Synchronization Enable For n = 2 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
19 DTEN1	Deadtime Enable For n = 2 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
20 DECAP1	Dual Edge Capture Mode Captures For n = 2 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if Dual Edge Capture – One-Shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
21 DECAPEN1	Dual Edge Capture Mode Enable For n = 2 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 12-4. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
22 COMP1	Complement Of Channel (n) For n = 2 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
23 COMBINE1	Combine Channels For n = 2 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 SYNCEN0	Synchronization Enable For n = 0 Enables PWM synchronization of registers C(n)V and C(n+1)V. 0 The PWM synchronization in this pair of channels is disabled. 1 The PWM synchronization in this pair of channels is enabled.
27 DTEN0	Deadtime Enable For n = 0 Enables the deadtime insertion in the channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The deadtime insertion in this pair of channels is disabled. 1 The deadtime insertion in this pair of channels is enabled.
28 DECAP0	Dual Edge Capture Mode Captures For n = 0 Enables the capture of the FTM counter value according to the channel (n) input event and the configuration of the dual edge capture bits.

Table continues on the next page...

FTMx_COMBINE field descriptions (continued)

Field	Description
	This field applies only when DECAPEN = 1. DECAP bit is cleared automatically by hardware if dual edge capture – one-shot mode is selected and when the capture of channel (n+1) event is made. 0 The dual edge captures are inactive. 1 The dual edge captures are active.
29 DECAPEN0	Dual Edge Capture Mode Enable For n = 0 Enables the Dual Edge Capture mode in the channels (n) and (n+1). This bit reconfigures the function of MSnA, ELSnB:ELSnA and ELS(n+1)B:ELS(n+1)A bits in Dual Edge Capture mode according to Table 12-4. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The Dual Edge Capture mode in this pair of channels is disabled. 1 The Dual Edge Capture mode in this pair of channels is enabled.
30 COMP0	Complement Of Channel (n) For n = 0 Enables Complementary mode for the combined channels. In Complementary mode the channel (n+1) output is the inverse of the channel (n) output. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 The channel (n+1) output is the same as the channel (n) output. 1 The channel (n+1) output is the complement of the channel (n) output.
31 COMBINE0	Combine Channels For n = 0 Enables the combine feature for channels (n) and (n+1). This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Channels (n) and (n+1) are independent. 1 Channels (n) and (n+1) are combined.

12.2.3.15 Deadtime Insertion Control (FTMx_DEADTIME)

This register selects the deadtime prescaler factor and deadtime value. All FTM channels use this clock prescaler and this deadtime value for the deadtime insertion.

Address: Base address + 68h offset

Bit	0–15	16–23	24	25	26–31
R	0		DTPS		DTVAL
W					
Reset	0	0	0	0	0

FTMx_DEADTIME field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FTMx_DEADTIME field descriptions (continued)

Field	Description
24–25 DTPS	Deadtime Prescaler Value Selects the division factor of the system clock. This prescaled clock is used by the deadtime counter. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0x Divide the system clock by 1. 10 Divide the system clock by 4. 11 Divide the system clock by 16.
26–31 DTVAL	Deadtime Value Selects the deadtime insertion value for the deadtime counter. The deadtime counter is clocked by a scaled version of the system clock. See the description of DTPS. Deadtime insert value = (DTPS × DTVAL). DTVAL selects the number of deadtime counts inserted as follows: When DTVAL is 0, no counts are inserted. When DTVAL is 1, 1 count is inserted. When DTVAL is 2, 2 counts are inserted. This pattern continues up to a possible 63 counts. This field is write protected. It can be written only when MODE[WPDIS] = 1.

12.2.3.16 FTM External Trigger (FTMx_EXTTRIG)

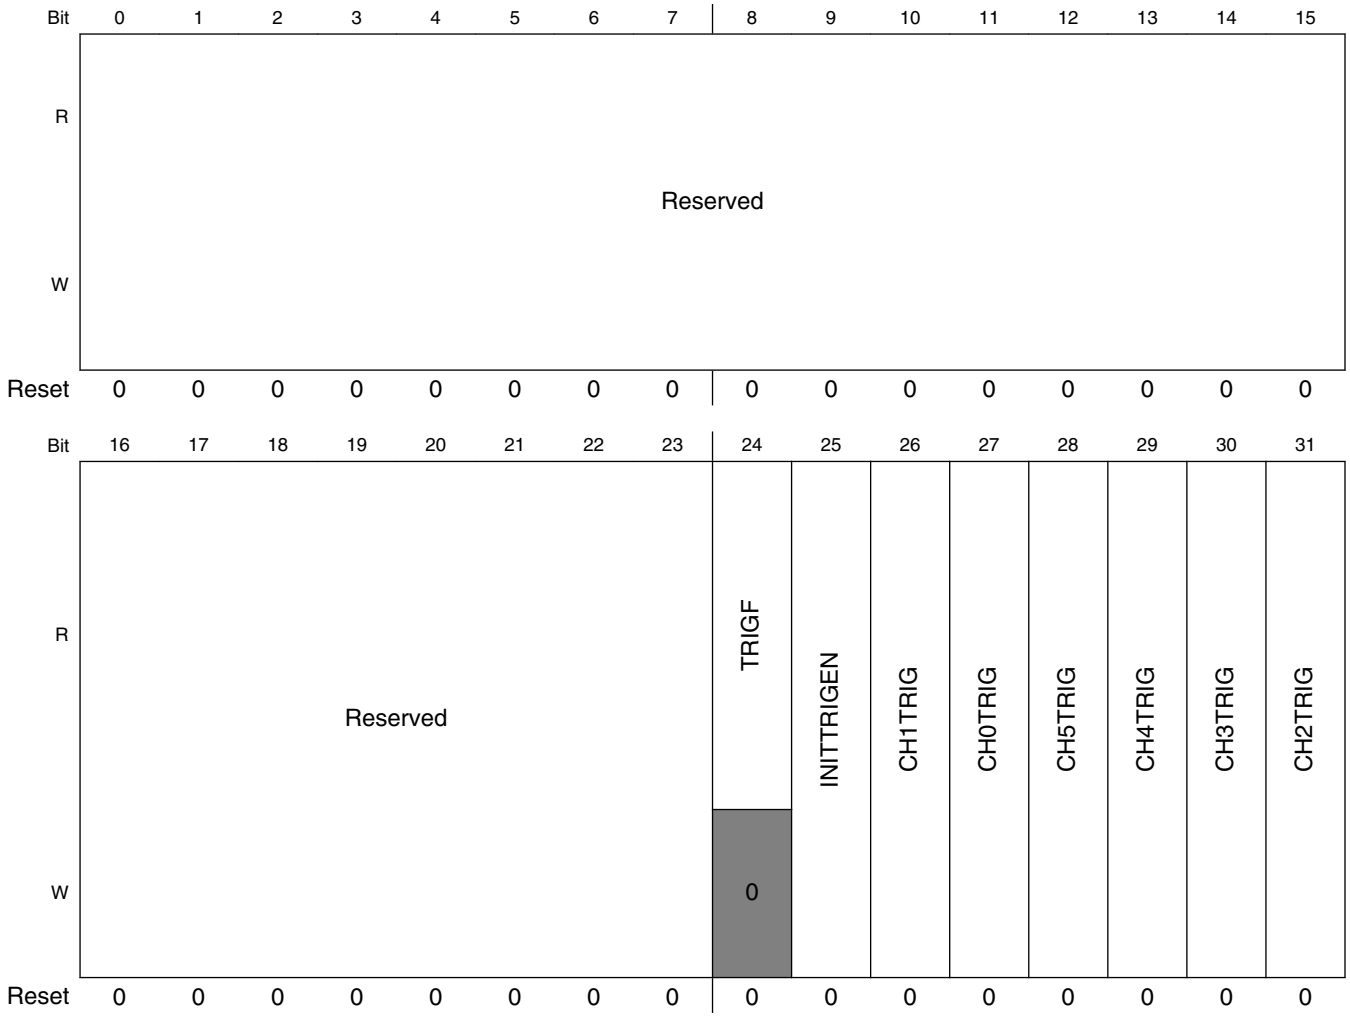
This register:

- Indicates when a channel trigger was generated
- Enables the generation of a trigger when the FTM counter is equal to its initial value
- Selects which channels are used in the generation of the channel triggers

Several channels can be selected to generate multiple triggers in one PWM period. See Channel trigger output and Initialization trigger.

Channels 6 and 7 are not used to generate channel triggers.

Address: Base address + 6Ch offset



FTMx_EXTTRIG field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 TRIGF	Channel Trigger Flag Set by hardware when a channel trigger is generated. Clear TRIGF by reading EXTTRIG while TRIGF is set and then writing a 0 to TRIGF. Writing a 1 to TRIGF has no effect. If another channel trigger is generated before the clearing sequence is completed, the sequence is reset so TRIGF remains set after the clear sequence is completed for the earlier TRIGF. 0 No channel trigger was generated. 1 A channel trigger was generated.
25 INITTRIGEN	Initialization Trigger Enable Enables the generation of the trigger when the FTM counter is equal to the CNTIN register. 0 The generation of initialization trigger is disabled. 1 The generation of initialization trigger is enabled.

Table continues on the next page...

FTMx_EXTTRIG field descriptions (continued)

Field	Description
26 CH1TRIG	Channel 1 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
27 CH0TRIG	Channel 0 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
28 CH5TRIG	Channel 5 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
29 CH4TRIG	Channel 4 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
30 CH3TRIG	Channel 3 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.
31 CH2TRIG	Channel 2 Trigger Enable Enables the generation of the channel trigger when the FTM counter is equal to the CnV register. 0 The generation of the channel trigger is disabled. 1 The generation of the channel trigger is enabled.

12.2.3.17 Channels Polarity (FTMx_POL)

This register defines the output polarity of the FTM channels.

NOTE

The safe value of a channel is the value of its POL bit.

Address: Base address + 70h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

12.2.3.19 Input Capture Filter Control (FTMx_FILTER)

This register selects the filter value for the inputs of channels.

Channels 4, 5, 6 and 7 do not have an input filter.

NOTE

Writing to the FILTER register has immediate effect and must be done only when the channels 0, 1, 2, and 3 are not in input modes. Failure to do this could result in a missing valid signal.

Address: Base address + 78h offset

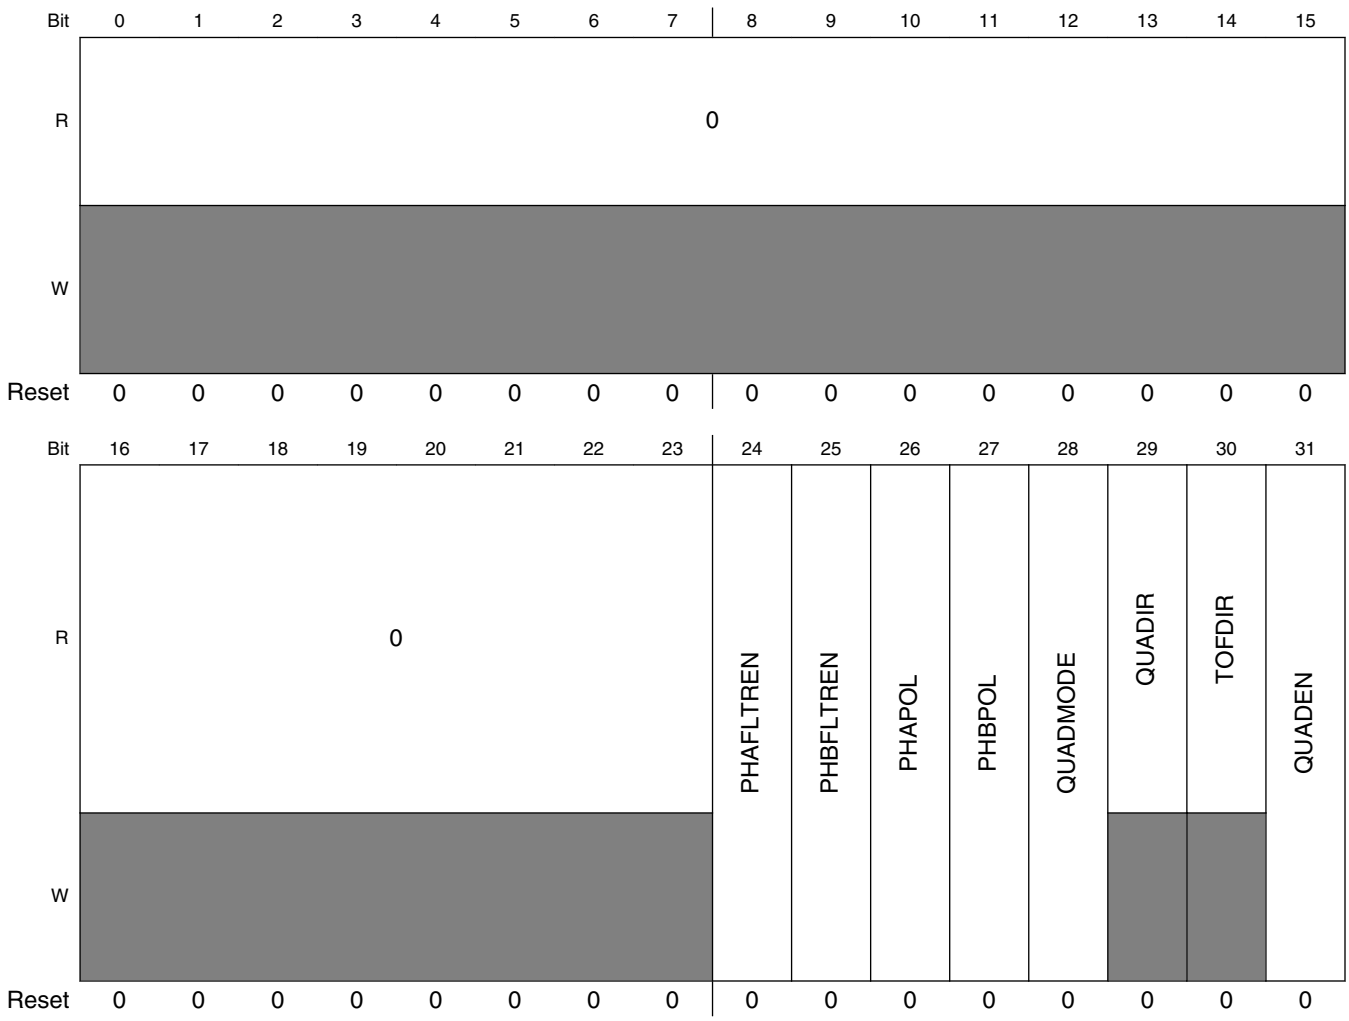
FTMx_FILTER field descriptions

Field	Description
0–15 Reserved	This field is reserved.
16–19 CH3FVAL	Channel 3 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
20–23 CH2FVAL	Channel 2 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
24–27 CH1FVAL	Channel 1 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.
28–31 CH0FVAL	Channel 0 Input Filter Selects the filter value for the channel input. The filter is disabled when the value is zero.

12.2.3.20 Quadrature Decoder Control And Status (FTMx_QDCTRL)

This register has the control and status bits for the Quadrature Decoder mode.

Address: Base address + 80h offset



FTMx_QDCTRL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 PHAFLTREN	Phase A Input Filter Enable Enables the filter for the quadrature decoder phase A input. The filter value for the phase A input is defined by the CH0FVAL field of FILTER. The phase A filter is also disabled when CH0FVAL is zero. 0 Phase A input filter is disabled. 1 Phase A input filter is enabled.

Table continues on the next page...

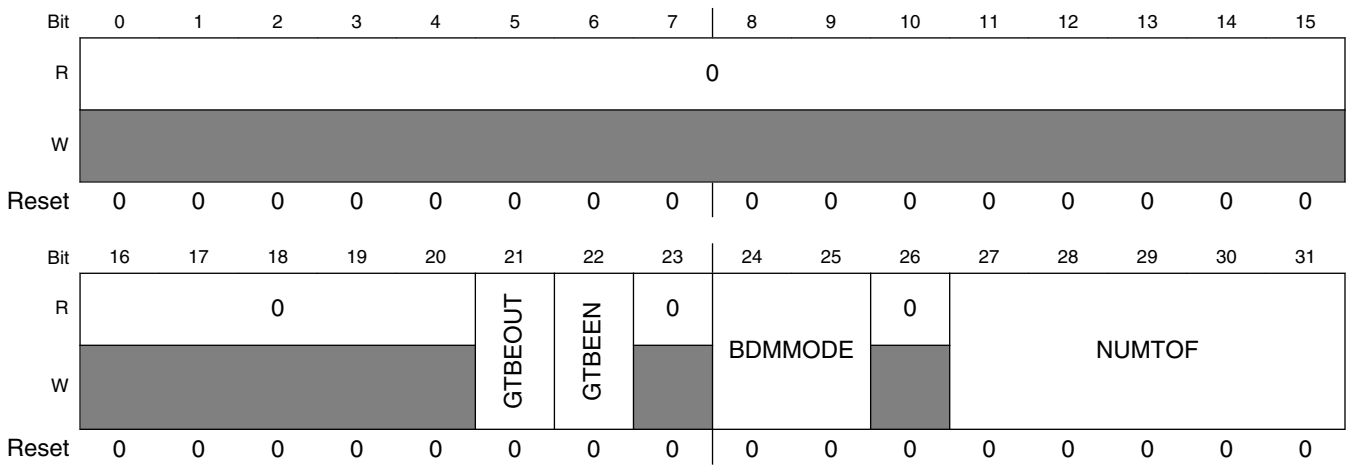
FTMx_QDCTRL field descriptions (continued)

Field	Description
25 PHBFLTREN	Phase B Input Filter Enable Enables the filter for the quadrature decoder phase B input. The filter value for the phase B input is defined by the CH1FVAL field of FILTER. The phase B filter is also disabled when CH1FVAL is zero. 0 Phase B input filter is disabled. 1 Phase B input filter is enabled.
26 PHAPOL	Phase A Input Polarity Selects the polarity for the quadrature decoder phase A input. 0 Normal polarity. Phase A input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase A input signal is inverted before identifying the rising and falling edges of this signal.
27 PHBPOL	Phase B Input Polarity Selects the polarity for the quadrature decoder phase B input. 0 Normal polarity. Phase B input signal is not inverted before identifying the rising and falling edges of this signal. 1 Inverted polarity. Phase B input signal is inverted before identifying the rising and falling edges of this signal.
28 QUADMODE	Quadrature Decoder Mode Selects the encoding mode used in the Quadrature Decoder mode. 0 Phase A and phase B encoding mode. 1 Count and direction encoding mode.
29 QUADIR	FTM Counter Direction In Quadrature Decoder Mode Indicates the counting direction. 0 Counting direction is decreasing (FTM counter decrement). 1 Counting direction is increasing (FTM counter increment).
30 TOFDIR	Timer Overflow Direction In Quadrature Decoder Mode Indicates if the TOF bit was set on the top or the bottom of counting. 0 TOF bit was set on the bottom of counting. There was an FTM counter decrement and FTM counter changes from its minimum value (CNTIN register) to its maximum value (MOD register). 1 TOF bit was set on the top of counting. There was an FTM counter increment and FTM counter changes from its maximum value (MOD register) to its minimum value (CNTIN register).
31 QUADEN	Quadrature Decoder Mode Enable Enables the Quadrature Decoder mode. In this mode, the phase A and B input signals control the FTM counter direction. The Quadrature Decoder mode has precedence over the other modes. See Table 12-4. This field is write protected. It can be written only when MODE[WPDIS] = 1. 0 Quadrature Decoder mode is disabled. 1 Quadrature Decoder mode is enabled.

12.2.3.21 Configuration (FTMx_CONF)

This register selects the number of times that the FTM counter overflow should occur before the TOF bit to be set, the FTM behavior in BDM modes, the use of an external global time base, and the global time base signal generation.

Address: Base address + 84h offset



FTMx_CONF field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 GTBEOUT	Global Time Base Output Enables the global time base signal generation to other FTMs. 0 A global time base signal generation is disabled. 1 A global time base signal generation is enabled.
22 GTBEEN	Global Time Base Enable Configures the FTM to use an external global time base signal that is generated by another FTM. 0 Use of an external global time base is disabled. 1 Use of an external global time base is enabled.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 BDMMODE	BDM Mode Selects the FTM behavior in BDM mode. See BDM mode.

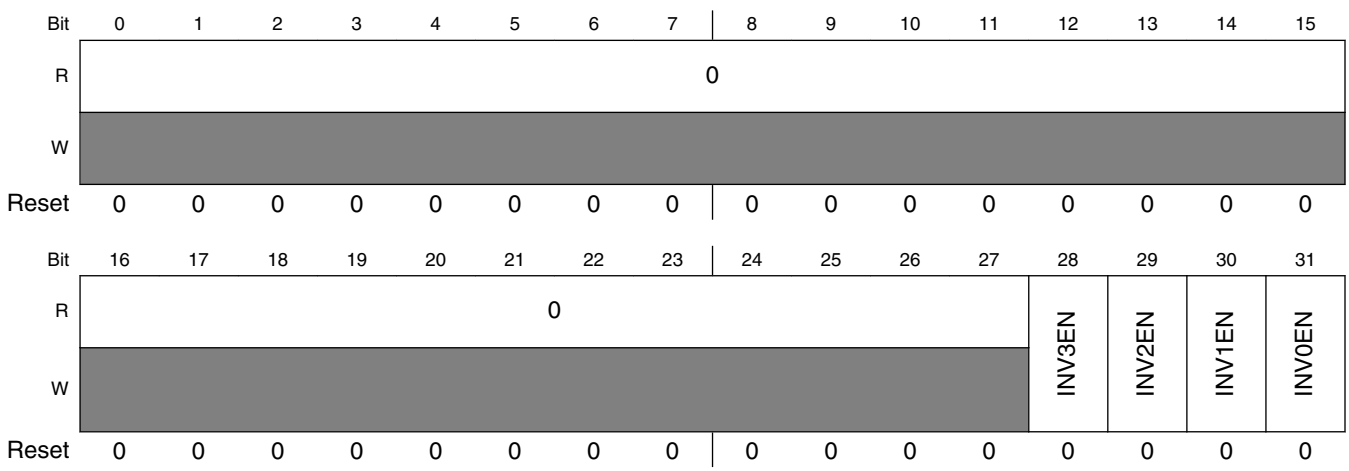
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CNTINC	CNTIN Register Synchronization 0 CNTIN register is updated with its buffer value at all rising edges of system clock. 1 CNTIN register is updated with its buffer value by the PWM synchronization.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HWTRIGMODE	Hardware Trigger Mode 0 FTM clears the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2. 1 FTM does not clear the TRIGj bit when the hardware trigger j is detected, where j = 0, 1,2.

12.2.3.23 FTM Inverting Control (FTMx_INVCTRL)

This register controls when the channel (n) output becomes the channel (n+1) output, and channel (n+1) output becomes the channel (n) output. Each INVmEN bit enables the inverting operation for the corresponding pair channels m.

This register has a write buffer. The INVmEN bit is updated by the INVCTRL register synchronization.

Address: Base address + 90h offset



FTMx_INVCTRL field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 INV3EN	Pair Channels 3 Inverting Enable 0 Inverting is disabled. 1 Inverting is enabled.
29 INV2EN	Pair Channels 2 Inverting Enable 0 Inverting is disabled. 1 Inverting is enabled.
30 INV1EN	Pair Channels 1 Inverting Enable 0 Inverting is disabled. 1 Inverting is enabled.
31 INV0EN	Pair Channels 0 Inverting Enable 0 Inverting is disabled. 1 Inverting is enabled.

12.2.3.24 FTM Software Output Control (FTMx_SWOCTRL)

This register enables software control of channel (n) output and defines the value forced to the channel (n) output:

- The CHnOC bits enable the control of the corresponding channel (n) output by software.
- The CHnOCV bits select the value that is forced at the corresponding channel (n) output.

This register has a write buffer. The fields are updated by the SWOCTRL register synchronization.

12.2.4 Functional description

The notation used in this document to represent the counters and the generation of the signals is shown in the following figure.

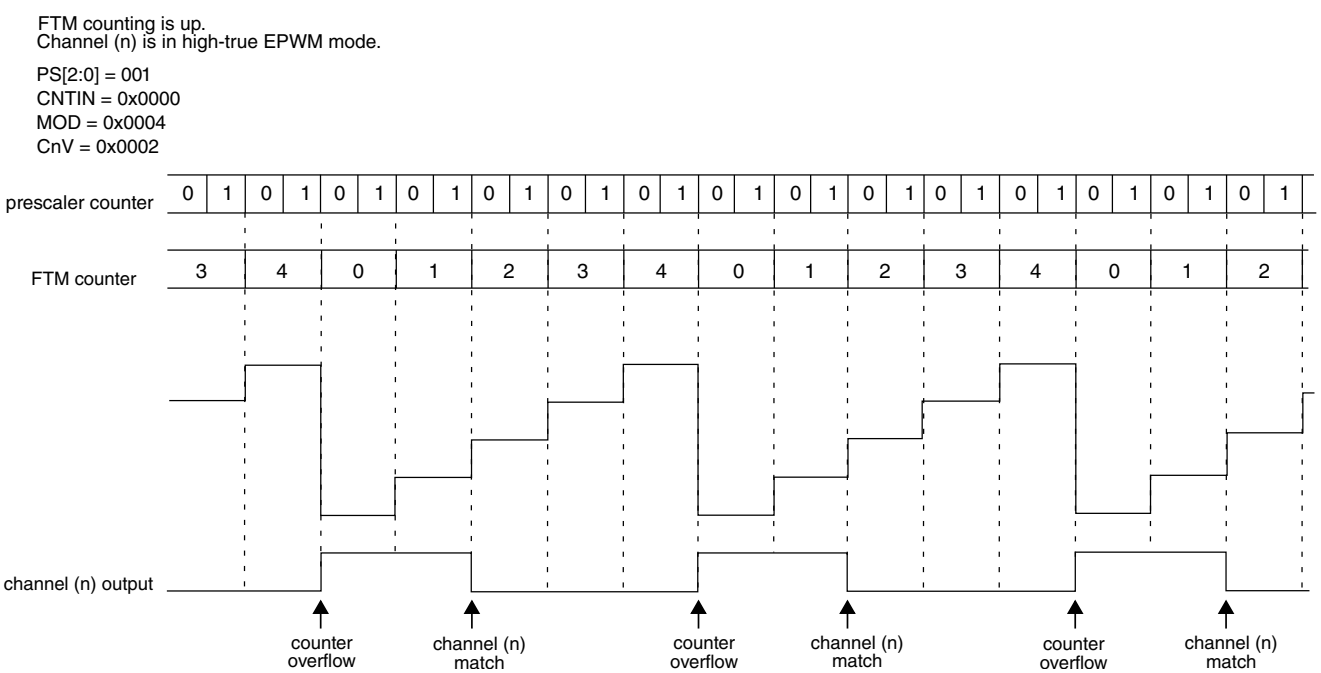

Figure 12-6. Notation used

12.2.4.1 Clock source

The FTM has only one clock domain: the system clock.

12.2.4.1.1 Counter clock source

The CLKS[1:0] bits in the SC register selects clock sources for the FTM counter or disables the FTM counter. After any chip reset, CLKS[1:0] = 0:0 so no clock source is selected.

The CLKS[1:0] bits may be read or written at any time. Disabling the FTM counter by writing 0:0 to the CLKS[1:0] bits does not affect the FTM counter value or other registers.

12.2.4.2 Prescaler

The selected counter clock source passes through a prescaler that is a 7-bit counter. The value of the prescaler is selected by the PS[2:0] bits. The following figure shows an example of the prescaler counter and FTM counter.

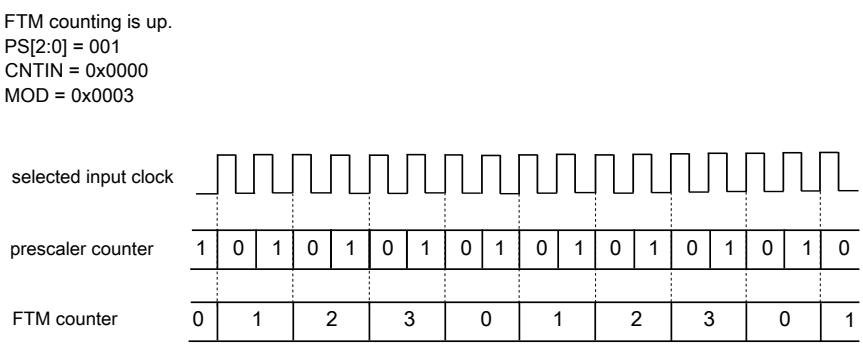

Figure 12-7. Example of the prescaler counter

12.2.4.3 Counter

The FTM has a 16-bit counter that is used by the channels either for input or output modes. The FTM counter clock is the selected clock divided by the prescaler.

The FTM counter has these modes of operation:

- Up counting
- Up-down counting
- Quadrature Decoder mode

12.2.4.3.1 Up counting

Up counting is selected when:

- QUADEN = 0, and
- CPWMS = 0

CNTIN defines the starting value of the count and MOD defines the final value of the count, see the following figure. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is reloaded with the value of CNTIN.

The FTM period when using up counting is (MOD – CNTIN + 0x0001) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to CNTIN.

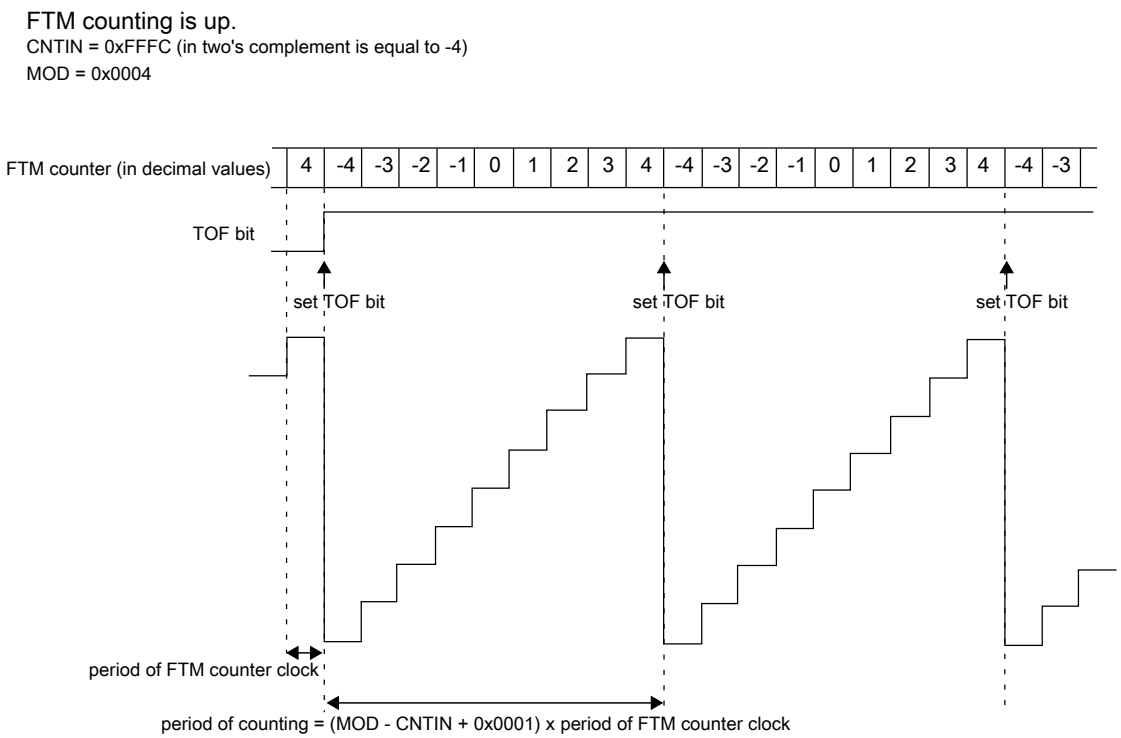

Figure 12-8. Example of FTM up and signed counting

Table 12-6. FTM counting based on CNTIN value

When	Then
CNTIN = 0x0000	The FTM counting is equivalent to TPM up counting, that is, up and unsigned counting. See the following figure.
CNTIN[15] = 1	The initial value of the FTM counter is a negative number in two's complement, so the FTM counting is up and signed.

Table continues on the next page...

Table 12-6. FTM counting based on CNTIN value (continued)

When	Then
CNTIN[15] = 0 and CNTIN ≠ 0x0000	The initial value of the FTM counter is a positive number, so the FTM counting is up and unsigned.

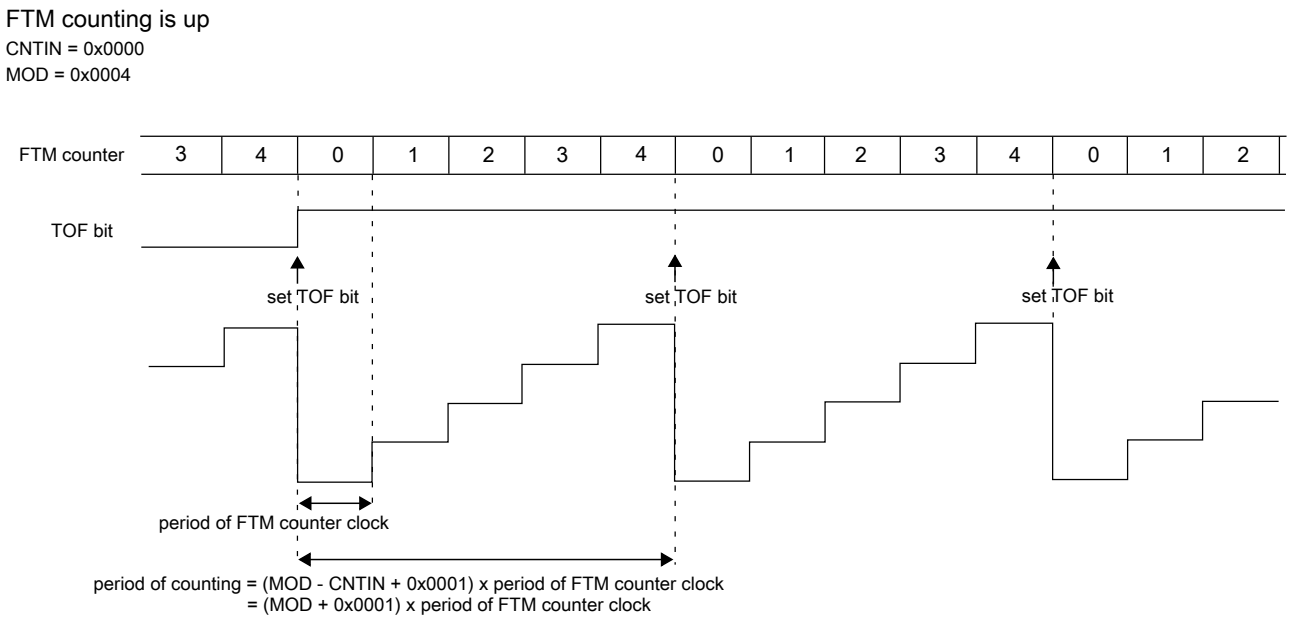

Figure 12-9. Example of FTM up counting with CNTIN = 0x0000

Note

- FTM operation is only valid when the value of the CNTIN register is less than the value of the MOD register, either in the unsigned counting or signed counting. It is the responsibility of the software to ensure that the values in the CNTIN and MOD registers meet this requirement. Any values of CNTIN and MOD that do not satisfy this criteria can result in unpredictable behavior.
- MOD = CNTIN is a redundant condition. In this case, the FTM counter is always equal to MOD and the TOF bit is set in each rising edge of the FTM counter clock.

- When MOD = 0x0000, CNTIN = 0x0000, for example after reset, and FTMEN = 1, the FTM counter remains stopped at 0x0000 until a non-zero value is written into the MOD or CNTIN registers.
- Setting CNTIN to be greater than the value of MOD is not recommended as this unusual setting may make the FTM operation difficult to comprehend. However, there is no restriction on this configuration, and an example is shown in the following figure.

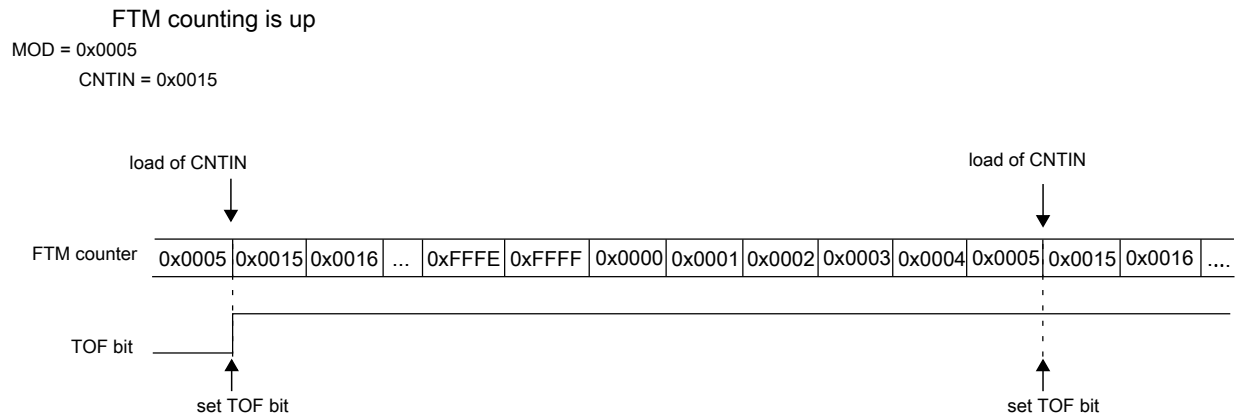

Figure 12-10. Example of up counting when the value of CNTIN is greater than the value of MOD

12.2.4.3.2 Up-down counting

Up-down counting is selected when:

- QUADEN = 0, and
- CPWMS = 1

CNTIN defines the starting value of the count and MOD defines the final value of the count. The value of CNTIN is loaded into the FTM counter, and the counter increments until the value of MOD is reached, at which point the counter is decremented until it returns to the value of CNTIN and the up-down counting restarts.

The FTM period when using up-down counting is 2 × (MOD – CNTIN) × period of the FTM counter clock.

The TOF bit is set when the FTM counter changes from MOD to (MOD – 1).

If (CNTIN = 0x0000), the FTM counting is equivalent to TPM up-down counting, that is, up-down and unsigned counting. See the following figure.

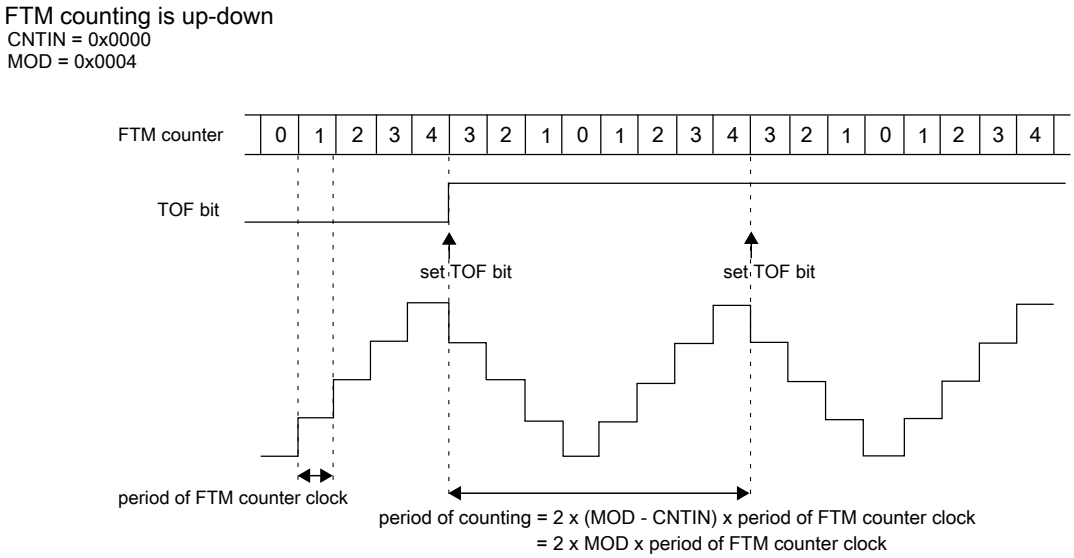

Figure 12-11. Example of up-down counting when CNTIN = 0x0000

Note

When CNTIN is different from zero in the up-down counting, a valid CPWM signal is generated:

- if CnV > CNTIN, or
- if CnV = 0 or if CnV[15] = 1. In this case, 0% CPWM is generated.

12.2.4.3.3 Free running counter

If (FTMEN = 0) and (MOD = 0x0000 or MOD = 0xFFFF), the FTM counter is a free running counter. In this case, the FTM counter runs free from 0x0000 through 0xFFFF and the TOF bit is set when the FTM counter changes from 0xFFFF to 0x0000. See the following figure.

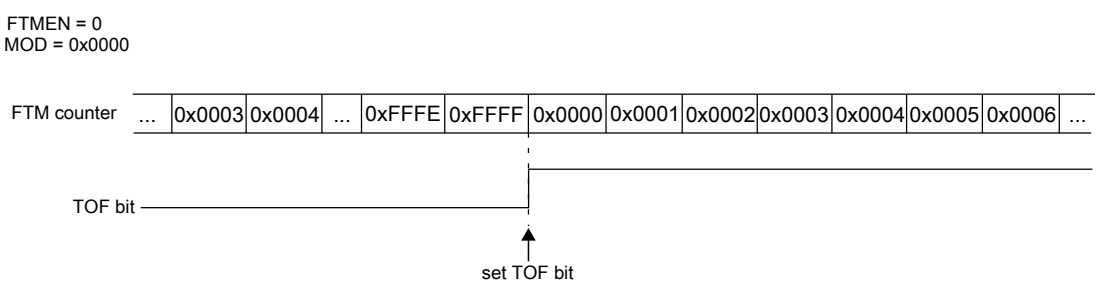

Figure 12-12. Example when the FTM counter is free running

The FTM counter is also a free running counter when:

- FTMEN = 1

- QUADEN = 0
- CPWMS = 0
- CNTIN = 0x0000, and
- MOD = 0xFFFF

12.2.4.3.4 Counter reset

Any one of the following cases resets the FTM counter to the value in the CNTIN register and the channels output to its initial value, except for channels in Output Compare mode.

- Any write to CNT.
- FTM counter synchronization.
- A channel in Input Capture mode with ICRST = 1 (FTM Counter Reset in Input Capture Mode).

12.2.4.3.5 When the TOF bit is set

The NUMTOF[4:0] bits define the number of times that the FTM counter overflow should occur before the TOF bit to be set. If NUMTOF[4:0] = 0x00, then the TOF bit is set at each FTM counter overflow.

Initialize the FTM counter, by writing to CNT, after writing to the NUMTOF[4:0] bits to avoid confusion about when the first counter overflow will occur.

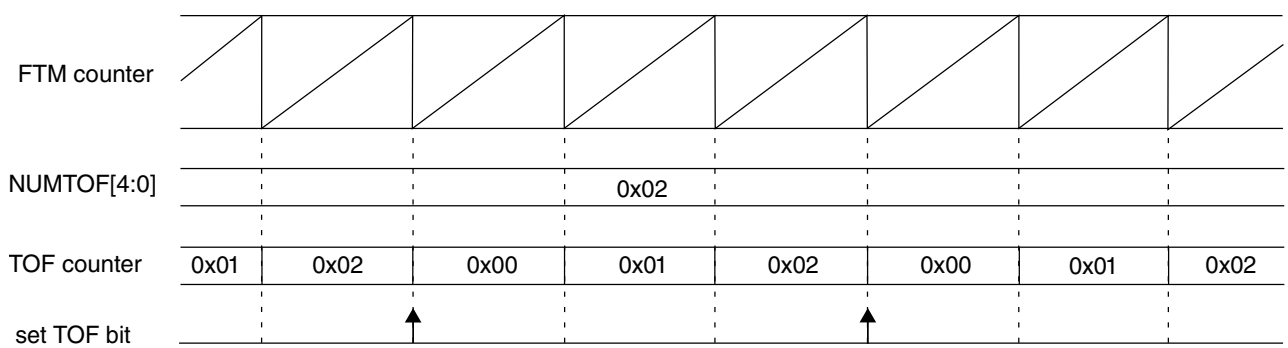

Figure 12-13. Periodic TOF when NUMTOF = 0x02

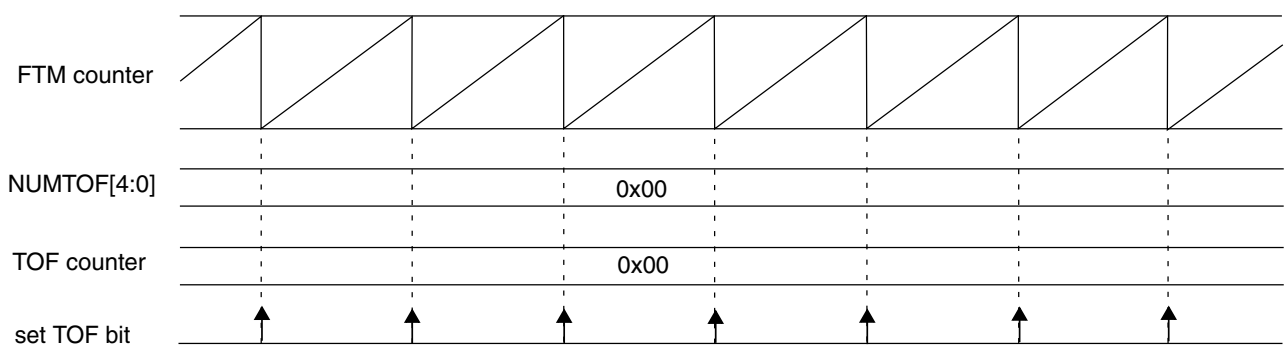

Figure 12-14. Periodic TOF when NUMTOF = 0x00

12.2.4.4 Input Capture mode

The Input Capture mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0
- MSnB:MSnA = 0:0, and
- ELSnB:ELSnA ≠ 0:0

When a selected edge occurs on the channel input, the current value of the FTM counter is captured into the CnV register, at the same time the CHnF bit is set and the channel interrupt is generated if enabled by CHnIE = 1. See the following figure.

When a channel is configured for input capture, the FTMxCHn pin is an edge-sensitive input. ELSnB:ELSnA control bits determine which edge, falling or rising, triggers input-capture event. Note that the maximum frequency for the channel input signal to be detected correctly is system clock divided by 4, which is required to meet Nyquist criteria for signal sampling.

Writes to the CnV register is ignored in Input Capture mode.

While in BDM, the input capture function works as configured. When a selected edge event occurs, the FTM counter value, which is frozen because of BDM, is captured into the CnV register and the CHnF bit is set.

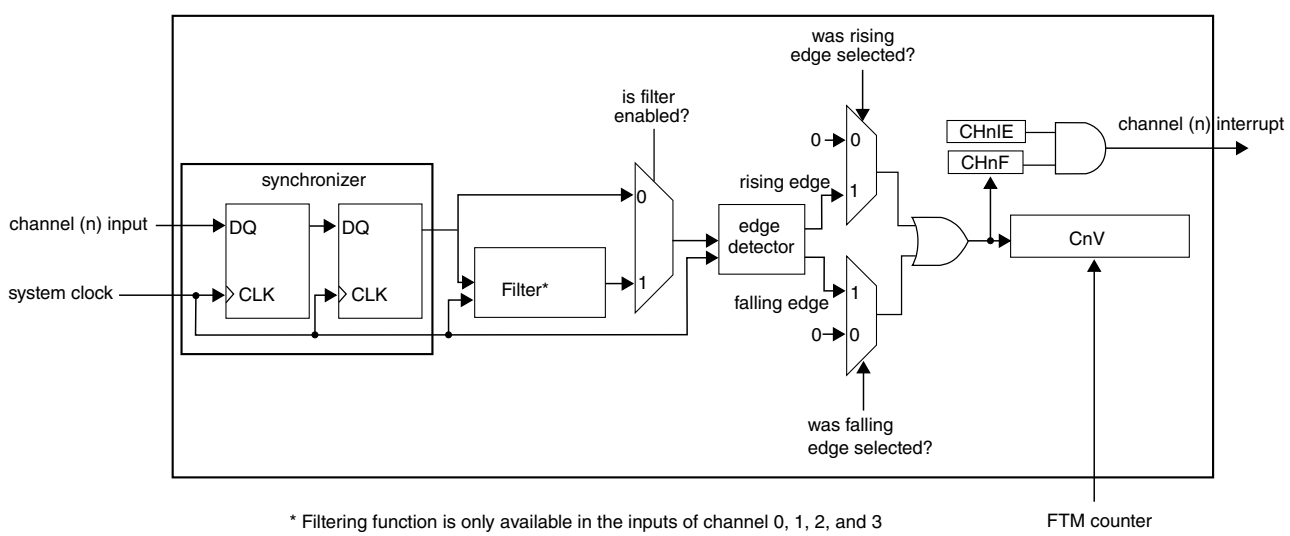

Figure 12-15. Input Capture mode

If the channel input does not have a filter enabled, then the input signal is always delayed 3 rising edges of the system clock, that is, two rising edges to the synchronizer plus one more rising edge to the edge detector. In other words, the CHnF bit is set on the third rising edge of the system clock after a valid edge occurs on the channel input.

12.2.4.4.1 Filter for Input Capture mode

The filter function is only available on channels 0, 1, 2, and 3.

First, the input signal is synchronized by the system clock. Following synchronization, the input signal enters the filter block. See the following figure.

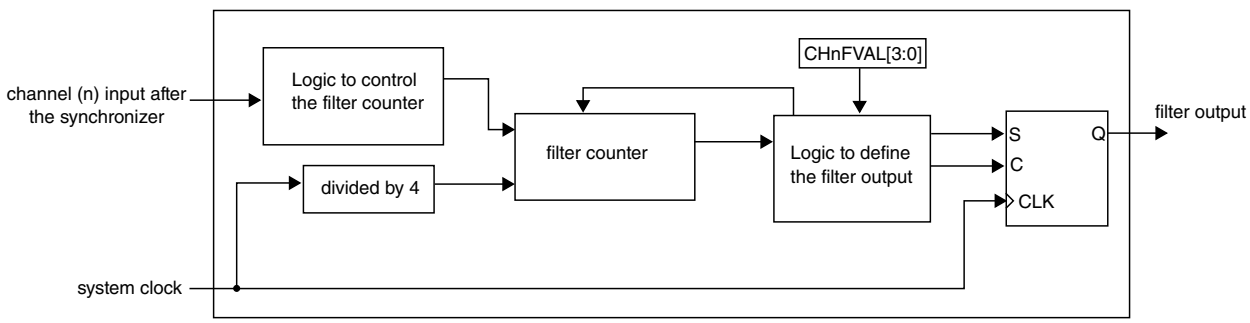

Figure 12-16. Channel input filter

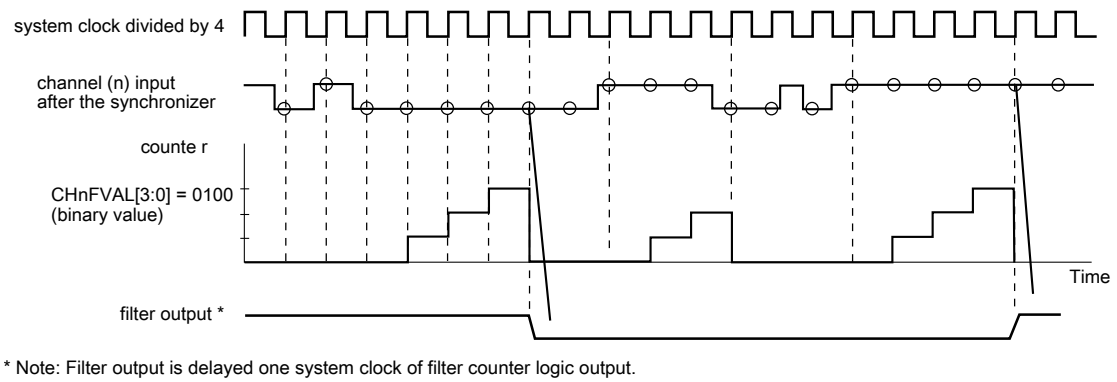
When there is a state change in the input signal, the counter is reset and starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to CHnFVAL[3:0], the state change of the input signal is validated. It is then transmitted as a pulse edge to the edge detector.

If the opposite edge appears on the input signal before it can be validated, the counter is reset. At the next input transition, the counter starts counting again. Any pulse that is shorter than the minimum value selected by CHnFVAL[3:0] (× 4 system clocks) is regarded as a glitch and is not passed on to the edge detector. A timing diagram of the input filter is shown in the following figure.

The filter function is disabled when CHnFVAL[3:0] bits are zero. In this case, the input signal is delayed 3 rising edges of the system clock. If (CHnFVAL[3:0] ≠ 0000), then the input signal is delayed by the minimum pulse width (CHnFVAL[3:0] × 4 system clocks) plus a further 4 rising edges of the system clock: two rising edges to the synchronizer, one rising edge to the filter output, plus one more to the edge detector. In other words, CHnF is set (4 + 4 × CHnFVAL[3:0]) system clock periods after a valid edge occurs on the channel input.

The clock for the counter in the channel input filter is the system clock divided by 4.



* Note: Filter output is delayed one system clock of filter counter logic output.

Figure 12-17. Channel input filter example

The figure below shows an example of input capture with filter enabled and the delay added by each part of the input capture logic. Note that the input signal is delayed only by the synchronizer and edge dector logic if the filter is disabled.

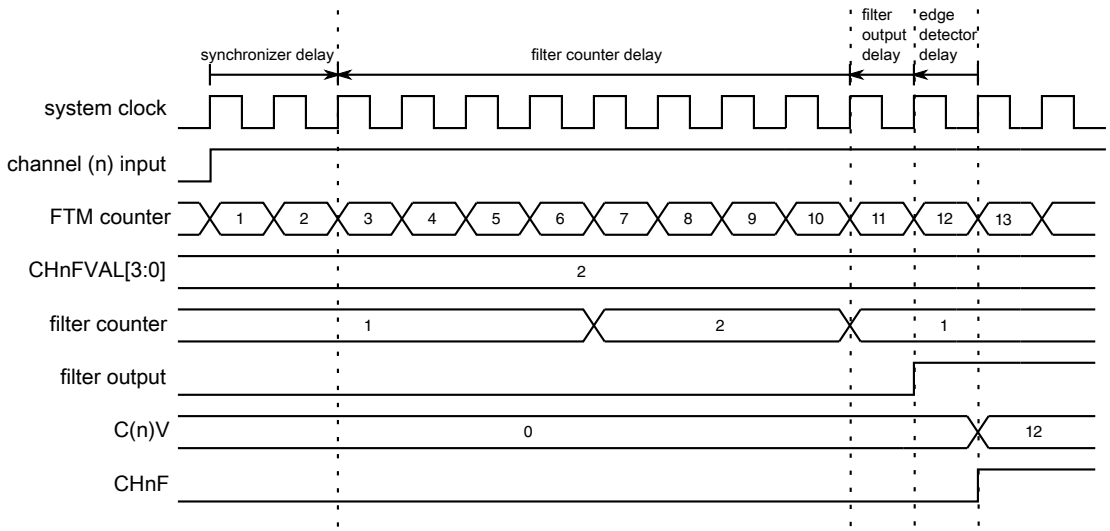


Figure 12-18. Input capture example

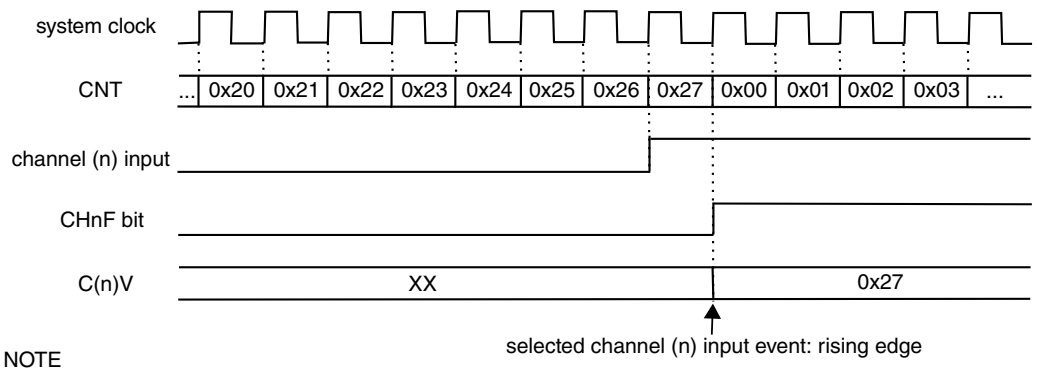
12.2.4.4.2 FTM Counter Reset in Input Capture Mode

If the channel (n) is in input capture mode and FTMx_CnSC [ICRST = 1], then when the selected input capture event occurs in the channel (n) input signal, the current value of the FTM counter is captured into the CnV register, the CHnF bit is set, the channel (n) interrupt is generated (if CHnIE = 1) and the FTM counter is reset to the CNTIN register value.

This allows the FTM to measure a period/pulse being applied to FTM_CHn (counts of the FTM clock input) without having to implement a subtraction calculation in software subsequent to the event occurring.

The figure below shows the FTM counter reset when the selected input capture event is detected in a channel in input capture mode with ICRST = 1.



NOTE
Channel (n) input after its synchronizer and filter
MOD = 0xFFFF
CNTIN = 0x0000
PS[2:0] = 3'b000
ICRST = 1'b1

Figure 12-19. Example of the Input Capture mode with ICRST = 1

NOTE

- It is expected that the ICRST bit be set only when the channel is in input capture mode.
- In this case, if the FTM counter is reset, then the prescaler counter (Prescaler) and the TOF counter (When the TOF bit is set) also are reset.

12.2.4.5 Output Compare mode

The Output Compare mode is selected when:

- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB:MSnA = 0:1

In Output Compare mode, the FTM can generate timed pulses with programmable position, polarity, duration, and frequency. When the counter matches the value in the CnV register of an output compare channel, the channel (n) output can be set, cleared, or toggled.

When a channel is initially configured to Toggle mode, the previous value of the channel output is held until the first output compare event occurs.

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV).

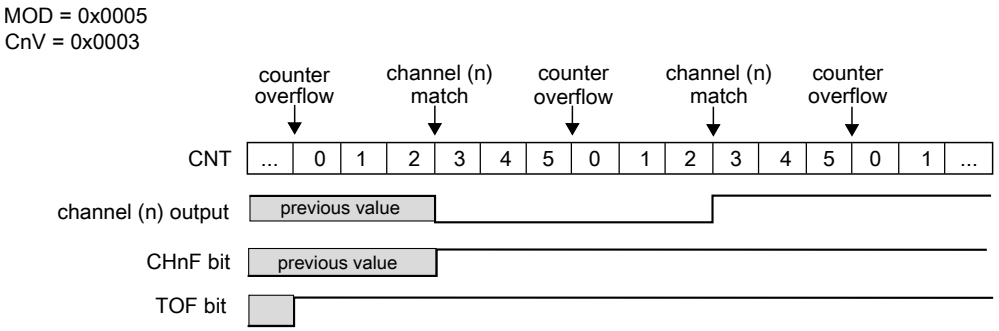


Figure 12-20. Example of the Output Compare mode when the match toggles the channel output

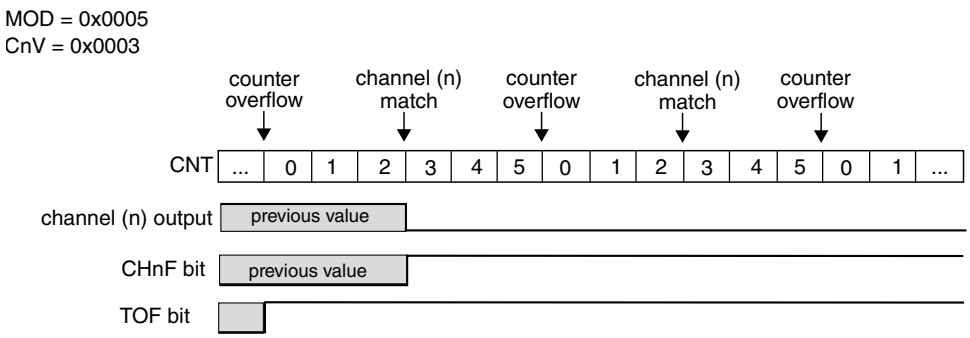

Figure 12-21. Example of the Output Compare mode when the match clears the channel output

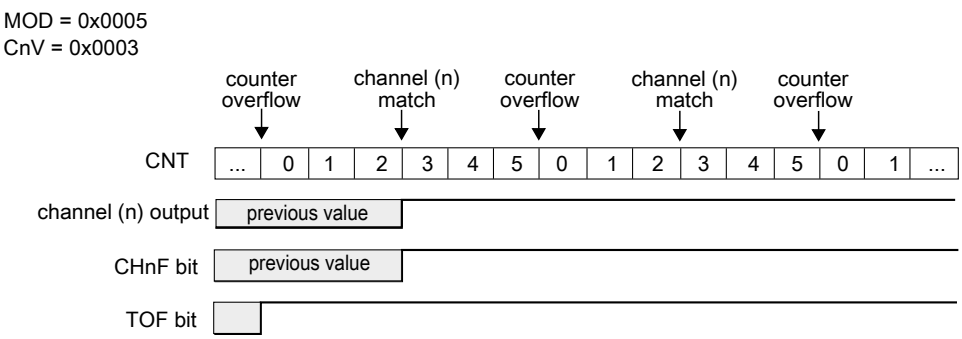

Figure 12-22. Example of the Output Compare mode when the match sets the channel output

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not modified and controlled by FTM.

12.2.4.6 Edge-Aligned PWM (EPWM) mode

The Edge-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0
- CPWMS = 0, and
- MSnB = 1

The EPWM period is determined by (MOD − CNTIN + 0x0001) and the pulse width (duty cycle) is determined by (CnV − CNTIN).

The CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1 at the channel (n) match (FTM counter = CnV), that is, at the end of the pulse width.

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within an FTM.

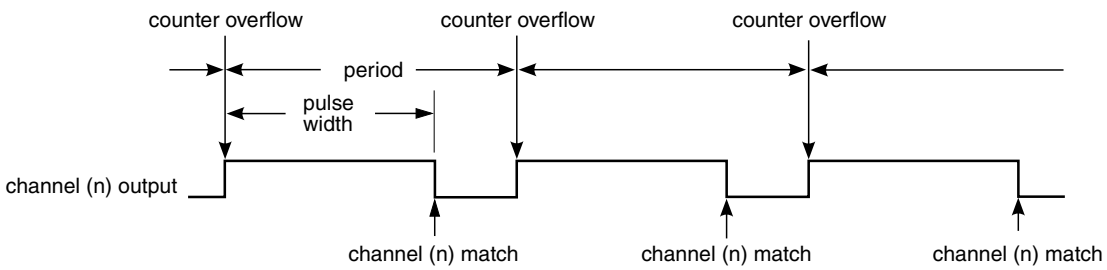

Figure 12-23. EPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated if CHnIE = 1, however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced low at the channel (n) match (FTM counter = CnV). See the following figure.

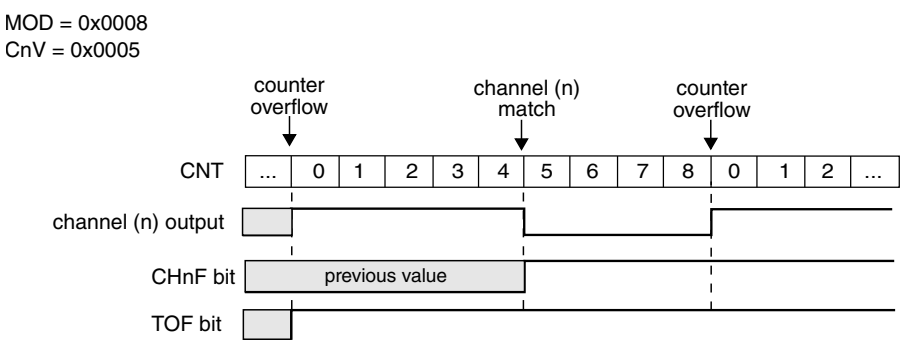

Figure 12-24. EPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the counter overflow when the CNTIN register value is loaded into the FTM counter, and it is forced high at the channel (n) match (FTM counter = CnV). See the following figure.

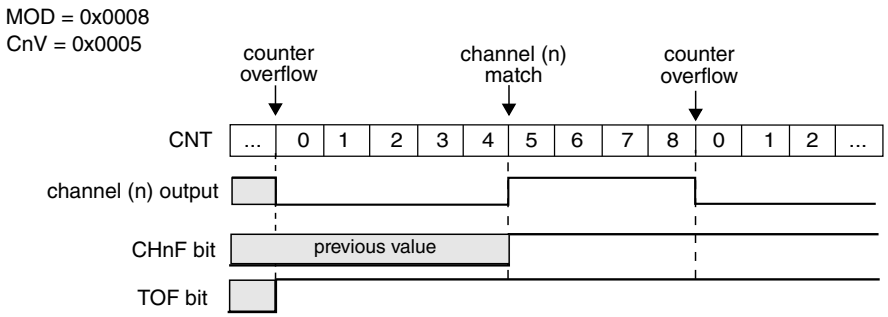

Figure 12-25. EPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000), then the channel (n) output is a 0% duty cycle EPWM signal and CHnF bit is not set even when there is the channel (n) match.

If (CnV > MOD), then the channel (n) output is a 100% duty cycle EPWM signal and CHnF bit is not set.Therefore, MOD must be less than 0xFFFF in order to get a 100% duty cycle EPWM signal.

Note

When CNTIN is different from zero the following EPWM signals can be generated:

- 0% EPWM signal if CnV = CNTIN,
- EPWM signal between 0% and 100% if CNTIN < CnV <= MOD,
- 100% EPWM signal when CNTIN > CnV or CnV > MOD.

12.2.4.7 Center-Aligned PWM (CPWM) mode

The Center-Aligned mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 0, and
- CPWMS = 1

The CPWM pulse width (duty cycle) is determined by 2 × (CnV − CNTIN) and the period is determined by 2 × (MOD − CNTIN). See the following figure. MOD must be kept in the range of 0x0001 to 0x7FFF because values outside this range can produce ambiguous results.

In the CPWM mode, the FTM counter counts up until it reaches MOD and then counts down until it reaches CNTIN.

The CHnF bit is set and channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = CnV) when the FTM counting is down (at the begin of the pulse width) and when the FTM counting is up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are aligned with the value of CNTIN.

The other channel modes are not compatible with the up-down counter (CPWMS = 1). Therefore, all FTM channels must be used in CPWM mode when (CPWMS = 1).

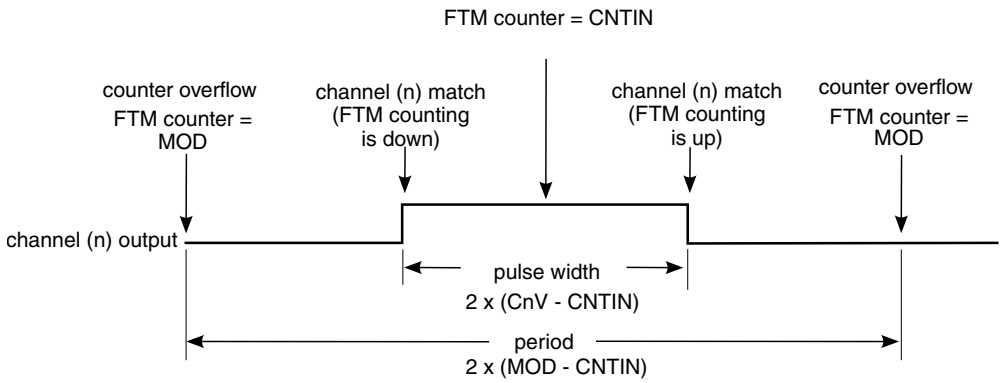

Figure 12-26. CPWM period and pulse width with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = 0:0) when the FTM counter reaches the value in the CnV register, the CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1), however the channel (n) output is not controlled by FTM.

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced high at the channel (n) match (FTM counter = CnV) when counting down, and it is forced low at the channel (n) match when counting up. See the following figure.

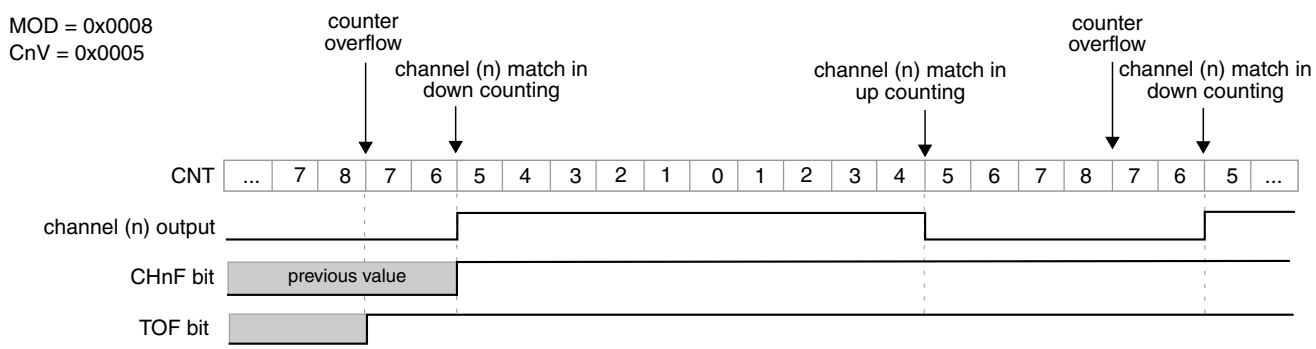

Figure 12-27. CPWM signal with ELSnB:ELSnA = 1:0

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced low at the channel (n) match (FTM counter = CnV) when counting down, and it is forced high at the channel (n) match when counting up. See the following figure.

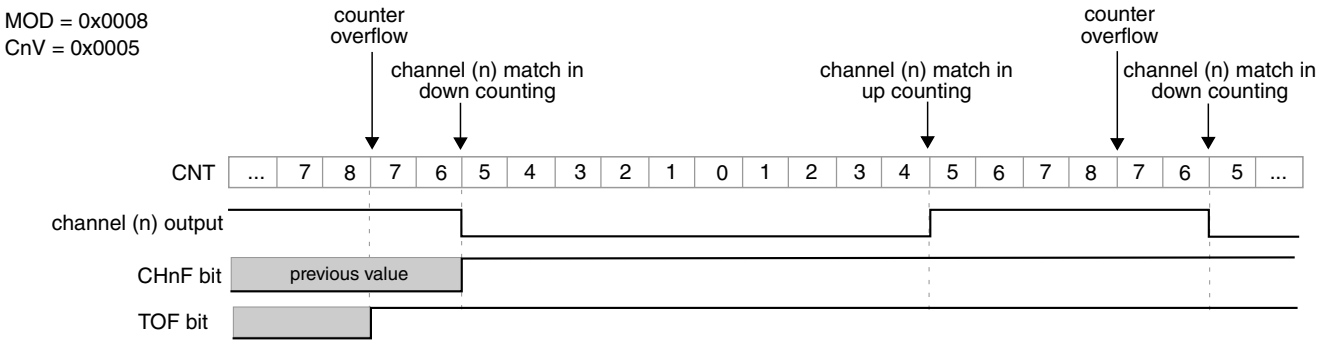

Figure 12-28. CPWM signal with ELSnB:ELSnA = X:1

If (CnV = 0x0000) or CnV is a negative value, that is (CnV[15] = 1), then the channel (n) output is a 0% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match.

If CnV is a positive value, that is (CnV[15] = 0), (CnV ≥ MOD), and (MOD ≠ 0x0000), then the channel (n) output is a 100% duty cycle CPWM signal and CHnF bit is not set even when there is the channel (n) match. This implies that the usable range of periods set by MOD is 0x0001 through 0x7FFE, 0x7FFF if you do not need to generate a 100% duty cycle CPWM signal. This is not a significant limitation because the resulting period is much longer than required for normal applications.

The CPWM mode must not be used when the FTM counter is a free running counter.

12.2.4.8 Combine mode

The Combine mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMBINE = 1, and
- CPWMS = 0

In Combine mode, an even channel (n) and adjacent odd channel (n+1) are combined to generate a PWM signal in the channel (n) output.

In the Combine mode, the PWM period is determined by (MOD − CNTIN + 0x0001) and the PWM pulse width (duty cycle) is determined by (|C(n+1)V − C(n)V|).

The CHnF bit is set and the channel (n) interrupt is generated (if CHnIE = 1) at the channel (n) match (FTM counter = C(n)V). The CH(n+1)F bit is set and the channel (n +1) interrupt is generated, if CH(n+1)IE = 1, at the channel (n+1) match (FTM counter = C(n+1)V).

If (ELSnB:ELSnA = 1:0), then the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n +1)V). It is forced high at the channel (n) match (FTM counter = C(n)V). See the following figure.

If (ELSnB:ELSnA = X:1), then the channel (n) output is forced high at the beginning of the period (FTM counter = CNTIN) and at the channel (n+1) match (FTM counter = C(n +1)V). It is forced low at the channel (n) match (FTM counter = C(n)V). See the following figure.

In Combine mode, the ELS(n+1)B and ELS(n+1)A bits are not used in the generation of the channels (n) and (n+1) output. However, if (ELSnB:ELSnA = 0:0) then the channel (n) output is not controlled by FTM, and if (ELS(n+1)B:ELS(n+1)A = 0:0) then the channel (n+1) output is not controlled by FTM.

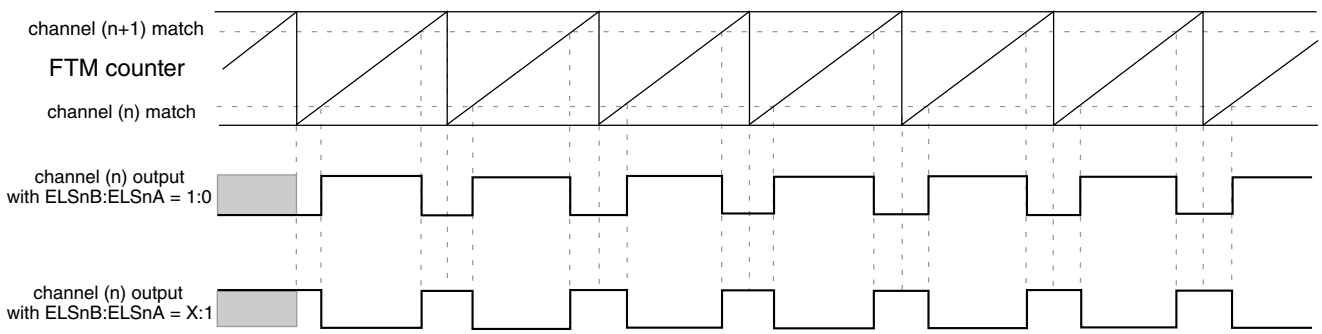

Figure 12-29. Combine mode

The following figures illustrate the PWM signals generation using Combine mode.

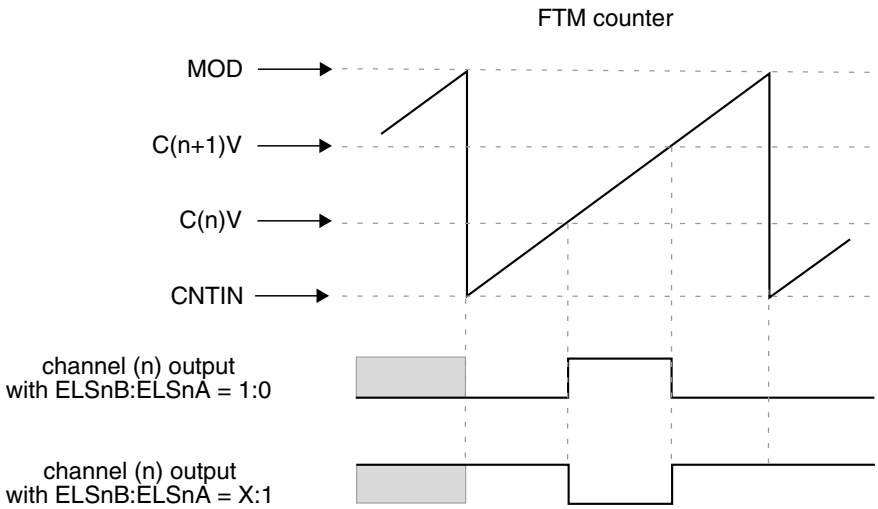

Figure 12-30. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V < C(n+1)V)

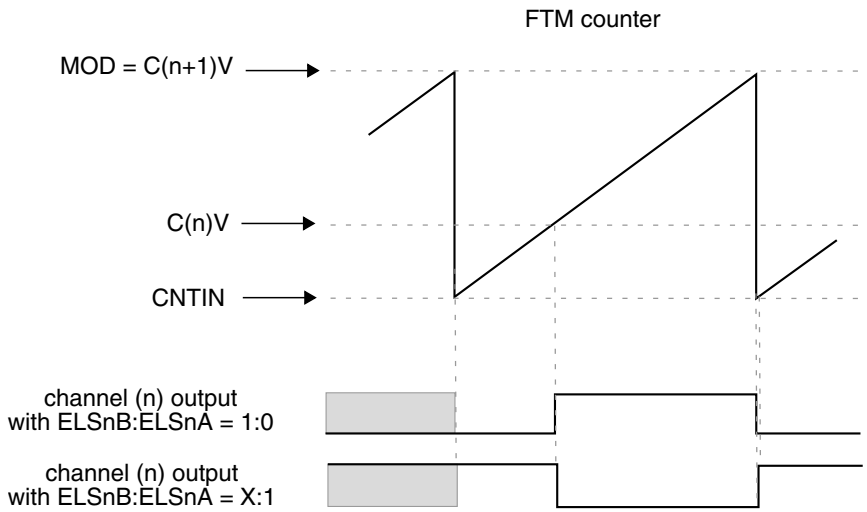

Figure 12-31. Channel (n) output if (CNTIN < C(n)V < MOD) and (C(n+1)V = MOD)

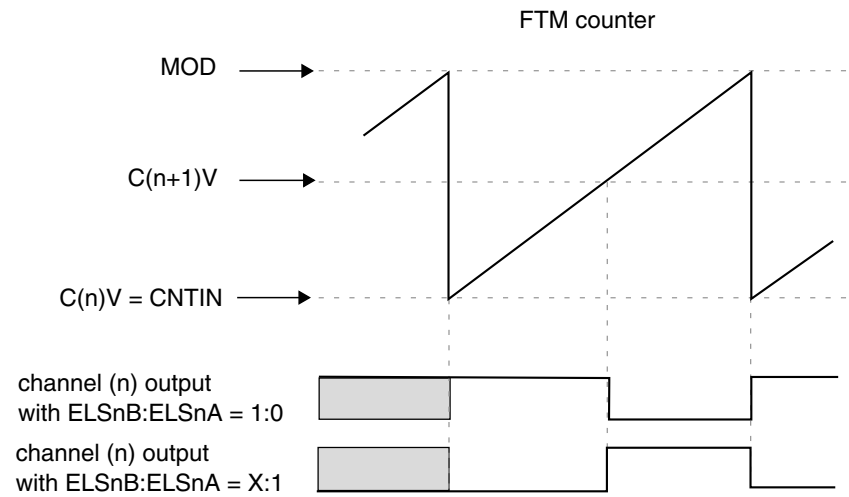

Figure 12-32. Channel (n) output if (C(n)V = CNTIN) and (CNTIN < C(n+1)V < MOD)

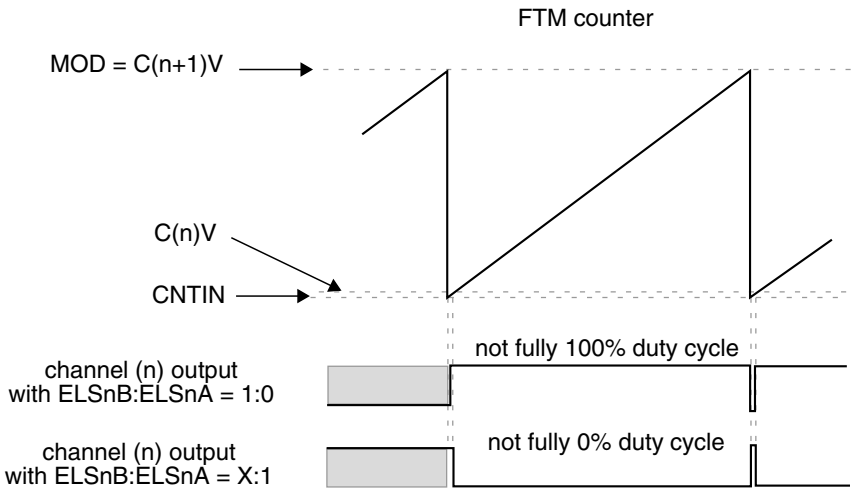

Figure 12-33. Channel (n) output if (CNTIN < C(n)V < MOD) and (C(n)V is Almost Equal to CNTIN) and (C(n+1)V = MOD)

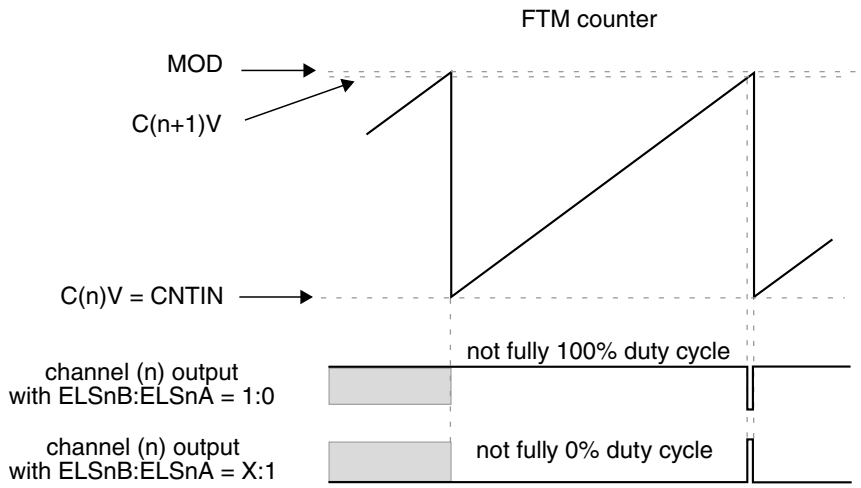

Figure 12-34. Channel (n) output if (C(n)V = CNTIN) and (CNTIN < C(n+1)V < MOD) and (C(n+1)V is Almost Equal to MOD)

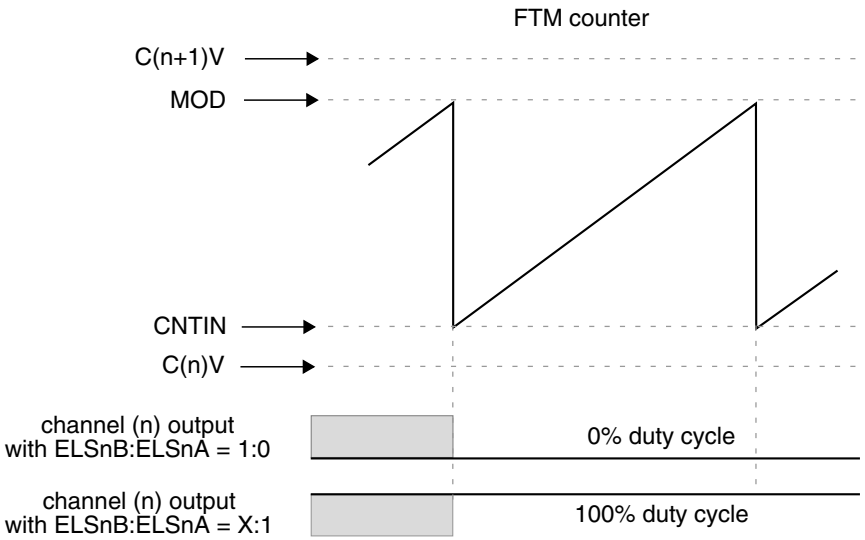

Figure 12-35. Channel (n) output if C(n)V and C(n+1)V are not between CNTIN and MOD

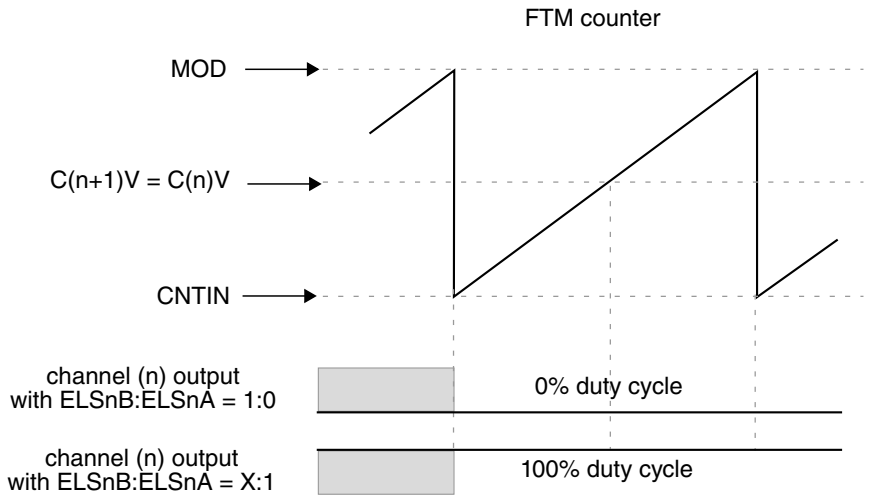

Figure 12-36. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V = C(n+1)V)

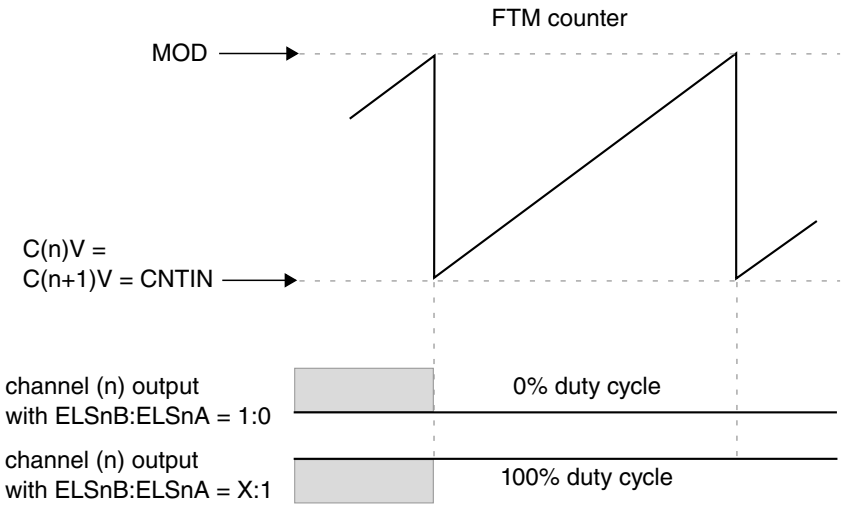

Figure 12-37. Channel (n) output if (C(n)V = C(n+1)V = CNTIN)

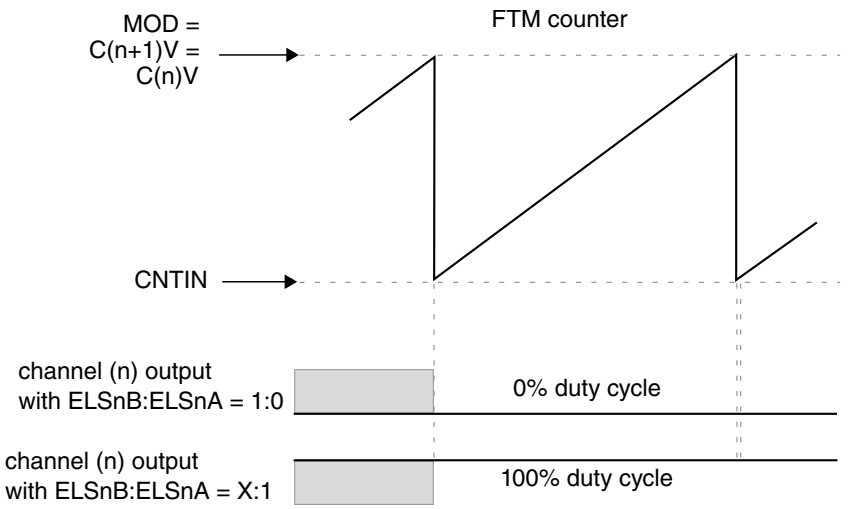

Figure 12-38. Channel (n) output if (C(n)V = C(n+1)V = MOD)

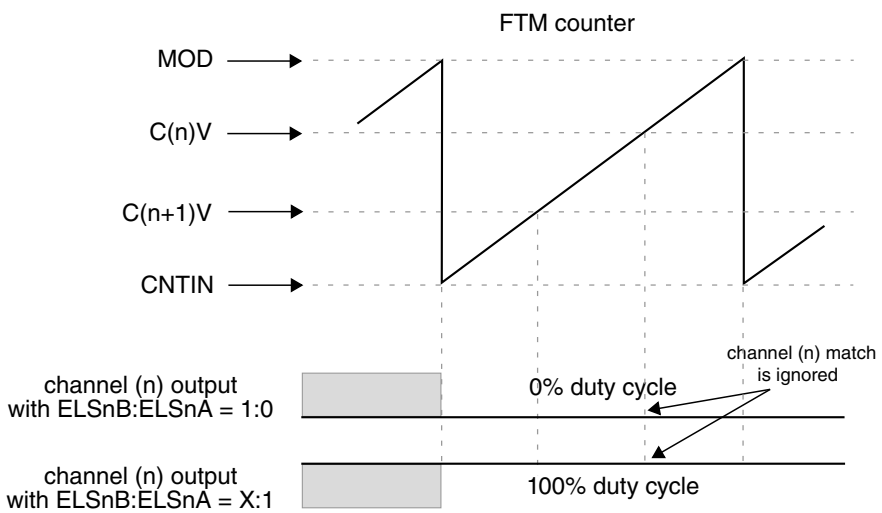

Figure 12-39. Channel (n) output if (CNTIN < C(n)V < MOD) and (CNTIN < C(n+1)V < MOD) and (C(n)V > C(n+1)V)

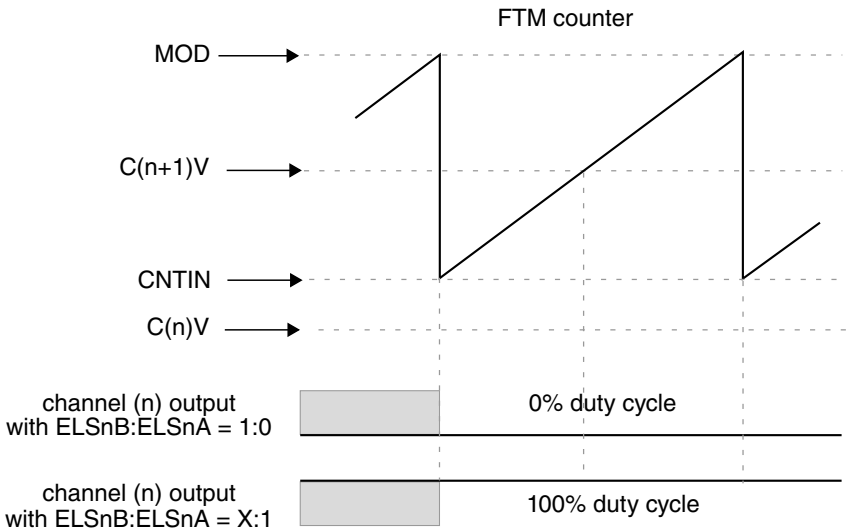

Figure 12-40. Channel (n) output if (C(n)V < CNTIN) and (CNTIN < C(n+1)V < MOD)

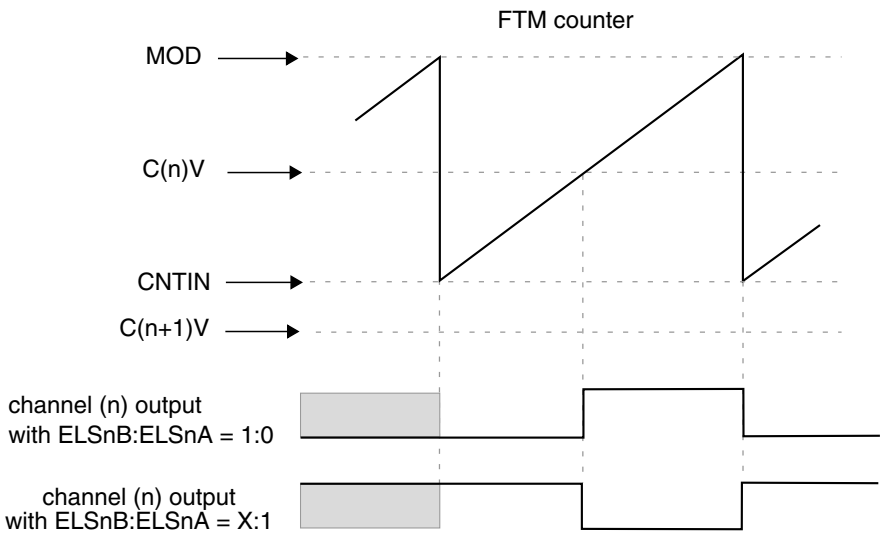

Figure 12-41. Channel (n) output if (C(n+1)V < CNTIN) and (CNTIN < C(n)V < MOD)

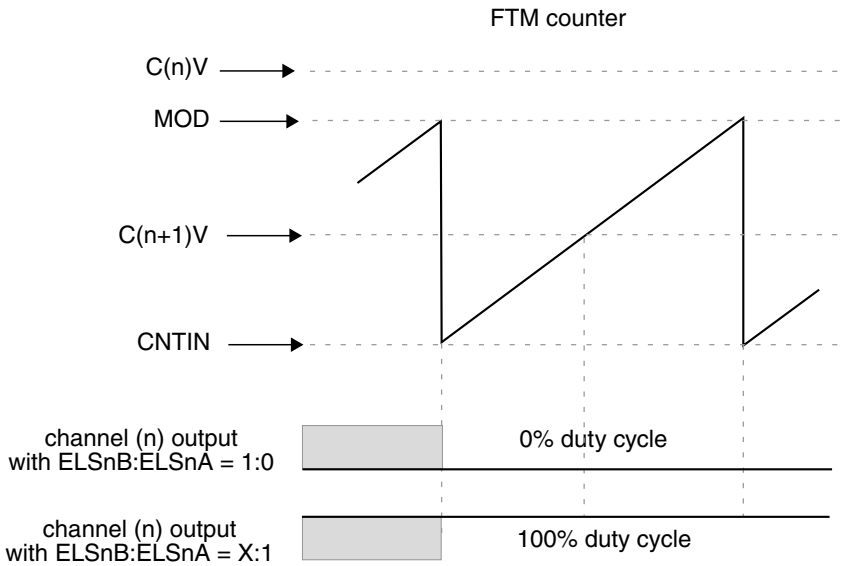

Figure 12-42. Channel (n) output if (C(n)V > MOD) and (CNTIN < C(n+1)V < MOD)

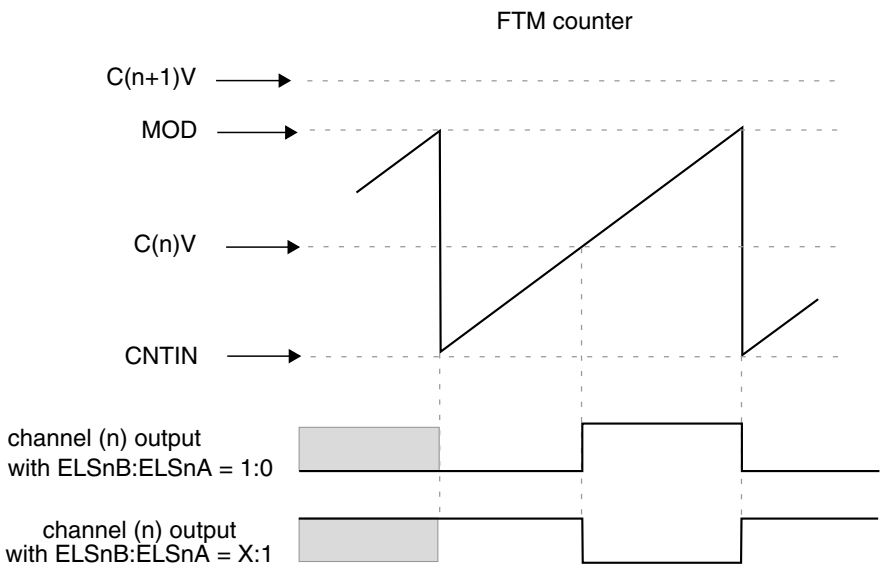

Figure 12-43. Channel (n) output if (C(n+1)V > MOD) and (CNTIN < C(n)V < MOD)

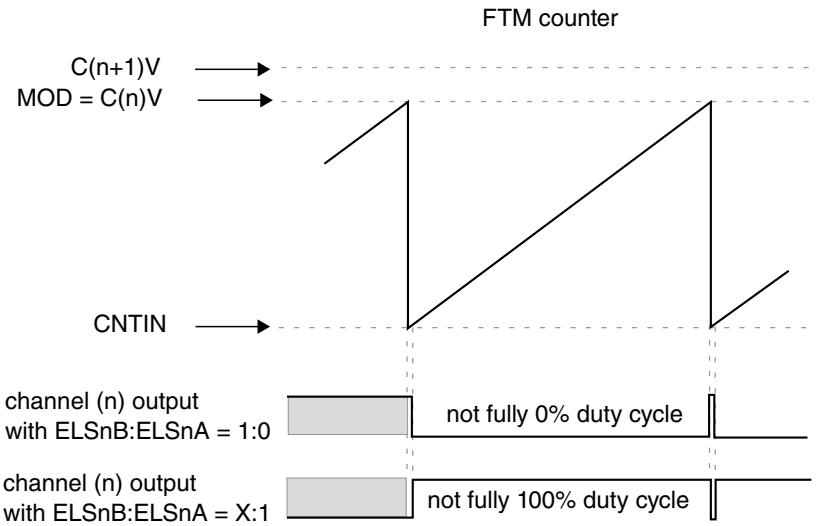

Figure 12-44. Channel (n) output if (C(n+1)V > MOD) and (CNTIN < C(n)V = MOD)

12.2.4.8.1 Asymmetrical PWM

In Combine mode, the control of the PWM signal first edge, when the channel (n) match occurs, that is, FTM counter = C(n)V, is independent of the control of the PWM signal second edge, when the channel (n+1) match occurs, that is, FTM counter = C(n+1)V. So, Combine mode allows the generation of asymmetrical PWM signals.

12.2.4.9 Complementary mode

The Complementary mode is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1

In Complementary mode, the channel (n+1) output is the inverse of the channel (n) output.

So, the channel (n+1) output is the same as the channel (n) output when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 0

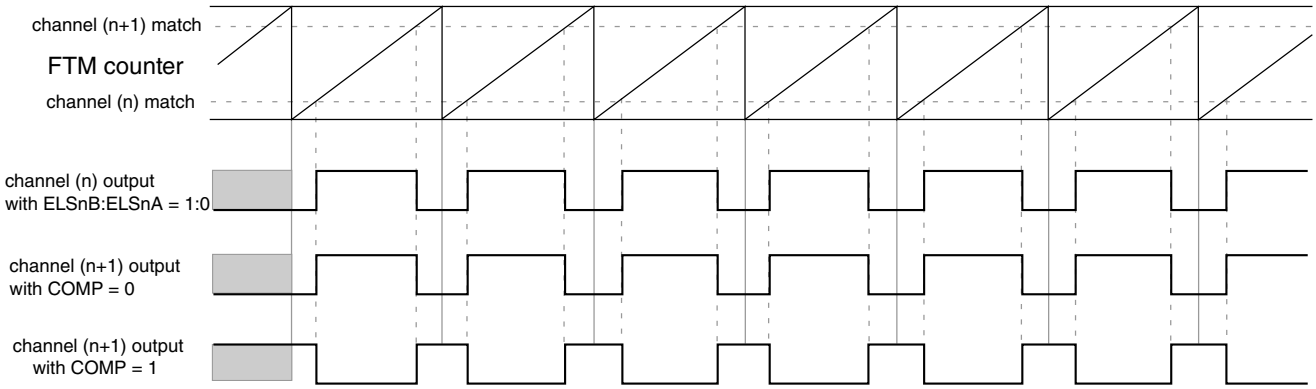

Figure 12-45. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = 1:0)

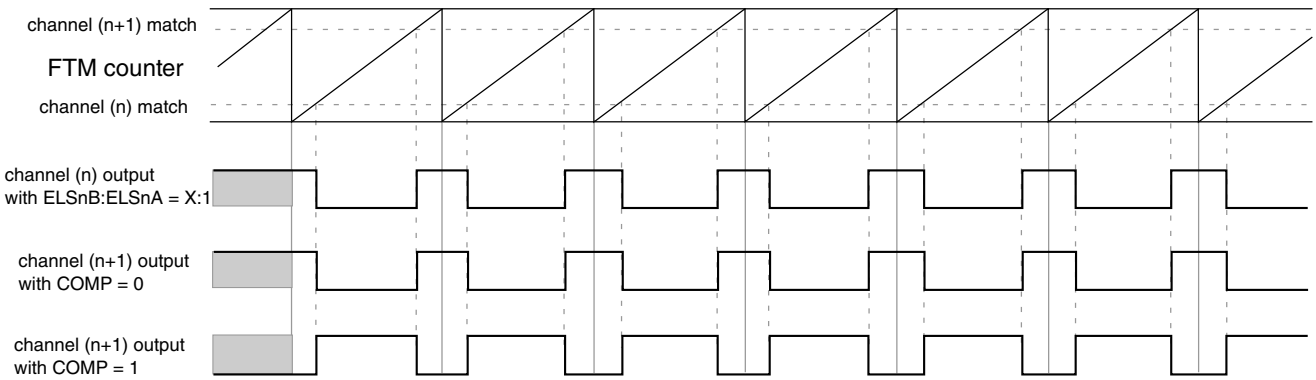

Figure 12-46. Channel (n+1) output in Complementary mode with (ELSnB:ELSnA = X:1)

NOTE

The complementary mode is not available in Output Compare mode.

12.2.4.10 Registers updated from write buffers

12.2.4.10.1 CNTIN register update

The following table describes when CNTIN register is updated:

Table 12-7. CNTIN register update

When	Then CNTIN register is updated
CLKS[1:0] = 0:0	When CNTIN register is written, independent of FTMEN bit.
• FTMEN = 0, or • CNTINC = 0	At the next system clock after CNTIN was written.
• FTMEN = 1, • SYNCMODE = 1, and • CNTINC = 1	By the CNTIN register synchronization.

12.2.4.10.2 MOD register update

The following table describes when MOD register is updated:

Table 12-8. MOD register update

When	Then MOD register is updated
CLKS[1:0] = 0:0	When MOD register is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the CPWMS bit, that is: • If the selected mode is not CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM then MOD register is updated after MOD register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	By the MOD register synchronization.

12.2.4.10.3 CnV register update

The following table describes when CnV register is updated:

Table 12-9. CnV register update

When	Then CnV register is updated
CLKS[1:0] = 0:0	When CnV register is written, independent of FTMEN bit.
• CLKS[1:0] ≠ 0:0, and • FTMEN = 0	According to the selected mode, that is: • If the selected mode is Output Compare, then CnV register is updated on the next FTM counter change, end of the prescaler counting, after CnV register was written. • If the selected mode is EPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to CNTIN. If the FTM counter is at free-running counter mode then this update occurs when the FTM counter changes from 0xFFFF to 0x0000. • If the selected mode is CPWM, then CnV register is updated after CnV register was written and the FTM counter changes from MOD to (MOD – 0x0001).
• CLKS[1:0] ≠ 0:0, and • FTMEN = 1	According to the selected mode, that is: • If the selected mode is output compare then CnV register is updated according to the SYNCEN bit. If (SYNCEN = 0) then CnV register is updated after CnV register was written at the next change of the FTM counter, the end of the prescaler counting. If (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization. • If the selected mode is not output compare and (SYNCEN = 1) then CnV register is updated by the C(n)V and C(n+1)V register synchronization.

12.2.4.11 PWM synchronization

The PWM synchronization provides an opportunity to update the MOD, CNTIN, CnV, OUTMASK, INVCTRL and SWOCTRL registers with their buffered value and force the FTM counter to the CNTIN register value.

Note

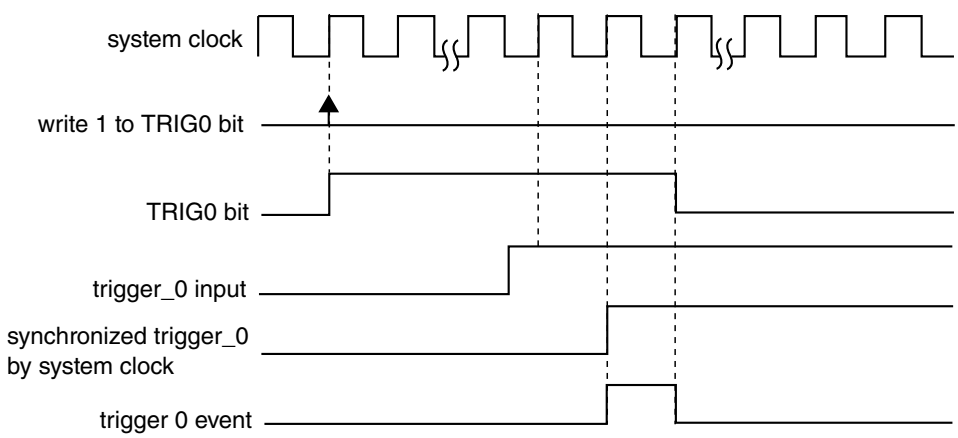
The legacy PWM synchronization (SYNCMODE = 0) is a subset of the enhanced PWM synchronization (SYNCMODE = 1). Thus, only the enhanced PWM synchronization must be used.

12.2.4.11.1 Hardware trigger

Three hardware trigger signal inputs of the FTM module are enabled when TRIGn = 1, where n = 0, 1 or 2 corresponding to each one of the input signals, respectively. The hardware trigger input n is synchronized by the system clock. The PWM synchronization with hardware trigger is initiated when a rising edge is detected at the enabled hardware trigger inputs.

If (HWTRIGMODE = 0) then the TRIGn bit is cleared when 0 is written to it or when the trigger n event is detected.

In this case, if two or more hardware triggers are enabled (for example, TRIG0 and TRIG1 = 1) and only trigger 1 event occurs, then only TRIG1 bit is cleared. If a trigger n event occurs together with a write setting TRIGn bit, then the synchronization is initiated, but TRIGn bit remains set due to the write operation.



Note
All hardware trigger inputs have the same behavior.

Figure 12-47. Hardware trigger event with HWTRIGMODE = 0

If HWTRIGMODE = 1, then the TRIGn bit is only cleared when 0 is written to it.

NOTE

The HWTRIGMODE bit must be 1 only with enhanced PWM synchronization (SYNCMODE = 1).

12.2.4.11.2 Software trigger

A software trigger event occurs when 1 is written to the SYNC[SWSYNC] bit. The SWSYNC bit is cleared when 0 is written to it or when the PWM synchronization, initiated by the software event, is completed.

If another software trigger event occurs (by writing another 1 to the SWSYNC bit) at the same time the PWM synchronization initiated by the previous software trigger event is ending, a new PWM synchronization is started and the SWSYNC bit remains equal to 1.

If SYNCMODE = 0 then the SWSYNC bit is also cleared by FTM according to PWMSYNC and REINIT bits. In this case if (PWMSYNC = 1) or (PWMSYNC = 0 and REINIT = 0) then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see Boundary cycle and loading points and the following figure. If (PWMSYNC = 0) and (REINIT = 1) then SWSYNC bit is cleared when the software trigger event occurs.

If SYNCMODE = 1 then the SWSYNC bit is also cleared by FTM according to the SWRSTCNT bit. If SWRSTCNT = 0 then SWSYNC bit is cleared at the next selected loading point after that the software trigger event occurred; see the following figure. If SWRSTCNT = 1 then SWSYNC bit is cleared when the software trigger event occurs.

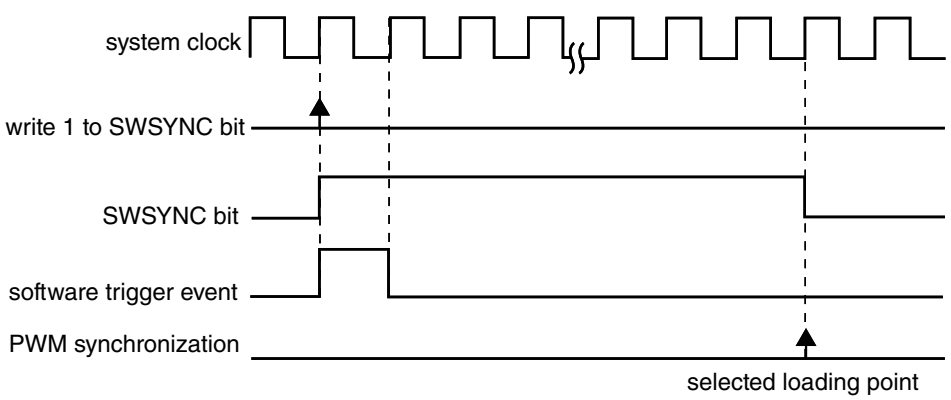


Figure 12-48. Software trigger event

12.2.4.11.3 Boundary cycle and loading points

The boundary cycle definition is important for the loading points for the registers MOD, CNTIN, and C(n)V.

In Up counting mode, the boundary cycle is defined as when the counter wraps to its initial value (CNTIN). If in Up-down counting mode, then the boundary cycle is defined as when the counter turns from down to up counting and when from up to down counting.

The following figure shows the boundary cycles and the loading points for the registers. In the Up Counting mode, the loading points are enabled if one of CNTMIN or CTMAX bits are 1. In the Up-Down Counting mode, the loading points are selected by CNTMIN and CNTMAX bits, as indicated in the figure. These loading points are safe places for register updates thus allowing a smooth transitions in PWM waveform generation.

For both counting modes, if neither CNTMIN nor CNTMAX are 1, then the boundary cycles are not used as loading points for registers updates. See the register synchronization descriptions in the following sections for details.

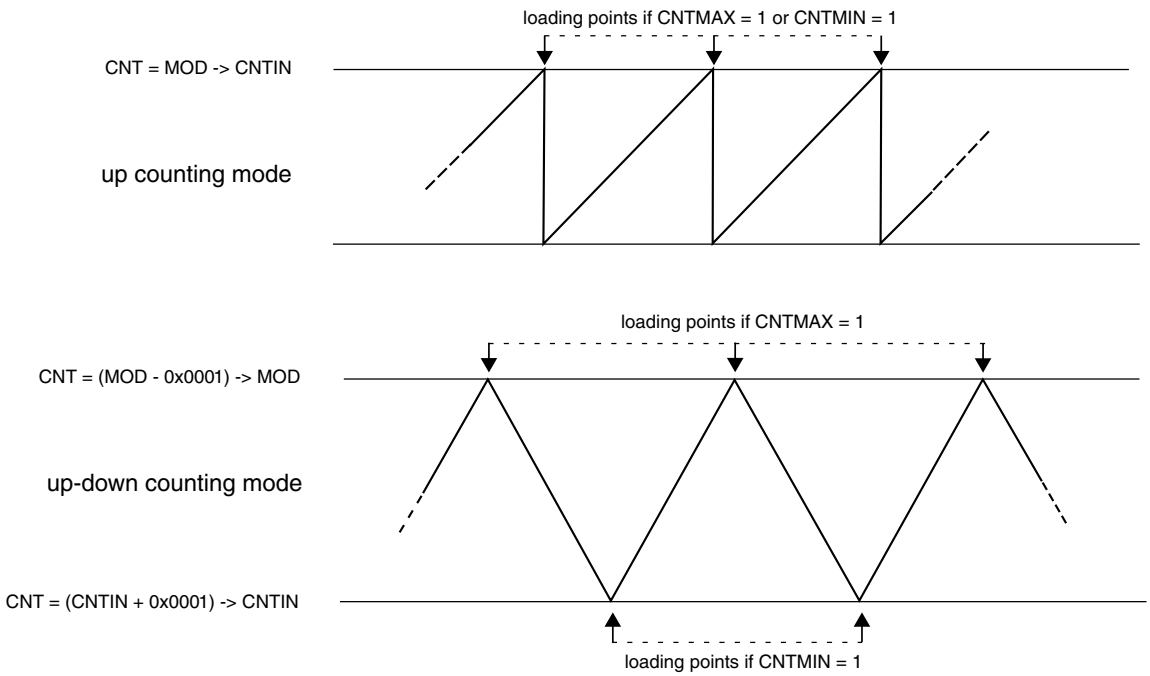

Figure 12-49. Boundary cycles and loading points

12.2.4.11.4 MOD register synchronization

The MOD register synchronization updates the MOD register with its buffer value. This synchronization is enabled if (FTMEN = 1).

The MOD register synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, it is expected that the MOD register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the MOD register synchronization depends on SWWRBUF, SWRSTCNT, HWWRBUF, and HWRSTCNT bits according to this flowchart:

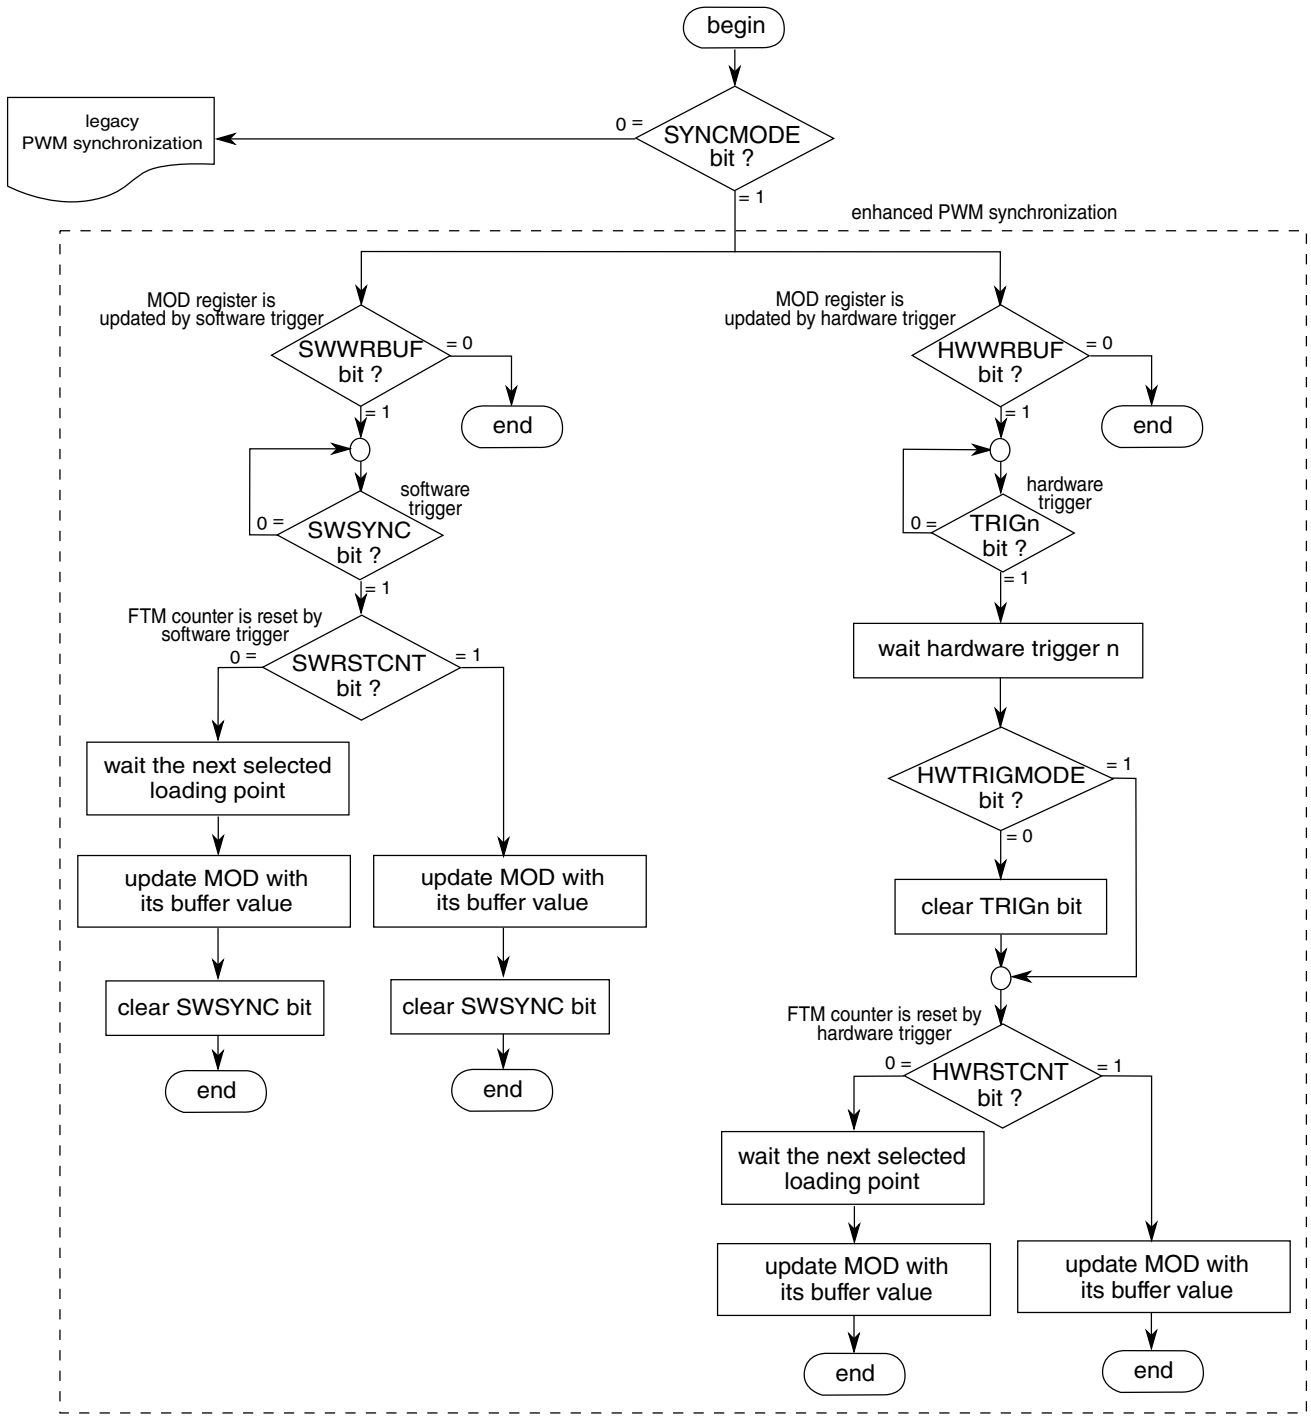

Figure 12-50. MOD register synchronization flowchart

In the case of legacy PWM synchronization, the MOD register synchronization depends on PWMSYNC and REINIT bits according to the following description.

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 0), then this synchronization is made on the next selected loading point after an enabled trigger event takes place. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the trigger enable bit (TRIGn) is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

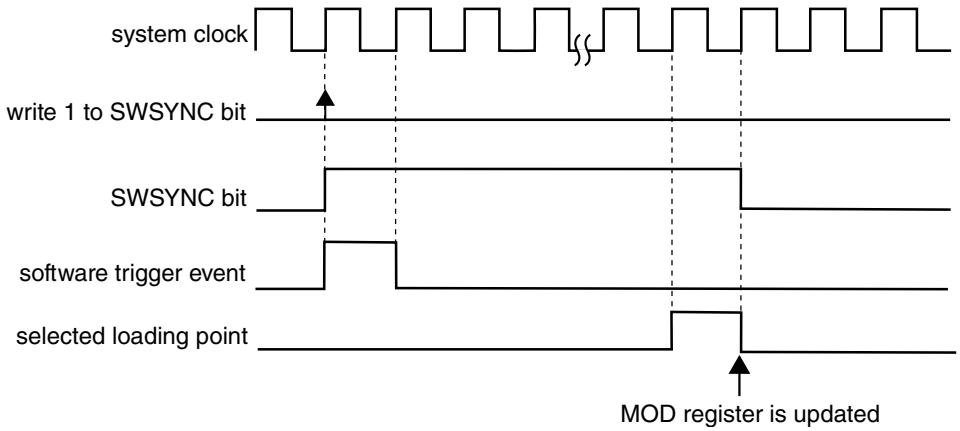

Figure 12-51. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 0), and software trigger was used

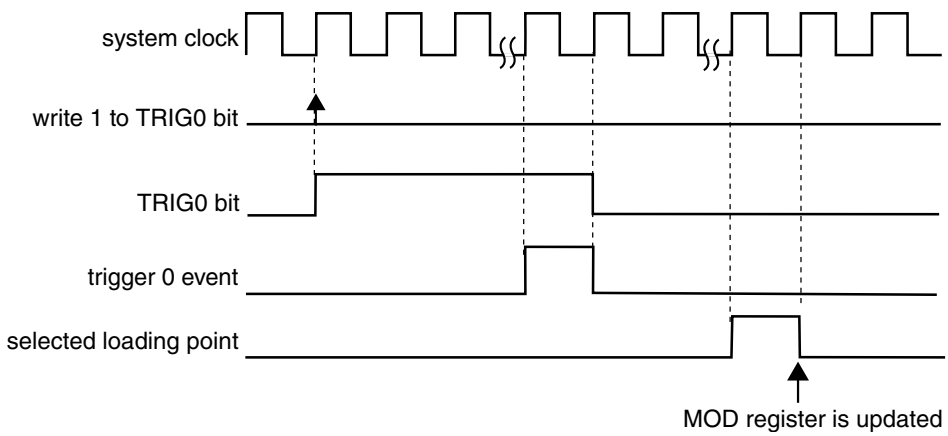

Figure 12-52. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 0), and a hardware trigger was used

If (SYNCMODE = 0), (PWMSYNC = 0), and (REINIT = 1), then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

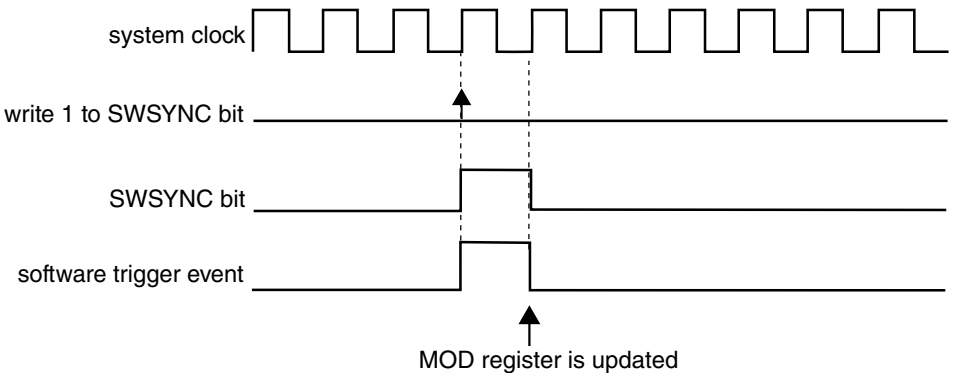

Figure 12-53. MOD synchronization with (SYNCMODE = 0), (PWMSYNC = 0), (REINIT = 1), and software trigger was used

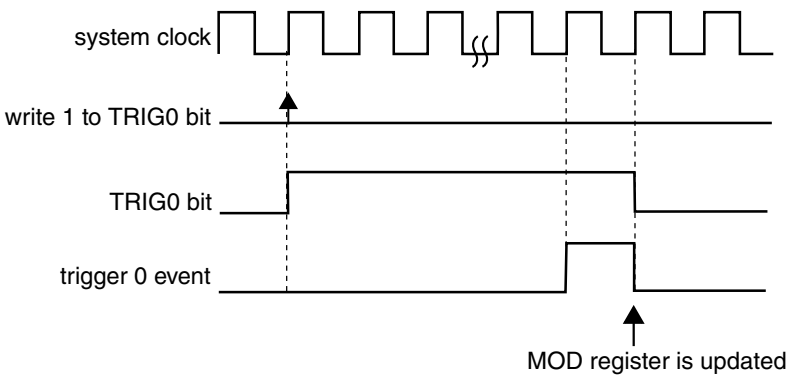

Figure 12-54. MOD synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (PWMSYNC = 0), (REINIT = 1), and a hardware trigger was used

If (SYNCMODE = 0) and (PWMSYNC = 1), then this synchronization is made on the next selected loading point after the software trigger event takes place. The SWSYNC bit is cleared on the next selected loading point:

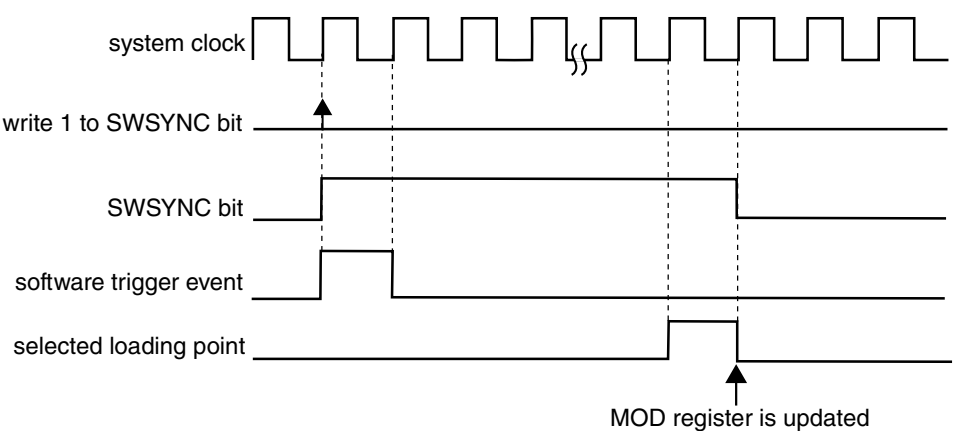

Figure 12-55. MOD synchronization with (SYNCMODE = 0) and (PWMSYNC = 1)

12.2.4.11.5 CNTIN register synchronization

The CNTIN register synchronization updates the CNTIN register with its buffer value.

This synchronization is enabled if (FTMEN = 1), (SYNCMODE = 1), and (CNTINC = 1). The CNTIN register synchronization can be done only by the enhanced PWM synchronization (SYNCMODE = 1). The synchronization mechanism is the same as the MOD register synchronization done by the enhanced PWM synchronization; see MOD register synchronization.

12.2.4.11.6 C(n)V and C(n+1)V register synchronization

The C(n)V and C(n+1)V registers synchronization updates the C(n)V and C(n+1)V registers with their buffer values.

This synchronization is enabled if (FTMEN = 1) and (SYNCEN = 1). The synchronization mechanism is the same as the MOD register synchronization. However, it is expected that the C(n)V and C(n+1)V registers be synchronized only by the enhanced PWM synchronization (SYNCMODE = 1).

12.2.4.11.7 OUTMASK register synchronization

The OUTMASK register synchronization updates the OUTMASK register with its buffer value.

The OUTMASK register can be updated at each rising edge of system clock (SYNCHOM = 0), by the enhanced PWM synchronization (SYNCHOM = 1 and SYNCMODE = 1) or by the legacy PWM synchronization (SYNCHOM = 1 and SYNCMODE = 0). However, it is expected that the OUTMASK register be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the OUTMASK register synchronization depends on SWOM and HWOM bits. See the following flowchart:

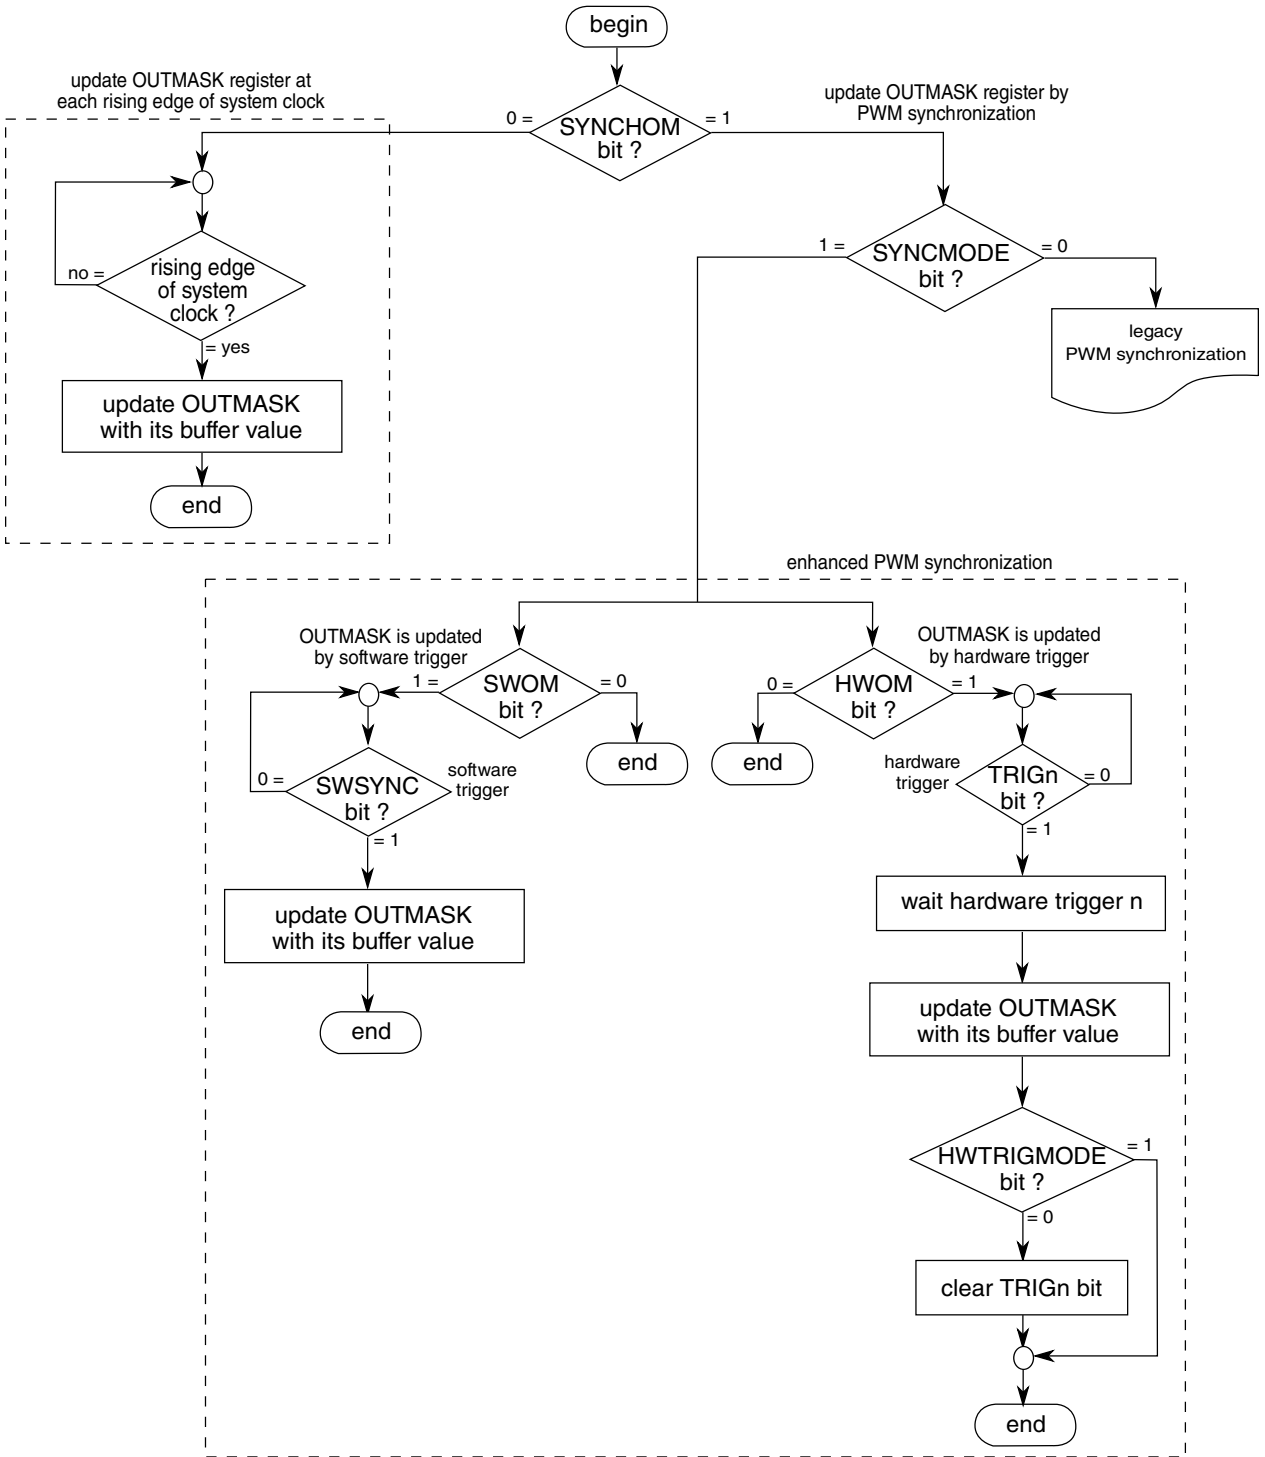

Figure 12-56. OUTMASK register synchronization flowchart

In the case of legacy PWM synchronization, the OUTMASK register synchronization depends on PWMSYNC bit according to the following description.

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 0), then this synchronization is done on the next enabled trigger event. If the trigger event was a software trigger, then the SWSYNC bit is cleared on the next selected loading point. If the trigger event was a hardware trigger, then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

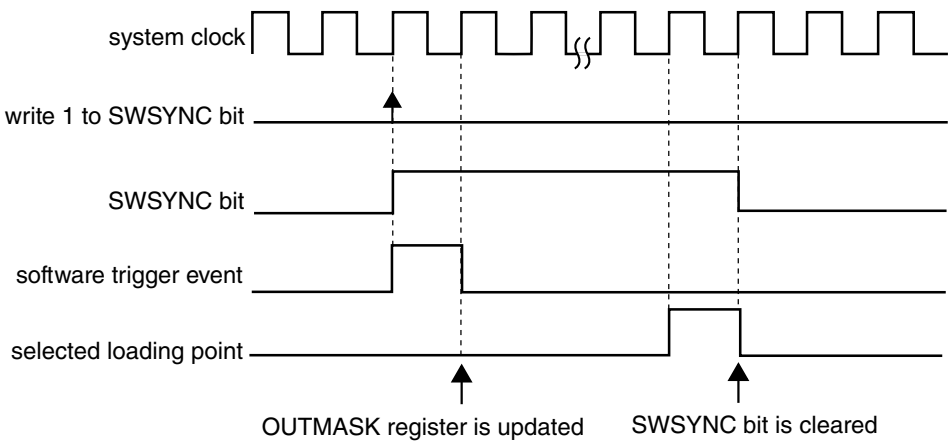

Figure 12-57. OUTMASK synchronization with (SYNCMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0) and software trigger was used

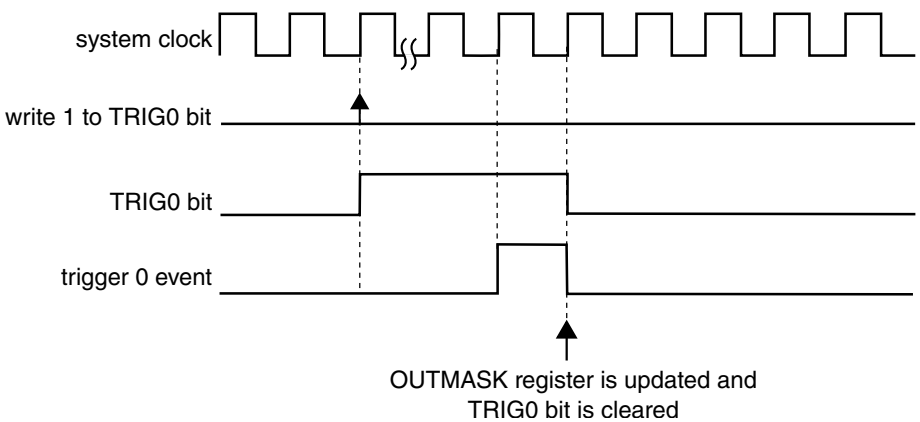

Figure 12-58. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (SYNCHOM = 1), and (PWMSYNC = 1), then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger. An example with a hardware trigger follows.

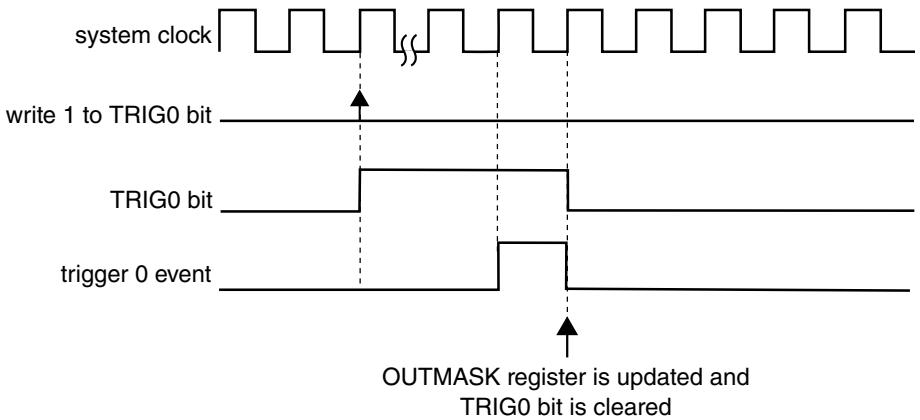

Figure 12-59. OUTMASK synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (SYNCHOM = 1), (PWMSYNC = 1), and a hardware trigger was used

12.2.4.11.8 INVCTRL register synchronization

The INVCTRL register synchronization updates the INVCTRL register with its buffer value.

The INVCTRL register can be updated at each rising edge of system clock (INVC = 0) or by the enhanced PWM synchronization (INVC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the INVCTRL register synchronization depends on SWINVC and HWINVC bits.

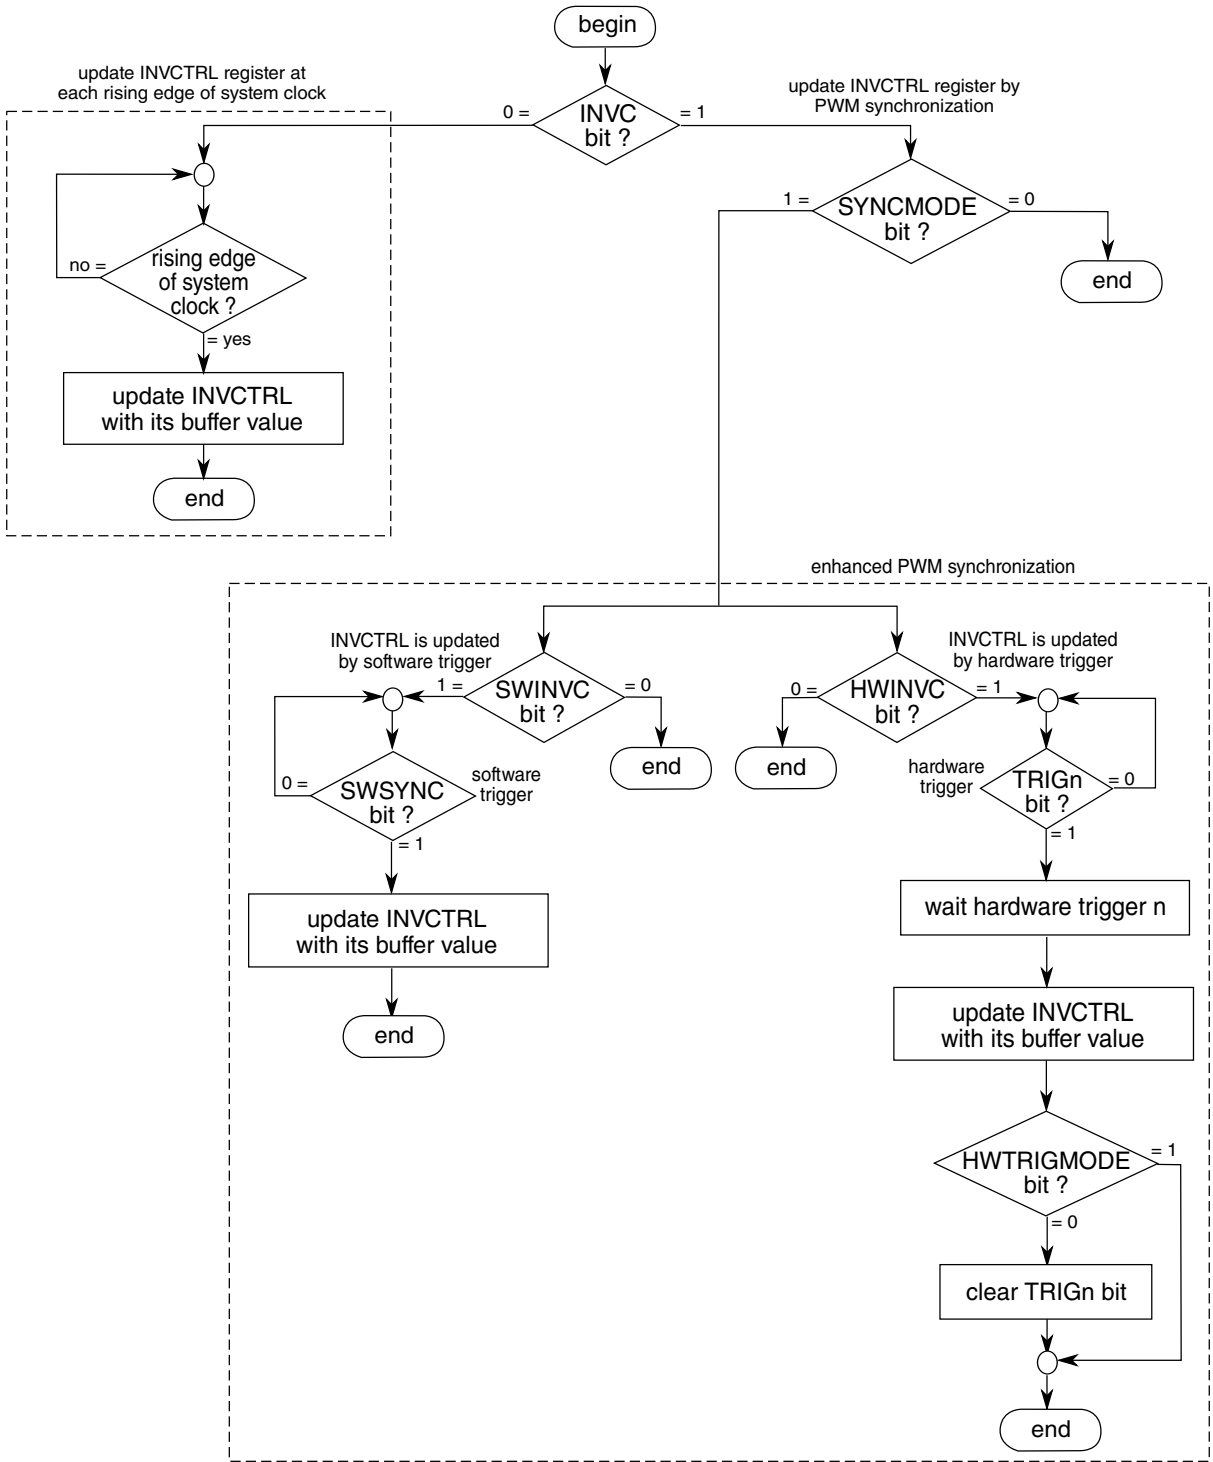

Figure 12-60. INVCTRL register synchronization flowchart

12.2.4.11.9 SWOCTRL register synchronization

The SWOCTRL register synchronization updates the SWOCTRL register with its buffer value.

The SWOCTRL register can be updated at each rising edge of system clock (SWOC = 0) or by the enhanced PWM synchronization (SWOC = 1 and SYNCMODE = 1) according to the following flowchart.

In the case of enhanced PWM synchronization, the SWOCTRL register synchronization depends on SWSOC and HWSOC bits.

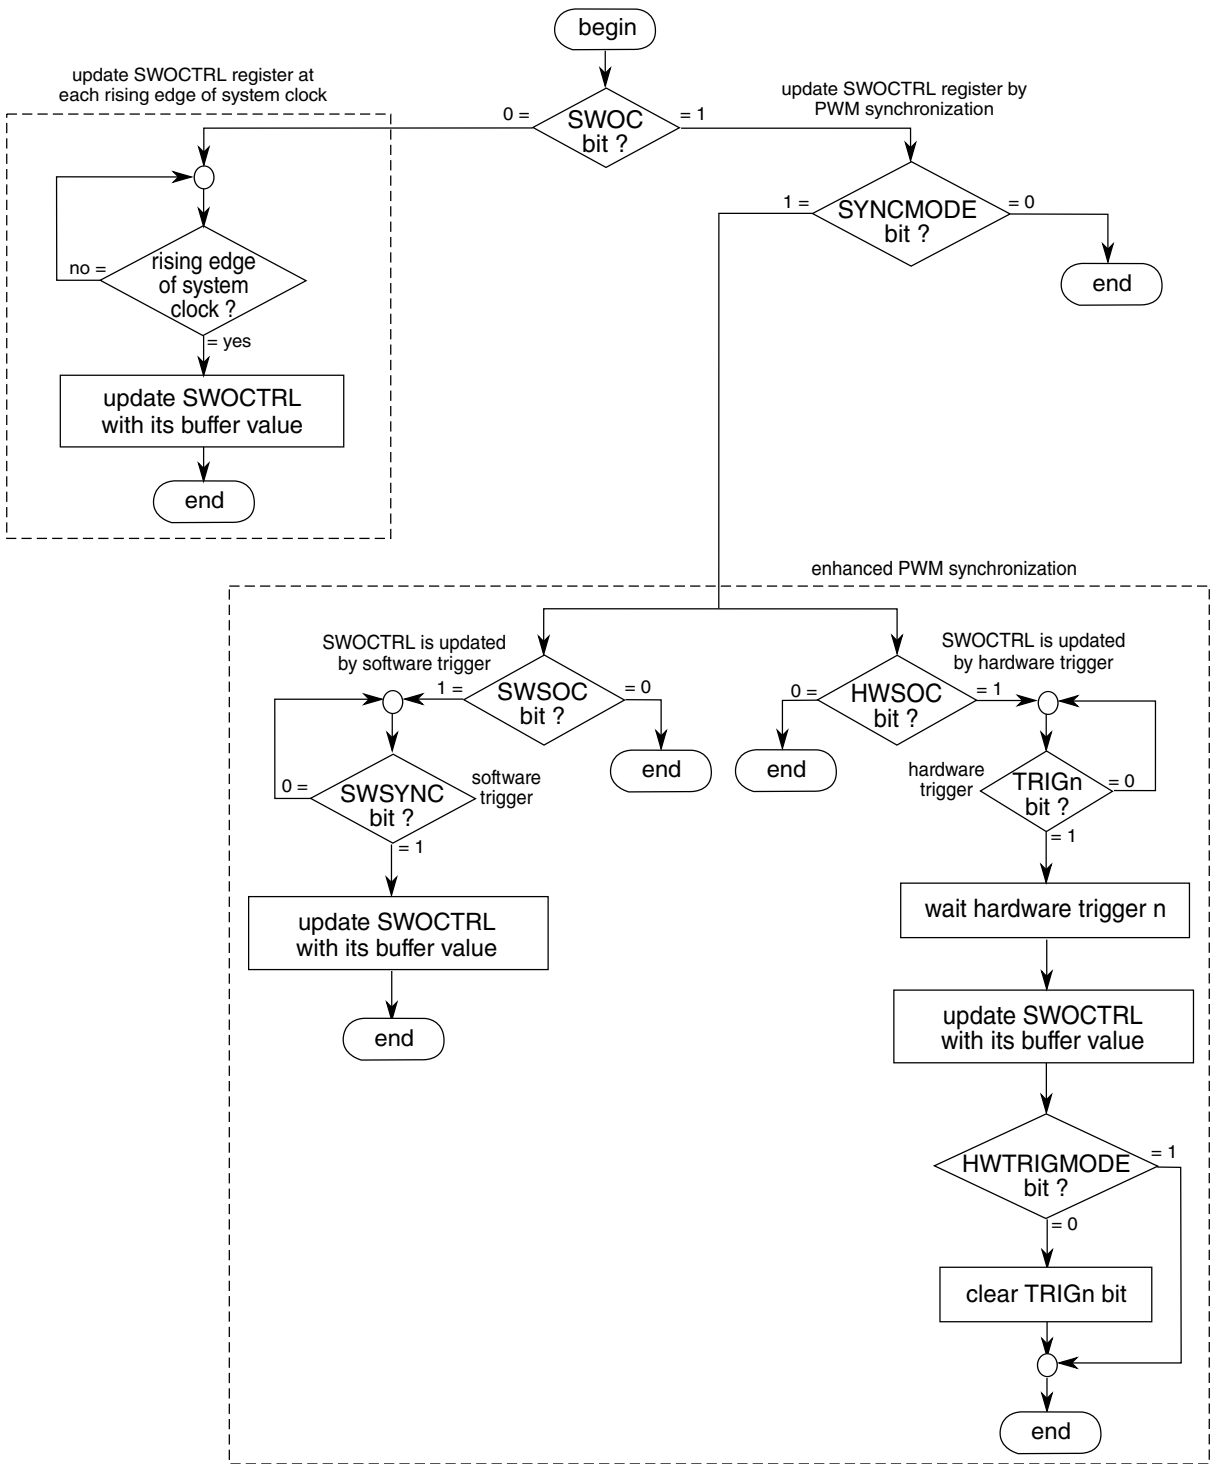

Figure 12-61. SWOCTRL register synchronization flowchart

12.2.4.11.10 FTM counter synchronization

The FTM counter synchronization is a mechanism that allows the FTM to restart the PWM generation at a certain point in the PWM period. The channels outputs are forced to their initial value, except for channels in Output Compare mode, and the FTM counter is forced to its initial counting value defined by CNTIN register.

The following figure shows the FTM counter synchronization. Note that after the synchronization event occurs, the channel (n) is set to its initial value and the channel (n +1) is not set to its initial value due to a specific timing of this figure in which the deadtime insertion prevents this channel output from transitioning to 1. If no deadtime insertion is selected, then the channel (n+1) transitions to logical value 1 immediately after the synchronization event occurs.

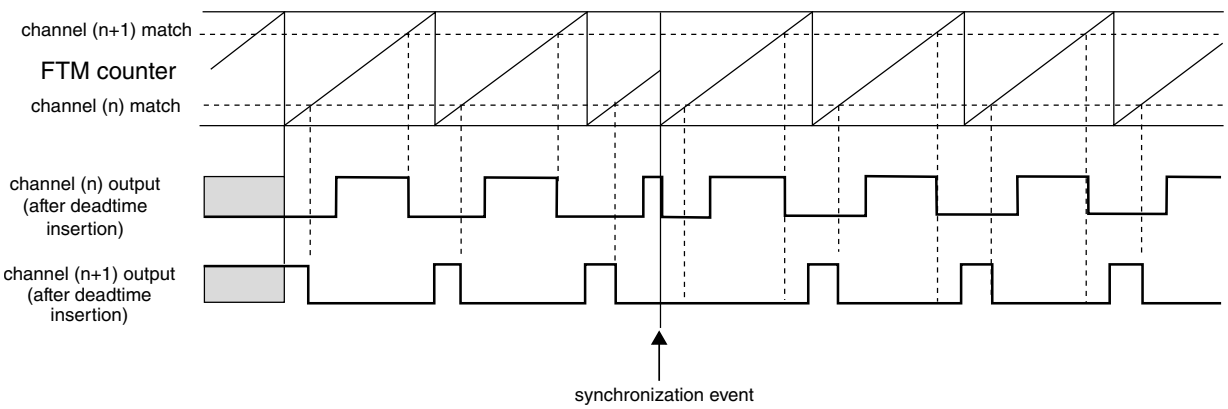

Figure 12-62. FTM counter synchronization

The FTM counter synchronization can be done by either the enhanced PWM synchronization (SYNCMODE = 1) or the legacy PWM synchronization (SYNCMODE = 0). However, the FTM counter must be synchronized only by the enhanced PWM synchronization.

In the case of enhanced PWM synchronization, the FTM counter synchronization depends on SWRSTCNT and HWRSTCNT bits according to the following flowchart.

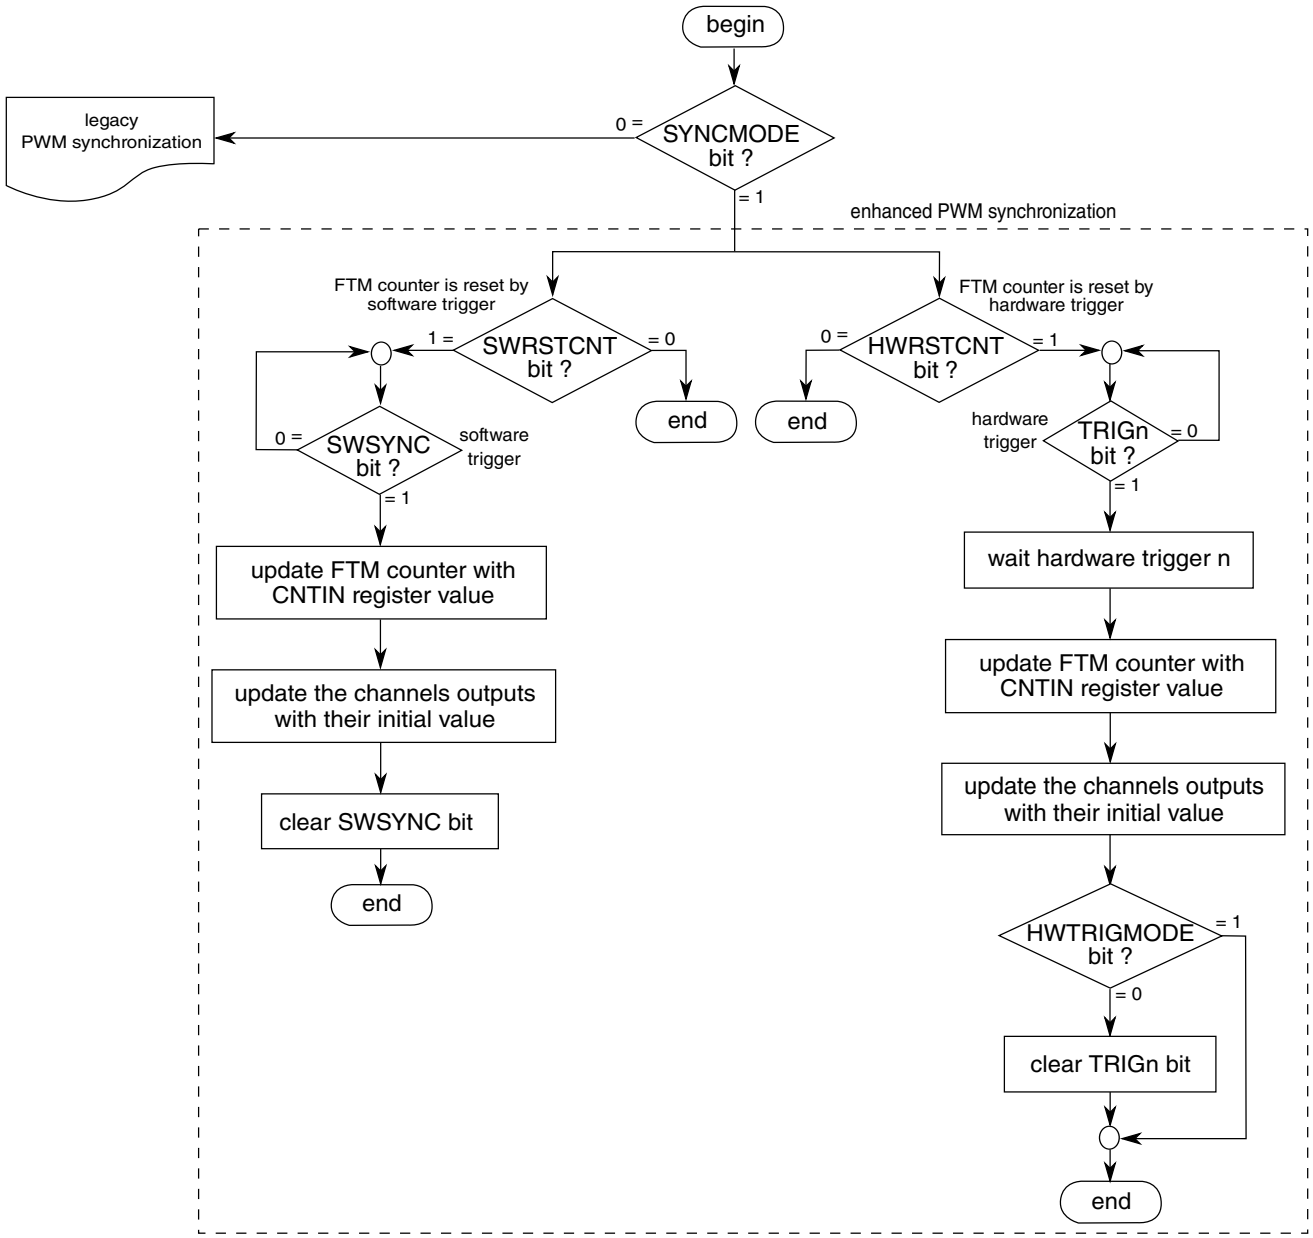

Figure 12-63. FTM counter synchronization flowchart

In the case of legacy PWM synchronization, the FTM counter synchronization depends on REINIT and PWMSYNC bits according to the following description.

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 0) then this synchronization is made on the next enabled trigger event. If the trigger event was a software trigger then the SWSYNC bit is cleared according to the following example. If the trigger event was a hardware trigger then the TRIGn bit is cleared according to Hardware trigger. Examples with software and hardware triggers follow.

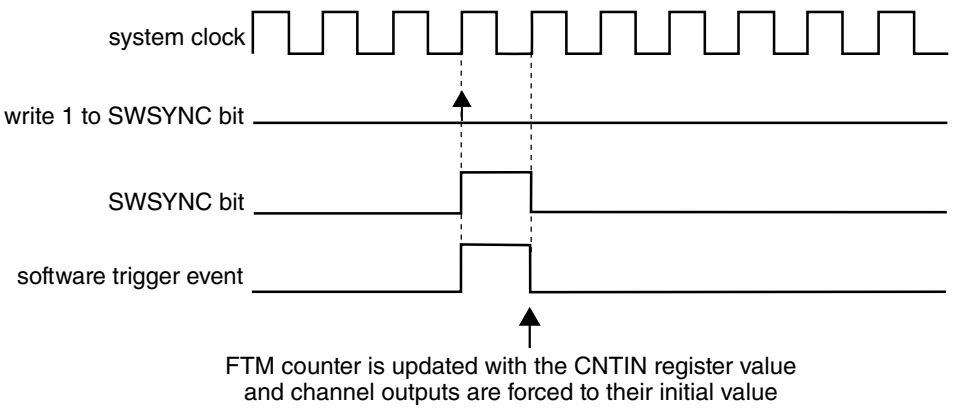

Figure 12-64. FTM counter synchronization with (SYNCMODE = 0), (REINIT = 1), (PWMSYNC = 0), and software trigger was used

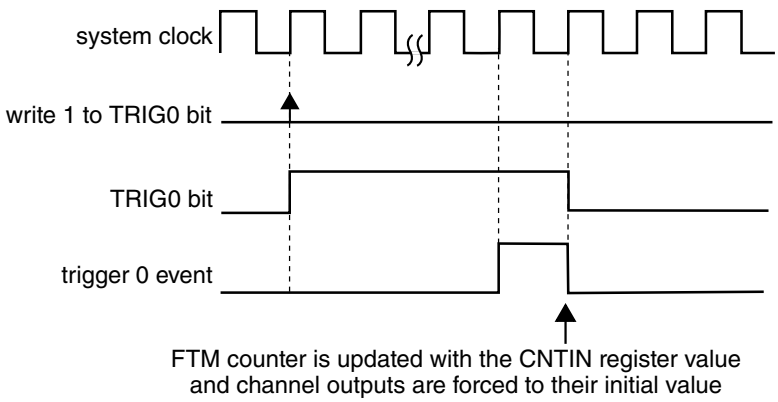

Figure 12-65. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 0), and a hardware trigger was used

If (SYNCMODE = 0), (REINIT = 1), and (PWMSYNC = 1) then this synchronization is made on the next enabled hardware trigger. The TRIGn bit is cleared according to Hardware trigger.

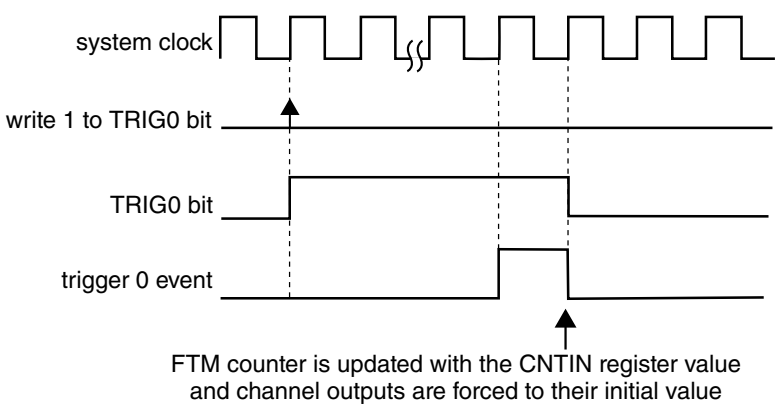

Figure 12-66. FTM counter synchronization with (SYNCMODE = 0), (HWTRIGMODE = 0), (REINIT = 1), (PWMSYNC = 1), and a hardware trigger was used

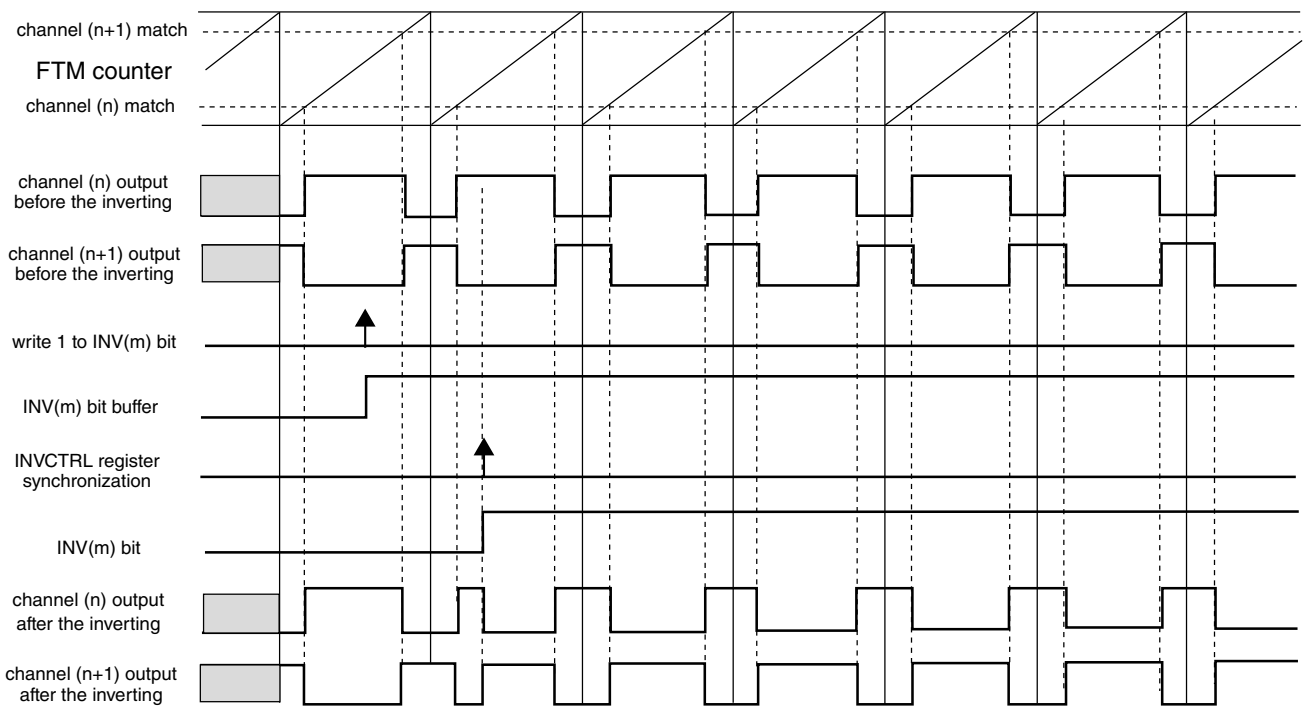
12.2.4.12 Inverting

The invert functionality swaps the signals between channel (n) and channel (n+1) outputs. The inverting operation is selected when:

- QUADEN = 0
- DECAPEN = 0
- COMP = 1, and
- INVm = 1 (where m represents a channel pair)

The INVm bit in INVCTRL register is updated with its buffer value according to INVCTRL register synchronization

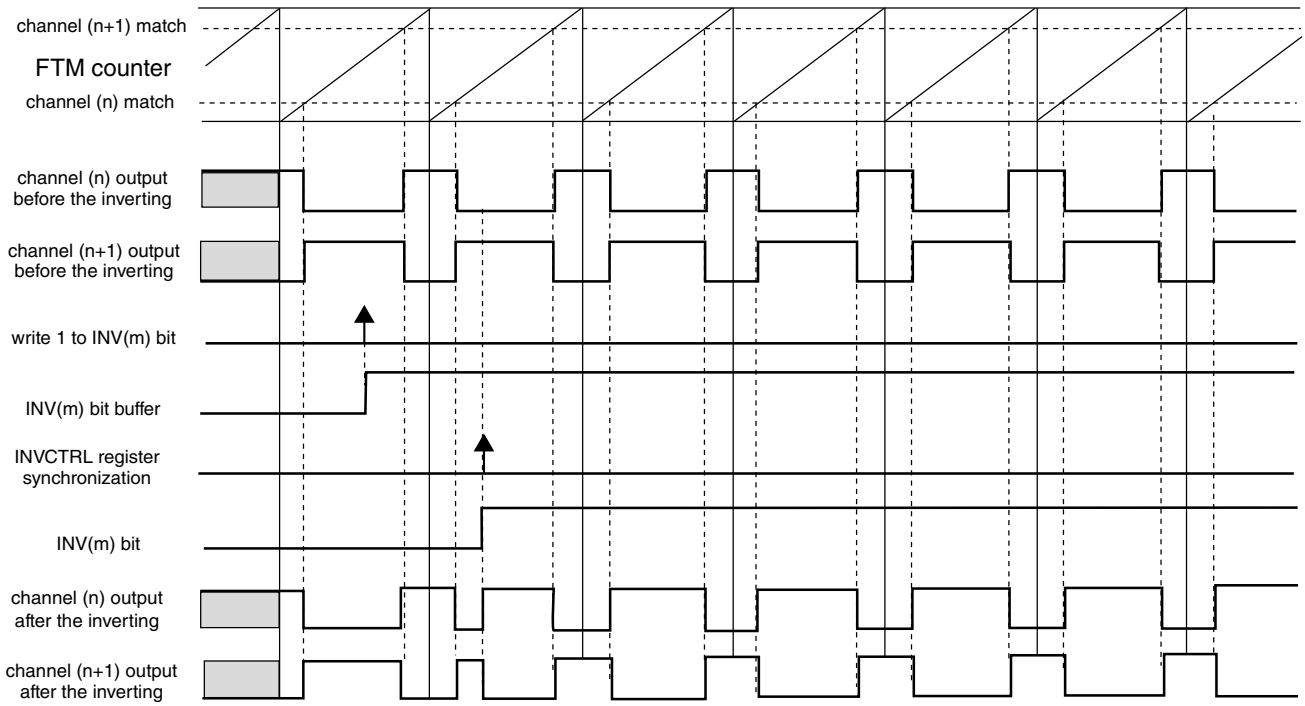
In High-True (ELSnB:ELSnA = 1:0) Combine mode, the channel (n) output is forced low at the beginning of the period (FTM counter = CNTIN), forced high at the channel (n) match and forced low at the channel (n+1) match. If the inverting is selected, the channel (n) output behavior is changed to force high at the beginning of the PWM period, force low at the channel (n) match and force high at the channel (n+1) match. See the following figure.



NOTE
INV(m) bit selects the inverting to the pair channels (n) and (n+1).

Figure 12-67. Channels (n) and (n+1) outputs after the inverting in High-True (ELSnB:ELSnA = 1:0) Combine mode

Note that the ELSnB:ELSnA bits value should be considered because they define the active state of the channels outputs. In Low-True (ELSnB:ELSnA = X:1) Combine mode, the channel (n) output is forced high at the beginning of the period, forced low at the channel (n) match and forced high at the channel (n+1) match. When inverting is selected, the channels (n) and (n+1) present waveforms as shown in the following figure.



NOTE
INV(m) bit selects the inverting to the pair channels (n) and (n+1).

Figure 12-68. Channels (n) and (n+1) outputs after the inverting in Low-True (ELSnB:ELSnA = X:1) Combine mode

Note

The inverting feature is not available in Output Compare mode.

12.2.4.13 Software output control

The software output control forces the channel output according to software defined values at a specific time in the PWM generation.

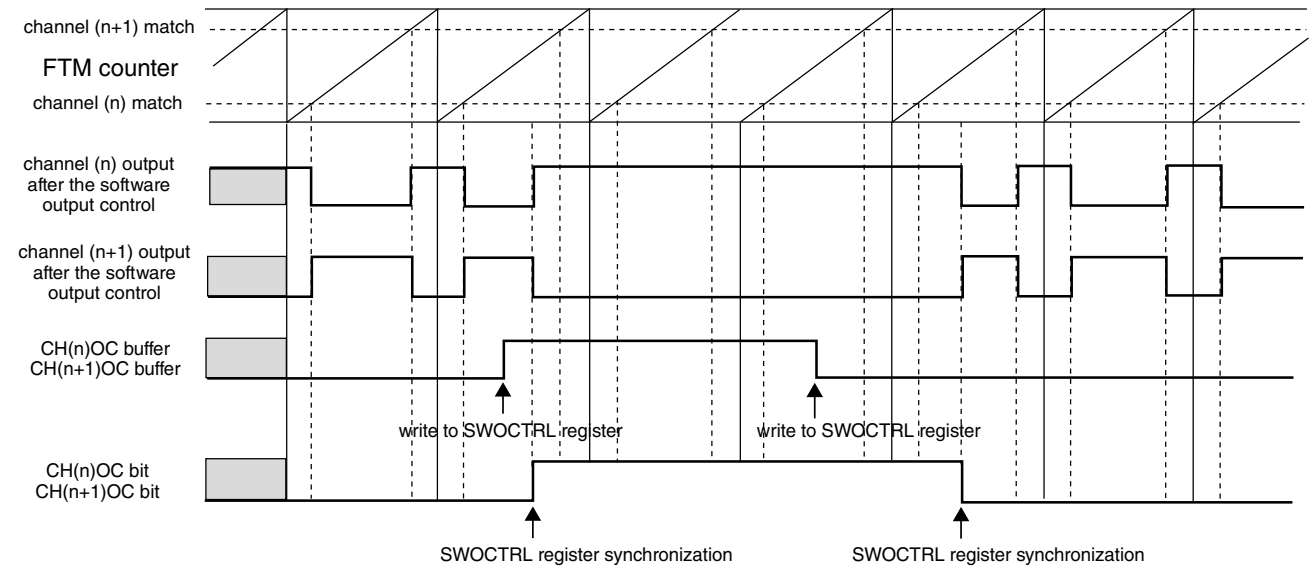
The software output control is selected when:

- QUADEN = 0
- DECAPEN = 0, and
- CHnOC = 1

The CHnOC bit enables the software output control for a specific channel output and the CHnOCV selects the value that is forced to this channel output.

Both CHnOC and CHnOCV bits in SWOCTRL register are buffered and updated with their buffer value according to SWOCTRL register synchronization.

The following figure shows the channels (n) and (n+1) outputs signals when the software output control is used. In this case the channels (n) and (n+1) are set to Combine and Complementary mode.



NOTE
CH(n)OCV = 1 and CH(n+1)OCV = 0.

Figure 12-69. Example of software output control in Combine and Complementary mode

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is zero.

Table 12-10. Software ouput control behavior when (COMP = 0)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to one

Software output control forces the following values on channels (n) and (n+1) when the COMP bit is one.

Table 12-11. Software ouput control behavior when (COMP = 1)

CH(n)OC	CH(n+1)OC	CH(n)OCV	CH(n+1)OCV	Channel (n) Output	Channel (n+1) Output
0	0	X	X	is not modified by SWOC	is not modified by SWOC
1	1	0	0	is forced to zero	is forced to zero
1	1	0	1	is forced to zero	is forced to one
1	1	1	0	is forced to one	is forced to zero
1	1	1	1	is forced to one	is forced to zero

Note

- The CH(n)OC and CH(n+1)OC bits should be equal.
- The COMP bit must not be modified when software output control is enabled, that is, CH(n)OC = 1 and/or CH(n +1)OC = 1.
- Software output control has the same behavior with disabled or enabled FTM counter (see the CLKS field description in the Status and Control register).

12.2.4.14 Deadtime insertion

The deadtime insertion is enabled when (DTEN = 1) and (DTVAL[5:0] is non- zero).

DEADTIME register defines the deadtime delay that can be used for all FTM channels. The DTPS[1:0] bits define the prescaler for the system clock and the DTVAL[5:0] bits define the deadtime modulo, that is, the number of the deadtime prescaler clocks.

The deadtime delay insertion ensures that no two complementary signals (channels (n) and (n+1)) drive the active state at the same time.

If POL(n) = 0, POL(n+1) = 0, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the low value until the end of the deadtime delay when the channel (n) output is set. Similarly, when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the low value until the end of the deadtime delay when the channel (n+1) output is set. See the following figures.

If POL(n) = 1, POL(n+1) = 1, and the deadtime is enabled, then when the channel (n) match (FTM counter = C(n)V) occurs, the channel (n) output remains at the high value until the end of the deadtime delay when the channel (n) output is cleared. Similarly,

when the channel (n+1) match (FTM counter = C(n+1)V) occurs, the channel (n+1) output remains at the high value until the end of the deadtime delay when the channel (n +1) output is cleared.

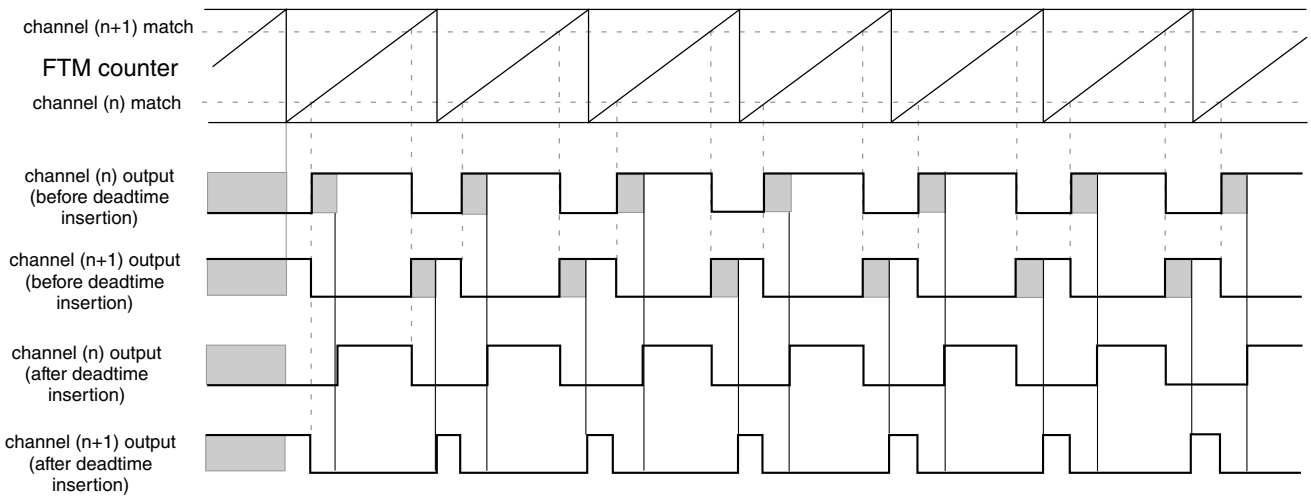


Figure 12-70. Deadtime insertion with ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0

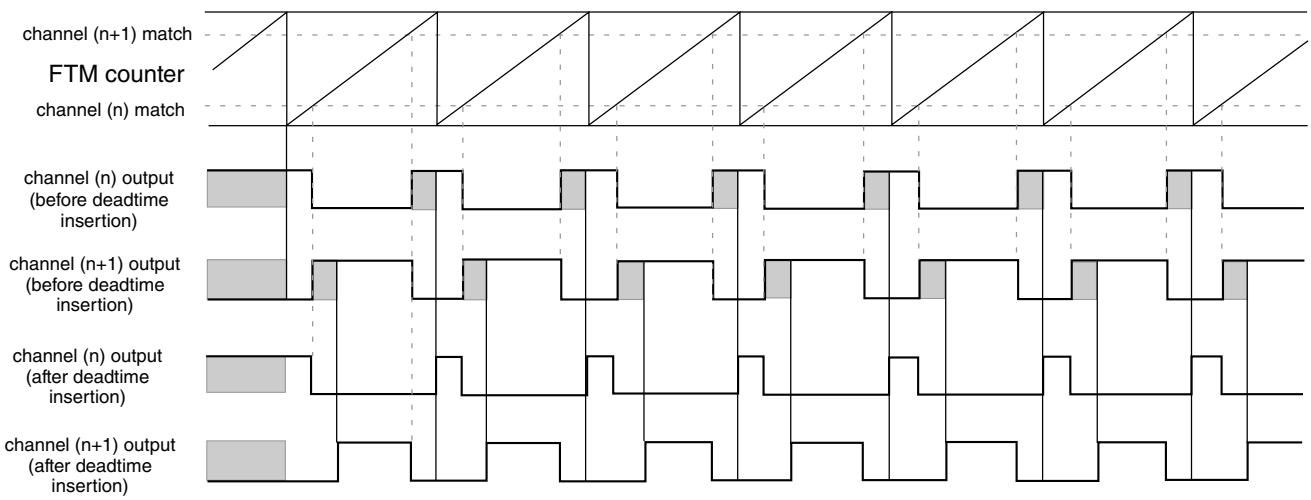

Figure 12-71. Deadtime insertion with ELSnB:ELSnA = X:1, POL(n) = 0, and POL(n+1) = 0

NOTE

- The deadtime feature must be used only in Complementary mode.
- The deadtime feature is not available in Output Compare mode.

12.2.4.14.1 Deadtime insertion corner cases

If (PS[2:0] is cleared), (DTPS[1:0] = 0:0 or DTPS[1:0] = 0:1):

- and the deadtime delay is greater than or equal to the channel (n) duty cycle ((C(n +1)V – C(n)V) × system clock), then the channel (n) output is always the inactive value (POL(n) bit value).
- and the deadtime delay is greater than or equal to the channel (n+1) duty cycle ((MOD – CNTIN + 1 – (C(n+1)V – C(n)V)) × system clock), then the channel (n+1) output is always the inactive value (POL(n+1) bit value).

Although, in most cases the deadtime delay is not comparable to channels (n) and (n+1) duty cycle, the following figures show examples where the deadtime delay is comparable to the duty cycle.

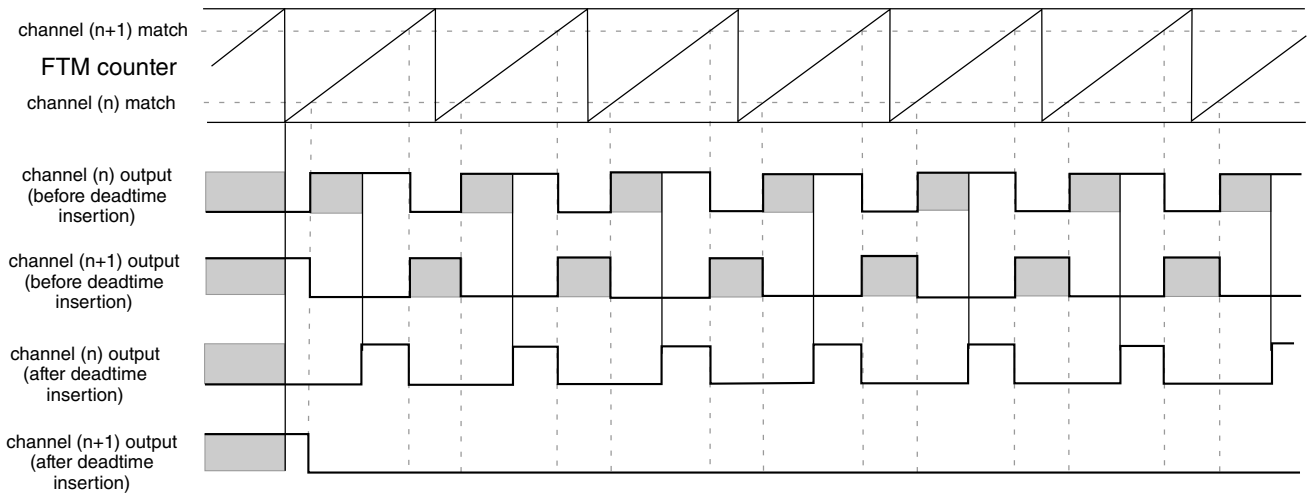

Figure 12-72. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channel (n+1) duty cycle

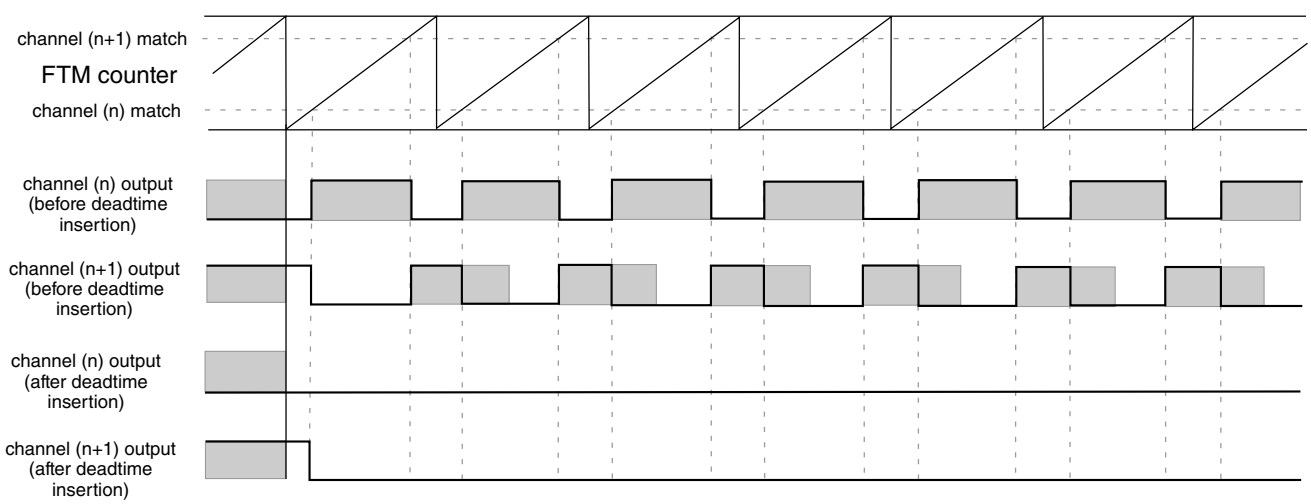

Figure 12-73. Example of the deadtime insertion (ELSnB:ELSnA = 1:0, POL(n) = 0, and POL(n+1) = 0) when the deadtime delay is comparable to channels (n) and (n+1) duty cycle

12.2.4.15 Output mask

The output mask can be used to force channels output to their inactive state through software. For example: to control a BLDC motor.

Any write to the OUTMASK register updates its write buffer. The OUTMASK register is updated with its buffer value by PWM synchronization; see OUTMASK register synchronization.

If CHnOM = 1, then the channel (n) output is forced to its inactive state (POLn bit value). If CHnOM = 0, then the channel (n) output is unaffected by the output mask. See the following figure.

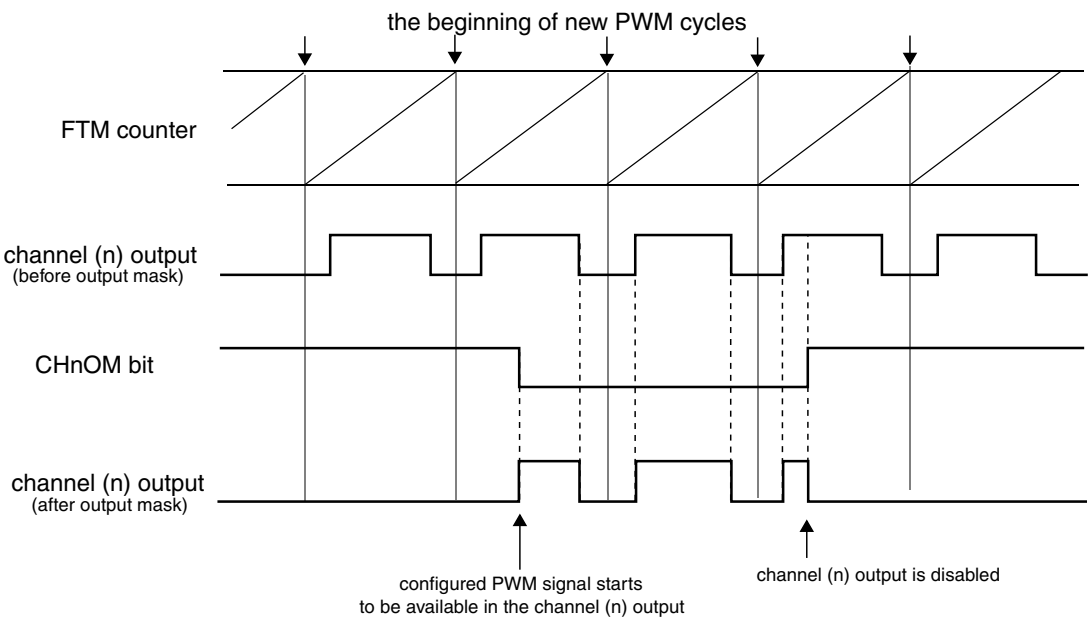

Figure 12-74. Output mask with POLn = 0

The following table shows the output mask result before the polarity control.

Table 12-12. Output mask result for channel (n) before the polarity control

CHnOM	Output Mask Input	Output Mask Result
0	inactive state	inactive state
	active state	active state
1	inactive state	inactive state
	active state	

12.2.4.16 Polarity control

The POLn bit selects the channel (n) output polarity:

- If POLn = 0, the channel (n) output polarity is high, so the logical one is the active state and the logical zero is the inactive state.
- If POLn = 1, the channel (n) output polarity is low, so the logical zero is the active state and the logical one is the inactive state.

12.2.4.17 Initialization

The initialization forces the CHnOI bit value to the channel (n) output when a one is written to the INIT bit.

The initialization depends on COMP and DTEN bits. The following table shows the values that channels (n) and (n+1) are forced by initialization when the COMP and DTEN bits are zero.

Table 12-13. Initialization behavior when (COMP = 0 and DTEN = 0)

CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	0	is forced to zero	is forced to zero
0	1	is forced to zero	is forced to one
1	0	is forced to one	is forced to zero
1	1	is forced to one	is forced to one

The following table shows the values that channels (n) and (n+1) are forced by initialization when (COMP = 1) or (DTEN = 1).

Table 12-14. Initialization behavior when (COMP = 1 or DTEN = 1)

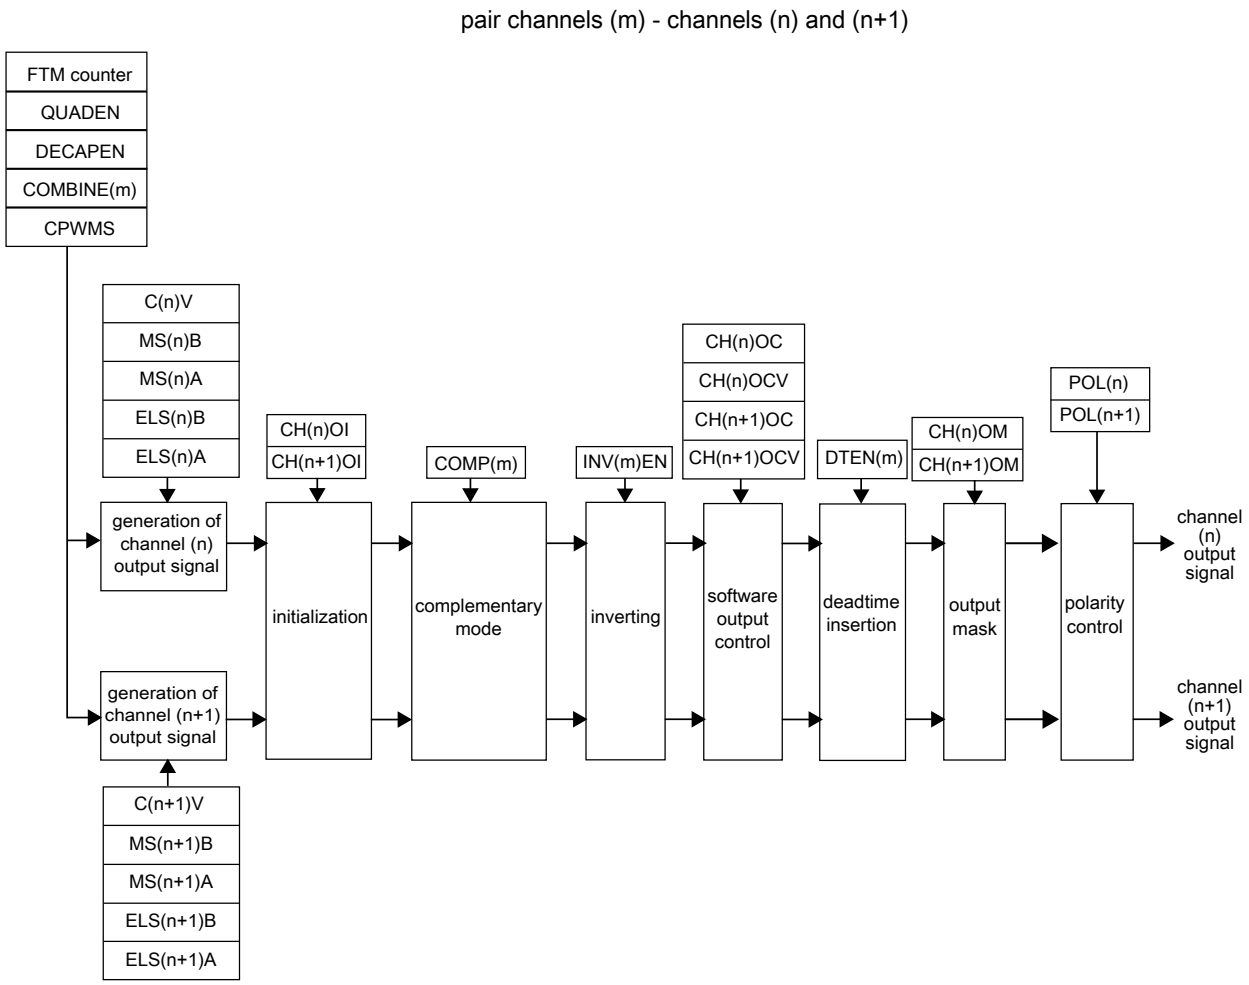
CH(n)OI	CH(n+1)OI	Channel (n) Output	Channel (n+1) Output
0	X	is forced to zero	is forced to one
1	X	is forced to one	is forced to zero

Note

The initialization feature must be used only with disabled FTM counter. See the description of the CLKS field in the Status and Control register.

12.2.4.18 Features priority

The following figure shows the priority of the features used at the generation of channels (n) and (n+1) outputs signals.



NOTE
The channels (n) and (n+1) are in output compare, EPWM, CPWM or combine modes.

Figure 12-75. Priority of the features used at the generation of channels (n) and (n+1) outputs signals

Note

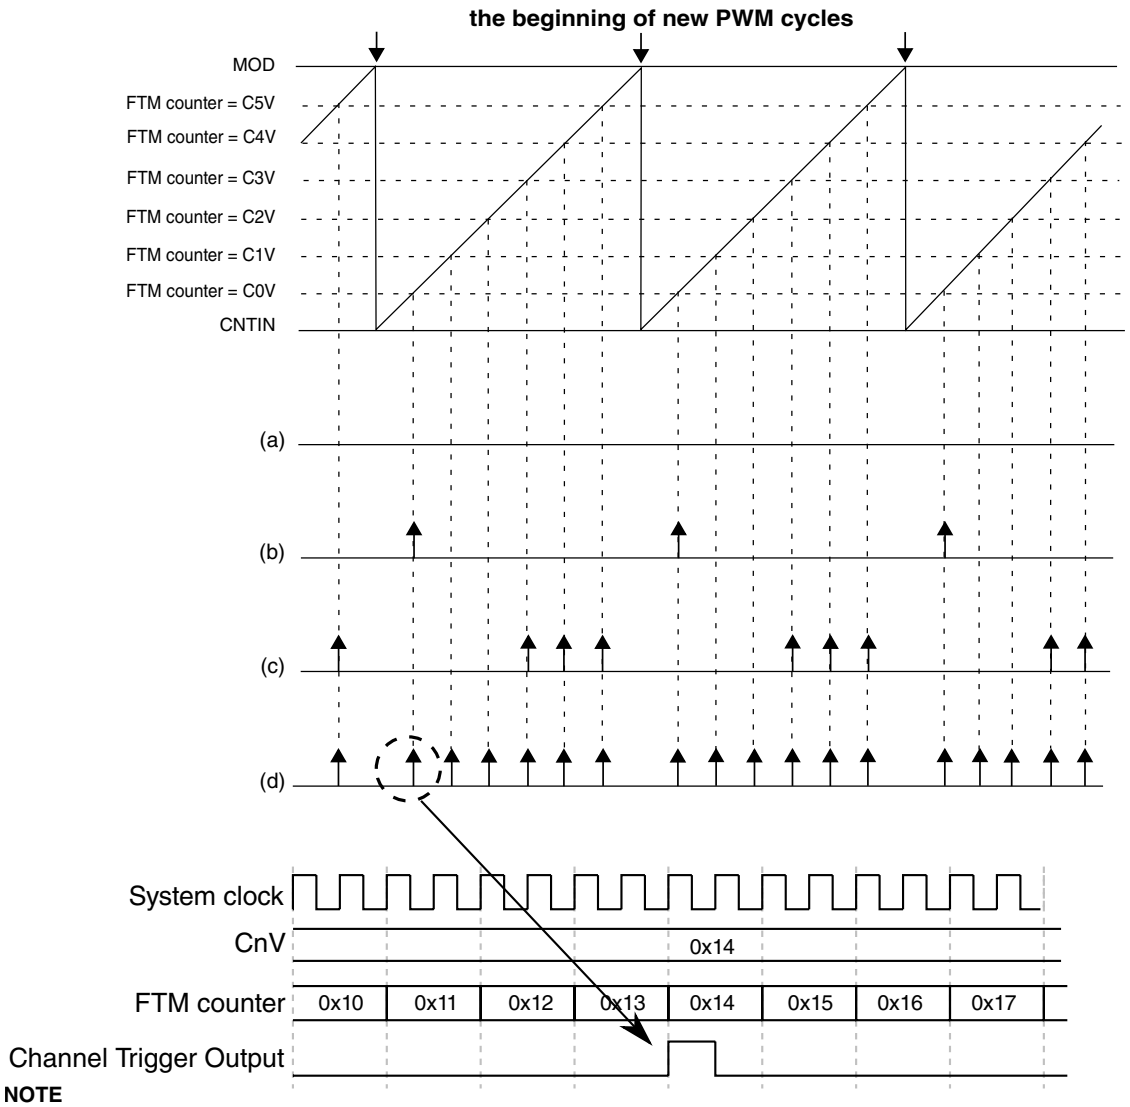
The Initialization feature must not be used with Inverting and Software output control features.

12.2.4.19 Channel trigger output

If CH(j)TRIG bit of the FTM External Trigger (FTM_EXTTRIG) register is set, where j = 0, 1, 2, 3, 4, or 5, then the FTM generates a trigger when the channel (j) match occurs (FTM counter = C(j)V).

The channel trigger output provides a trigger signal which has one FTM clock period width and is used for on-chip modules.

The FTM is able to generate multiple triggers in one PWM period. Because each trigger is generated for a specific channel, several channels are required to implement this functionality. This behavior is described in the following figure.



NOTE

(a) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0
(b) CH0TRIG = 1, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 0, CH4TRIG = 0, CH5TRIG = 0
(c) CH0TRIG = 0, CH1TRIG = 0, CH2TRIG = 0, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1
(d) CH0TRIG = 1, CH1TRIG = 1, CH2TRIG = 1, CH3TRIG = 1, CH4TRIG = 1, CH5TRIG = 1

Figure 12-76. Channel match trigger

12.2.4.20 Initialization trigger

If INITTRIGEN = 1, then the FTM generates a trigger when the FTM counter is updated with the CNTIN register value in the following cases.

- The FTM counter is automatically updated with the CNTIN register value by the selected counting mode.
- When there is a write to CNT register.
- When there is the FTM counter synchronization.
- If (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits.
- If the channel (n) is in Input Capture mode, (ICRST = 1) and the selected input capture event occurs in the channel (n) input.

The following figures show these cases.

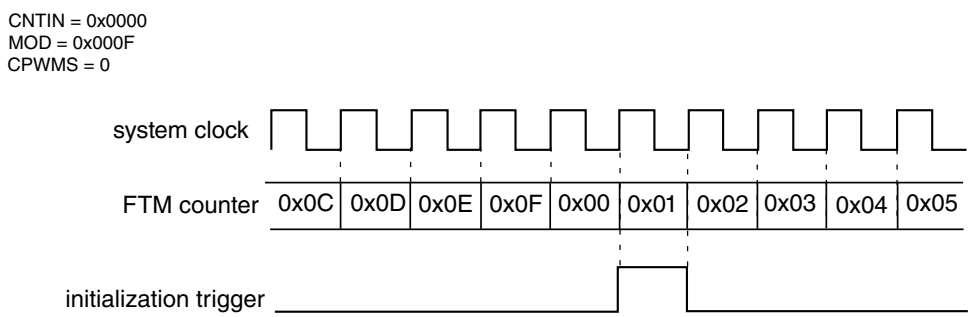


Figure 12-77. Initialization trigger is generated when the FTM counting achieves the CNTIN register value

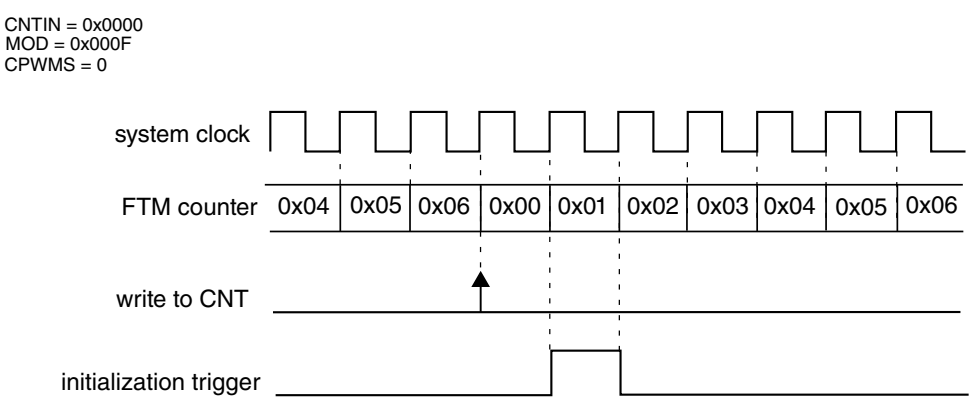

Figure 12-78. Initialization trigger is generated when there is a write to CNT register

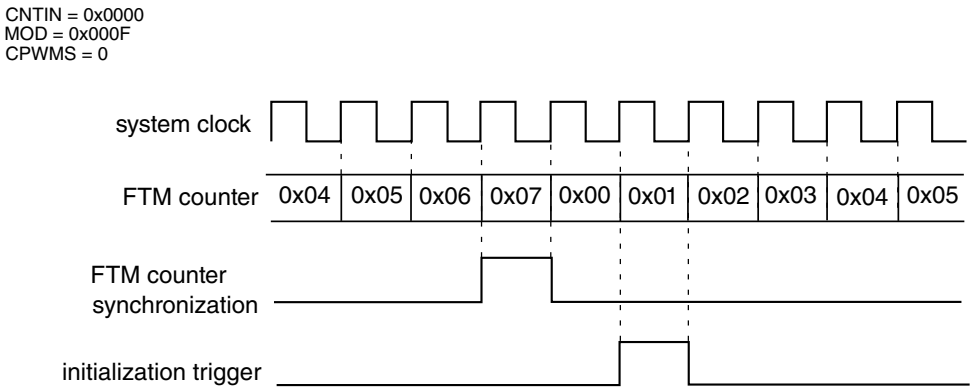

Figure 12-79. Initialization trigger is generated when there is the FTM counter synchronization

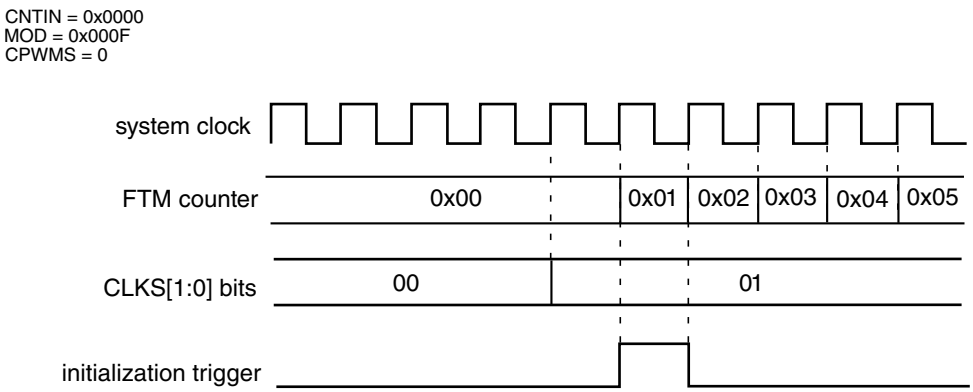

Figure 12-80. Initialization trigger is generated if (CNT = CNTIN), (CLKS[1:0] = 0:0), and a value different from zero is written to CLKS[1:0] bits

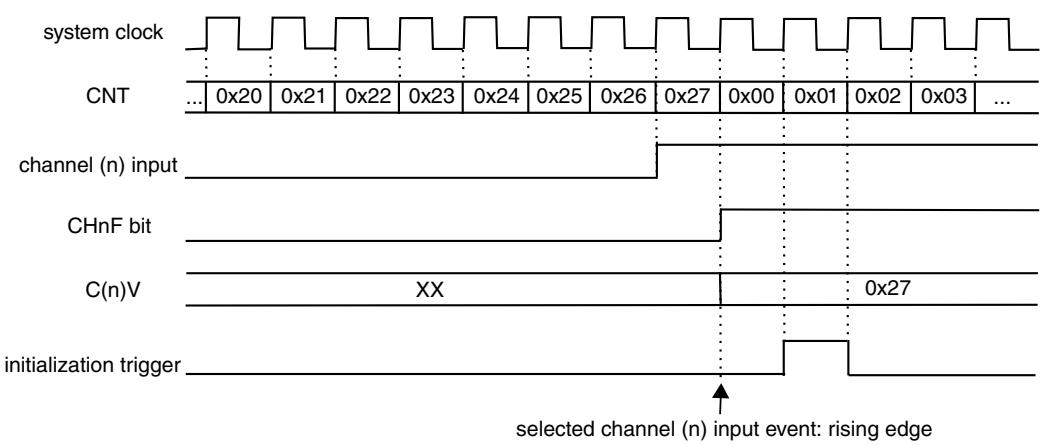


NOTE
Channel (n) input after its synchronizer and filter
MOD = 0xFFFF
CNTIN = 0x0000
PS[2:0] = 3'b000
ICRST = 1'b1

Figure 12-81. Initialization trigger is generated if the channel (n) is in Input Capture mode, ICRST = 1 and the selected input capture event occurs in the channel (n) input

The initialization trigger output provides a trigger signal that is used for on-chip modules.

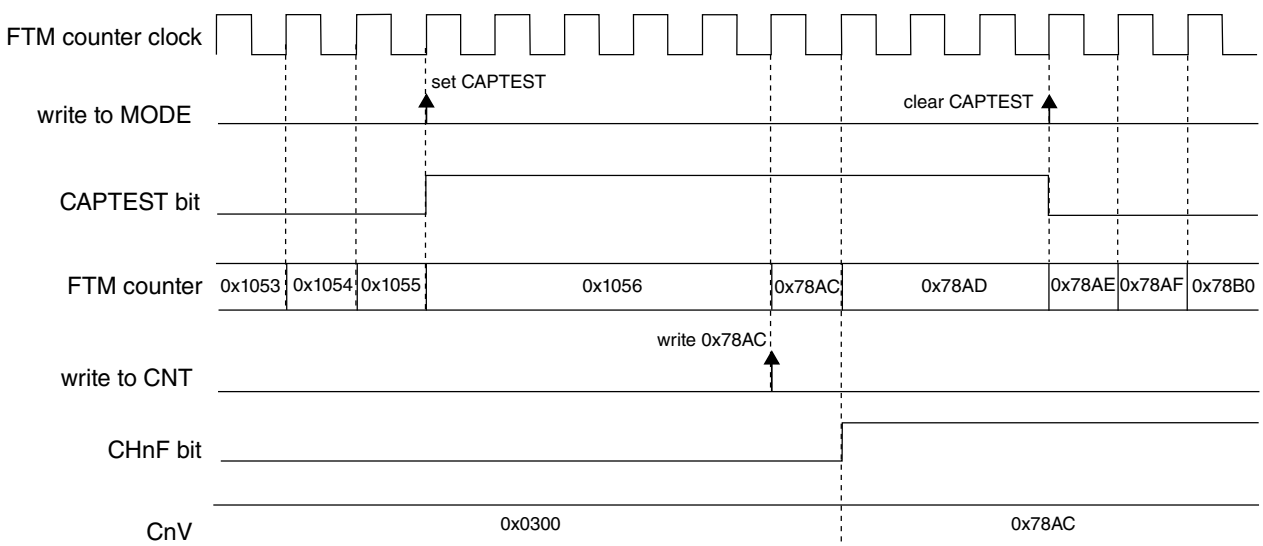
12.2.4.21 Capture Test mode

The Capture Test mode allows to test the CnV registers, the FTM counter and the interconnection logic between the FTM counter and CnV registers.

In this test mode, all channels must be configured for Input Capture mode and FTM counter must be configured to the Up counting.

When the Capture Test mode is enabled (CAPTEST = 1), the FTM counter is frozen and any write to CNT register updates directly the FTM counter; see the following figure. After it was written, all CnV registers are updated with the written value to CNT register and CHnF bits are set. Therefore, the FTM counter is updated with its next value according to its configuration. Its next value depends on CNTIN, MOD, and the written value to FTM counter.

The next reads of CnV registers return the written value to the FTM counter and the next reads of CNT register return FTM counter next value.



NOTE
- FTM counter configuration: (FTMEN = 1), (QUADEN = 0), (CAPTEST = 1), (CPWMS = 0), (CNTIN = 0x0000), and (MOD = 0xFFFF)
- FTM channel n configuration: input capture mode - (DECAPEN = 0), (COMBINE = 0), and (MSnB:MSnA = 0:0)

Figure 12-82. Capture Test mode

12.2.4.22 DMA

The channel generates a DMA transfer request according to DMA and CHnIE bits. See the following table.

Table 12-15. Channel DMA transfer request

DMA	CHnIE	Channel DMA Transfer Request	Channel Interrupt
0	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
0	1	The channel DMA transfer request is not generated.	The channel interrupt is generated if (CHnF = 1).
1	0	The channel DMA transfer request is not generated.	The channel interrupt is not generated.
1	1	The channel DMA transfer request is generated if (CHnF = 1).	The channel interrupt is not generated.

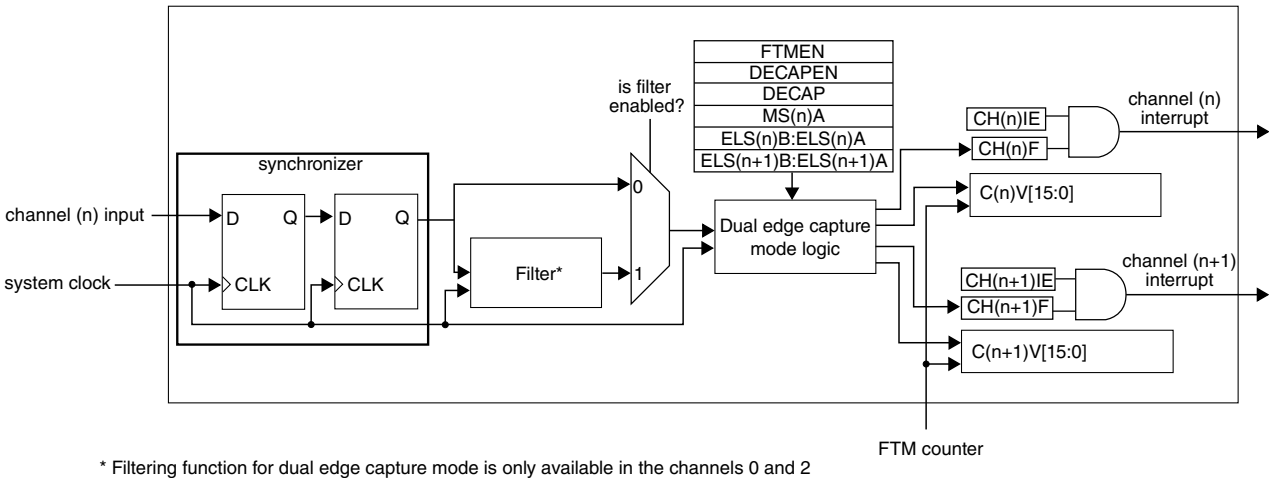
If DMA = 1, the CHnF bit is cleared either by channel DMA transfer done or reading CnSC while CHnF is set and then writing a zero to CHnF bit according to CHnIE bit. See the following table.

Table 12-16. Clear CHnF bit when DMA = 1

CHnIE	How CHnF Bit Can Be Cleared
0	CHnF bit is cleared either when the channel DMA transfer is done or by reading CnSC while CHnF is set and then writing a 0 to CHnF bit.
1	CHnF bit is cleared when the channel DMA transfer is done.

12.2.4.23 Dual Edge Capture mode

The Dual Edge Capture mode is selected if DECAPEN = 1. This mode allows to measure a pulse width or period of the signal on the input of channel (n) of a channel pair. The channel (n) filter can be active in this mode when n is 0 or 2.



* Filtering function for dual edge capture mode is only available in the channels 0 and 2

Figure 12-83. Dual Edge Capture mode block diagram

The MS(n)A bit defines if the Dual Edge Capture mode is one-shot or continuous.

The ELS(n)B:ELS(n)A bits select the edge that is captured by channel (n), and ELS(n +1)B:ELS(n+1)A bits select the edge that is captured by channel (n+1). If both ELS(n)B:ELS(n)A and ELS(n+1)B:ELS(n+1)A bits select the same edge, then it is the period measurement. If these bits select different edges, then it is a pulse width measurement.

In the Dual Edge Capture mode, only channel (n) input is used and channel (n+1) input is ignored.

If the selected edge by channel (n) bits is detected at channel (n) input, then CH(n)F bit is set and the channel (n) interrupt is generated (if CH(n)IE = 1). If the selected edge by channel (n+1) bits is detected at channel (n) input and (CH(n)F = 1), then CH(n+1)F bit is set and the channel (n+1) interrupt is generated (if CH(n+1)IE = 1).

The C(n)V register stores the value of FTM counter when the selected edge by channel (n) is detected at channel (n) input. The C(n+1)V register stores the value of FTM counter when the selected edge by channel (n+1) is detected at channel (n) input.

In this mode, a coherency mechanism ensures coherent data when the C(n)V and C(n +1)V registers are read. The only requirement is that C(n)V must be read before C(n +1)V.

Note

- The CH(n)F, CH(n)IE, MS(n)A, ELS(n)B, and ELS(n)A bits are channel (n) bits.

- The CH(n+1)F, CH(n+1)IE, MS(n+1)A, ELS(n+1)B, and ELS(n+1)A bits are channel (n+1) bits.
- The Dual Edge Capture mode must be used with ELS(n)B:ELS(n)A = 0:1 or 1:0, ELS(n+1)B:ELS(n+1)A = 0:1 or 1:0 and the FTM counter in Free running counter.

12.2.4.23.1 One-Shot Capture mode

The One-Shot Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 0). In this capture mode, only one pair of edges at the channel (n) input is captured. The ELS(n)B:ELS(n)A bits select the first edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the second edge to be captured.

The edge captures are enabled while DECAP bit is set. For each new measurement in One-Shot Capture mode, first the CH(n)F and CH(n+1) bits must be cleared, and then the DECAP bit must be set.

In this mode, the DECAP bit is automatically cleared by FTM when the edge selected by channel (n+1) is captured. Therefore, while DECAP bit is set, the one-shot capture is in process. When this bit is cleared, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

Similarly, when the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers.

12.2.4.23.2 Continuous Capture mode

The Continuous Capture mode is selected when (DECAPEN = 1), and (MS(n)A = 1). In this capture mode, the edges at the channel (n) input are captured continuously. The ELS(n)B:ELS(n)A bits select the initial edge to be captured, and ELS(n+1)B:ELS(n+1)A bits select the final edge to be captured.

The edge captures are enabled while DECAP bit is set. For the initial use, first the CH(n)F and CH(n+1)F bits must be cleared, and then DECAP bit must be set to start the continuous measurements.

When the CH(n+1)F bit is set, both edges were captured and the captured values are ready for reading in the C(n)V and C(n+1)V registers. The latest captured values are always available in these registers even after the DECAP bit is cleared.

In this mode, it is possible to clear only the CH(n+1)F bit. Therefore, when the CH(n+1)F bit is set again, the latest captured values are available in C(n)V and C(n+1)V registers.

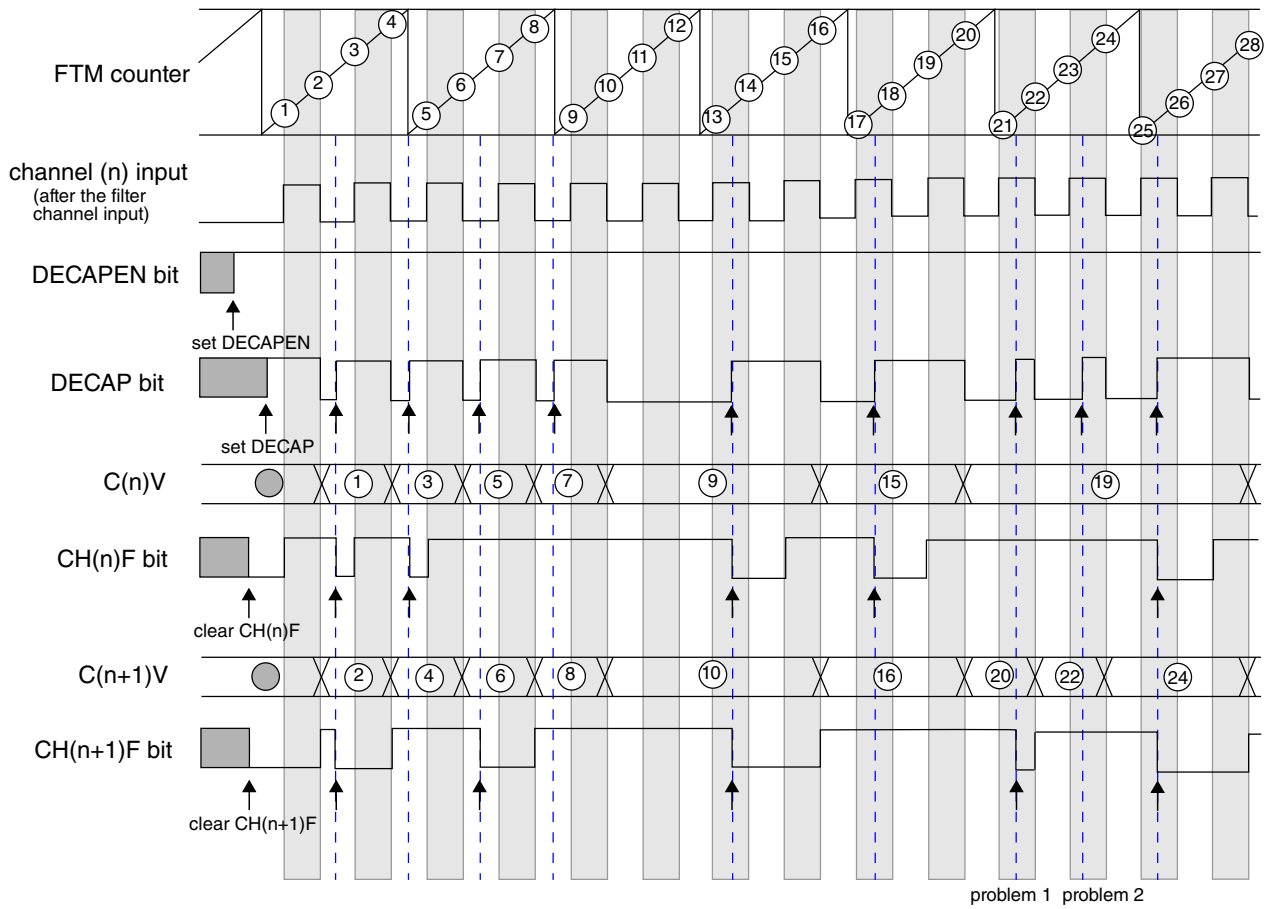
For a new sequence of the measurements in the Dual Edge Capture – Continuous mode, clear the CH(n)F and CH(n+1)F bits to start new measurements.

12.2.4.23.3 Pulse width measurement

If the channel (n) is configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1) and the channel (n+1) to capture falling edges (ELS(n+1)B:ELS(n+1)A = 1:0), then the positive polarity pulse width is measured. If the channel (n) is configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0) and the channel (n+1) to capture rising edges (ELS(n +1)B:ELS(n+1)A = 0:1), then the negative polarity pulse width is measured.

The pulse width measurement can be made in One-Shot Capture mode or Continuous Capture mode.

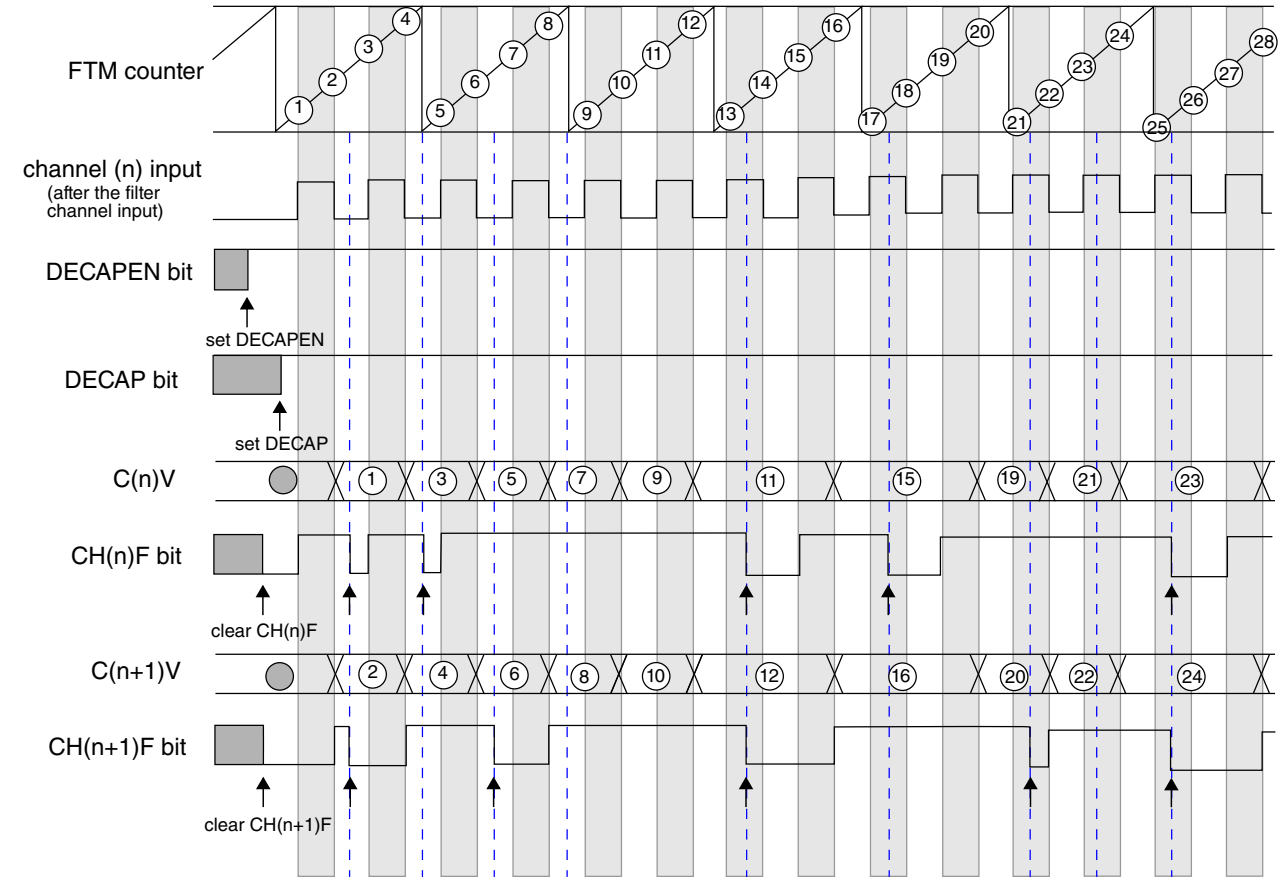
The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the measurement of next positive polarity pulse width. The CH(n)F bit is set when the first edge of this pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second edge of this pulse is detected, that is, the edge selected by ELS(n+1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 12-84. Dual Edge Capture – One-Shot mode for positive polarity pulse width measurement

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the positive polarity pulse width. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first edge of the positive polarity pulse is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second edge of this pulse is detected, that is, the edge selected by ELS(n +1)B:ELS(n+1)A bits. The CH(n+1)F bit indicates when two edges of the pulse were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 12-85. Dual Edge Capture – Continuous mode for positive polarity pulse width measurement

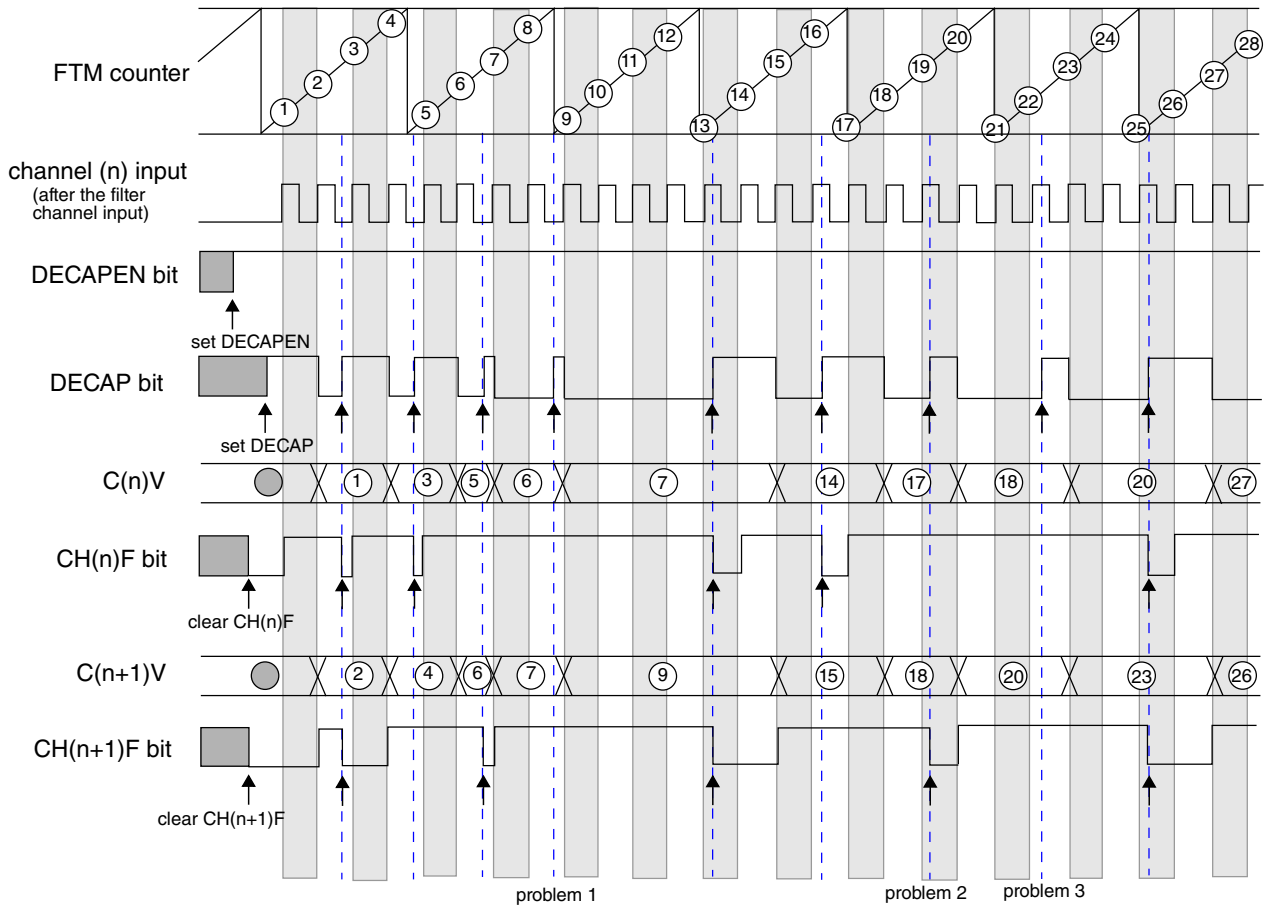
12.2.4.23.4 Period measurement

If the channels (n) and (n+1) are configured to capture consecutive edges of the same polarity, then the period of the channel (n) input signal is measured. If both channels (n) and (n+1) are configured to capture rising edges (ELS(n)B:ELS(n)A = 0:1 and ELS(n +1)B:ELS(n+1)A = 0:1), then the period between two consecutive rising edges is measured. If both channels (n) and (n+1) are configured to capture falling edges (ELS(n)B:ELS(n)A = 1:0 and ELS(n+1)B:ELS(n+1)A = 1:0), then the period between two consecutive falling edges is measured.

The period measurement can be made in One-Shot Capture mode or Continuous Capture mode.

The following figure shows an example of the Dual Edge Capture – One-Shot mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. The DECAP bit is set to enable the

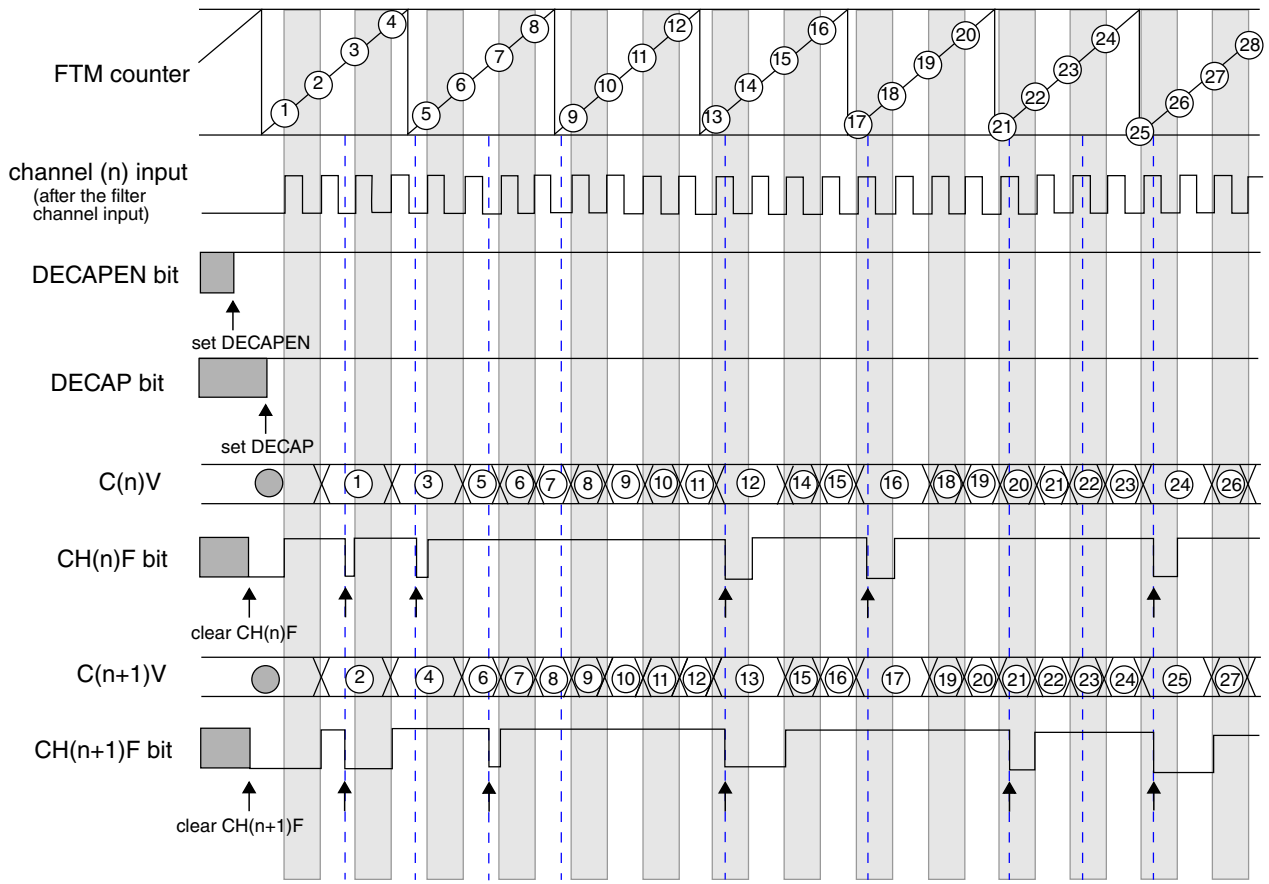
measurement of next period. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set and DECAP bit is cleared when the second rising edge is detected, that is, the edge selected by ELS(n +1)B:ELS(n+1)A bits. Both DECAP and CH(n+1)F bits indicate when two selected edges were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.
- Problem 1: channel (n) input = 0, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.
- Problem 2: channel (n) input = 1, set DECAP, not clear CH(n)F, and clear CH(n+1)F.
- Problem 3: channel (n) input = 1, set DECAP, not clear CH(n)F, and not clear CH(n+1)F.

Figure 12-86. Dual Edge Capture – One-Shot mode to measure of the period between two consecutive rising edges

The following figure shows an example of the Dual Edge Capture – Continuous mode used to measure the period between two consecutive rising edges. The DECAPEN bit selects the Dual Edge Capture mode, so it remains set. While the DECAP bit is set the configured measurements are made. The CH(n)F bit is set when the first rising edge is detected, that is, the edge selected by ELS(n)B:ELS(n)A bits. The CH(n+1)F bit is set when the second rising edge is detected, that is, the edge selected by ELS(n+1)B:ELS(n +1)A bits. The CH(n+1)F bit indicates when two edges of the period were captured and the C(n)V and C(n+1)V registers are ready for reading.



Note
- The commands set DECAPEN, set DECAP, clear CH(n)F, and clear CH(n+1)F are made by the user.

Figure 12-87. Dual Edge Capture – Continuous mode to measure of the period between two consecutive rising edges

12.2.4.23.5 Read coherency mechanism

The Dual Edge Capture mode implements a read coherency mechanism between the FTM counter value captured in C(n)V and C(n+1)V registers. The read coherency mechanism is illustrated in the following figure. In this example, the channels (n) and (n +1) are in Dual Edge Capture – Continuous mode for positive polarity pulse width measurement. Thus, the channel (n) is configured to capture the FTM counter value when there is a rising edge at channel (n) input signal, and channel (n+1) to capture the FTM counter value when there is a falling edge at channel (n) input signal.

When a rising edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n) capture buffer. The channel (n) capture buffer value is transferred to C(n)V register when a falling edge occurs in the channel (n) input signal.

C(n)V register has the FTM counter value when the previous rising edge occurred, and the channel (n) capture buffer has the FTM counter value when the last rising edge occurred.

When a falling edge occurs in the channel (n) input signal, the FTM counter value is captured into channel (n+1) capture buffer. The channel (n+1) capture buffer value is transferred to C(n+1)V register when the C(n)V register is read.

In the following figure, the read of C(n)V returns the FTM counter value when the event 1 occurred and the read of C(n+1)V returns the FTM counter value when the event 2 occurred.

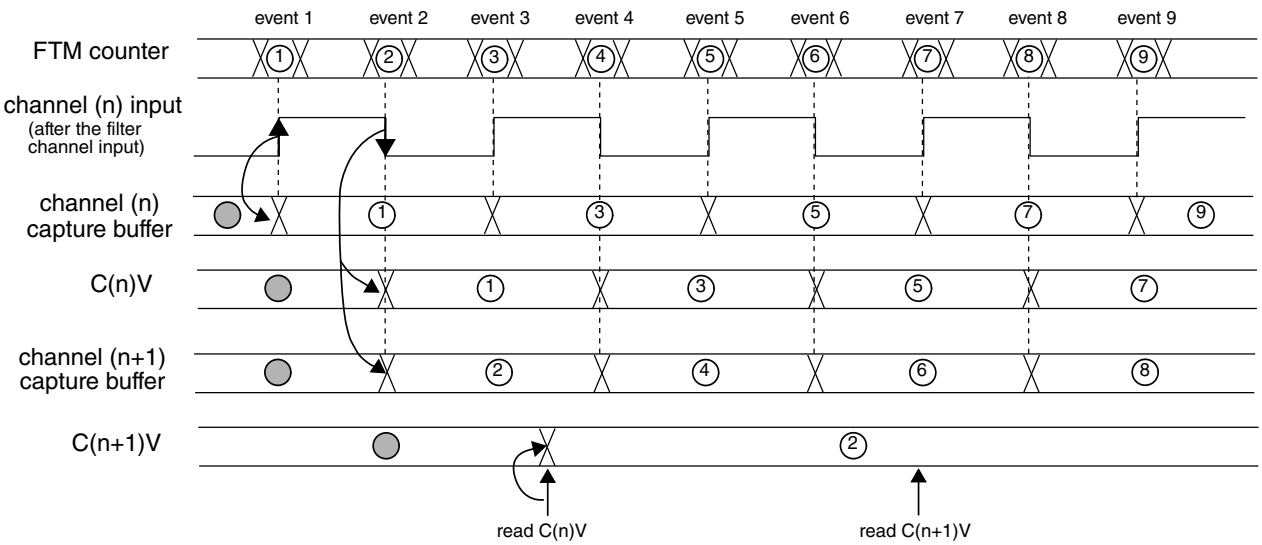


Figure 12-88. Dual Edge Capture mode read coherency mechanism

C(n)V register must be read prior to C(n+1)V register in dual edge capture one-shot and continuous modes for the read coherency mechanism works properly.

12.2.4.24 Quadrature Decoder mode

The Quadrature Decoder mode is selected if (QUADEN = 1). The Quadrature Decoder mode uses the input signals phase A and B to control the FTM counter increment and decrement. The following figure shows the quadrature decoder block diagram.

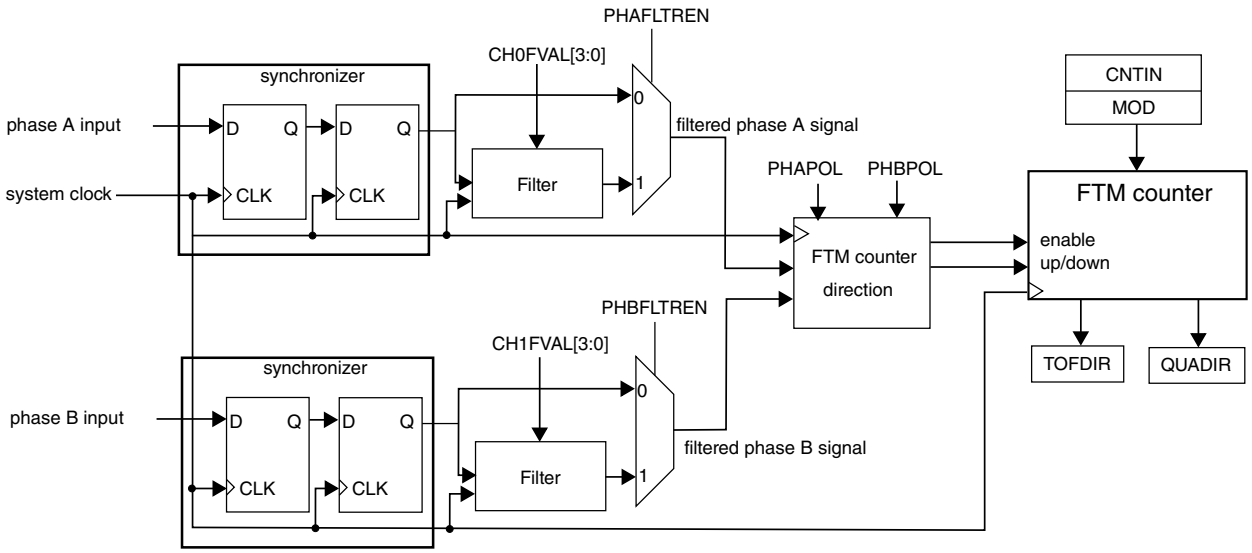

Figure 12-89. Quadrature Decoder block diagram

Each one of input signals phase A and B has a filter that is equivalent to the filter used in the channels input; Filter for Input Capture mode. The phase A input filter is enabled by PHAFLTREN bit and this filter's value is defined by CH0FVAL[3:0] bits (CH(n)FVAL[3:0] bits in FILTER0 register). The phase B input filter is enabled by PHBFLTREN bit and this filter's value is defined by CH1FVAL[3:0] bits (CH(n +1)FVAL[3:0] bits in FILTER0 register).

Except for CH0FVAL[3:0] and CH1FVAL[3:0] bits, no channel logic is used in Quadrature Decoder mode.

Note

Notice that the FTM counter is clocked by the phase A and B input signals when quadrature decoder mode is selected. Therefore it is expected that the Quadrature Decoder be used only with the FTM channels in input capture or output compare modes.

Note

An edge at phase A must not occur together an edge at phase B and vice-versa.

The PHAPOL bit selects the polarity of the phase A input, and the PHBPOL bit selects the polarity of the phase B input.

The QUADMODE selects the encoding mode used in the Quadrature Decoder mode. If QUADMODE = 1, then the count and direction encoding mode is enabled; see the following figure. In this mode, the phase B input value indicates the counting direction, and the phase A input defines the counting rate. The FTM counter is updated when there is a rising edge at phase A input signal.

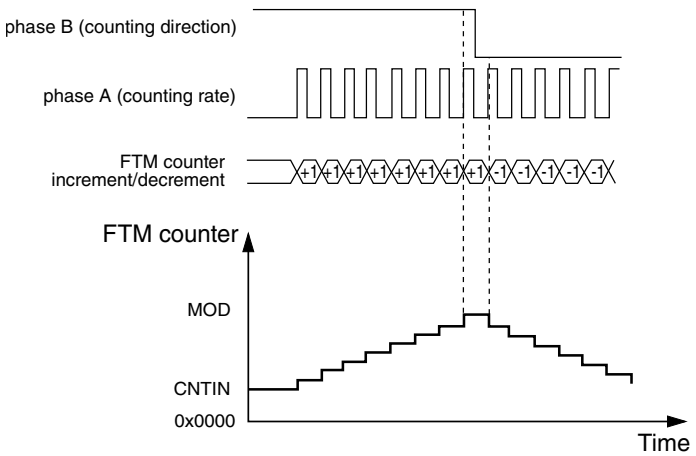

Figure 12-90. Quadrature Decoder – Count and Direction Encoding mode

If QUADMODE = 0, then the Phase A and Phase B Encoding mode is enabled; see the following figure. In this mode, the relationship between phase A and B signals indicates the counting direction, and phase A and B signals define the counting rate. The FTM counter is updated when there is an edge either at the phase A or phase B signals.

If PHAPOL = 0 and PHBPOL = 0, then the FTM counter increment happens when:

- there is a rising edge at phase A signal and phase B signal is at logic zero;
- there is a rising edge at phase B signal and phase A signal is at logic one;
- there is a falling edge at phase B signal and phase A signal is at logic zero;
- there is a falling edge at phase A signal and phase B signal is at logic one;

and the FTM counter decrement happens when:

- there is a falling edge at phase A signal and phase B signal is at logic zero;
- there is a falling edge at phase B signal and phase A signal is at logic one;
- there is a rising edge at phase B signal and phase A signal is at logic zero;
- there is a rising edge at phase A signal and phase B signal is at logic one.

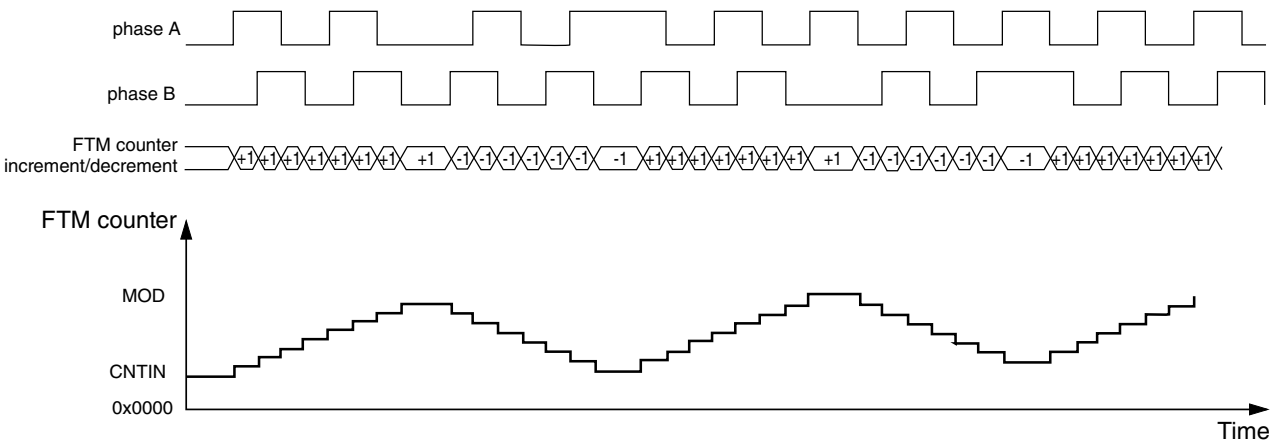

Figure 12-91. Quadrature Decoder – Phase A and Phase B Encoding mode

The following figure shows the FTM counter overflow in up counting. In this case, when the FTM counter changes from MOD to CNTIN, TOF and TOFDIR bits are set. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was up when the FTM counter overflow occurred.

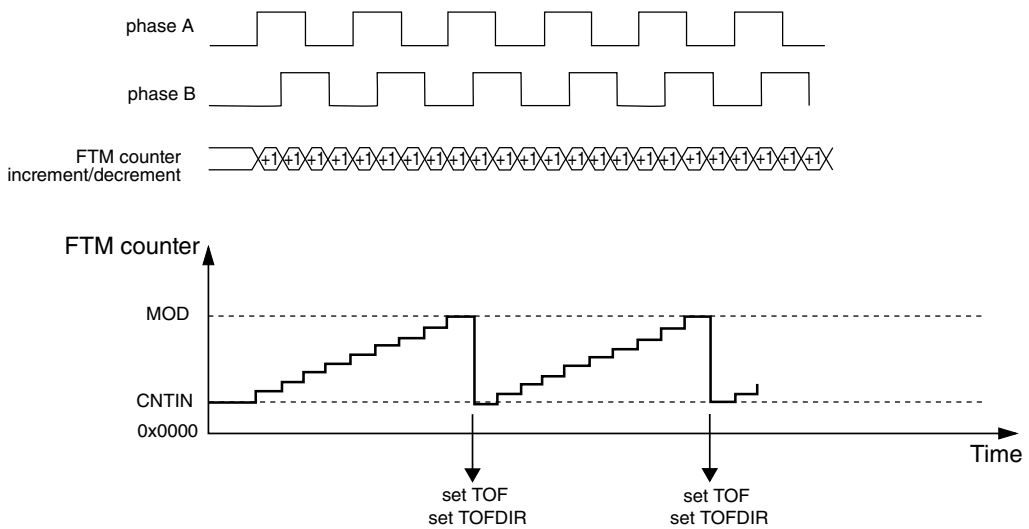

Figure 12-92. FTM Counter overflow in up counting for Quadrature Decoder mode

The following figure shows the FTM counter overflow in down counting. In this case, when the FTM counter changes from CNTIN to MOD, TOF bit is set and TOFDIR bit is cleared. TOF bit indicates the FTM counter overflow occurred. TOFDIR indicates the counting was down when the FTM counter overflow occurred.

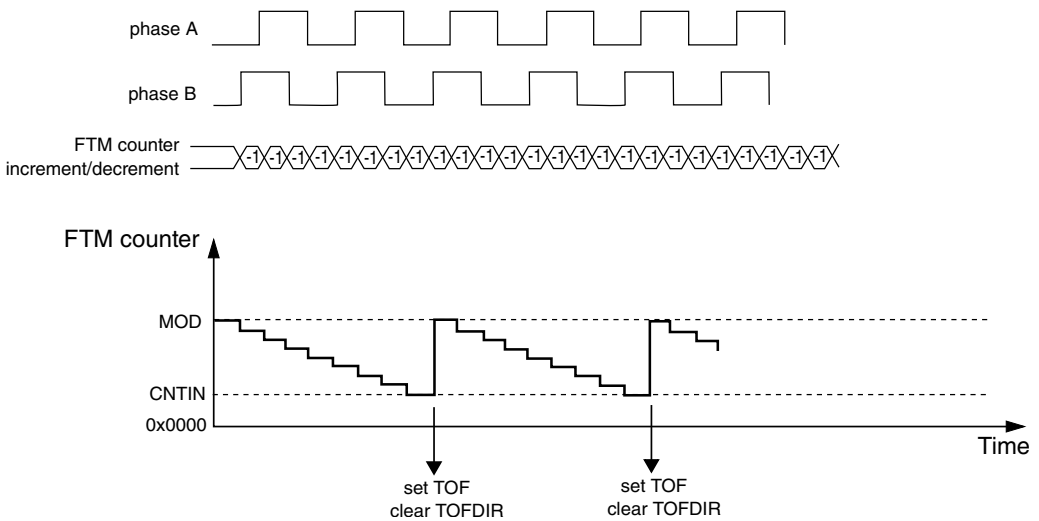

Figure 12-93. FTM counter overflow in down counting for Quadrature Decoder mode

12.2.4.24.1 Quadrature Decoder boundary conditions

The following figures show the FTM counter responding to motor jittering typical in motor position control applications.

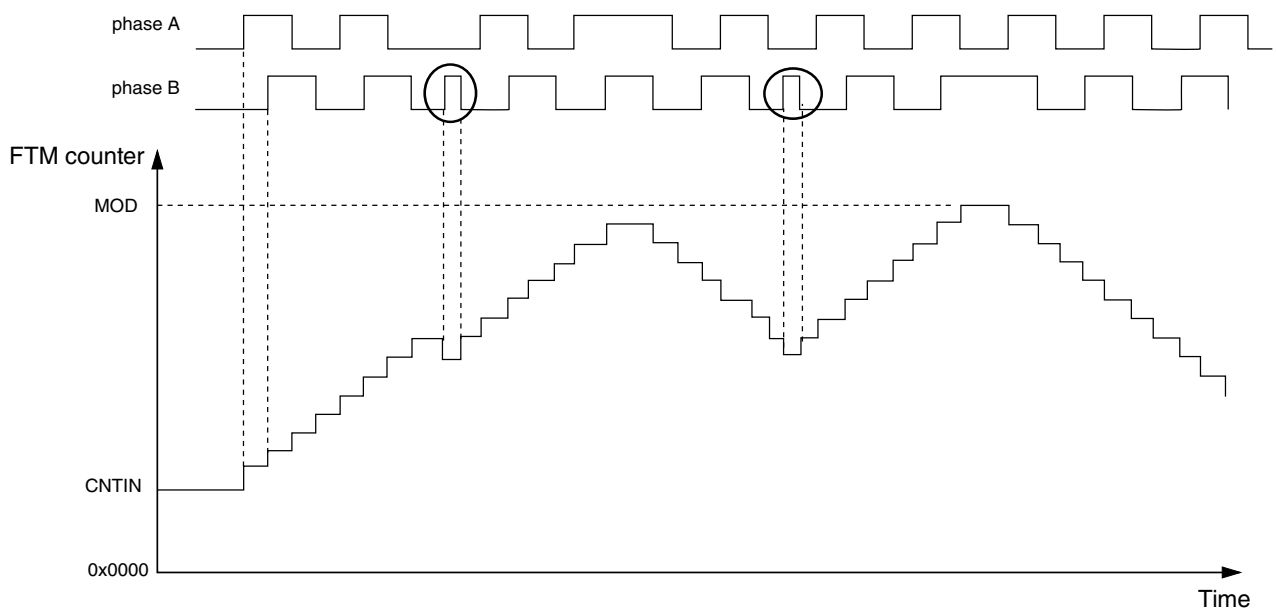

Figure 12-94. Motor position jittering in a mid count value

The following figure shows motor jittering produced by the phase B and A pulses respectively:

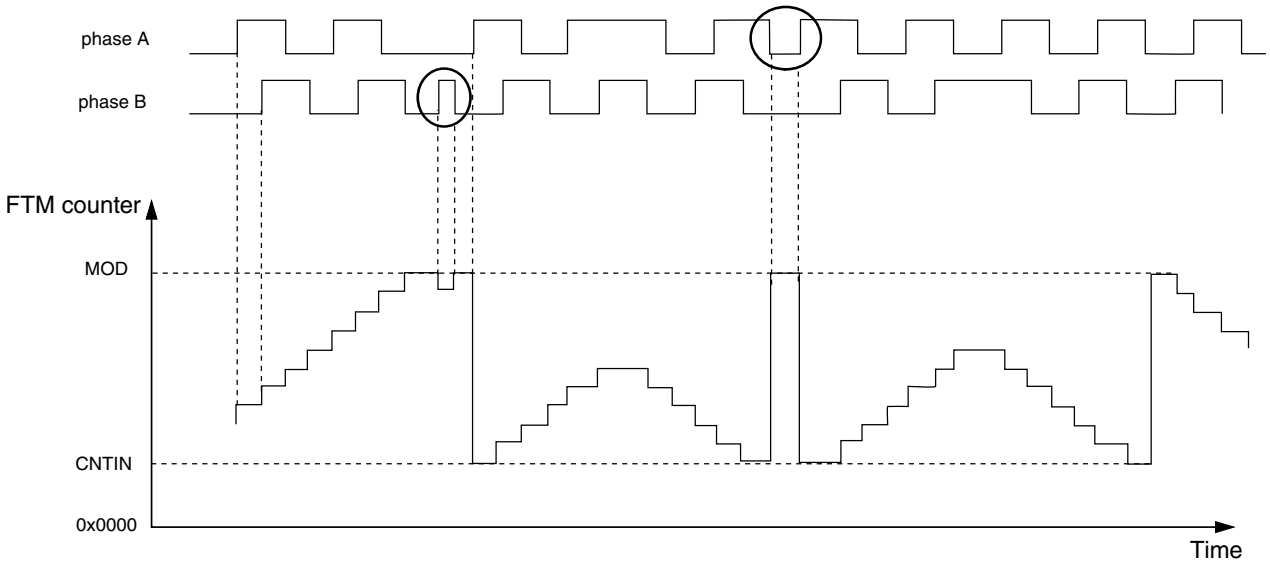

Figure 12-95. Motor position jittering near maximum and minimum count value

The first highlighted transition causes a jitter on the FTM counter value near the maximum count value (MOD). The second indicated transition occurs on phase A and causes the FTM counter transition between the maximum and minimum count values which are defined by MOD and CNTIN registers.

The appropriate settings of the phase A and phase B input filters are important to avoid glitches that may cause oscillation on the FTM counter value. The preceding figures show examples of oscillations that can be caused by poor input filter setup. Thus, it is important to guarantee a minimum pulse width to avoid these oscillations.

12.2.4.25 Intermediate load

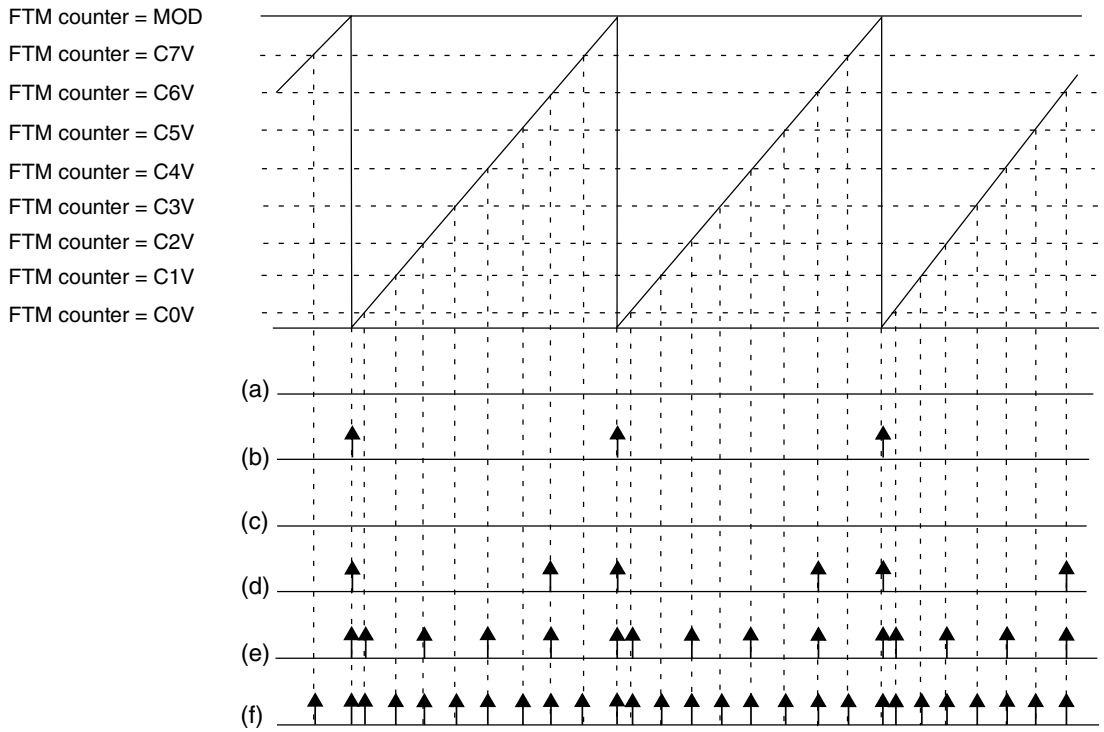
The PWMLOAD register allows to update the MOD, CNTIN, and C(n)V registers with the content of the register buffer at a defined load point. In this case, it is not required to use the PWM synchronization.

There are multiple possible loading points for intermediate load:

Table 12-17. When possible loading points are enabled

Loading point	Enabled
When the FTM counter wraps from MOD value to CNTIN value	Always
At the channel (j) match (FTM counter = C(j)V)	When CHjSEL = 1

The following figure shows some examples of enabled loading points.



NOTE

(a) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(b) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(c) LDOK = 0, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 1, CH4SEL = 0, CH5SEL = 0, CH6SEL = 0, CH7SEL = 0
(d) LDOK = 1, CH0SEL = 0, CH1SEL = 0, CH2SEL = 0, CH3SEL = 0, CH4SEL = 0, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
(e) LDOK = 1, CH0SEL = 1, CH1SEL = 0, CH2SEL = 1, CH3SEL = 0, CH4SEL = 1, CH5SEL = 0, CH6SEL = 1, CH7SEL = 0
(f) LDOK = 1, CH0SEL = 1, CH1SEL = 1, CH2SEL = 1, CH3SEL = 1, CH4SEL = 1, CH5SEL = 1, CH6SEL = 1, CH7SEL = 1

Figure 12-96. Loading points for intermediate load

After enabling the loading points, the LDOK bit must be set for the load to occur. In this case, the load occurs at the next enabled loading point according to the following conditions:

Table 12-18. Conditions for loads occurring at the next enabled loading point

When a new value was written	Then
To the MOD register	The MOD register is updated with its write buffer value.
To the CNTIN register and CNTINC = 1	The CNTIN register is updated with its write buffer value.
To the C(n)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n)V register is updated with its write buffer value.
To the C(n+1)V register and SYNCENm = 1 – where m indicates the pair channels (n) and (n+1)	The C(n+1)V register is updated with its write buffer value.

NOTE

- If ELSjB and ELSjA bits are different from zero, then the channel (j) output signal is generated according to the configured output mode. If ELSjB and ELSjA bits are zero,

then the generated signal is not available on channel (j) output.
- If CHjIE = 1, then the channel (j) interrupt is generated when the channel (j) match occurs.
- At the intermediate load neither the channels outputs nor the FTM counter are changed. Software must set the intermediate load at a safe point in time.

12.2.4.26 Global time base (GTB)

The global time base (GTB) is a FTM function that allows the synchronization of multiple FTM modules on a chip. The following figure shows an example of the GTB feature used to synchronize two FTM modules. In this case, the FTM A and B channels can behave as if just one FTM module was used, that is, a global time base.

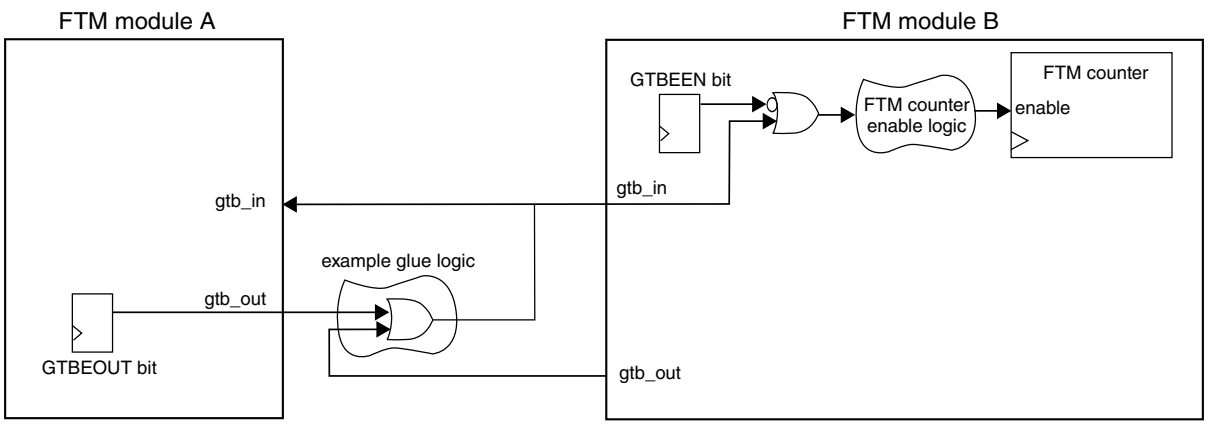


Figure 12-97. Global time base (GTB) block diagram

The GTB functionality is implemented by the GTBEEN and GTBEOUT bits in the CONF register, the input signal *gtb_in*, and the output signal *gtb_out*. The GTBEEN bit enables gtb_in to control the FTM counter enable signal:

- If GTBEEN = 0, each one of FTM modules works independently according to their configured mode.
- If GTBEEN = 1, the FTM counter update is enabled only when gtb_in is 1.

In the configuration described in the preceding figure, FTM modules A and B have their FTM counters enabled if at least one of the gtb_out signals from one of the FTM modules is 1. There are several possible configurations for the interconnection of the gtb_in and gtb_out signals, represented by the example glue logic shown in the figure. Note that these configurations are chip-dependent and implemented outside of the FTM modules. See the chip-specific FTM information for the chip's specific implementation.

NOTE

- In order to use the GTB signals to synchronize the FTM counter of different FTM modules, the configuration of each FTM module should guarantee that its FTM counter starts counting as soon as the gtb_in signal is 1.
- The GTB feature does not provide continuous synchronization of FTM counters, meaning that the FTM counters may lose synchronization during FTM operation. The GTB feature only allows the FTM counters to *start* their operation synchronously.

12.2.4.26.1 Enabling the global time base (GTB)

To enable the GTB feature, follow these steps for each participating FTM module:

1. Stop the FTM counter: Write 00b to SC[CLKS].
2. Program the FTM to the intended configuration. The FTM counter mode needs to be consistent across all participating modules.
3. Write 1 to CONF[GTBEEN] and write 0 to CONF[GTBEOUT] at the same time.
4. Select the intended FTM counter clock source in SC[CLKS]. The clock source needs to be consistent across all participating modules.
5. Reset the FTM counter: Write any value to the CNT register.

To initiate the GTB feature in the configuration described in the preceding figure, write 1 to CONF[GTBEOUT] in the FTM module used as the time base.

12.2.5 Reset overview

The FTM is reset whenever any chip reset occurs.

When the FTM exits from reset:

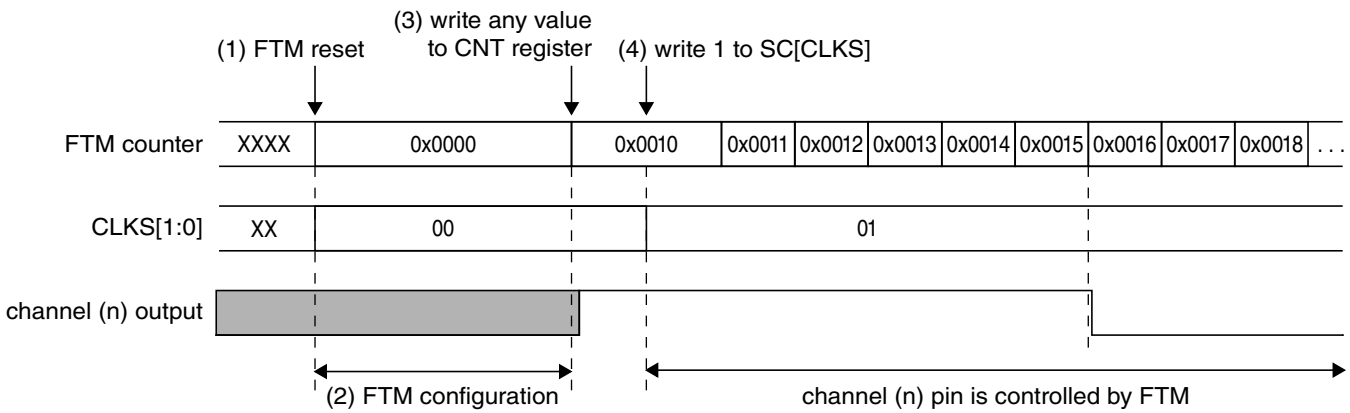
- the FTM counter and the prescaler counter are zero and are stopped (CLKS[1:0] = 00b);
- the timer overflow interrupt is zero, see Timer Overflow Interrupt;
- the channels interrupts are zero, see Channel (n) Interrupt;
- the channels are in input capture mode, see Input Capture mode;
- the channels outputs are zero;
- the channels pins are not controlled by FTM (ELS(n)B:ELS(n)A = 0:0) (See the table in the description of CnSC register).

The following figure shows the FTM behavior after the reset. At the reset (item 1), the FTM counter is disabled (see the description of the CLKS field in the Status and Control register), its value is updated to zero and the pins are not controlled by FTM (See the table in the description of CnSC register).

After the reset, the FTM should be configurated (item 2). It is necessary to define the FTM counter mode, the FTM counting limits (MOD and CNTIN registers value), the channels mode and CnV registers value according to the channels mode.

Thus, it is recommended to write any value to CNT register (item 3). This write updates the FTM counter with the CNTIN register value and the channels output with its initial value (except for channels in output compare mode) (Counter reset).

The next step is to select the FTM counter clock by the CLKS[1:0] bits (item 4). It is important to highlight that the pins are only controlled by FTM when CLKS[1:0] bits are different from zero (See the table in the description of CnSC register).



NOTES:
- CNTIN = 0x0010
- Channel (n) is in low-true combine mode with CNTIN < C(n)V < C(n+1)V < MOD
- C(n)V = 0x0015

Figure 12-98. FTM behavior after reset when the channel (n) is in Combine mode

The following figure shows an example when the channel (n) is in Output Compare mode and the channel (n) output is toggled when there is a match. In the Output Compare mode, the channel output is not updated to its initial value when there is a write to CNT register (item 3). In this case, use the software output control (Software output control) or the initialization (Initialization) to update the channel output to the selected value (item 4).

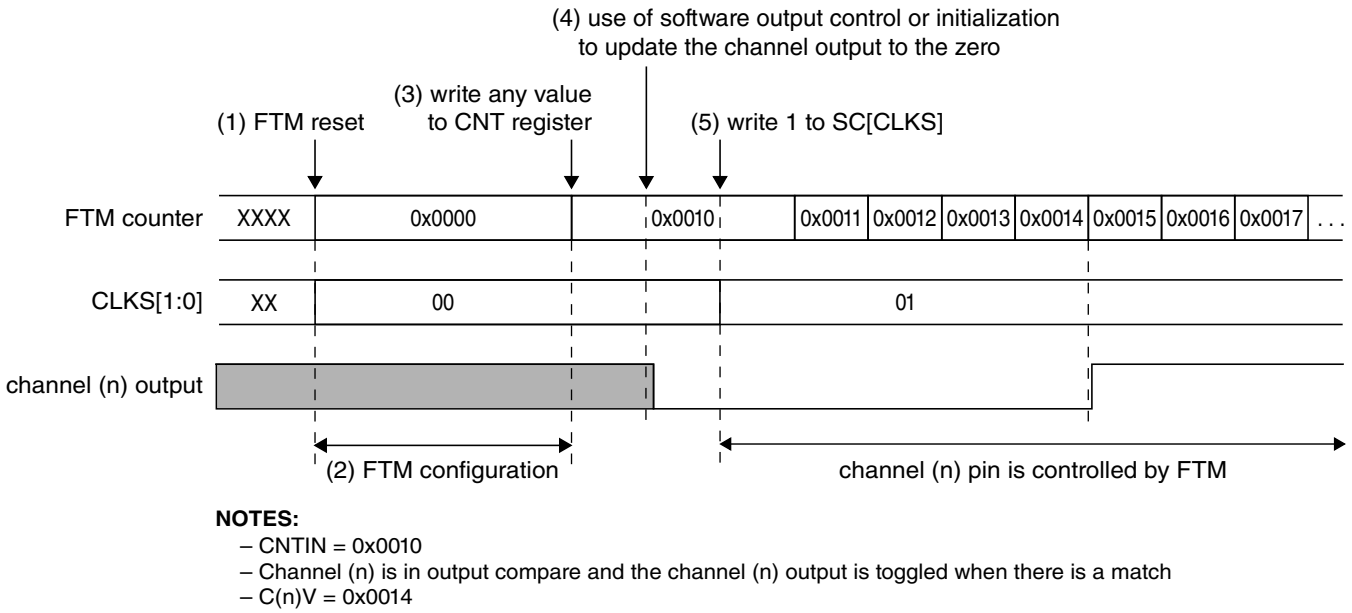


Figure 12-99. FTM behavior after reset when the channel (n) is in Output Compare mode

12.2.6 FTM Interrupts

12.2.6.1 Timer Overflow Interrupt

The timer overflow interrupt is generated when (TOIE = 1) and (TOF = 1).

12.2.6.2 Channel (n) Interrupt

The channel (n) interrupt is generated when (CHnIE = 1) and (CHnF = 1).

12.2.7 Initialization Procedure

The following initialization procedure is recommended to configure the FlexTimer operation. This procedure can also be used to do a new configuration of the FlexTimer operation.

- Define the POL bits.
- Mask the channels outputs using SYNCHOM = 0. Two clocks after the write to OUTMASK, the channels output are in the safe value.
- (Re)Configuration FTM counter and channels to generation of periodic signals - Disable the clock. If the selected mode is Quadrature Decoder, then disable this mode. Examples of the (re)configuration:

- Write to MOD.
- Write to CNTIN.
- Select OC, EPWM, CPWM, Combine, Complement modes for all channels that will be used
- Select the high-true and low-true channels modes.
- Write to CnV for all channels that will be used .
- (Re)Configure deadtime.
- Do not use the SWOC without SW synchronization (see item 6).
- Do not use the Inverting without SW synchronization (see item 6).
- Do not use the Initialization.
- Do not change the polarity control.
- Do not configure the HW synchronization

- Write any value to CNT. The FTM Counter is reset and the channels output are updated according to new configuration.
- Enable the clock. Write to CLKS[1:0] bits a value different from zero. If in the Quadrature Decoder mode, enable this mode.
- Configure the SW synchronization for SWOC (if it is necessary), Inverting (if it is necessary) and Output Mask (always)
  - Select synchronization for Output Mask Write to SYNC (SWSYNC = 0, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)
  - Write to SYNCONF.
    - HW Synchronization can not be enabled (HWSOC = 0, HWINVC = 0, HWOM = 0, HWWRBUF = 0, HWRSTCNT = 0, HWTRIGMODE = 0).
    - SW Synchronization for SWOC (if it is necessary): SWSOC = [0/1] and SWOC = [0/1].
    - SW Synchronization for Inverting (if it is necessary): SWINVC = [0/1] and INVC = [0/1].
    - SW Synchronization for SWOM (always): SWOM = 1. No enable the SW Synchronization for write buffers (because the writes to registers with write buffer are done using CLKS[1:0] = 2’b00): SWWRBUF = 0 and CNTINC = 0 .
    - SW Synchronization for counter reset (always): SWRSTCNT = 1.
    - Enhanced synchronization (always): SYNCMODE = 1
  - If the SWOC is used (SWSOC = 1 and SWOC = 1), then write to SWOCTRL register.
  - If the Inverting is used (SWINVC = 1 and INVC = 1), then write to INVCTRL register.
  - Write to OUTMASK to enable the masked channels.
- Generate the Software Trigger Write to SYNC (SWSYNC = 1, TRIG2 = 0, TRIG1 = 0, TRIG0 = 0, SYNCHOM = 1, REINIT = 0, CNTMAX = 0, CNTMIN = 0)

12.3 Pulse Width Modulation (PWM)

12.3.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. A block diagram of the PWM module is shown in the figure below.

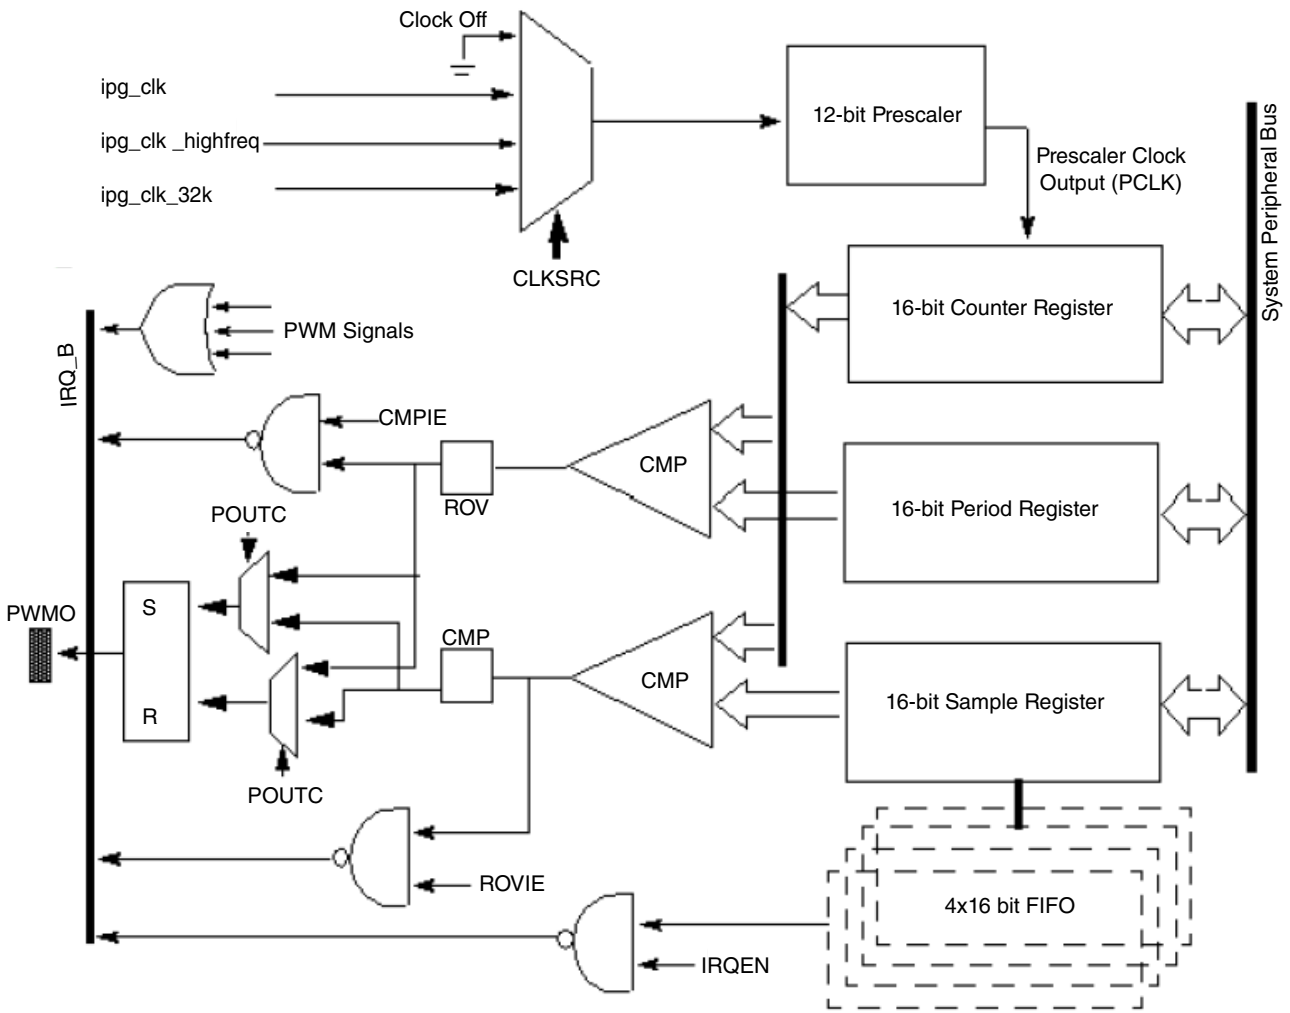

Figure 12-100. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

12.3.2 External Signals

The PWM follows IP Bus protocol when interfacing with the processor core. PWM does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal.

The following table outlines the external signals.

Table 12-19. PWM External Signals

Signal	Description	Pad	Mode	Direction
PWM1_OUT	This is the PWM1 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_RDATA0	ALT1	O
		GPIO1_IO01	ALT1	
		GPIO1_IO08	ALT7	
PWM2_OUT	This is the PWM2 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_RDATA1	ALT1	O
		GPIO1_IO02	ALT1	
		GPIO1_IO09	ALT7	
PWM3_OUT	This is the PWM3 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_TDATA0	ALT1	O
		GPIO1_IO03	ALT1	
		GPIO1_IO10	ALT7	
PWM4_OUT	This is the PWM4 functional output of the PWM. A modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the cycle of 50%.	ENET1_TDATA1	ALT1	O
		GPIO1_IO00	ALT1	
		GPIO1_IO11	ALT7	

12.3.3 Clocks

The table found here describes the clock sources for PWM.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 12-20. PWM Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_32k	ckil_sync_clk_root	low-frequency reference clock (32 kHz)
ipg_clk_highfreq	perclk_clk_root	high-frequency reference clock
ipg_clk_s	ipg_clk_root	Peripheral access clock

The clock that feeds the prescaler can be selected from:

- High-frequency reference clock (ipg_clk_highfreq) pat_ref or CKIH

  This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be on in the low power mode when the ipg_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low-frequency reference clock (ipg_clk_32k, CKIL)

  This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when ipg_clk is turned off. Thus, PWM can be run on this clock in the low power mode.

- Peripheral clock (ipg_clk)

  This clock should be on in normal operations. In low power mode, it can be switched off.

- Peripheral access clock (ipg_clk_s)

  This clock is used for register read/write.

The clock input source is determined by the PWM control register field PWM_CR[CLKSRC]. The CLKSRC value should only be changed when the PWM is disabled.

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

12.3.4 Functional Description

The following sections detail the PWM operation and function.

12.3.4.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the PWM_PR + 1. After this match occurs the counter is reset to 0x0000.

At the beginning of a count period cycle, the PWMO pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWMO signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled, the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers being cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

12.3.4.1.1 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianess can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write to the PWM_SAR sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM_SR[FIFOAV] field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

12.3.4.1.2 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PWM_PR[PERIOD] + 1 and resumes counting thereafter. This event is referred to as a rollover. For example, if PWM_PR[PERIOD] = 0x0000, the counter is reset when it equals 0x0001. When PWM_PR[PERIOD] = 0xFFFF or 0xFFFE, the counter is reset when it equals 0xFFFF. For more information, see the PWM Period Register (PWM_PR) description.

During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

12.3.4.1.3 Low Power Mode Behavior

In low power mode, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

12.3.4.1.4 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

12.3.5 Enable Sequence for the PWM

The sequence found here should be used to enable the PWM.

1. Configure the desired settings for the PWM Control Register (PWMx_PWMCR) while keeping the PWM disabled (PWMx_PWMCR[0]=0).
2. Enable the desired interrupts in the PWM Interrupt Register (PWMx_PWMIR).
3. One to three initial samples may be written to the PWM Sample Register (PWMx_PWMSAR). The initial sample values will be loaded into the PWM FIFO even if the PWM is not yet enabled. Do not write a 4th sample because the FIFO will become full and trigger a FIFO Write Error (FWE). This error will prevent the PWM from starting once it is enabled.
4. Check the FIFO Write Error status bit (FWE), the Compare status bit (CMP) and the Roll-over status bit (ROV) in the PWM Status Register (PWMx_PWMSR) to make sure they are all zero. Any non-zero status bits should be cleared by writing a 1 to them.
5. Write the desired period to the PWM Period Register (PWMx_PWMPR).
6. Enable the PWM by writing a 1 to the PWM Enable bit, PWMx_PWMCR[0], while maintaining the other register bits in their previously configured state.

12.3.6 Disable Sequence for the PWM

The PWM can be disabled at any time by clearing the PWM enable bit, PWMx_PWMCR[0] to 0.

Any data remaining in the FIFO will not be produced at the PWM output after the PWM has been disabled and will remain in the FIFO until the PWM is enabled again. A software reset (setting PWMx_PWMCR[3] to 1) or a hardware reset will clear the FIFO and any remaining data will be lost.

12.3.7 PWM Memory Map/Register Definition

The PWM includes six user-accessible 32-bit registers.

PWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3066_0000	PWM Control Register (PWM1_PWMCR)	32	R/W	0000_0000h	12.3.7.1/ 3530
3066_0004	PWM Status Register (PWM1_PWMSR)	32	w1c	0000_0008h	12.3.7.2/ 3532

Table continues on the next page...

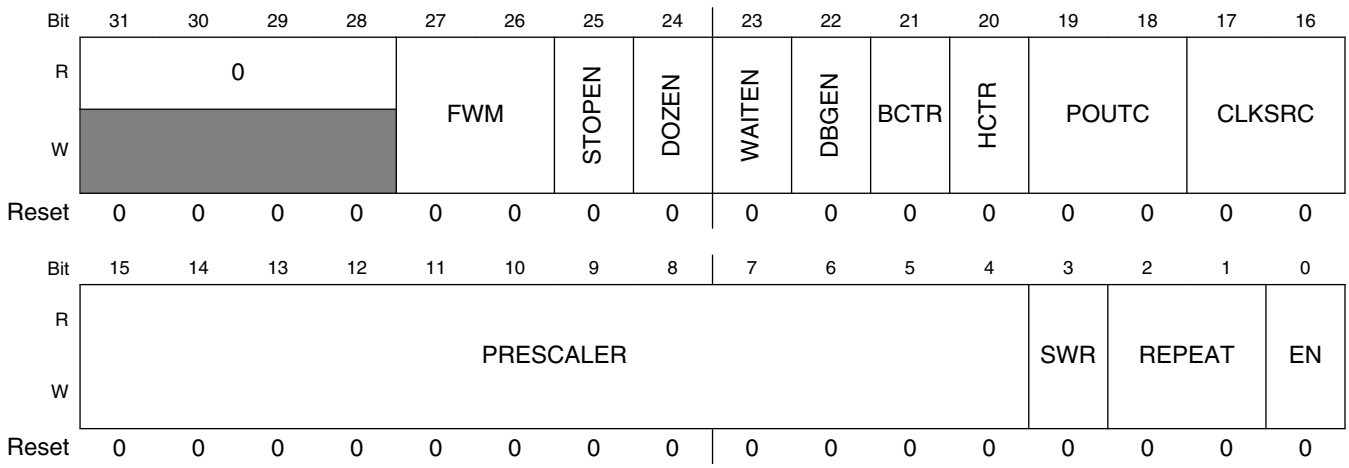
PWM memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3066_0008	PWM Interrupt Register (PWM1_PWMIR)	32	R/W	0000_0000h	12.3.7.3/ 3533
3066_000C	PWM Sample Register (PWM1_PWMSAR)	32	R/W	0000_0000h	12.3.7.4/ 3534
3066_0010	PWM Period Register (PWM1_PWMPR)	32	R/W	0000_FFFEh	12.3.7.5/ 3535
3066_0014	PWM Counter Register (PWM1_PWMCNR)	32	R	0000_0000h	12.3.7.6/ 3535
3067_0000	PWM Control Register (PWM2_PWMCR)	32	R/W	0000_0000h	12.3.7.1/ 3530
3067_0004	PWM Status Register (PWM2_PWMSR)	32	w1c	0000_0008h	12.3.7.2/ 3532
3067_0008	PWM Interrupt Register (PWM2_PWMIR)	32	R/W	0000_0000h	12.3.7.3/ 3533
3067_000C	PWM Sample Register (PWM2_PWMSAR)	32	R/W	0000_0000h	12.3.7.4/ 3534
3067_0010	PWM Period Register (PWM2_PWMPR)	32	R/W	0000_FFFEh	12.3.7.5/ 3535
3067_0014	PWM Counter Register (PWM2_PWMCNR)	32	R	0000_0000h	12.3.7.6/ 3535
3068_0000	PWM Control Register (PWM3_PWMCR)	32	R/W	0000_0000h	12.3.7.1/ 3530
3068_0004	PWM Status Register (PWM3_PWMSR)	32	w1c	0000_0008h	12.3.7.2/ 3532
3068_0008	PWM Interrupt Register (PWM3_PWMIR)	32	R/W	0000_0000h	12.3.7.3/ 3533
3068_000C	PWM Sample Register (PWM3_PWMSAR)	32	R/W	0000_0000h	12.3.7.4/ 3534
3068_0010	PWM Period Register (PWM3_PWMPR)	32	R/W	0000_FFFEh	12.3.7.5/ 3535
3068_0014	PWM Counter Register (PWM3_PWMCNR)	32	R	0000_0000h	12.3.7.6/ 3535
3069_0000	PWM Control Register (PWM4_PWMCR)	32	R/W	0000_0000h	12.3.7.1/ 3530
3069_0004	PWM Status Register (PWM4_PWMSR)	32	w1c	0000_0008h	12.3.7.2/ 3532
3069_0008	PWM Interrupt Register (PWM4_PWMIR)	32	R/W	0000_0000h	12.3.7.3/ 3533
3069_000C	PWM Sample Register (PWM4_PWMSAR)	32	R/W	0000_0000h	12.3.7.4/ 3534
3069_0010	PWM Period Register (PWM4_PWMPR)	32	R/W	0000_FFFEh	12.3.7.5/ 3535
3069_0014	PWM Counter Register (PWM4_PWMCNR)	32	R	0000_0000h	12.3.7.6/ 3535

12.3.7.1 PWM Control Register (PWMx_PWMCR)

The PWM control register (PWM_PWMCR) is used to configure the operating settings of the PWM. It contains the prescaler for the clock division.

Address: Base address + 0h offset



PWMx_PWMCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 0xfff Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
0 EN	PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins. To make the PWM work with softreset and disable/enable, users can do software reset by seting the SWR bit, wait software reset done, configure the registers, and then enable the PWM by setting this bit to "1" Users can also disable/enable the PWM if PWM would like to be stopped and resumed with same registers configurations . 0 PWM disabled 1 PWM enabled

12.3.7.2 PWM Status Register (PWMx_PWMSR)

The PWM status register (PWM_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0									FWE	CMP	ROV	FE	FIFOAV		
W										w1c	w1c	w1c	w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

PWMx_PWMSR field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 FWE	FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full. 0 FIFO write error not occurred 1 FIFO write error occurred
5 CMP	Compare Status. This bit shows that a compare event has occurred. 0 Compare event not occurred 1 Compare event occurred

Table continues on the next page...

PWMx_PWMSR field descriptions (continued)

Field	Description
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

12.3.7.3 PWM Interrupt Register (PWMx_PWMIR)

The PWM Interrupt register (PWM_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0													CIE	RIE	FIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMIR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt.

Table continues on the next page...

PWMx_PWMIR field descriptions (continued)

Field	Description
	0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

12.3.7.4 PWM Sample Register (PWMx_PWMSAR)

The PWM sample register (PWM_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the PWMO output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																SAMPLE															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMSAR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

12.3.7.5 PWM Period Register (PWMx_PWMPR)

The PWM period register (PWM_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

PWMO (Hz) = PCLK(Hz) / (period +2)

A value of zero in the PWM_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM_PWMPR results in the counter being reset to zero and the start of a new count period.

NOTE

Settings PWM_PWMPR to 0xFFFF when PWMx_PWMCR REPEAT bits are set to non-zero values is not allowed.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																PERIOD															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

PWMx_PWMPR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

12.3.7.6 PWM Counter Register (PWMx_PWMCNR)

The read-only pulse-width modulator counter register (PWM_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																COUNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMCNR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

Chapter 13
Multimedia

13.1 Multimedia

13.1.1 Display and camera subsystem

The chip display and camera subsystem consists of the dedicated modules found here.

- LCD Interface (LCDIF): 24-bit parallel RGB LCD interface
- PXP pixel pipeline: pixel/image processing engine for LCD display
- CSI (camera sensor interface): up to 24-bit parallel interface for image sensor
- MIPI DSI Host controller with associated MIPI D-PHY Tx (one clock lane, two Data lanes)
- MIPI CSI-2 Host controller with associated MIPI D-PHY Rx (one clok lane, two Data lanes)

The following figure shows the high-level integration scheme of the chip display and camera system.

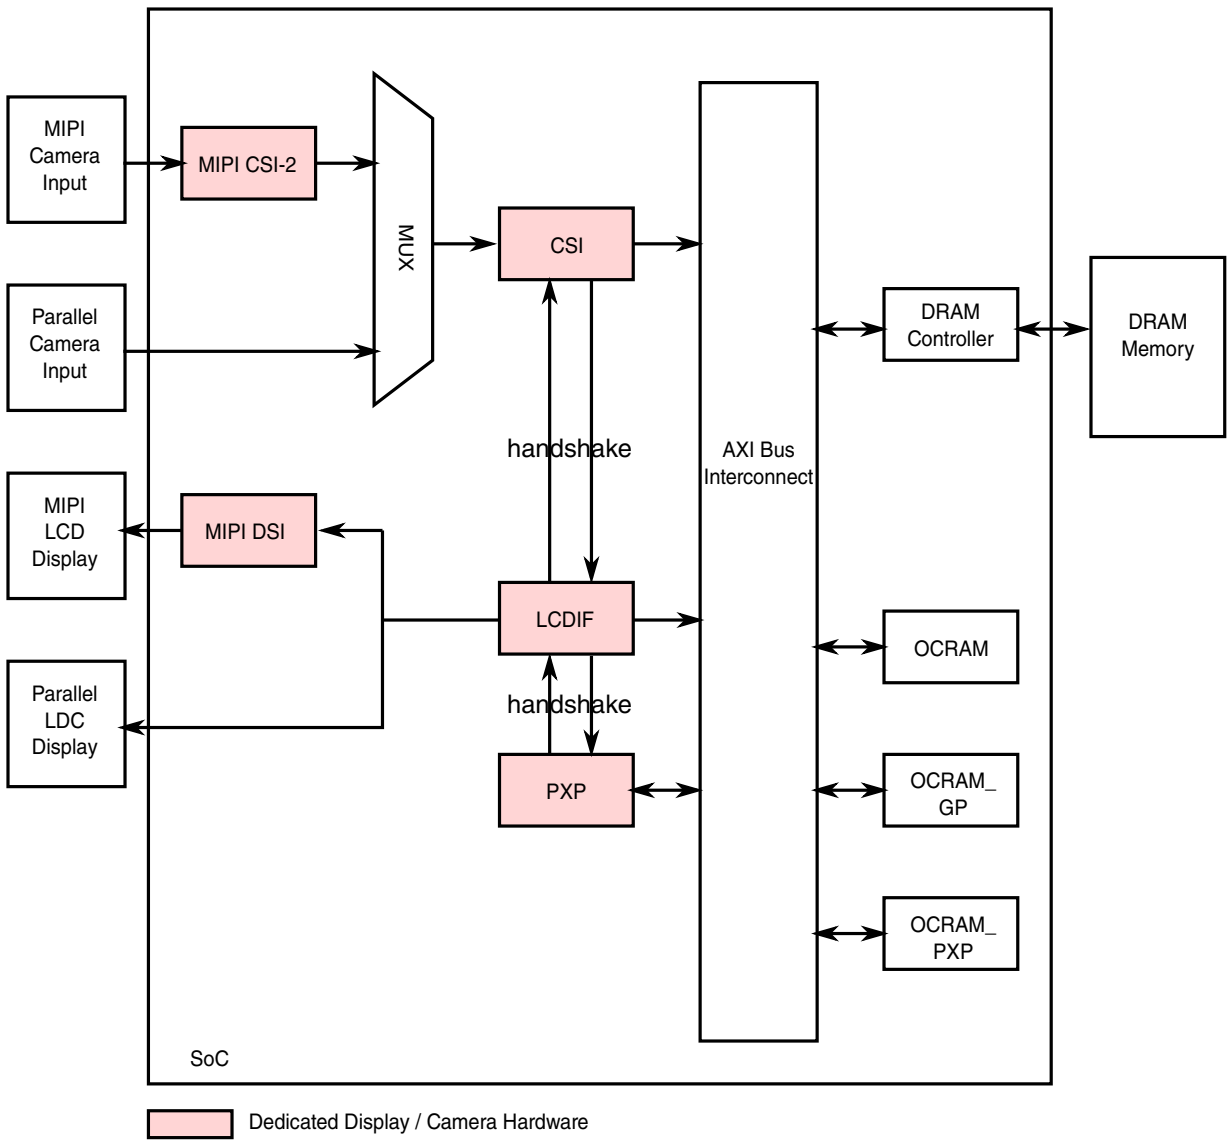


Figure 13-1. Chip display and camera subsystem

13.1.1.1 PiXel Processing Pipeline

The pixel processing pipeline is used to perform image processing on image/video buffers before sending to an LCD display.

The main features of PXP include:

- Multiple input/output format support, including YUV/RGB/Grayscale
- Supports both RGB/YUV scaling
- Supports overlay with Alpha blending
- Supports 2D Blit operation

- Supports HW dithering with configurable dithering algorithm
- Single-pass pixel processing for scaling, alpha blending, CSC, rotation and dithering without multiple access to DRAM
- Supports flexible programmable pixel processing engine

13.1.1.2 LCD Interface

The LCDIF is a general purpose display controller that is used to drive a wide range of display devices. These displays can vary in size and capability. Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers. In addition to these displays, it is also common to provide support for digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals. The LCDIF block supports these different interfaces by providing fully programmable functionality.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal CPU overhead.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

13.1.1.3 Parallel CMOS Sensor Interface

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit data port for YCC, YUV, or RGB data input.
- 8-bit/10-bit/16-bit/24-bit data port for generic data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit/pixel data format to 64-bit receive FIFO packing.
- 256 × 64 FIFO to store received image pixel data. Receive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support for 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support for double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources:
  - Start of Frame
  - End of Frame
  - Change of Field
  - FIFO full
  - FIFO overrun
  - DMA transfer done
  - CCIR error
  - AHB bus response error
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

13.1.2 Display / Sensor MIPI interfaces

13.1.2.1 Introduction

i.MX Application Processor features MIPI DSI/CSI-2 interfaces that includes:

- MIPI DSI Host controller with associated MIPI D-PHY Tx (One clock lane, two Data lanes)
- MIPI CSI-2 Host controller with associated MIPI D-PHY Rx (one clock lane, Data Lanes)

13.1.2.2 MIPI DSI

MIPI DSI is a high performance serial interconnect bus for mobile applications connecting display system to the host system.

There is one instance of DSI port in the chip. This interface support from 80 Mbps up to 1.5 Gbps speed per data lane. The DSI Receiver core can mange one clock lane and up to 2 data lanes through the lane management, however two data lanes are implemented in the transmitter D-PHY, therefore the maximum throughput of display port is 3Gbps.

The DSI port supports the following standards:

- MIPI DSI Compliant
- DSI Version 1.01
- DPI Version 2.0
- DBI Version 2.0
- DCS Version 1.02
- PPI for D-PHY
- MIPI D-PHY Version 1.0

DSI host core is capable of supporting a variety of resolutions and formats:

- Resolution:
  - QQVGA
  - QCIF, QVGA
  - CIF
  - VGA
  - WVGA
  - SVGA
  - XVGA
  - WXGA
- Pixel format:
  - RGB565
  - LRGB565
  - RGB666
  - RGB888

The DSI can support both command and video modes and up to four virtual channels to accommodate multiple displays.

- Command and video mode support (type 1, 2, 3, and 4 display architecture)
- Mode switching: low power and ultra low power
- Burst mode: dual video channel
- Non-burst mode: single video channel

- Bus turnaround
- Fault error recovery scheme

DPI and DBI could coexists in the system but only one of them could be active in a certain time moment

13.1.2.3 MIPI CSI-2

MIPI CSI-2 is a high performance serial interconnect bus for mobile applications connecting camera sensors to the host system.

There is one instance of CSI-2 port in the chip. This interface support from 80 Mbps up to 1.5 Gbps speed per data lane. The CSI-2 Receiver core can mange one clock lane and up to two data lanes through the lane management and de-packetization, providing a maximum throughput of 3 Gbps transfer rate.

The CSI-2 port supports the following standards:
- MIPI CSI-2 Version 1.0
- MIPI PPI interface for D-PHY
- MIPI D-PHY Version 1.0

13.1.3 Audio subsystem

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3, and MQS. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

Audio Subsystem Module Overview provides an overview of each of the audio subsystem component modules, followed by a module-specific section.

13.1.3.1 Audio Subsystem Module Overview

The following figure shows a high level block diagram of the audio subsystem.

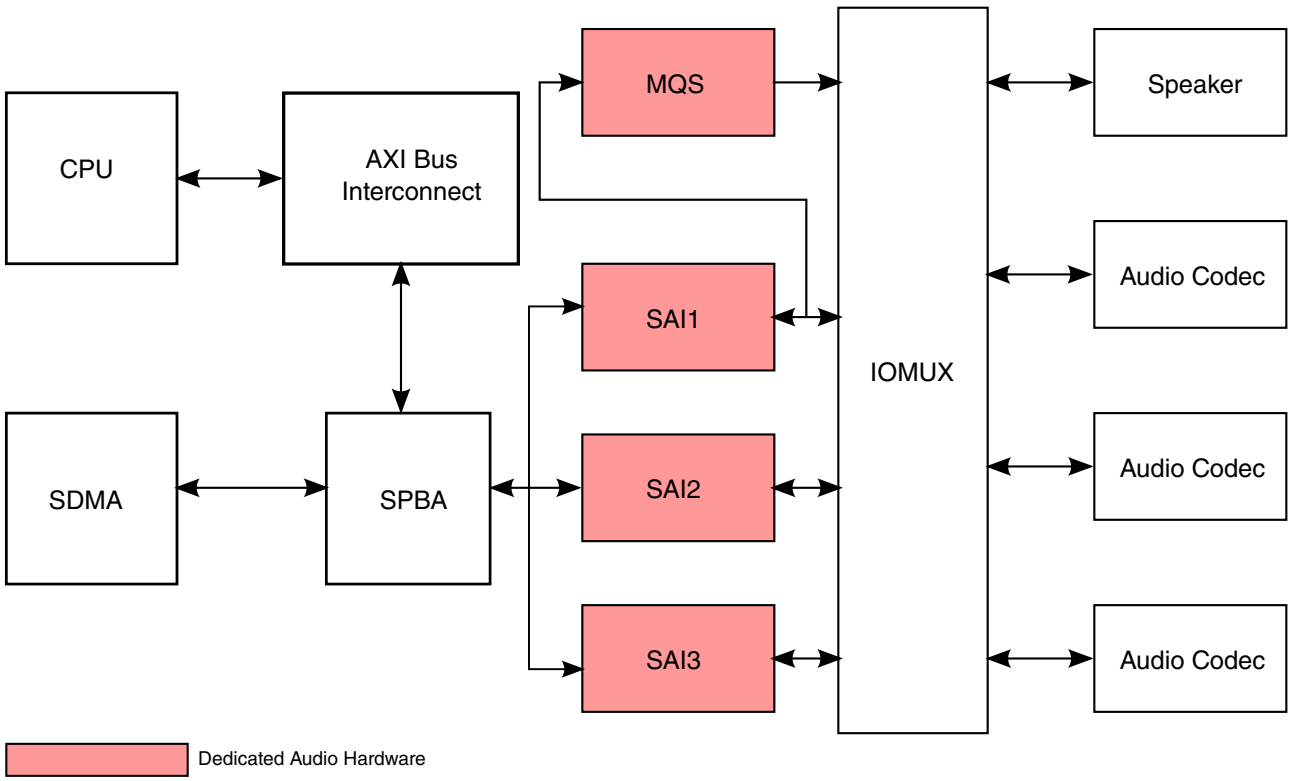

Figure 13-2. Audio subsystem block diagram

SAI1–3 are synchronous serial interfaces used to transfer audio data. SAI1–3 are on the shared peripheral bus. They can be accessed by both the SDMA and ARM CPUs. Their input/output are connected to the pads through IOMUX.

MQS (medium quality speaker) is used to convert the I2S audio data from SAI to PWM signals that can drive external speaker directly. Its audio source comes from SAI-1 and its output is connected to pads through IOMUX.

13.1.3.2 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting 1 data line
- Receiver with independent Bit Clock and Frame Sync supporting 1 data line
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame.
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

13.2 Enhanced LCD Interface (eLCDIF)

13.2.1 Overview

The eLCDIF is a general purpose display controller used to drive a wide range of display devices varying in size and capability.

Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers. In addition to these displays, it is also common to provide support for digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals. The eLCDIF block supports these interfaces by providing fully programmable functionality.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.
- PIO interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24/32 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

13.2.2 External Signals

The following table describes the external signals of LCD:

Table 13-1. LCD External Signals

13.2.3 Clocks

The following table describes the clock sources for eLCDIF. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 13-2. eLCDIF Clocks

Clock name	Clock Root	Description
apb_clk	MAIN_AXI_CLK_ROOT	AXI clock
pix_clk	LCDIF_PIXEL_CLK_ROOT	Pixel clock
ipg_clk_s	MAIN_AXI_CLK_ROOT	Peripheral access clock

13.2.4 Functional Description

Bus Interface Mechanisms through Initializing the eLCDIF, describe the internal pipeline for the MPU write/read interface, VSYNC, DOTCLK, and DVI interfaces. Differences for each mode are then described in separate sections, as follows:

- MPU Interface
- VSYNC Interface
- DOTCLK Interface
- ITU-R BT.656 Digital Video Interface (DVI)

eLCDIF pin usage by interface mode is described in eLCDIF Pin Usage by Interface Mode.

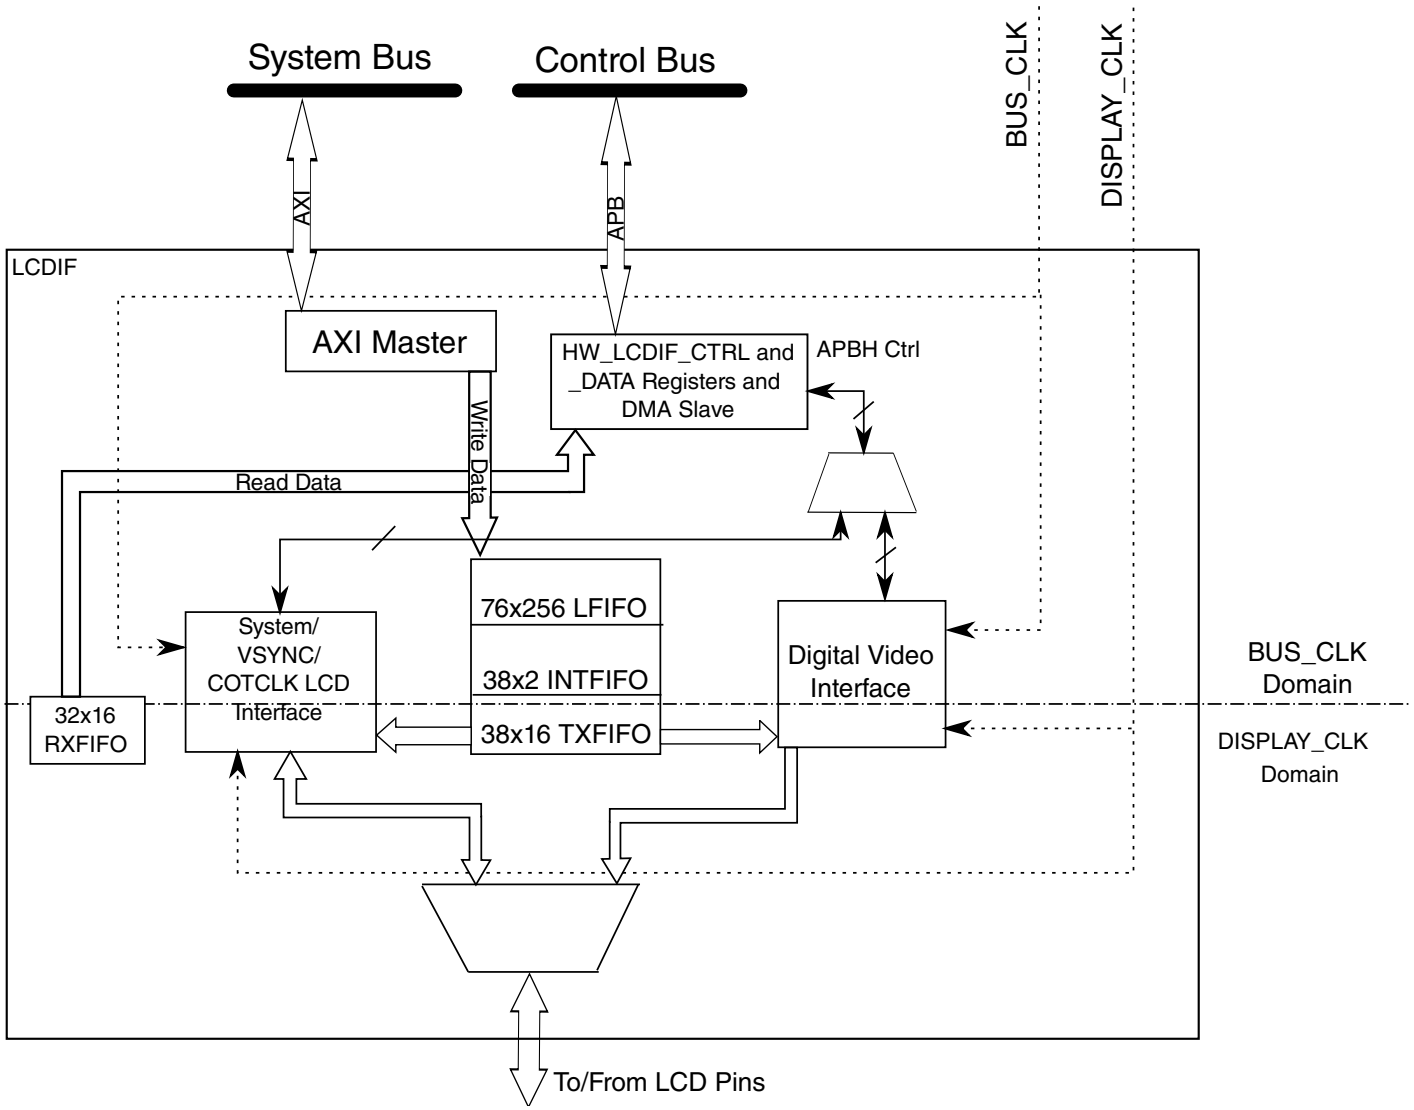

Figure 13-3. Top-Level Block Diagram of eLCDIF subsystem

13.2.4.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types. Bus mastering can also be used for MPU mode data writes.

The PIO interface is used to interface to "Smart" displays to transfer frame buffer data and control information to/from the external display. The host CPU executes display drivers to manage the display solution.

The following sections describe the system bus interface mechanisms.

13.2.4.1.1 Bus Master Operation in Write/Display Modes

The eLCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

In the MPU and VSYNC modes, single frames are transferred. When a complete frame is transferred, eLCDIF enters idle and clears the RUN bit in the CTRL register. For subsequent frame transmission, the eLCDIF setup sequence should be repeated.

The DOTCLK and DVI modes are used to refresh the display at the desired refresh rate and resolution. These modes are used to drive displays that do not integrate a display buffer memory. When the display is refreshed, the eLCDIF will automatically update the LCDIF_CUR_BUF_ADDR register with the value in LCDIF_NEXT_BUF_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF_ADDR register was not updated within a frame refresh cycle, eLCDIF will keep transmitting the last frame until a new value is programmed into that register.

eLCDIF also provides the capability of interlacing a progressive frame by fetching odd lines in the first field and then fetching even lines in the second field. This feature can be used in the DVI mode and can be turned on by setting the INTERLACE_FIELDS bit in the LCDIF_CTRL1 register.

13.2.4.1.2 System Bus Master Performance

The performance of the eLCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2_OUTSTANDING_REQS field will control how many requests the eLCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2_BURST_LEN_8 bit will set the number of 64 bit words requested for each eLCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the eLCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

The LCDIF_THRES register can also be used to optimize bus throughput and power consumption.

The LCDIF_THRES_PANIC value can be used to raise the priority of requests initiated by the eLCDIF to alter how the eLCDIF requests are arbitrated by the system bus infrastructure. The panic output control signal is raised when the number of 32bpp pixel equivalents in the LFIFO is less than this programmed value. Since the LFIFO is arranged as a 256x64bit quadword FIFO, it contains two 32bpp pixels per quadword, or 512 32bpp pixels total. To set the panic output when 3/4s of the LFIFO is empty, set the LCDIF_THRES_PANIC value to 3/4 * 512, or 128. The panic signal output is used to assess higher priority to eLCDIF system requests to avoid eLCDIF under run errors during periods of high system bandwidth utilization.

The features available with the LCDIF_THRES register require support from system clocking and dynamic priority control. Refer to the appropriate block documentation to assess the system support for these features.

13.2.4.2 Write Data Path

eLCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The INPUT_DATA_SWIZZLE field in the LCDIF_CTRL register provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The WORD_LENGTH field of LCDIF_CTRL register indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The H_COUNT field of this register indicates the number of pixels per line and V_COUNT indicates the total number of lines per frame. A special bit field in the LCDIF_CTRL1 register, called the BYTE_PACKING_FORMAT, can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, BYTE_PACKING_FORMAT should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then BYTE_PACKING_FORMAT should be set to 0x7.

The LCD_DATABUS_WIDTH field in LCDIF_CTRL register suggests the width of the bus going to the external display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. Refer to the system I/O muxing options for support of this feature. If the LCD_DATABUS_WIDTH is not the same as WORD_LENGTH, eLCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, eLCDIF will pad the MSBs of each color to the LSBs

of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, eLCDIF will drop the LSBs of each color channel to convert to the lower color depth. eLCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the ODD_LINE_PATTERN and the EVEN_LINE_PATTERN bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

eLCDIF also supports RGB to YCbCr 4:2:2 color space conversion. This is useful in the DVI mode since the TV encoder requires input in YCbCr 4:2:2 format. The LCDIF_CSC* registers have complete programmability over the CSC coefficients and offsets. The values must be written into these registers in the signed two's complement format.

The following list shows how the different input/output combinations can be obtained:

- WORD_LENGTH=1 indicates that the input is 8-bit data. This is most likely going to be used for sending commands in MPU interface, or maybe a gray scale image. Any combination of BYTE_PACKING_FORMAT [3:0] is permissible.

  Limitation: H_COUNT must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0]. LCD_DATABUS_WIDTH must be 1, indicating an 8-bit data bus.

- WORD_LENGTH=0 implies the input frame buffer is RGB 16 bits per pixel. DATA_FORMAT_16_BIT field determines the pixels are RGB 555 or RGB 565.

  Limitation: BYTE_PACKING_FORMAT [3:0] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and H_COUNT will be restricted to be a multiple of 2 pixels.

- WORD_LENGTH=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the DATA_FORMAT_18_BIT bit.

  Limitation: BYTE_PACKING_FORMAT can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case. H_COUNT can be any number.

- WORD_LENGTH=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If BYTE_PACKING_FORMAT [3:0] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on H_COUNT. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.

Limitation: If BYTE_PACKING_FORMAT [3:0] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and H_COUNT must be a multiple of 4 pixels.

- YCBCR422_INPUT=1 implies that the input frame is in YCbCr 4:2:2 format. BYTE_PACKING_FORMAT must be 0xF.

  Limitation: LCD_DATABUS_WIDTH must be 8-bit and H_COUNT must be a multiple of 2 pixels.

  ODD_LINE_PATTERN and EVEN_LINE_PATTERN must be 0 when any of RGB_TO_YCBCR422_CSC or INTERLACE_FIELDS or YCBCR422_INPUT bits is 1.

After the RGB to RGB or RGB to YCbCr 4:2:2 color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the CSC_DATA_SWIZZLE field in the LCDIF_CTRL register, and it provides the same options as the INPUT_DATA_SWIZZLE register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the SHIFT_DIR and SHIFT_NUM_BITS fields in LCDIF_CTRL register.

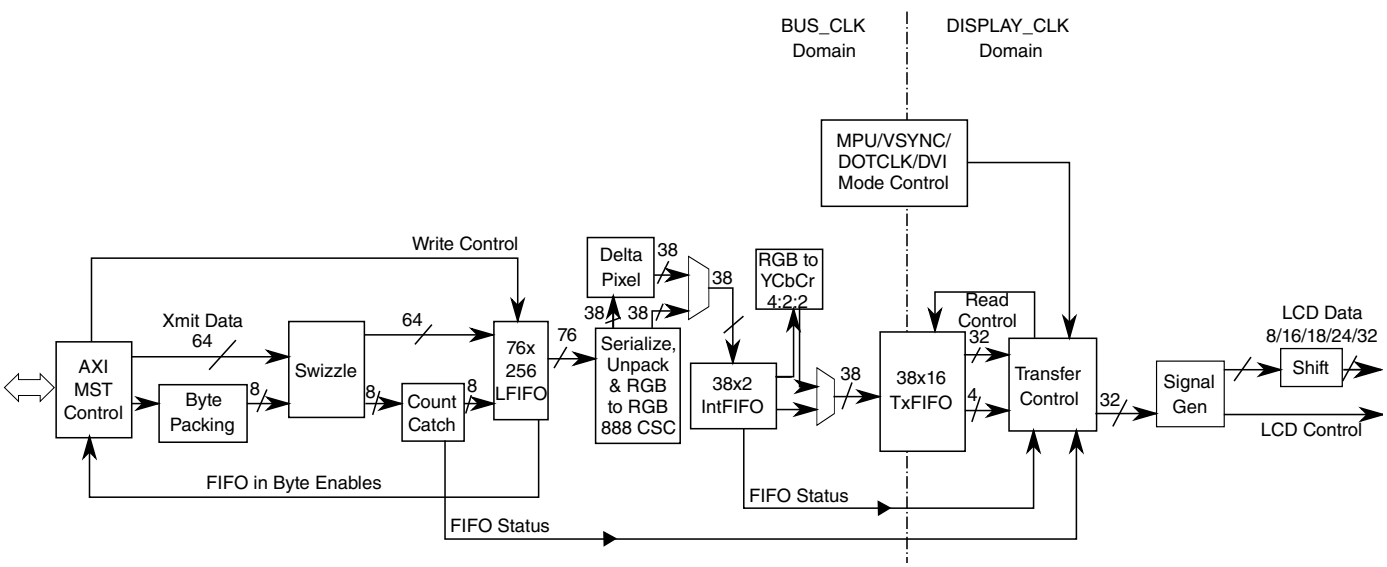

Figure 13-4. General Operations in Write Data Path

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to I/O bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

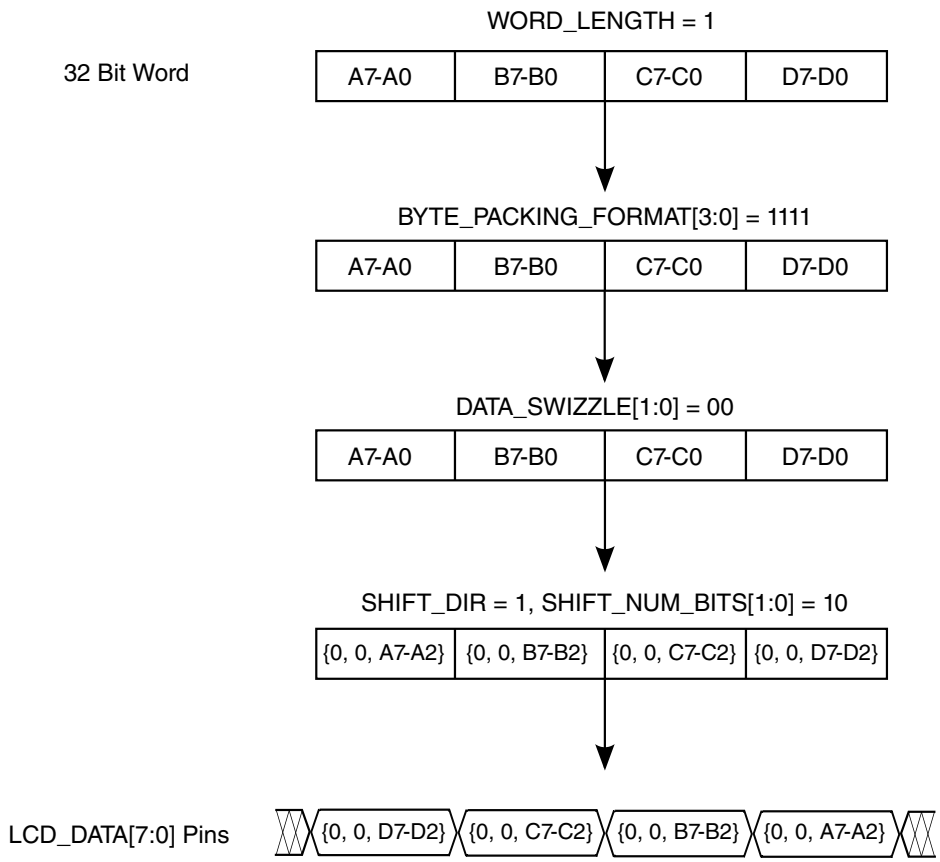

Figure 13-5. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

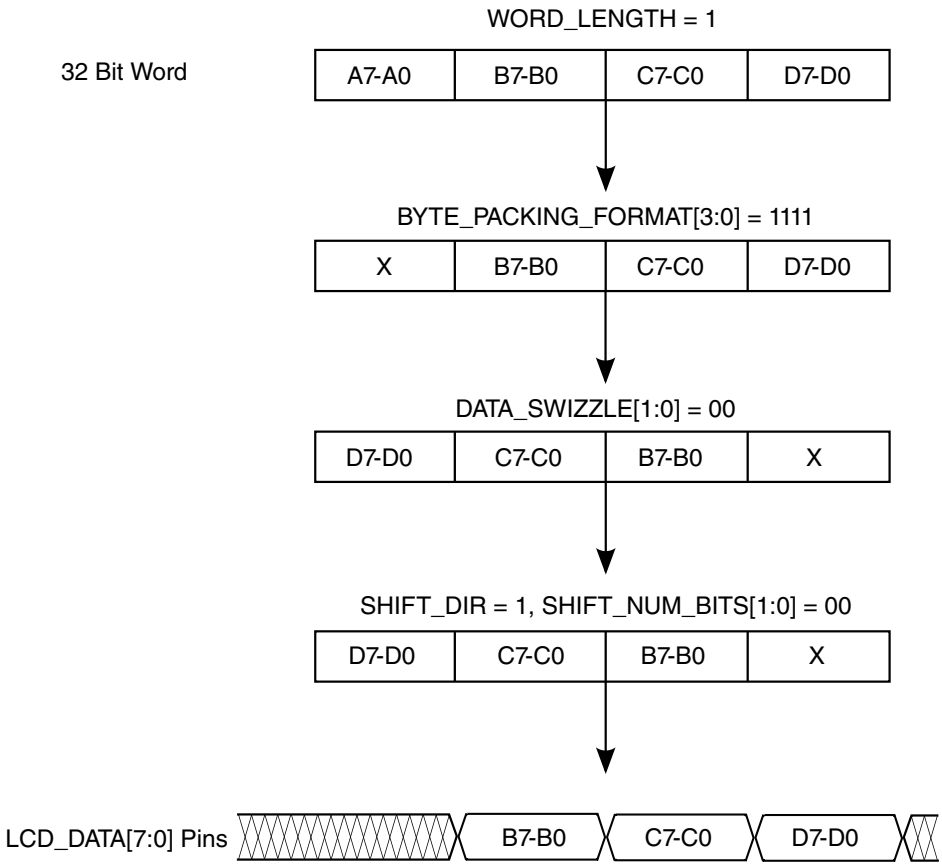

Figure 13-6. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

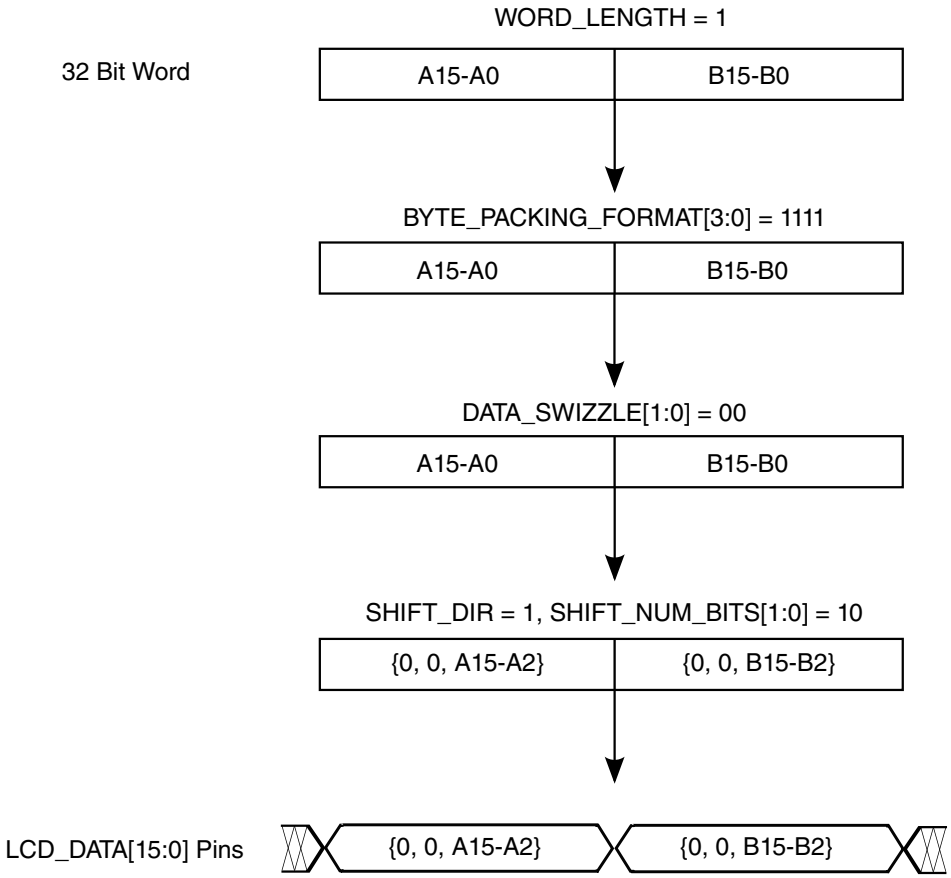

Figure 13-7. Register programming for write mode

This example indicates how an unpacked frame buffer can sourced for display. Only a single 16 bit half word within the 32 bit word is tranferred out via the 16 display bus.

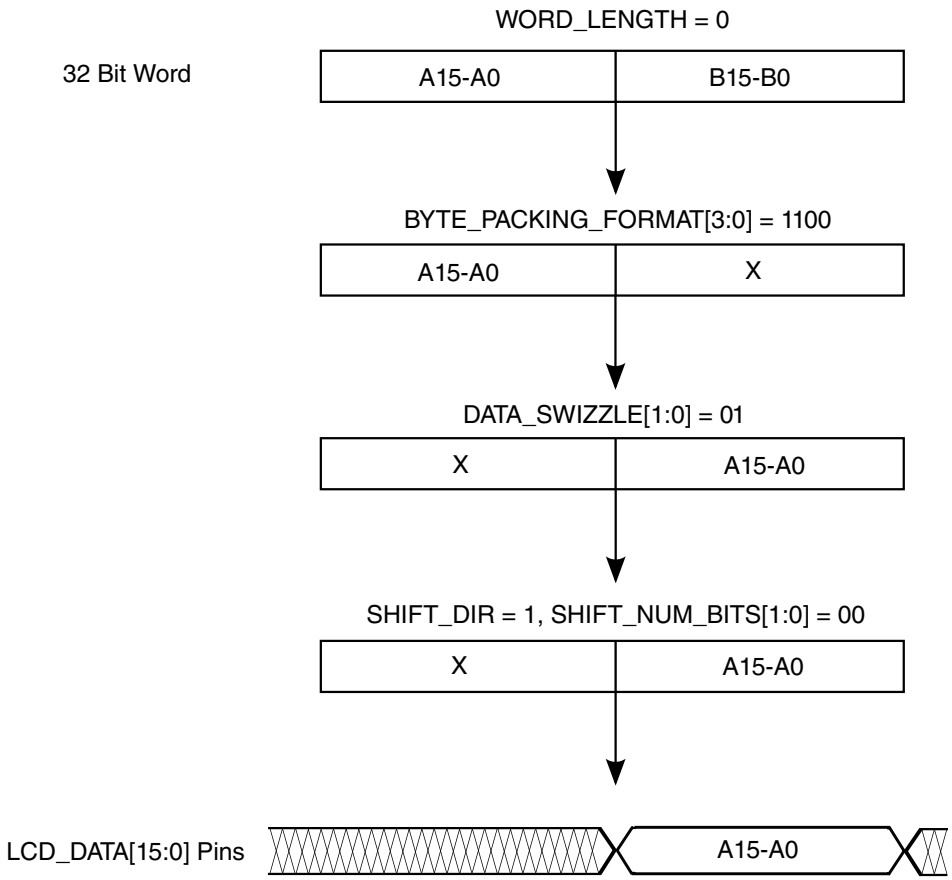

Figure 13-8. Register programming for write mode

13.2.4.3 Read Data Path

Figure 13-9 shows the MPU read data path in detail.

eLCDIF can read from an external display that follows the 6800/8080 MPU protocol.

The display bus width is determined by the LCD_DATABUS_WIDTH bit field. The data sampled at every read strobe is called a subword and the number of subwords that can be packed in a 32-bit word is given by the READ_MODE_NUM_PACKED_SUBWORDS bit field. The INITIAL_DUMMY_READ bit field directs the eLCDIF to skip the number of programmed subwords before starting to process read data. This feature is useful in the case of an LCD controller that returns the last written data the first time a read is issued, and then sends the correct data thereafter. SHIFT_DIR and SHIFT_NUM_BITS bit fields indicate whether the data needs to be shifted before getting stored in the internal registers. For example, a value of 2 in READ_MODE_NUM_PACKED_SUBWORDS if lcd databus width is 8 bits indicates two bytes should be packed in a 32-bit word, while if the lcd databus width is 16 bits, it indicates that two half words (or 4 bytes) should be packed.

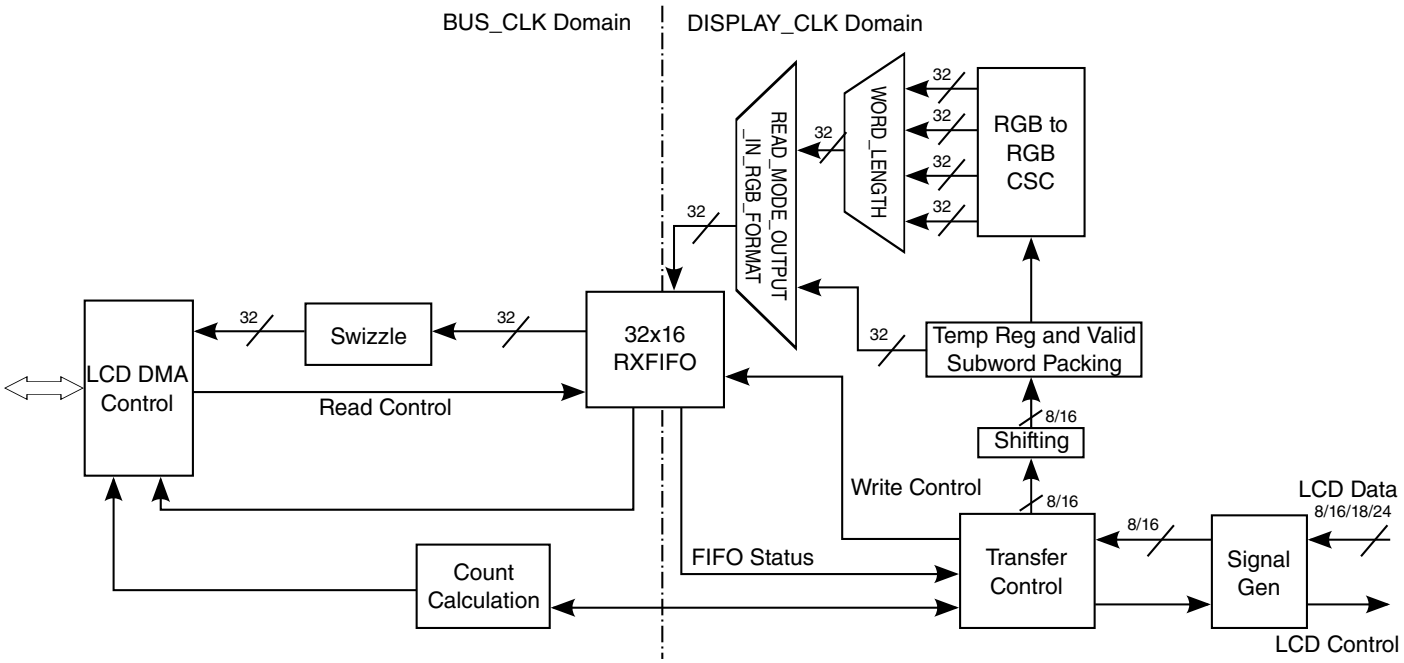

Figure 13-9. MPU Read Data Path

After the last subword within a word is reached, the block looks at the READ_PACK_DIR in the HW_LCDIF_CTRL2 register. If this bit is set, the block will swizzle the data, but only within the valid bytes, unlike in the write mode, where swizzle occurs across all 4 bytes. If the READ_MODE_OUTPUT_IN_RGB_FORMAT bit is set, eLCDIF will convert the data obtained from the READ_PACK_DIR operation into 24-bit unpacked RGB and then re-convert it into 16/18/24 bpp RGB depending on the WORD_LENGTH field. The DATA_FORMAT_16/18/24_BIT bit fields are also considered while converting to 24-bit unpacked RGB format. For example, if DATA_FORMAT_18_BIT is 1, the RGB666 data will be packed in the upper bits [31:4]of a 32-bit word, and that bit is 0, the data will be packed in the lower bits [17:0]. After all these operations, the data gets written into the RXFIFO.

The following figures show some examples of how data is handled in different MPU read modes.

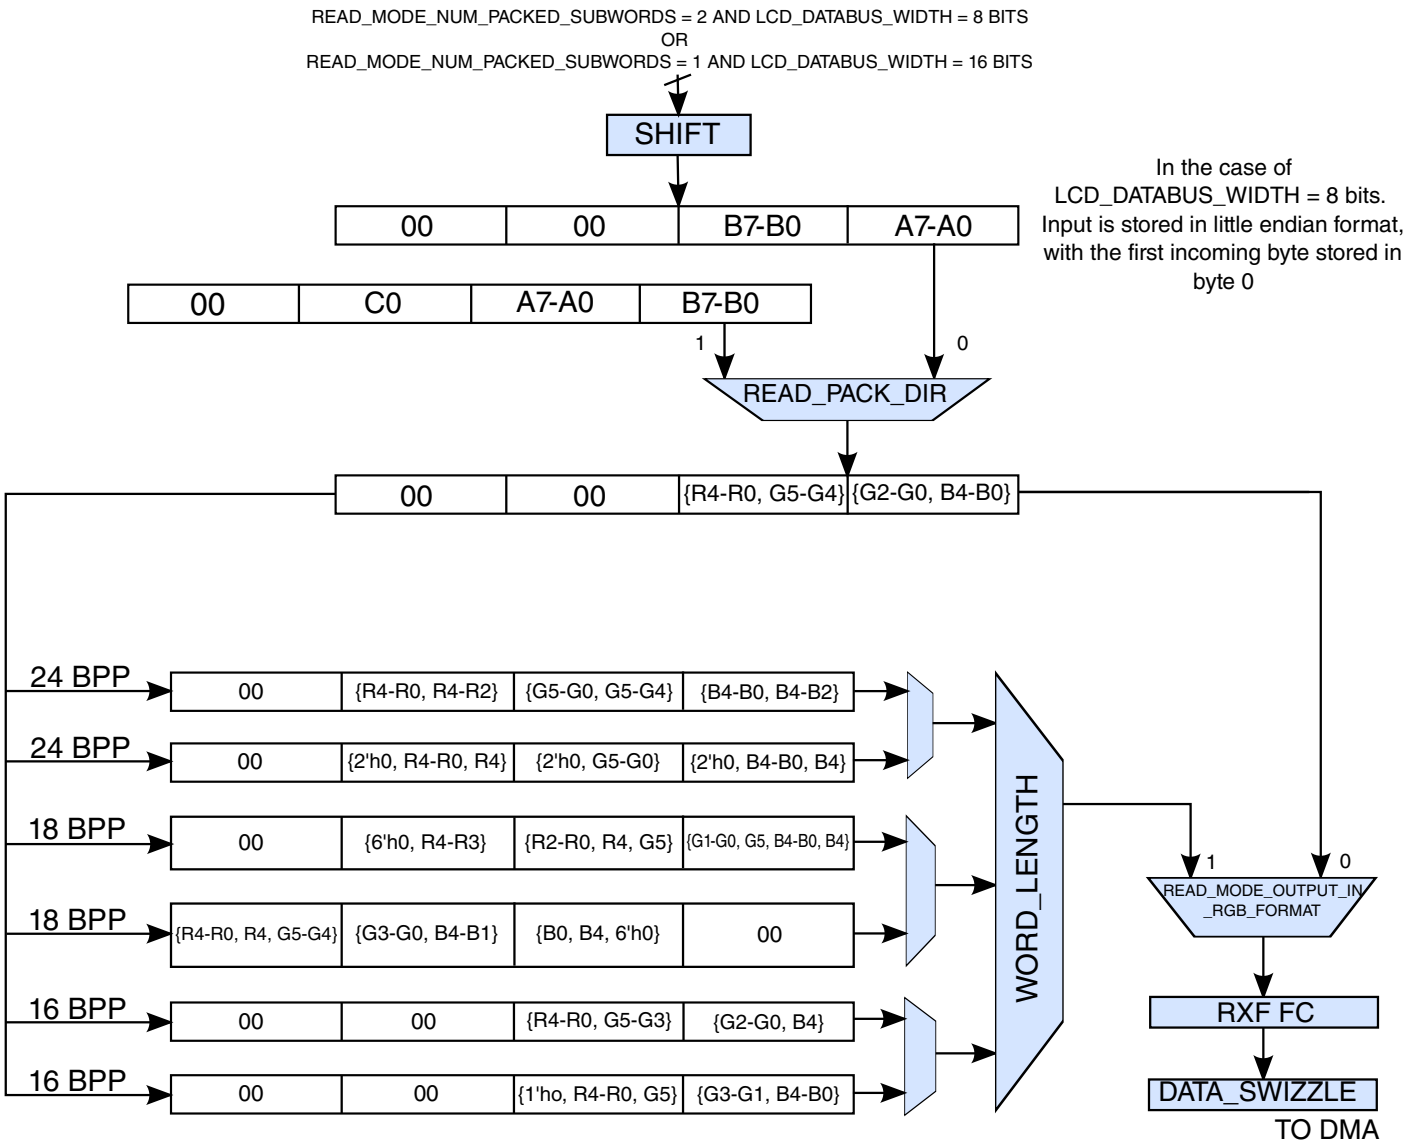

Figure 13-10. Data in MPU read mode

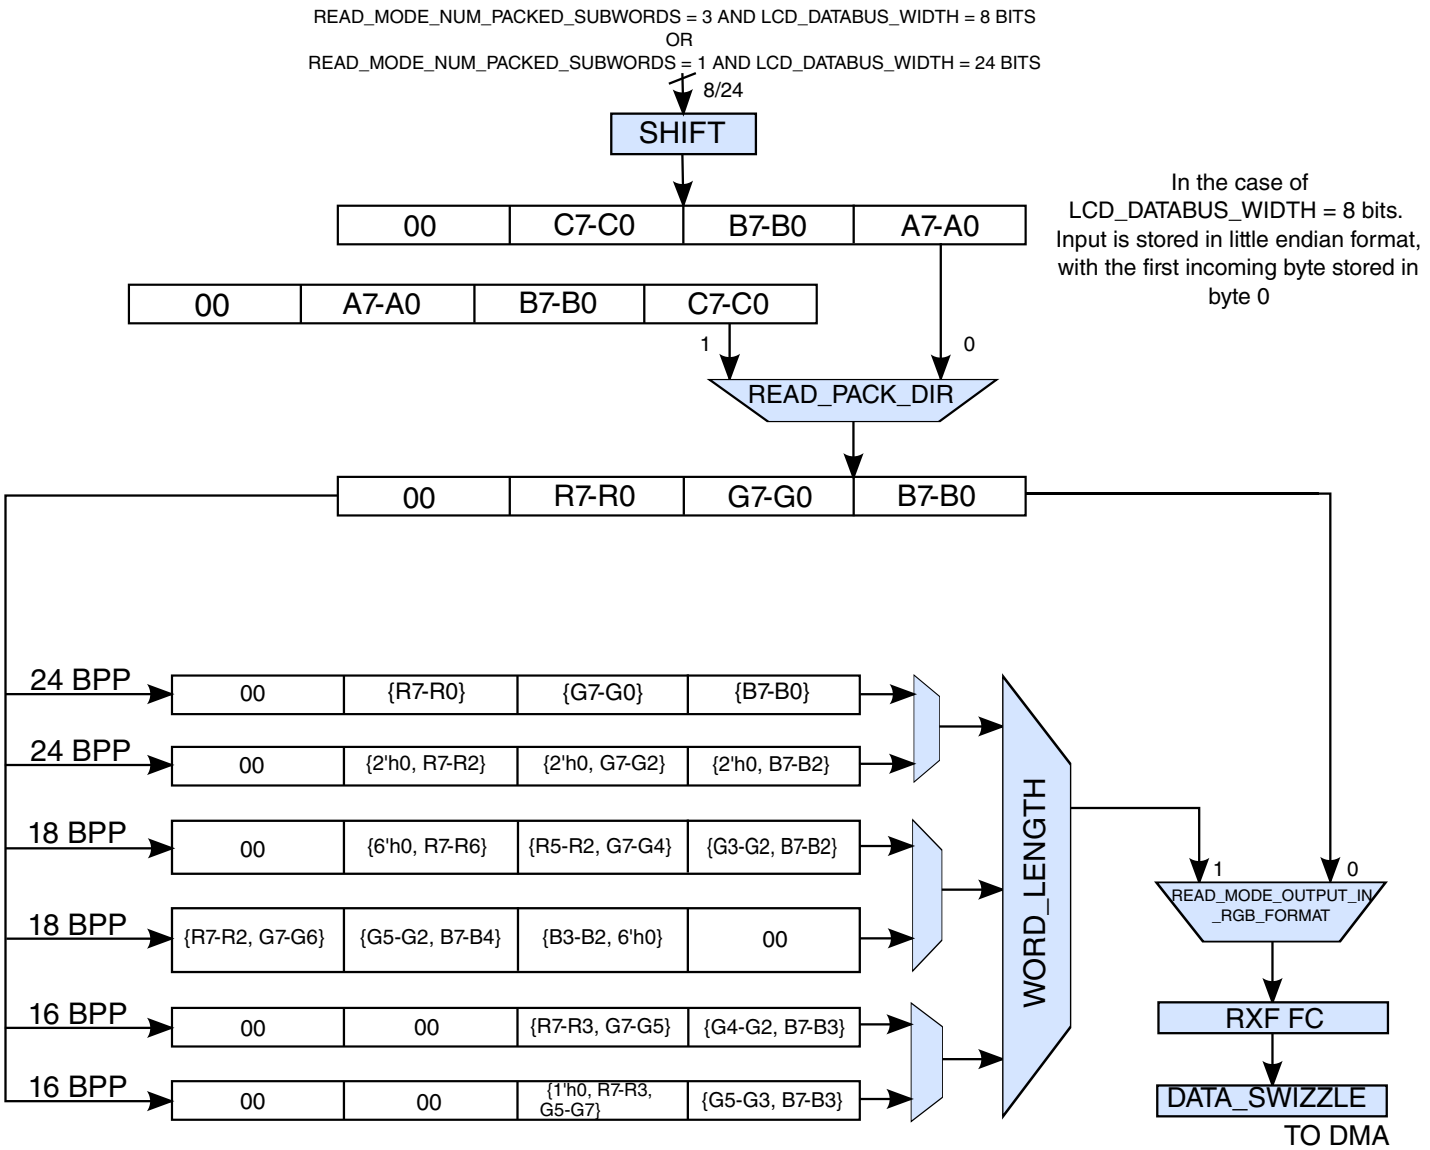

Figure 13-11. Data in MPU read mode

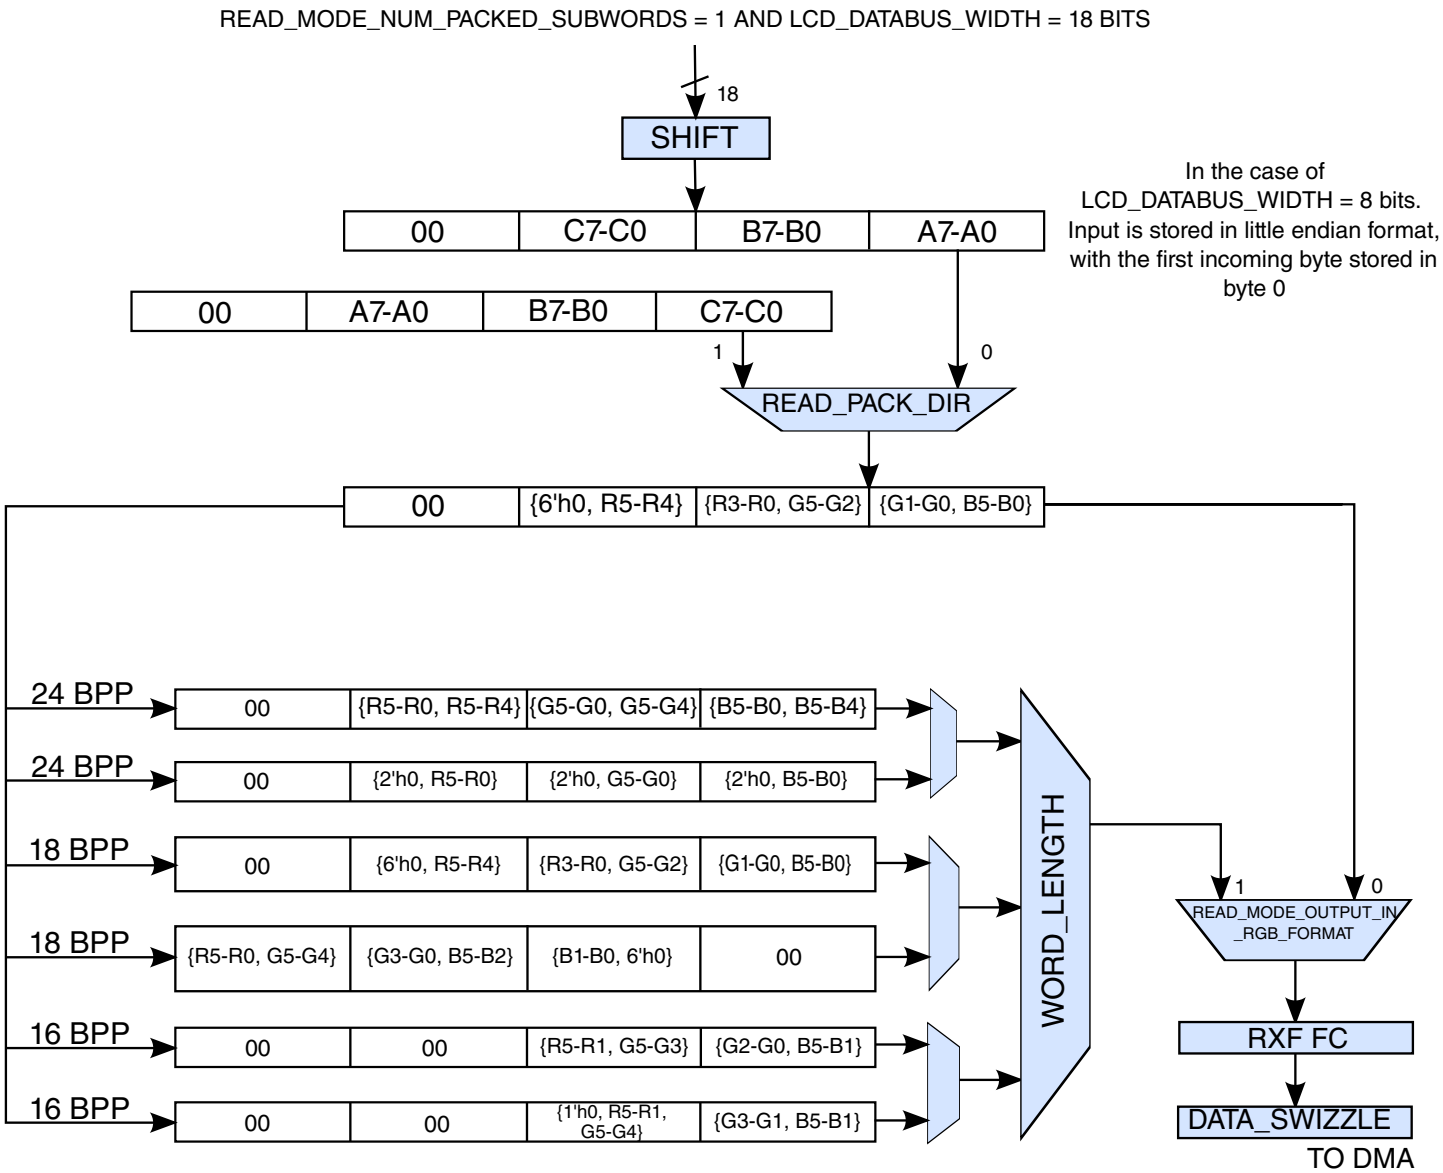

Figure 13-12. Data in MPU read mode

Restrictions:

READ_PACK_DIR should only be used if it is required to swizzle the subwords before doing RGB to RGB CSC, otherwise the DATA_SWIZZLE field should be used to swizzle across bytes.

READ_PACK_DIR must be 0 if LCD_DATABUS_WIDTH is 8 bits and READ_MODE_NUM_PACKED_SUBWORDS =1

If READ_MODE_OUTPUT_IN_RGB_FORMAT bit is set, the following restrictions should be followed:

- If LCD_DATABUS_WIDTH = 8 bits, then READ_MODE_NUM_PACKED_SUBWORDS <= 3.
- If LCD_DATABUS_WIDTH = 16/18/24 bits, then READ_MODE_NUM_PACKED_SUBWORDS = 1.

13.2.4.4 eLCDIF Interrupts

eLCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by eLCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold. In the read mode, it will be asserted if the RxFIFO becomes full and the block reads more data.
- VSYNC edge interrupt will be asserted every time a leading VSYNC edge occurs.
- Cur_frame_done interrupt occurs at the end of every frame in all modes except DVI. In DVI mode, if IRQ_ON_ALTERNATE_FIELDS bit is set, it will occur at the end of every frame, otherwise it will occur at the end of every field.

13.2.4.5 Initializing the eLCDIF

This section describes write modes and MPU read mode.

13.2.4.5.1 Write Modes

The following initialization steps are common to all eLCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY_CLK clock and set the appropriate frequency by programming the registers in CCM.

3. Start the BUS_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and disable the clock gate bit.
5. Reset the LCD controller by setting LCDIF_CTRL1_RESET bit appropriately, being careful to observe the reset requirements of the controller. See Behavior During Reset for more information on Reset requirements.
6. Make sure READ_WRITEB bit in HW_LCDIF_CTRL register is 0.
7. Select the transfer mode of operation. The LCDIF_MASTER bit in HW_LCDIF_CTRL register determines the transfer mode selected. Bus master (LCDIF_MASTER =1) or PIO (LCDIF_MASTER =0) mode are the transfer modes to select.
8. Set the INPUT_DATA_SWIZZLE according to the endianness of the LCD controller. Also, set the DATA_SHIFT_DIR and SHIFT_NUM_BITS if it is required to shift the data left or right before it is output.
9. Set the WORD_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in HW_LCDIF_CTRL register.
10. Set the BYTE_PACKING_FORMAT field in HW_LCDIF_CTRL1 according to the input frame.
11. Set the LCD_DATABUS_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
12. Enable the necessary IRQs.

13.2.4.5.2 MPU Read Mode

The following initialization steps should be done to enter the MPU read mode of operation:

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY_CLK and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and clock gate.
5. Reset the LCD controller by setting LCDIF_CTRL1_RESET bit appropriately, being careful to observe the reset requirements of the controller.
6. Set the READ_WRITEB bit in LCDIF_CTRL register to 1.
7. Set the LCDIF_MASTER bit in LCDIF_CTRL register to 0. Bus master mode is not supported for reading data from the display.

8. Also, set the DATA_SHIFT_DIR and SHIFT_NUM_BITS if it is required to shift the data left or right before it is output.
9. Indicate if the read data needs to color-space-converted and stored in a different RGB format by setting the READ_MODE_OUTPUT_IN_RGB_FORMAT field accordingly.
10. Set the WORD_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24-bit input if READ_MODE_OUTPUT_IN_RGB_FORMAT is required. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
11. Set the READ_MODE_NUM_PACKED_SUBWORDS field in LCDIF_CTRL2 according to the number of subwords per word required to be packed.
12. Set the READ_PACK_DIR to 1 if it is required to store the data in big-endian format.
13. Set the LCD_DATABUS_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24-bit output.
14. Enable the necessary IRQs.

13.2.4.6 MPU Interface

The MPU interface is used to transfer data and commands between the SoC via the eLCDIF and the external display at modest data rates.

Bus master or PIO transactions using the LCDIF_DATA register can be used for MPU mode write operations. For MPU mode read operations, only PIO can be used. eLCDIF can support the 6800 as well as the 8080 MPU protocol. If DOTCLK_MODE, DVI_MODE and VSYNC_MODE bits in LCDIF_CTRL registers are 0, it implies that the block is in MPU interface mode of operation. The LCDIF MPU mode has four basic timing parameters: Setup and Hold for the Command/Data register selection (TCS, TCH) and Setup and Hold for the Data bus (TDS, TDH). These parameters are expressed in DISPLAY_CLK cycles. The LCD_WR signal is used as the write strobe while LCD_RS signal is typically used to switch between command and data modes.

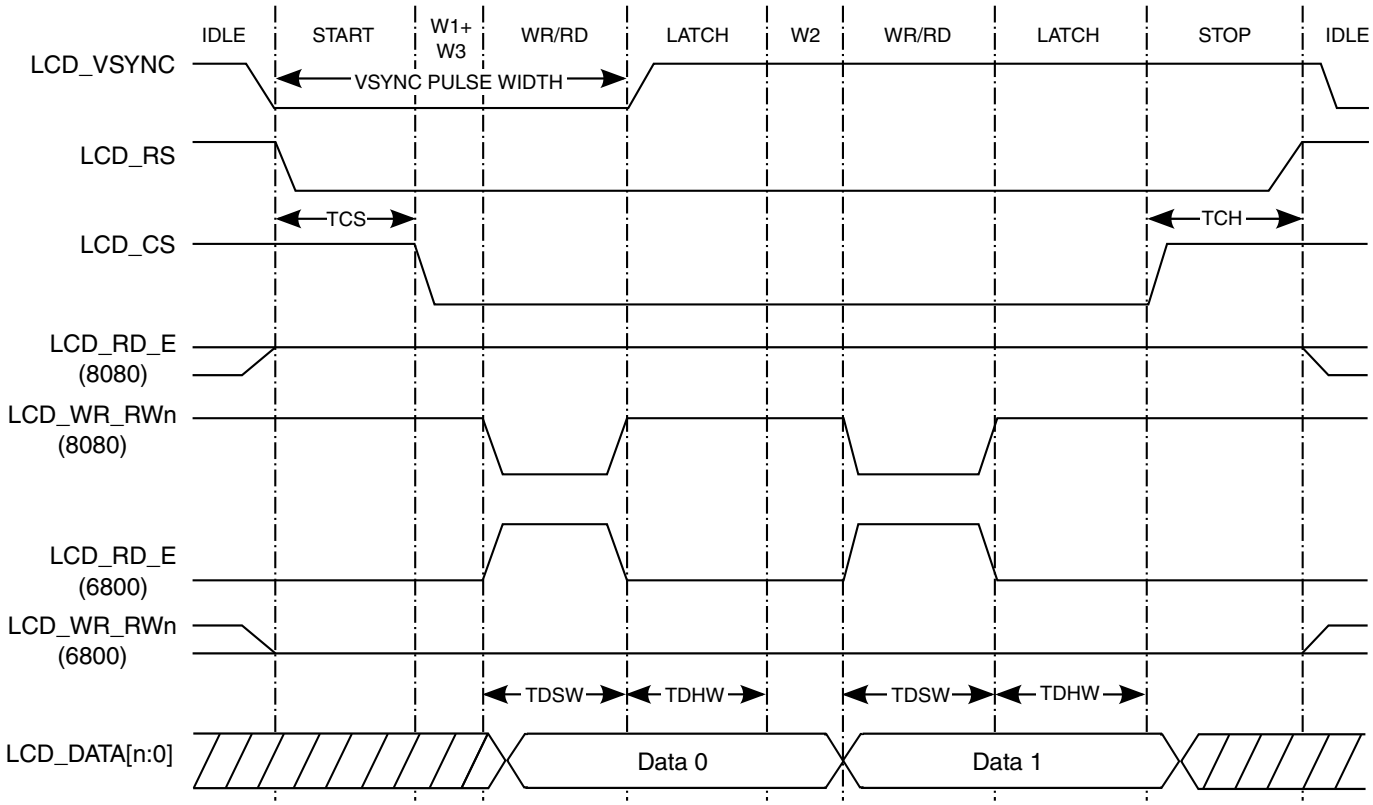

Figure 13-13. Timing in write mode of 6800 and 8080 protocols

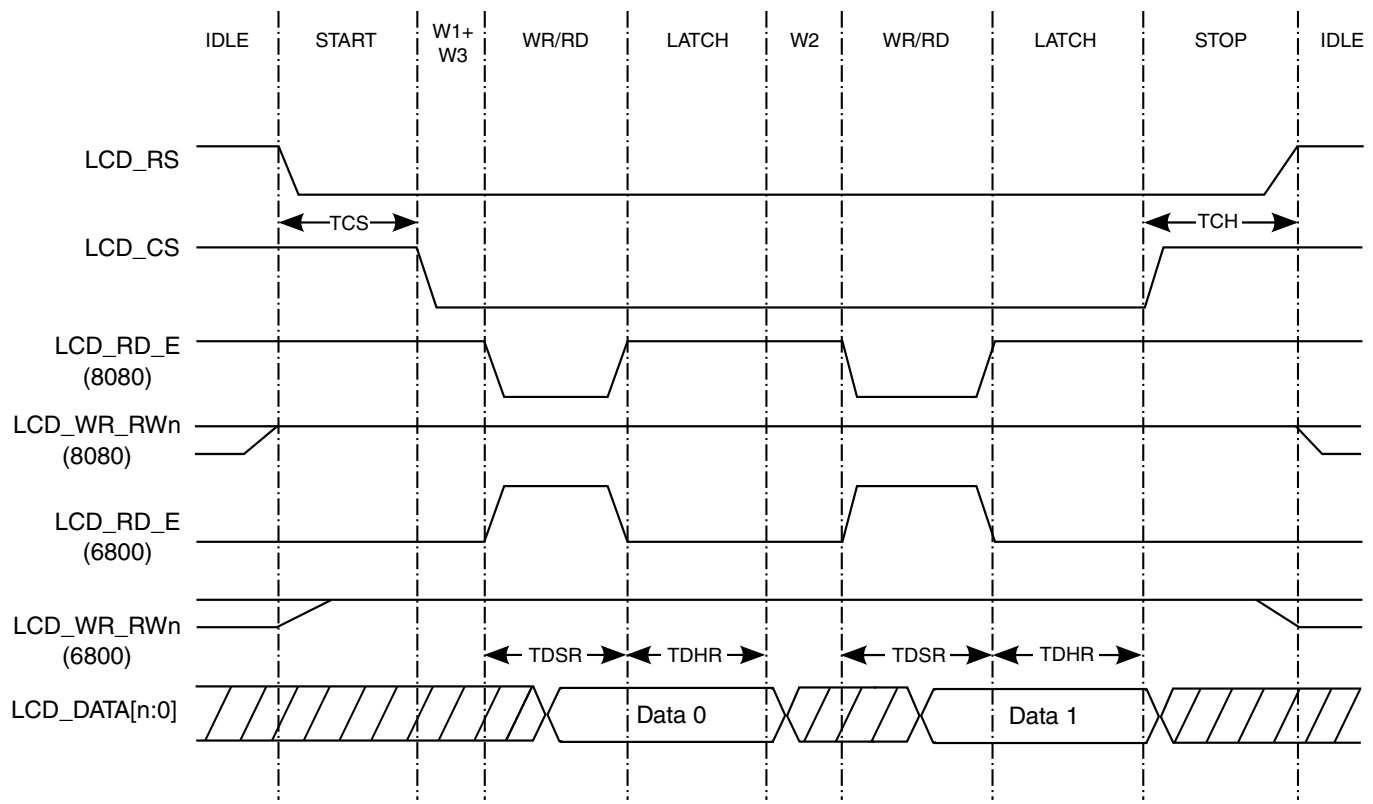

Figure 13-14. Read timing interface in 6800 and 8080 protocols

The eLCDIF has flexible pin and strobe timings which enable it to optimally support a wide range of LCDs. The minimum cycle time is two DISPLAY_CLK cycles (TDS=TDH=1). For example, this results in a maximum LCD data rate of 12 MB/s when DISPLAY_CLK is 24 MHz. TDS and TDH are 8-bit values, so the minimum eLCDIF period is 510 DISPLAY_CLK cycles (47 KHz with a 24 MHz DISPLAY_CLK). The timings are not automatically adjusted if the DISPLAY_CLK frequency changes, so it may be necessary to adjust the timings if DISPLAY_CLK changes.

In the MPU interface mode, the LCDIF_CTRL_ BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

13.2.4.6.1 Code Example to Initialize the eLCDIF in MPU Write Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1(LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that the
                                    // idle state for LCD_RS signal is high, regardless of the
                                     // programming of the DATA_SELECT register.
BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, READ_WRITEB, 0);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 1);//Only if LCD controller implements a busy line
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2);  //Values
based
                              // on DISPLAY_CLK frequency and timing requirements of
controller.
                             // Note that these register must be non-zero for correct
operation.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data via bus master PIO write transactions using the LCDIF_DATA register. Note that when using the PIO write operations to the LCDIF_DATA register, the software will need to poll the FIFO STATUS bits to ensure that it does not overflow the eLCDIF data buffers. When eLCDIF is done transmitting H_COUNT x V_COUNT pixels, it will stop, turn off the RUN bit and assert the cur_frame_done interrupt.

13.2.4.7 VSYNC Interface

The VSYNC interface uses the same protocol as the MPU interface, with an additional signal VSYNC at the frame rate of the display, as shown in the figure given in MPU Interface section.

It is used in the moving picture display mode where data has to be written to the internal LCD buffer at a speed higher than the display rate and displayed in synchronization with the VSYNC signal. This mode is selected by setting the VSYNC_MODE bit in

LCDIF_CTRL register. The VSYNC signal is programmable for period, polarity and direction. Many other programmable parameters are shared with the MPU interface. The VSYNC_OEB bit in LCDIF_VDCTRL0 register indicates whether the display controller will send the VSYNC signal, or whether it should be generated by eLCDIF. The timing of the VSYNC signal is based on the DISPLAY_CLK (make sure VSYNC_PULSE_WIDTH_UNIT = VSYNC_PERIOD_UNIT = 0 and VSYNC_ONLY = 1) and it is determined by the VSYNC_PERIOD, VSYNC_PULSE_WIDTH and VSYNC_POL fields in LCDIF_VDCTRL0-4 registers. The SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set if the target requires the VSYNC signal to be generated by eLCDIF. If the WAIT_FOR_VSYNC_EDGE bit in LCDIF_CTRL register is set, it indicates that the hardware should wait until it sees the leading VSYNC edge before starting the data transfer. The VERITCAL_WAIT_CNT indicates the number of DISPLAY_CLK cycles from the leading VSYNC edge after which data transfer will be started on the interface.

In the VSYNC interface mode, the LCDIF_CTRL_ BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

13.2.4.7.1 Code Example to Initialize eLCDIF in VSYNC Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that
//the idle state for LCD_RS signal is high, regardless of the programming of the DATA_SELECT
//register.

BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 0);
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2);  //Values
//based on DISPLAY_CLK frequency and timing requirements of controller. Note that these
//register must be non-zero for the MPU and VSYNC modes.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240);//For a 320 RGB x 240 display
//The following section indicates setting up the VSYNC signal timing when VSYNC is an output
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Making VSYNC signal an output
BF_CS1 (LCDIF_VDCTRL4, VSYNC_ONLY, 1); //Only need to generate VSYNC signal
BF_CS1 (VDCTRL0, VSYNC_POL, 0); //Setting the polarity of VSYNC signal to be low during
//VSYNC_PULSE_WIDTH time
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 0, VSYNC_PULSE_WIDTH_UNIT, 0);
BF_CS2 (LCDIF_VDCTRL1, VSYNC_PERIOD, 400000, VSYNC_PULSE_WIDTH, 100);//Frame display rate in
//terms of number of DISPLAY_CLKs.
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 0, HSYNC_PERIOD, 0);
BF_CS1 (LCDIF_VDCTRL3, VERTICAL_WAIT_CNT, 50);
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS2 (LCDIF_CTRL, VSYNC_MODE, 1, WAIT_FOR_VSYNC_EDGE, 1); //set WAIT_FOR_VSYNC_EDGE if
//software wishes to transfer the next frame after the VSYNC edge occurs.
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data via bus master requests or PIO writes to the LCDIF_DATA register. When eLCDIF is done transmitting H_COUNT x V_COUNT pixels, it will stop, turn off the RUN bit and assert the cur_frame_done interrupt.

13.2.4.8 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

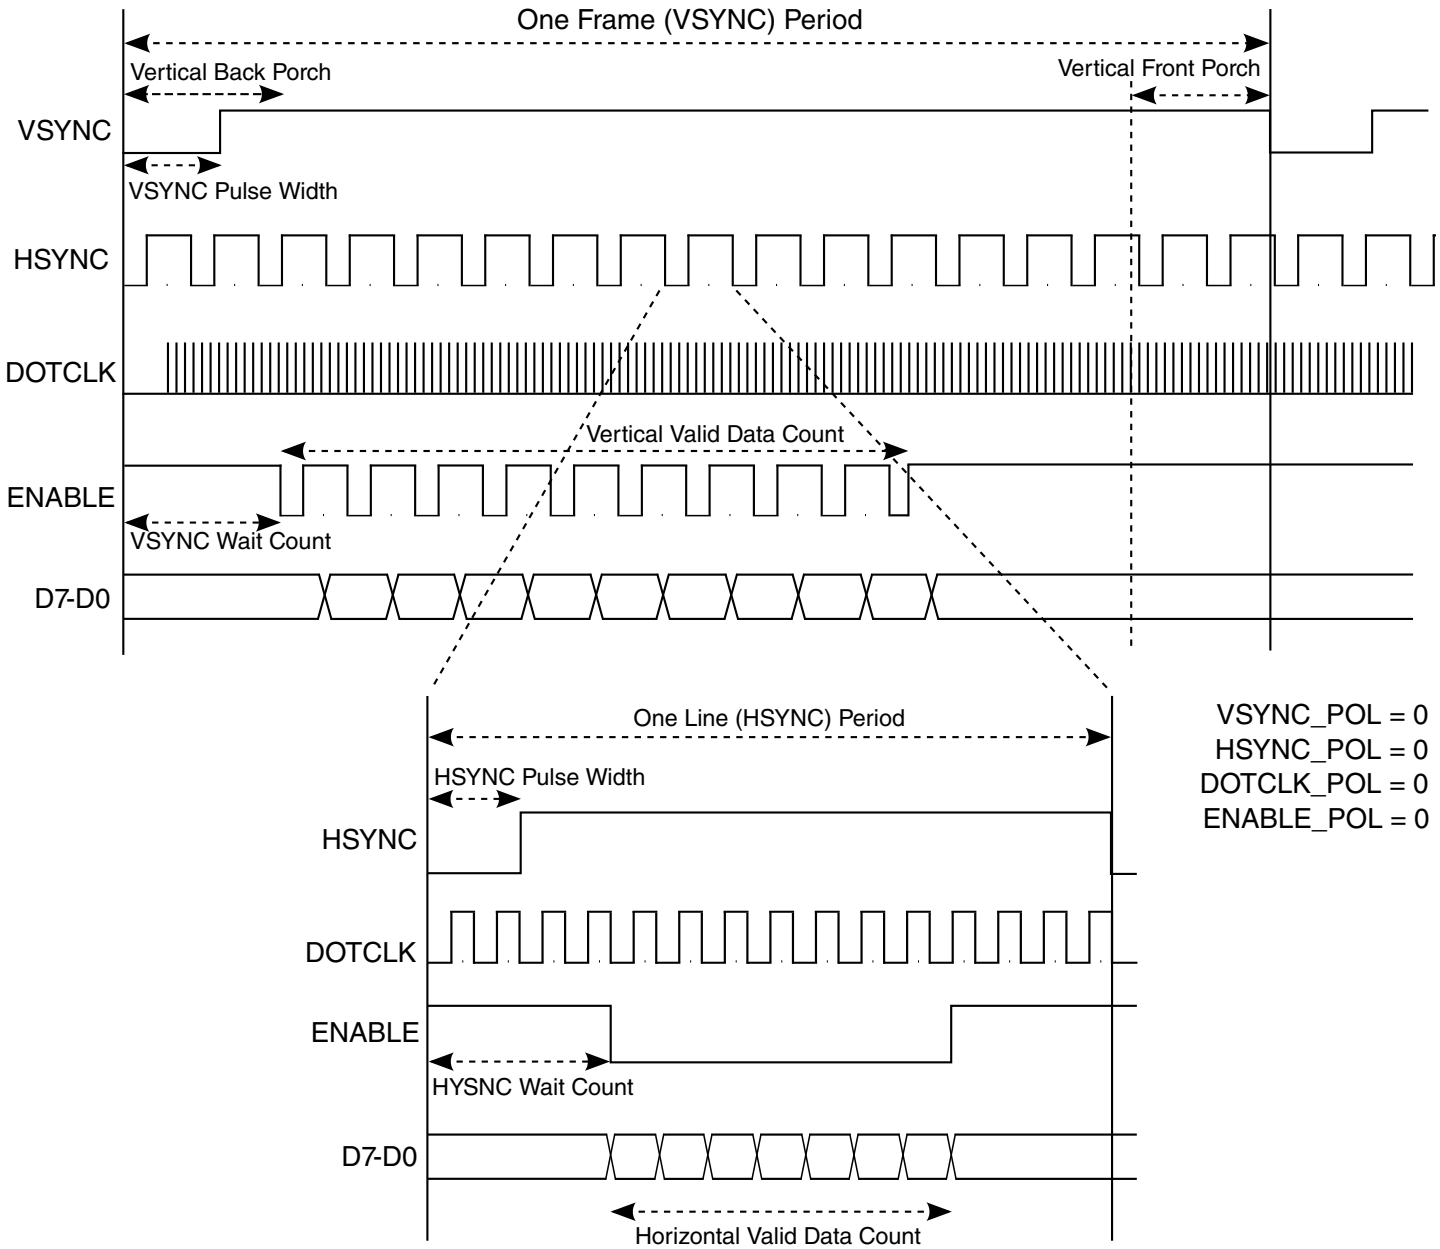

Figure 13-15. DOTCLK protocol with programmable parameters

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY_CLK frequency is managed by the CCM.

In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

13.2.4.8.1 Code Example

The following code shows an example for programming a 320x240 display. Note that setting up the display must be done through the MPU mode or via SPI.

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
                                                    //  LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320);//Note that DOTCLK_V_VALID_DATA_CNT is
                              //implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

13.2.4.9 CSI HANDSHAKE INTERFACE

The LCDIF and CSI support a pipeline mode to use double buffers inside OCRAM for the video pass through from CSI to LCDIF, the pipeline buffer size can be 8 line or 16 line as configurable. The pipeline will be handle by hardware handshake signals between CSI and LCDIF. The LCDIF will have the capability to synchronize display with CSI based on the VSYNC signal from CSI. When LCDIF is enabled to start display,it can optionally wait for the VSYNC edge from CSI before it starts the display for next frame,The delay from VSYNC input to the start of next frame is programmable by LCDIF_SYNC_DELAY register.

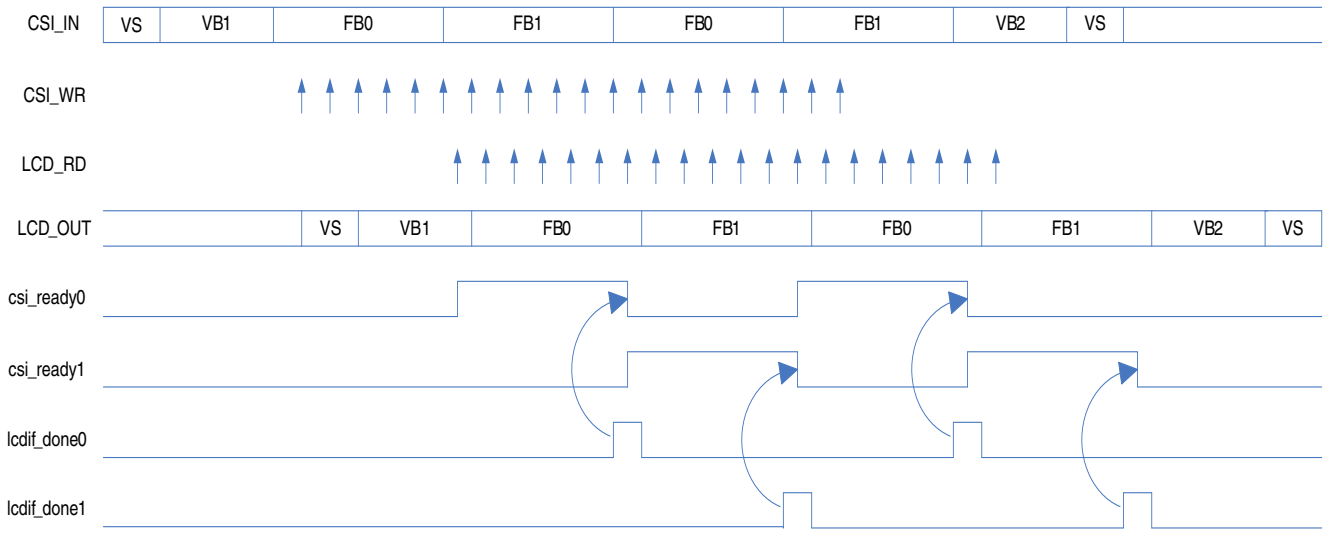

Figure 13-16. CSI HandShake Interface

When this mode is enabled ,The hardware handshake protocol will process. At the start of CSI with camera input,the CSI will put the input data to one frame buffer.When the frame buffer is ready for LCDIF display,CSI will assert csi_ready signal to indicate LCDIF to read the buffer and LCDIF will display data in this buffer.When one frame buffer reading finished ,LCDIF will set the lcdif_done signal to indicate CSI this buffer has been displayed and can be written again.With this double buffer handshake mode,the LCDIF can display the video input within very short delay and minimize DRAM bandwidth.

13.2.4.10 Alpha Blending Interface

The LCDIF have the capability to add an extra overlay on the normal display buffer,LCDIF can fetch data from two buffers and combine them before display,one buffer data can have the alpha value with the RGB pixels. With LCDIF_AS_CTRL[AS_ENABLE] is set, the LCDIF will start fetching alpha surface buffer data in bus master mode and combine it with another buffer.

The LCDIF_AS_CTRL[ALPHA_CTRL] bits determines how the alpha value is constructed for the alpha surface and alpha blending process is as same as in PXP block, for the alpha blend and color key process refer to the PXP block descriptions.

13.2.4.11 ITU-R BT.656 Digital Video Interface (DVI)

ITU-R BT.656 Digital Video Interface shown below transmits 4:2:2 YCbCr digital component video to a digital video encoder that can translate it into 525/60 or 625/50 analog TV signal.

Unique timing codes (timing reference signals) are embedded within the video stream to indicate the different timing events that would have been otherwise indicated by VSYNC, HSYNC and BLANK signals. The hardware supports 8-bit data transfers; the pins are shared with the lower 8 bits of LCD data bus. The LCD_RS pin is shared with the clock signal of the interface (called CCIRCLK here for uniqueness). CCIRCLK also can be obtained on the LCD_DOTCK pin. The mode shares the write FIFO with the LCD interface and the associated pipeline. The programmable parameters in registers LCDIF_DVICTRL0-3 allow setting the total number of horizontal lines per frame, vertical and horizontal blanking interval, odd and even field start and end positions, and so on. In short, these parameters are provided to ensure that the hardware has enough flexibility to generate the right 525/60 or 625/50 data streams. Most of the initialization steps in Initializing the eLCDIF such as data shifting, swizzle, and so on, are applicable to DVI mode also. The register descriptions in the programmable registers section at the end of this chapter include example code for programming the DVICTRL0-3 registers.

In DVI mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DVI_MODE bit the value 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and assert the cur_frame_done interrupt.

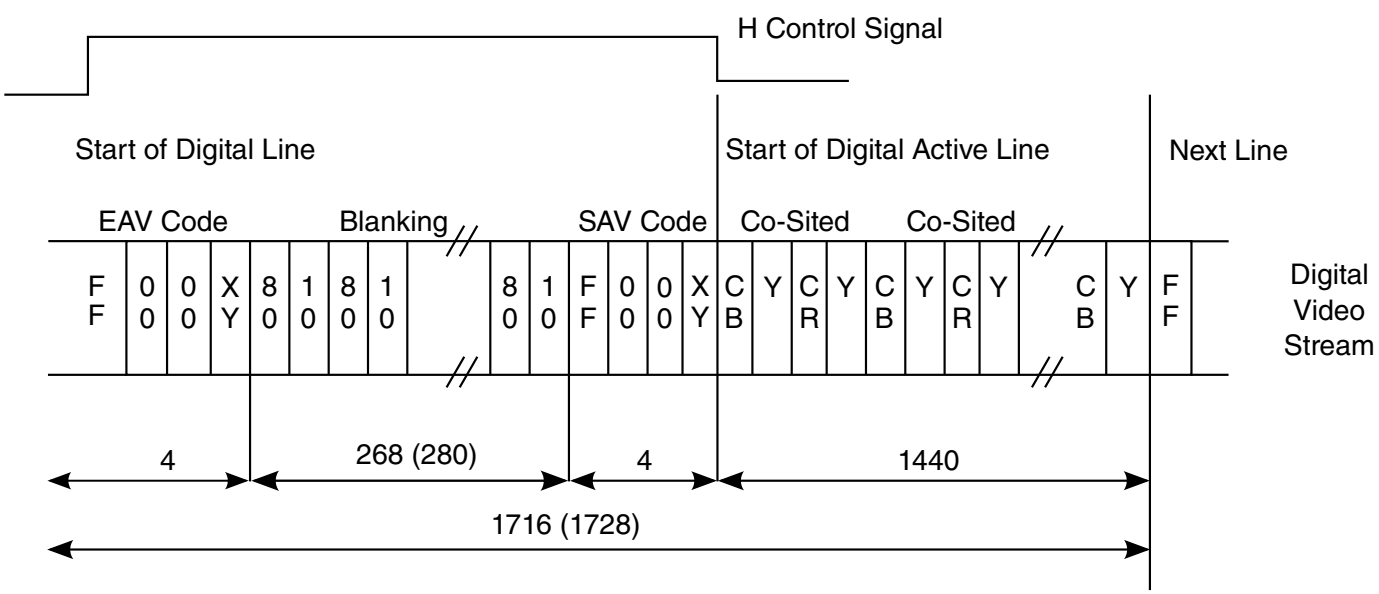

Figure 13-17. Digital Video Interface

13.2.4.12 eLCDIF Pin Usage by Interface Mode

Table 13-3 and Table 13-4 indicates how the eLCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired eLCDIF operating mode.

The VSYNC signal has been mapped onto two pins, LCD_BUSY and LCD_VSYNC. The pin multiplexing can be programmed to select either of those pins to function as VSYN.

NOTE

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the MUX_SYNC_SIGNALS bit in the VDCTRL0 register. There is also an option to internally mux the LCD_WR_RWn and LCD_RD_E pins in the CTRL1 register for backward compatibility.

13.2.5 Behavior During Reset

BUS_CLK and DISPLAY_CLK must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

13.2.6 ELCDIF Memory Map/Register Definition

eLCDIF Hardware Register Format Summary

13.2.6.1 eLCDIF General Control Register (LCDIF*x*_RL*n*)

The LCD Interface Control Register provides overall control of the eLCDIF block. The eLCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: Base address + 0h offset + (4d × i), where i=0d to 3d

LCDIF*x*_RL*n* field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the eLCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 YCBCR422_INPUT	Zero implies input data is in RGB color space. One implies input data is in YCbCr 4:2:2 format, such that YCbYCr are packed in a 32-bit word. It also means that there are 2 pixels in 4 bytes. If this bit is set, software should program the H_COUNT field in the TRANSFER_COUNT register to the total number of pixels that will have to be fetched by the eLCDIF block per line and the BYTE_PACKING_FORMAT should be 0xF. The WORD_LENGTH does not matter in this case.

Table continues on the next page...

LCDIF*x*_RL*n* field descriptions (continued)

Field	Description
28 READ_WRITEB	By default, eLCDIF is in the write mode. Setting this bit to 1 will make the hardware go into 6800/8080 MPU read mode. The LCDIF_MASTER bit must be 0, since bus master mode can only be used for writing the display.
27 WAIT_FOR_ VSYNC_EDGE	Setting this bit to 1 will make the hardware wait for the triggering VSYNC edge before starting write transfers to the LCD. Used only in the VSYNC mode of operation.
26 DATA_SHIFT_ DIR	Use this bit to determine the direction of shift of transmit data. In the DVI mode, it works only on the active data, not on the timing codes and ancillary data. 0x0 **TXDATA_SHIFT_LEFT** — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 **TXDATA_SHIFT_RIGHT** — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_ BITS	The data to be transmitted is shifted left or right by this number of bits.
20 DVI_MODE	Set this bit to 1 to get into the ITU-R BT.656 digital video interface mode. Toggle this bit from 1 to 0 to make the hardware go out of DVI mode after completing all data transfer and after the RUN bit has been deasserted.
19 BYPASS_ COUNT	When this bit is 0, it means that eLCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 VSYNC_MODE	Setting this bit to 1 will make the eLCDIF hardware go into VSYNC mode. WAIT_FOR_VSYNC_EDGE can be used only if this bit is set. If VSYNC signal is required to be an output from the block, SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set.
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 DATA_SELECT	Command Mode polarity bit. This bit should only be changed when RUN is 0. 0x0 **CMD_MODE** — Command Mode. DCn signal is Low. 0x1 **DATA_MODE** — Data Mode. DCn signal is High.
15–14 INPUT_DATA_ SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
13–12 CSC_DATA_ SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian)

Table continues on the next page...

LCDIF*x*_RL*n* field descriptions (continued)

Field	Description
	0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
11–10 LCD_DATABUS_WIDTH	LCD Data bus transfer width. 0x0 **16_BIT** — 16-bit data bus mode. 0x1 **8_BIT** — 8-bit data bus mode. 0x2 **18_BIT** — 18-bit data bus mode. 0x3 **24_BIT** — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 **16_BIT** — Input data is 16 bits per pixel. 0x1 **8_BIT** — Input data is 8 bits wide. 0x2 **18_BIT** — Input data is 18 bits per pixel. 0x3 **24_BIT** — Input data is 24 bits per pixel.
7 RGB_TO_YCBCR422_CSC	Set this bit to 1 to enable conversion from RGB to YCbCr colorspace. See the LCDIF_CSC_ registers for further details.
6 ENABLE_PXP_HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the eLCDIF will act as bus master and the handshake mechanism between eLCDIF and PXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the eLCDIF act as a bus master. If this bit is reset, the eLCDIF will support or PIO mode.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_FORMAT_16_BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_FORMAT_18_BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 **LOWER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 **UPPER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_FORMAT_24_BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 **ALL_24_BITS_VALID** — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 **DROP_UPPER_2_BITS_PER_BYTE** — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the eLCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

13.2.6.2 eLCDIF General Control1 Register (LCDIF*x*_CTRL1*n*)

The eLCDIF Control Register provides overall control of the eLCDIF block.

The eLCDIF Control1 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Address: Base address + 10h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LCDIF*x*_CTRL1*n* field descriptions

Field	Description
31–28 RSRVD1	This field is reserved. Reserved bits. Write as 0.
27 COMBINE_MPU_WR_STRB	If this bit is not set, the write strobe will be driven on LCD_WR_RWn pin in the 8080 mode and on the LCD_RD_E pin in the 6800 mode. If it is set, the write strobe of both the 6800 and 8080 modes will be driven only on the LCD_WR_RWn pin. Note that this does not work for read strobe.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the eLCDIF master mode.
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the eLCDIF is in master mode and an error response was returned by the slave.

Table continues on the next page...

LCDIF*x*_CTRL1*n* field descriptions (continued)

Field	Description
	0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
24 RECOVER_ON_ UNDERFLOW	Set this bit to enable the eLCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_ FIELDS	Set this bit if it is required that the eLCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the eLCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set. This feature is only available in DOTCLK and DVI modes.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have be transmitted). When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of pixels that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF.(Note - YCBCR422_INPUT = 1 implies 2 pixels per 32 bits).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes.

Table continues on the next page...

LCDIF*x*_CTRL1*n* field descriptions (continued)

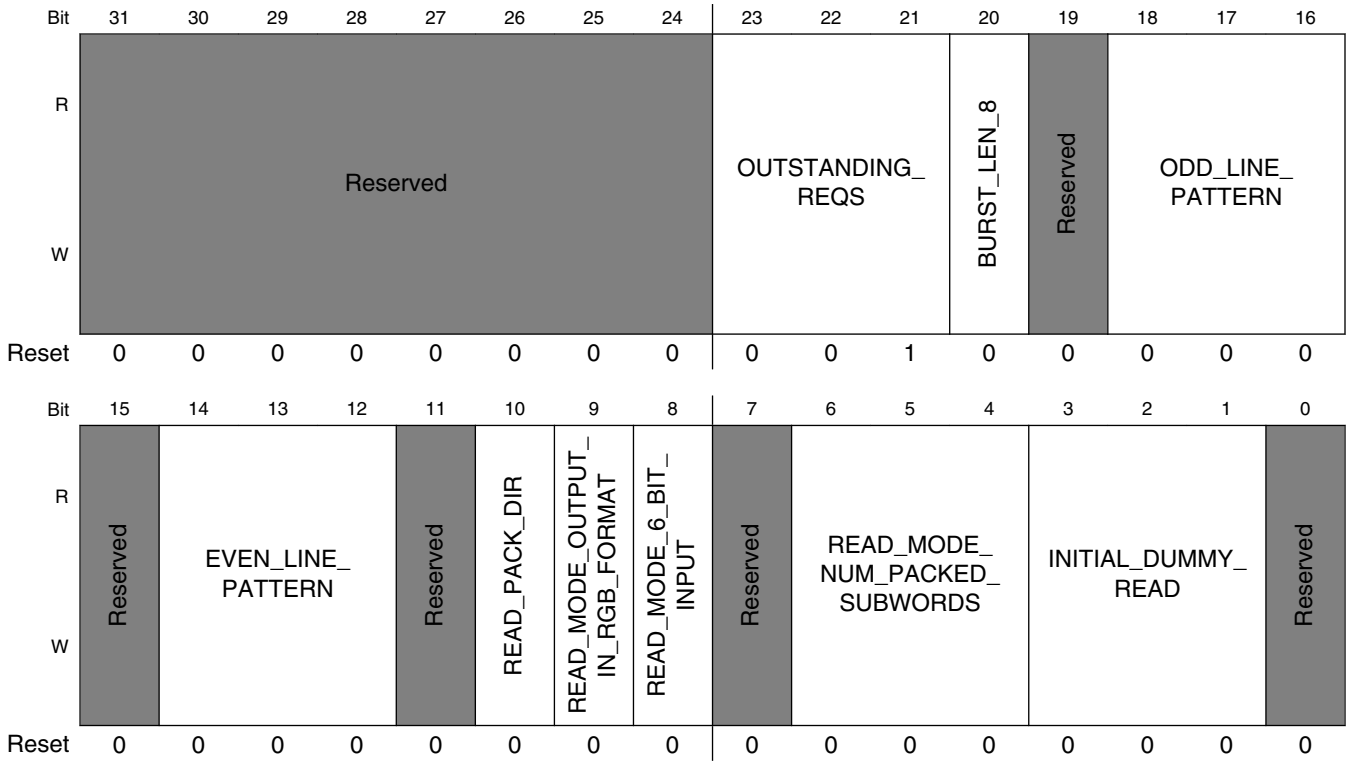
Field	Description
	0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
9 CUR_FRAME_DONE_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
8 VSYNC_EDGE_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
7–3 RSRVD0	This field is reserved. Reserved bits. Write as 0.
2 BUSY_ENABLE	This bit enables the use of the interface's busy signal input. This should be enabled for LCD controllers that implement a busy line (to stall the eLCDIF from sending more data until ready). Otherwise this bit should be cleared. 0x0 **BUSY_DISABLED** — The busy signal from the LCD controller will be ignored. 0x1 **BUSY_ENABLED** — Enable the use of the busy signal from the LCD controller.
1 MODE86	This bit is used to select between the 8080 and 6800 series of microprocessor modes. This bit should only be changed when RUN is 0. 0x0 **8080_MODE** — Pins LCD_WR_RWn and LCD_RD_E function as active low WR and active low RD signals respectively. 0x1 **6800_MODE** — Pins LCD_WR_RWn and LCD_RD_E function as Read/Write and active high Enable signals respectively.
0 RESET	Reset bit for the external LCD controller. This bit can be changed at any time. It CANNOT be reset by SFTRST. 0x0 **LCDRESET_LOW** — LCD_RESET output signal is low. 0x1 **LCDRESET_HIGH** — LCD_RESET output signal is high.

13.2.6.3 eLCDIF General Control2 Register (LCDIF*x*_CTRL2*n*)

The eLCDIF Control Register provides overall control of the eLCDIF block.

The eLCDIF Control2 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application.

Address: Base address + 20h offset + (4d × i), where i=0d to 3d



LCDIFx_CTRL2*n* field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that eLCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions. 0x0 **REQ_1** — 0x1 **REQ_2** — 0x2 **REQ_4** — 0x3 **REQ_8** — 0x4 **REQ_16** —
20 BURST_LEN_8	By default, when the eLCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,..). This bitfield must be 0 in DVI mode. 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** —

Table continues on the next page...

LCDIF*x*_CTRL2*n* field descriptions (continued)

Field	Description
	0x4 **BRG** — 0x5 **BGR** —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,..). This bitfield must be 0 in DVI mode. 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —
11 RSRVD2	This field is reserved. Reserved bits. Write as 0.
10 READ_PACK_DIR	The default value of 0 indicates data is stored in the little endian format. When LCD_DATABUS_WIDTH is 8-bit, this bit provides the option of rearranging the data byte-wise in the big endian format. For example, if READ_MODE_NUM_PACKED_SUBWORDS = 3 and the order of incoming data is 0x11, 0x22 and 0x33, then setting this bit to 1 will cause the data to be stored as 0x00112233 as opposed to the default 0x00332211. This operation occurs after the shifting operation done by SHIFT_NUM_BITS bitfield.
9 READ_MODE_ OUTPUT_IN_ RGB_FORMAT	Setting this bit will enable the eLCDIF to convert the incoming data to the RGB format given by WORD_LENGTH bitfield. This feature is not available when WORD_LENGTH is set to 8 bits. eLCDIF performs this operation of converting to RGB format after the endianness has been determined by the READ_PACK_DIR bitfield.
8 READ_MODE_6_ BIT_INPUT	Setting this bit to 1 indicates to eLCDIF that even though LCD_DATABUS_WIDTH is set to 8 bits, the input data is actually only 6 bits wide and exists on D5-D0.
7 RSRVD1	This field is reserved. Reserved bits. Write as 0.
6–4 READ_MODE_ NUM_PACKED_ SUBWORDS	Indicates the number of valid 8/16/18/24-bit subwords that will be packed into the 32-bit word in read mode. The subword size (8,16, 18 or 24 bits) is determined by the LCD_DATABUS_WIDTH field. The swizzle operation is performed after READ_MODE_NUM_PACKED_SUBWORDS number of subwords has been received and stored in little-endian format. For example, if LCD_DATABUS_WIDTH is set to 8-bit and data to be read back has to be stored in memory in 24-bit unpacked RGB format, set READ_MODE_NUM_PACKED_SUBWORDS to 0x3 so that each 32-bit word will contain only 3 valid bytes (RGB). Maximum value of READ_MODE_NUM_PACKED_SUBWORDS is 4 for 8-bit databus, 2 for 16-bit databus and 1 for 18/24-bit databus.
3–1 INITIAL_DUMMY_ READ	The value in this field determines the number of dummy 8/16/18/24-bit subwords that have to be read back from the LCD panel/controller. They will then not be stored in the read FIFO.
0 RSRVD0	This field is reserved. Reserved bits. Write as 0.

13.2.6.4 eLCDIF Horizontal and Vertical Valid Data Count Register (LCDIFx_TRANSFER_COUNT)

This register tells the eLCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	V_COUNT																H_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_TRANSFER_COUNT field descriptions

Field	Description
31–16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame. In DVI mode, V_COUNT should be the number of active horizontal lines per frame, and not per field.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of 32-bit words that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

13.2.6.5 LCD Interface Current Buffer Address Register (LCDIFx_CUR_BUF)

This register indicates the address of the current frame being transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_CUR_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by eLCDIF.

13.2.6.6 LCD Interface Next Buffer Address Register (LCDIFx_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the eLCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the eLCDIF. This address must always be double-word aligned.

Address: Base address + 50h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_NEXT_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by eLCDIF.

13.2.6.7 LCD Interface Timing Register (LCDIFx_TIMING)

The LCD interface timing register controls the various setup and hold times enforced by the LCD interface in the 6800/8080 MPU and VSYNC modes of operation.

The values used in this register are dependent on the particular LCD controller used, consult the users manual for the particular controller for required timings. Each field of the register must be non-zero, therefore the minimum value is: 0x01010101. NOTE: the timings are not automatically adjusted if the CLK_DIS_LCDIFn frequency changes—it may be necessary to adjust the timings if CLK_DIS_LCDIFn changes. NOTE: Each field in this register must be non-zero for the MPU and VSYNC modes to function. The settings in this register do not affect the DOTCLK and DVI modes.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMD_HOLD								CMD_SETUP								DATA_HOLD								DATA_SETUP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_TIMING field descriptions

Field	Description
31–24 CMD_HOLD	Number of CLK_DIS_LCDIFn cycles that the DCn signal is active after CEn is deasserted.
23–16 CMD_SETUP	Number of CLK_DIS_LCDIFn cycles that the DCn signal is active before CEn is asserted.
15–8 DATA_HOLD	Data bus hold time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is deasserted in a cycle
DATA_SETUP	Data bus setup time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is asserted in a cycle.

13.2.6.8 eLCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIFx_VDCTRL0*n*)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Address: Base address + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved		VSYNC_OEB	ENABLE_PRESENT	VSYNC_POL	HSYNC_POL	DOTCLK_POL	ENABLE_POL	Reserved		VSYNC_PERIOD_UNIT	VSYNC_PULSE_WIDTH_UNIT	HALF_LINE	HALF_LINE_MODE	VSYNC_PULSE_WIDTH	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VSYNC_PULSE_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL0*n* field descriptions

Field	Description
31–30 RSRVD2	This field is reserved. Reserved bits. Write as 0.

Table continues on the next page...

LCDIFx_VDCTRL0*n* field descriptions (continued)

Field	Description
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode. 0x0 **VSYNC_OUTPUT** — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the eLCDIF block. 0x1 **VSYNC_INPUT** — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_ PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_ PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines. CLK_DIS_LCDIFn cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_ WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines.
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_ MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
VSYNC_PULSE_ WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of CLK_DIS_LCDIFn cycles only.

13.2.6.9 eLCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF*x*_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: Base address + 80h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VSYNC_PERIOD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL1 field descriptions

Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

13.2.6.10 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIFx_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: Base address + 90h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	HSYNC_PULSE_WIDTH																HSYNC_PERIOD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_VDCTRL2 field descriptions

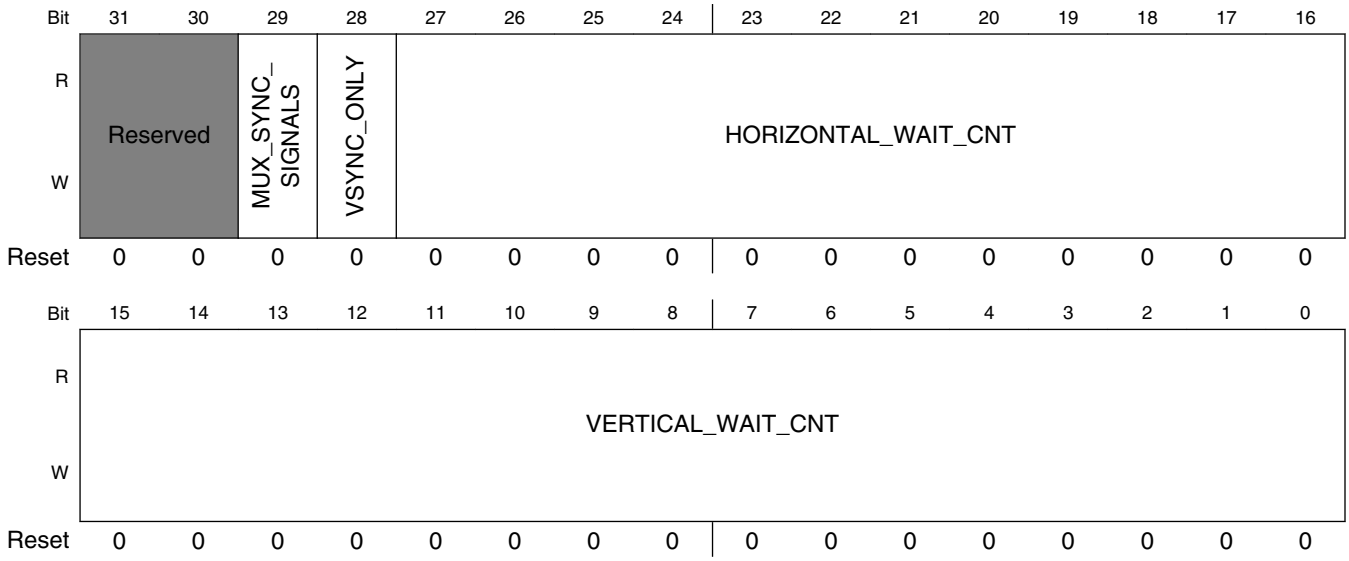
Field	Description
31–18 HSYNC_PULSE_WIDTH	Number of CLK_DIS_LCDIFn cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of CLK_DIS_LCDIFn cycles between two positive or two negative edges of the HSYNC signal.

13.2.6.11 eLCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIFx_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: Base address + A0h offset



LCDIFx_VDCTRL3 field descriptions

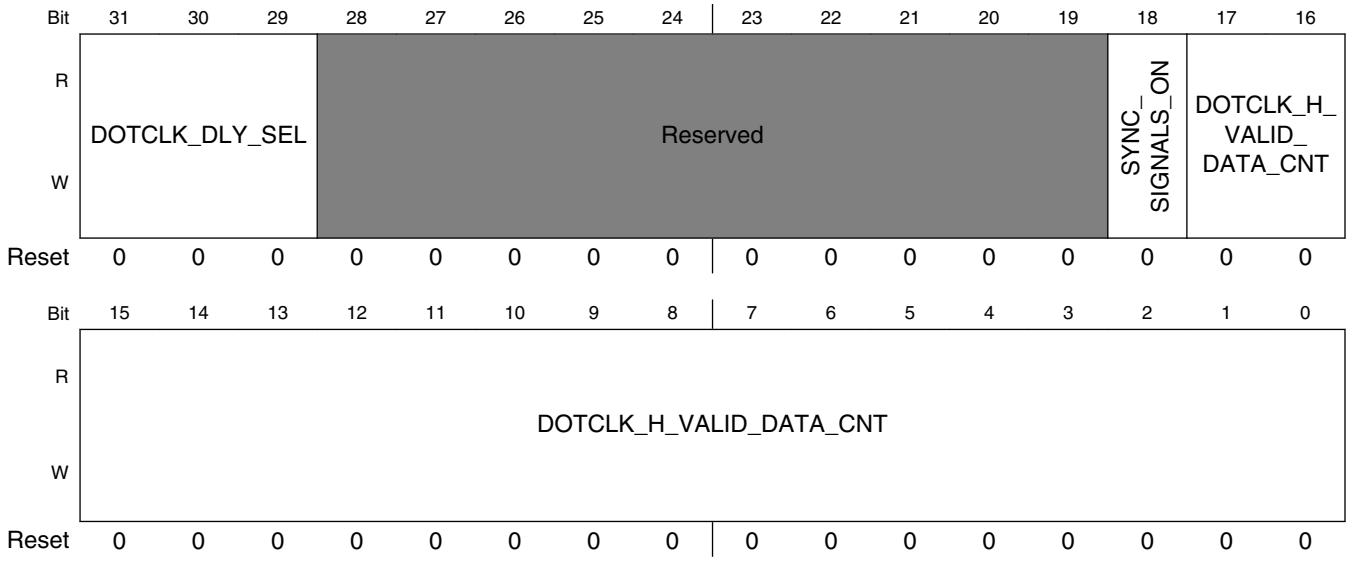
Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29 MUX_SYNC_SIGNALS	When this bit is set, the eLCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL_WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL_WAIT_CNT	In the VSYNC interface mode, wait for this number of CLK_DIS_LCDIFn cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

13.2.6.12 eLCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIFx_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V_COUNT bitfield in the LCDIF_TRANSFER_COUNT register.

Address: Base address + B0h offset



LCDIFx_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_ SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	This field is reserved. Reserved bits, write as 0.
18 SYNC_ SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_ VALID_DATA_ CNT	Total number of CLK_DIS_LCDIFn cycles on each horizontal line that carry valid data in DOTCLK mode.

13.2.6.13 Digital Video Interface Control0 Register (LCDIFx_DVICTRL0)

The Digital Video interface Control0 register provides the overall control of the Digital Video interface.

This register gives information about the horizontal active, horizontal blanking and total number of lines in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
```

```
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0);//1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x106);//262
//625/50 video system
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0);//1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x112);//274
```

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved				H_ACTIVE_CNT												Reserved				H_BLANKING_CNT

LCDIFx_DVICTRL0 field descriptions

Field	Description
31–28 RSRVD1	This field is reserved. Reserved bits, write as 0.
27–16 H_ACTIVE_CNT	Number of active video samples to be transmitted. (Mostly will be 1440 for both PAL and NTSC). Must always be a multiple of 4.
15–12 RSRVD0	This field is reserved. Reserved bits, write as 0.
H_BLANKING_ CNT	Number of blanking samples to be inserted between EAV and SAV during horizontal blanking interval.

13.2.6.14 Digital Video Interface Control1 Register (LCDIFx_DVICTRL1)

The Digital Video interface Control1 register provides the overall control of the Digital Video interface.

This register contains information about the Field1 start and end, and the Field2 start in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x4);//4
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x109);//265
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x10A);//266
//625/50 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x1);//1
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x138);//312
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x139);//313
```

Address: Base address + D0h offset

LCDIFx_DVICTRL1 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F1_START_LINE	Vertical line number from which Field 1 begins.
19–10 F1_END_LINE	Vertical line number at which Field1 ends.
F2_START_LINE	Vertical line number from which Field 2 begins.

13.2.6.15 Digital Video Interface Control2 Register (LCDIFx_DVICTRL2)

The Digital Video interface Control2 register provides the overall control of the Digital Video interface.

This register contains information about the Field2 end, and the Vertical Blanking1 interval in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x3);//3
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x108);//264
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x11A);//282
//625/50 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x271);//625
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x137);//311
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x14F);//335
```

Address: Base address + E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LCDIFx_DVICTRL2 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F2_END_LINE	Vertical line number at which Field 2 ends.
19–10 V1_BLANK_ START_LINE	Vertical line number towards the end of Field1 where first Vertical Blanking interval starts.
V1_BLANK_ END_LINE	Vertical line number in the beginning part of Field2 where first Vertical Blanking interval ends.

13.2.6.16 Digital Video Interface Control3 Register (LCDIFx_DVICTRL3)

The Digital Video interface Control3 register provides the overall control of the Digital Video interface.

This register contains information about the Vertical Blanking2 interval in the ITU-R BT. 656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x1);//1
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x13);//19
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x20D);//525
//625/50 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x270);//624
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x16);//22
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x271);//625

LCDIFx_DVICTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

LCDIFx_DVICTRL3 field descriptions (continued)

Field	Description
29–20 V2_BLANK_ START_LINE	Vertical line number towards the end of Field2 where second Vertical Blanking interval starts.
19–10 V2_BLANK_ END_LINE	Vertical line number in the beginning part of Field1 where second Vertical Blanking interval ends.
V_LINES_CNT	Total number of vertical lines per frame (generally 525 or 625)

13.2.6.17 Digital Video Interface Control4 Register (LCDIFx_DVICTRL4)

The Digital Video interface Control4 register provides the overall control of the Digital Video interface.

This register is used to add side borders to the output if the input frame width is less than 720 pixels.

EXAMPLE

```
                //If input frame has only 640 pixels per line, but output is supposed to have
720 pixels per line.
                HW_LCDIF_DVICTRL4_H_FILL_CNT_WR(0x50);//80
                HW_LCDIF_DVICTRL4_Y_FILL_VALUE_WR(0x10);//16

LCDIFx_DVICTRL4 field descriptions

Field	Description
31–24 Y_FILL_VALUE	Value of Y component of filler data
23–16 CB_FILL_VALUE	Value of CB component of filler data
15–8 CR_FILL_VALUE	Value of CR component of filler data.
H_FILL_CNT	Number of active video samples that have to be filled with the filler data in the front and back portions of the active horizontal interval. Must be a multiple of 4. This field will have to be programmed if the input frame has less than 720 pixels per line.

13.2.6.18 RGB to YCbCr 4:2:2 CSC Coefficient0 Register (LCDIFx_CSC_COEFF0)

LCDIF_CSC_COEFF0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF0_C0_WR(0x41);//0.257x256=65
HW_LCDIF_CSC_COEFF0_CSC_SUBSAMPLE_FILTER_WR(0x3);
```

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								C0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved														CSC_ SUBSAMPL E_FILTER	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_CSC_COEFF0 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C0	Two's complement red multiplier coefficient for Y
15–2 RSRVD0	This field is reserved. Reserved bits, write as 0.
CSC_ SUBSAMPLE_ FILTER	This register describes the filtering and subsampling scheme to be performed on the chroma components in order to convert from YCbCr 4:4:4 to YCbCr 4:2:2 space. Note that the following descriptions apply individually to Cb and Cr. 0x0 **SAMPLE_AND_HOLD** — No filtering, simply keep every chroma value for samples numbered 2n and discard chroma values associated with all samples numbered 2n+1. 0x1 **RSRVD** — Reserved 0x2 **INTERSTITIAL** — Chroma samples numbered 2n and 2n+1 are averaged (weights 1/2, 1/2) and that chroma value replaces the two chroma values at 2n and 2n+1. This chroma now exists horizontally halfway between the two luma samples. 0x3 **COSITED** — Chroma samples numbered 2n-1, 2n, and 2n+1 are averaged (weights 1/4, 1/2, 1/4) and that chroma value exists at the same site as the luma sample numbered 2n and the chroma samples at 2n+1 are discarded.

13.2.6.19 RGB to YCbCr 4:2:2 CSC Coefficient1 Register (LCDIFx_CSC_COEFF1)

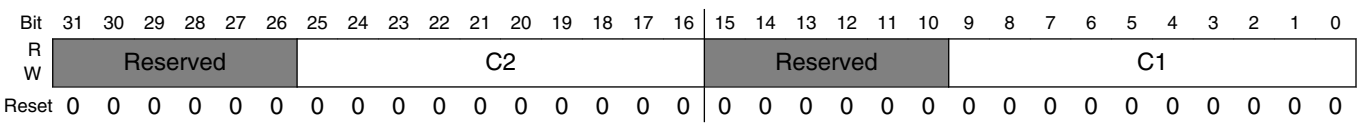
LCDIF_CSC_COEFF1 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF1_C1_WR(0x81);//0.504x256=129
HW_LCDIF_CSC_COEFF1_C2_WR(0x19);//0.098x256=25
```

Address: Base address + 120h offset



LCDIFx_CSC_COEFF1 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C2	Two's complement blue multiplier coefficient for Y
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C1	Two's complement green multiplier coefficient for Y

13.2.6.20 RGB to YCbCr 4:2:2 CSC Coefficent2 Register (LCDIFx_CSC_COEFF2)

LCDIF_CSC_COEFF2 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF2_C3_WR(0x3DB);//-0.148x256=-37
HW_LCDIF_CSC_COEFF2_C4_WR(0x3B6);//-0.291x256=-74
```

Address: Base address + 130h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_CSC_COEFF2 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C4	Two's complement green multiplier coefficient for Cb
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C3	Two's complement red multiplier coefficient for Cb

13.2.6.21 RGB to YCbCr 4:2:2 CSC Coefficient3 Register (LCDIFx_CSC_COEFF3)

LCDIF_CSC_COEFF3 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF3_C5_WR(0x70);//0.439x256=112
HW_LCDIF_CSC_COEFF3_C6_WR(0x70);//0.439x256=112
```

Address: Base address + 140h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_CSC_COEFF4 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C8	Two's complement blue multiplier coefficient for Cr
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C7	Two's complement green multiplier coefficient for Cr

13.2.6.23 RGB to YCbCr 4:2:2 CSC Offset Register (LCDIFx_CSC_OFFSET)

LCDIF_CSC_ register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

Address: Base address + 160h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved							CBCR_OFFSET									Reserved							Y_OFFSET								
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

LCDIFx_CSC_OFFSET field descriptions

Field	Description
31–25 RSRVD1	This field is reserved. Reserved bits, write as 0.
24–16 CBCR_OFFSET	Two's complement offset for the Cb and Cr components
15–9 RSRVD0	This field is reserved. Reserved bits, write as 0.
Y_OFFSET	Two's complement offset for the Y component

13.2.6.24 RGB to YCbCr 4:2:2 CSC Limit Register (LCDIFx_CSC_LIMIT)

LCDIF_CSC_CTRL0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC. Note that the values in this register are unsigned.

EXAMPLE

```
HW_LCDIF_CSC_LIMIT_CBCR_MIN_WR(0x10);//16
HW_LCDIF_CSC_LIMIT_CBCR_MAX_WR(0xF0);//240
HW_LCDIF_CSC_LIMIT_Y_MIN_WR(0x10);//16
HW_LCDIF_CSC_LIMIT_Y_MAX_WR(0xEB);//235
```

Address: Base address + 170h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CBCR_MIN								CBCR_MAX								Y_MIN								Y_MAX							
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

LCDIFx_CSC_LIMIT field descriptions

Field	Description
31–24 CBCR_MIN	Lower limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
23–16 CBCR_MAX	Upper limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
15–8 Y_MIN	Lower limit of Y after RGB to 4:2:2 YCbCr conversion
Y_MAX	Upper limit of Y after RGB to 4:2:2 YCbCr conversion

13.2.6.25 LCD Interface Data Register (LCDIFx_DATA)

This register is used to transfer data using the PIO interface mode of operation. In MPU mode, data written to this register will be transferred out to the display device. When receiving data from the display, data is read from this register using PIO operations. During write operations, data can be written to this register (from the processor's perspective) as bytes, half-words (16 bits), or words (32 bits) as desired.

This register holds the 32-bit word written by the ARM platform into LCDIF. This data then gets sent out by the block across the interface.

Address: Base address + 180h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA_THREE								DATA_TWO								DATA_ONE								DATA_ZERO							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_DATA field descriptions

Field	Description
31–24 DATA_THREE	Byte 3 (most significant byte) of data written to LCDIF.
23–16 DATA_TWO	Byte 2 of data written to eLCDIF.
15–8 DATA_ONE	Byte 1 of data written to eLCDIF.
DATA_ZERO	Byte 0 (least significant byte) of data written to eLCDIF.

13.2.6.26 Bus Master Error Status Register (LCDIFx_BM_ERROR_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM_ERROR_IRQ is asserted, the address of the bus error is updated in the register.

Address: Base address + 190h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_BM_ERROR_STAT field descriptions

Field	Description
ADDR	Virtual address at which bus master error occurred.

13.2.6.27 CRC Status Register (LCDIFx_CRC_STAT)

This register reflects the CRC value of each frame sent out by eLCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD_DATABUS_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR_FRAME_DONE_IRQ is asserted. In the case of DVI mode, the CRC is calculated for the entire frame, not separately for each field in the frame.

Address: Base address + 1A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CRC_VALUE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_CRC_STAT field descriptions

Field	Description
CRC_VALUE	Calculated CRC value.

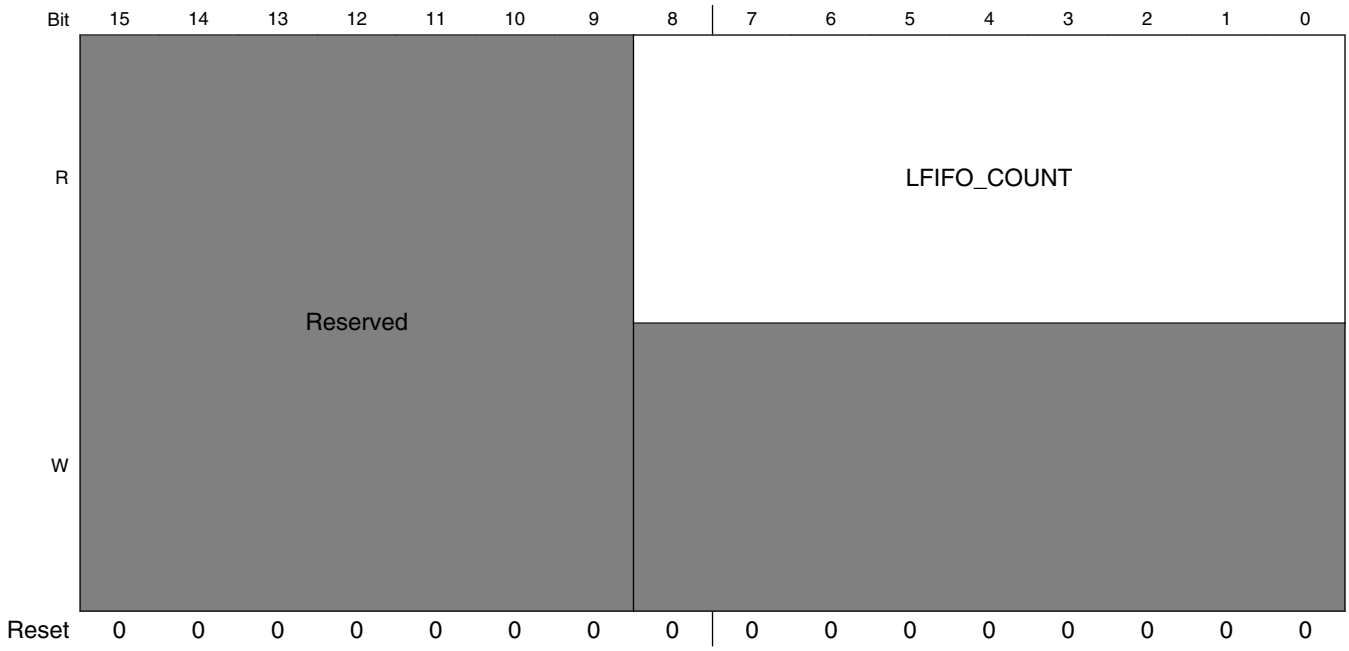
13.2.6.28 LCD Interface Status Register (LCDIFx_STAT)

The LCD interface status register can be used to check the current status of the eLCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: Base address + 1B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	PRESENT	Reserved	LFIFO_FULL	LFIFO_EMPTY	TXFIFO_FULL	TXFIFO_EMPTY	BUSY	DVI_CURRENT_FIELD	Reserved							
W																
Reset	1	0	0	1	0	1	0	1	0	0	0	0	0	0	0	0



LCDIFx_STAT field descriptions

Field	Description
31 PRESENT	0: eLCDIF not present on this product 1: eLCDIF is present.
30 -	This field is reserved. Reserved.
29 LFIFO_FULL	Read only view of the signal that indicates that LCD read datapath FIFO is full, will be generally used in the write mode of the LCD interface.
28 LFIFO_EMPTY	Read only view of the signal that indicates that LCD read dapatath FIFO is empty, will be generally used in the read mode of the LCD interface.
27 TXFIFO_FULL	Read only view of the signal that indicates that LCD write datapath FIFO is full, will be generally used in the write mode of the LCD interface.
26 TXFIFO_EMPTY	Read only view of the signal that indicates that LCD write dapatath FIFO is empty, will be generally used in the read mode of the LCD interface.
25 BUSY	Read only view of the input busy signal from the external LCD controller.
24 DVI_CURRENT_FIELD	Read only view of the current field being transmitted. DVI_CURRENT_FIELD = 0 means field 1. DVI_CURRENT_FIELD = 1 means field 2.
23–9 RSRVD0	This field is reserved. Reserved bits. Write as 0.
LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

13.2.6.29 LCD Interface Version Register (LCDIFx_VERSION)

The LCD interface version register can be used to read the version of the eLCDIF IP being used in this SoC.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_VERSION field descriptions

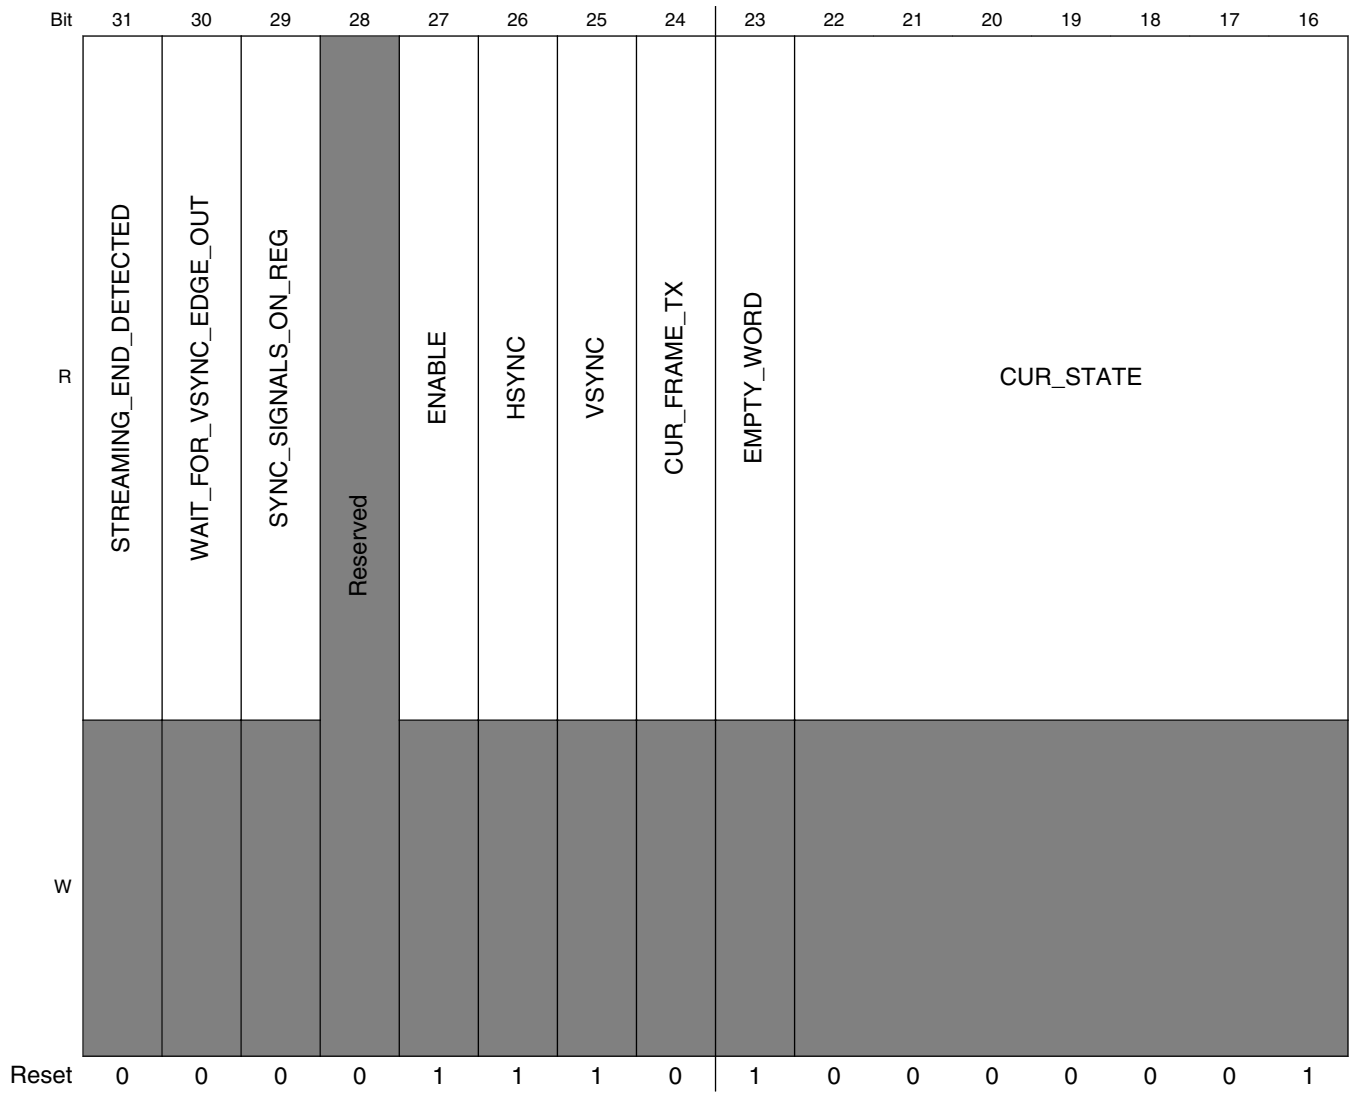
Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of RTL version.
STEP	Fixed read-only value reflecting the stepping of RTL version.

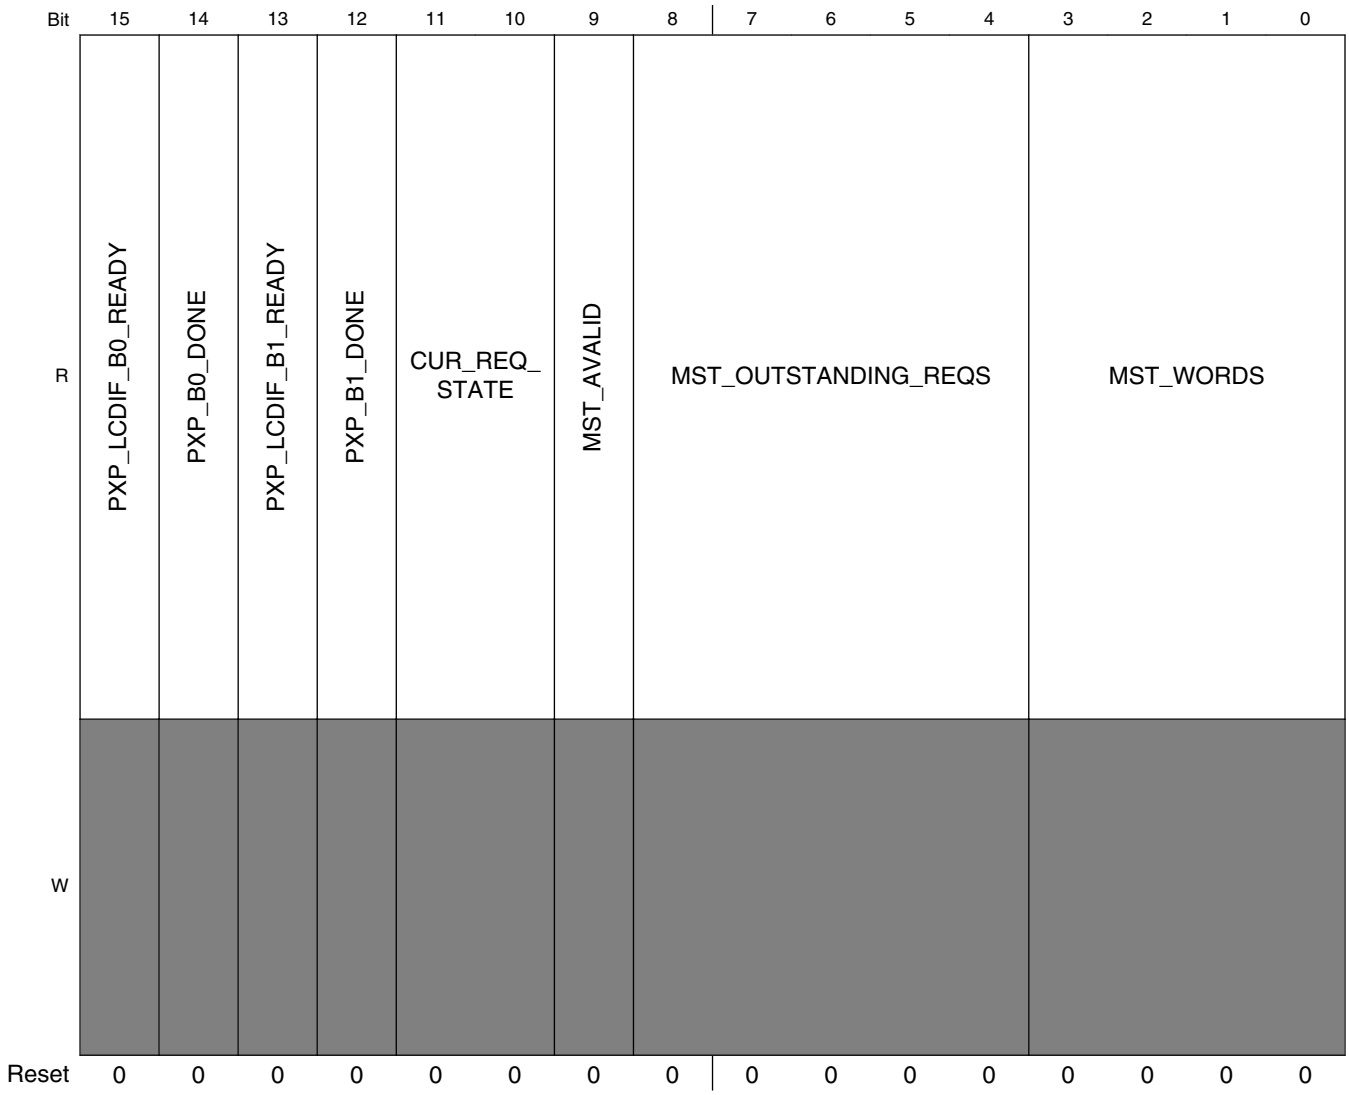
13.2.6.30 LCD Interface Debug0 Register (LCDIFx_DEBUG0)

The LCD interface debug0 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1D0h offset





LCDIFx_DEBUG0 field descriptions

Field	Description
31 STREAMING_ END_DETECTED	Read only view of the DOTCLK_MODE or DVI_MODE bit going from 1 to 0.
30 WAIT_FOR_ VSYNC_EDGE_ OUT	Read only view of WAIT_FOR_VSYNC_EDGE bit in the VSYNC mode after it comes out of the TXFIFO.
29 SYNC_SIGNALS_ ON_REG	Read only view of internal sync_signals_on_reg signal.
28 -	This field is reserved. Reserved.
27 ENABLE	Read only view of ENABLE signal.

Table continues on the next page...

LCDIFx_DEBUG0 field descriptions (continued)

Field	Description
26 HSYNC	Read only view of HSYNC signal.
25 VSYNC	Read only view of VSYNC signal.
24 CUR_FRAME_TX	This bit is 1 for the time the current frame is being transmitted in the VSYNC mode. Useful for VSYNC mode debug.
23 EMPTY_WORD	Indicates that the current word is empty.
22–16 CUR_STATE	Read only view of the current state machine state in the current mode of operation.
15 PXP_LCDIF_B0_READY	Buffer0 ready signal issued by PXP.
14 PXP_B0_DONE	Buffer0 done signal issued by eLCDIF.
13 PXP_LCDIF_B1_READY	Buffer1 ready signal issued by PXP.
12 PXP_B1_DONE	Buffer1 done signal issued by eLCDIF.
11–10 CUR_REQ_STATE	Read only view of the request state machine.
9 MST_AVALID	Read only view of the mst_avalid signal issued by the AXI bus master.
8–4 MST_OUTSTANDING_REQS	Read only view of the current outstanding requests issued by the AXI bus master.
MST_WORDS	Read only view of the current bursts issued by the AXI bus master.

13.2.6.31 LCD Interface Debug1 Register (LCDIFx_DEBUG1)

The LCD interface debug1 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_DEBUG1 field descriptions

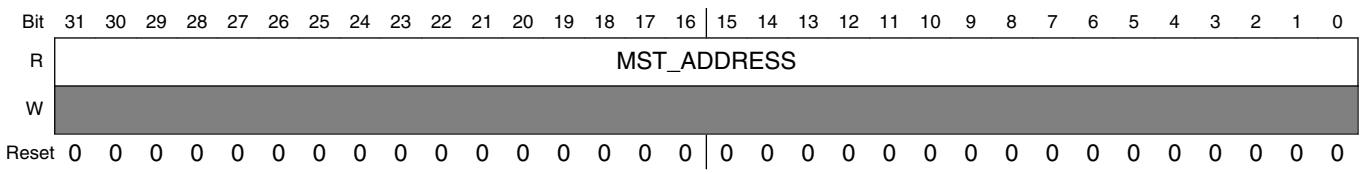
Field	Description
31–16 H_DATA_ COUNT	Read only view of the current state of the horizontal data counter.
V_DATA_ COUNT	Read only view of the current state of the vertical data counter.

13.2.6.32 LCD Interface Debug2 Register (LCDIFx_DEBUG2)

The LCD interface debug2 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: Base address + 1F0h offset



LCDIFx_DEBUG2 field descriptions

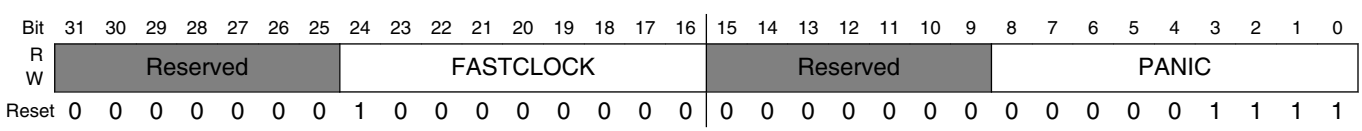
Field	Description
MST_ADDRESS	Read only view of the current address issued by the AXI bus master.

13.2.6.33 eLCDIF Threshold Register (LCDIFx_THRES)

This register is used to activate control signals when the number of pixels reaches the programmed threshold. These control signals, in turn, can be used to manipulate access priority or dynamically change the input clock frequency to meet the required pixel throughput.

Memory request priority threshold register.

Address: Base address + 200h offset



LCDIFx_THRES field descriptions

Field	Description
31–25 RSRVD2	This field is reserved. Reserved bits. Write as 0.
24–16 FASTCLOCK	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the fast clock control output will be raised. This signal can be used to reduce the system bus clock frequency to save power during horizontal or vertical blanking intervals. This value should also be programmed to a value that is greater than the "PANIC" threshold value. This will allow a faster clock to recover the number of pixels in the FIFO before a "panic" level is encountered.
15–9 RSRVD1	This field is reserved. Reserved bits. Write as 0.
PANIC	This value should be set to a value of pixels from 0 to 511. When the number of pixels in the input pixel FIFO is less than this value, the internal panic control output will be raised. This signal can be used to raise the access eLCDIF's access priority.

13.2.6.34 eLCDIF AS Buffer Control Register (LCDIFx_AS_CTRL)

The Alpha Surface Parameter register provides additional controls for AS.

Address: Base address + 210h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_AS_CTRL field descriptions

Field	Description
31 CSI_VSYNC_ENABLE	When this bit is set by software, the LCDIF work as sync mode with CSI input.
30 CSI_VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.

Table continues on the next page...

LCDIFx_AS_CTRL field descriptions (continued)

Field	Description
29 CSI_VSYNC_MODE	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
28 CSI_SYNC_ON_IRQ_EN	This bit is set to enable an interrupt when LCDIF lock with CSI vsync input.
27 CSI_SYNC_ON_IRQ	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
26–24 RVDS1	Reserved, always set to zero.
23 PS_DISABLE	When this bit is set by software, the LCDIF will disable PS buffer data.
22–21 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes either in the HW_LCDIF_DATA register or those fetched by the AXI master part of LCDIF. The swizzle function is independent of the WORD_LENGTH bit. See the explanation of the HW_LCDIF_DATA below for names and definitions of data register fields. The supported swizzle configurations are: NO_SWAP = 0x0 No byte swapping.(Little endian) LITTLE_ENDIAN = 0x0 Little Endian byte ordering (same as NO_SWAP). BIG_ENDIAN_SWAP = 0x1 Big Endian swap (swap bytes 0, 3 and 1, 2). SWAP_ALL_BYTES = 0x1 Swizzle all bytes, swap bytes 0, 3 and 1, 2 (aka Big Endian). HWD_SWAP = 0x2 Swap half-words. HWD_BYTE_SWAP = 0x3 Swap bytes within each half-word.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. MASKAS = 0x0 AS AND PS MASKNOTAS = 0x1 nAS AND PS MASKASNOT = 0x2 AS AND nPS MERGEAS = 0x3 AS OR PS MERGENOTAS = 0x4 nAS OR PS MERGEASNOT = 0x5 AS OR nPS NOTCOPYAS = 0x6 nAS NOT = 0x7 nPS NOTMASKAS = 0x8 AS NAND PS NOTMERGEAS = 0x9 AS NOR PS XORAS = 0xA AS XOR PS NOTXORAS = 0xB AS XNOR PS

Table continues on the next page...

LCDIFx_AS_CTRL field descriptions (continued)

Field	Description
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in REG_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. ARGB8888 = 0x0 32-bit pixels with alpha RGB888 = 0x4 32-bit pixels without alpha (unpacked 24-bit format) ARGB1555 = 0x8 16-bit pixels with alpha ARGB4444 = 0x9 16-bit pixels with alpha RGB555 = 0xC 16-bit pixels without alpha RGB444 = 0xD 16-bit pixels without alpha RGB565 = 0xE 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Embedded = 0x0 Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. Override = 0x1 Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Multiply = 0x2 Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. ROPs = 0x3 Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 AS_ENABLE	When this bit is set by software, the LCDIF will start fetching AS buffer data in bus master mode and combine it with another buffer.

13.2.6.35 Alpha Surface Buffer Pointer (LCDIFx_AS_BUF)

This register is used to indicate the base address of the AS buffer.

Address: Base address + 220h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR

LCDIFx_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

13.2.6.36 LCDIFx_AS_NEXT_BUF

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is upto the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: Base address + 230h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIFx_AS_NEXT_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by eLCDIF.

13.2.6.37 eLCDIF Overlay Color Key Low (LCDIFx_AS_CLRKEYLOW)

If a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. Colorkey operations are higher priority than alpha or ROP operations.

Address: Base address + 240h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_AS_CLRKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer

13.2.6.39 LCD working insync mode with CSI for VSYNC delay (LCDIFx_SYNC_DELAY)

The LCDIF DOTCLK mode VSYNC will delay from CSI_VSYNC as
(V_COUNT_DELAY * HSYNC_PERIOD + H_COUNT_DELAY) PIXCLK cycles

Address: Base address + 260h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

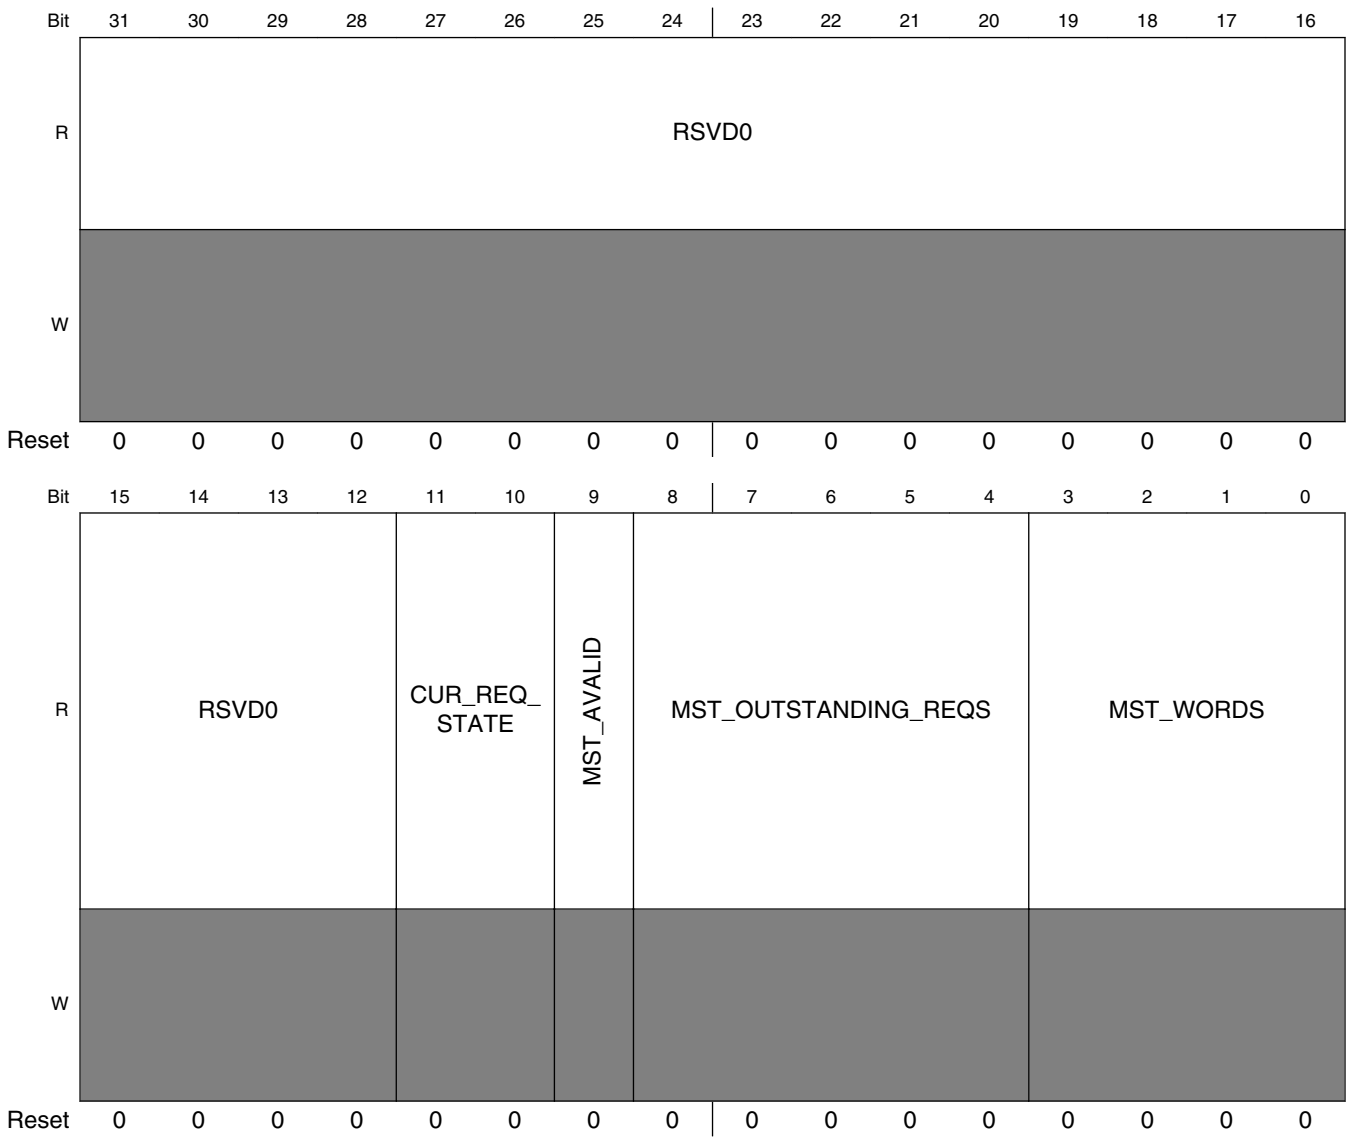
LCDIFx_SYNC_DELAY field descriptions

Field	Description
31–16 V_COUNT_ DELAY	LCDIF VSYNC delayed counter for CSI_VSYNC.
H_COUNT_ DELAY	LCDIF VSYNC delayed counter for CSI_VSYNC.

13.2.6.40 eLCDIF Interface Debug3 Register (LCDIFx_DEBUG3)

The LCD interface debug register is for diagnostic use only.

Address: Base address + 270h offset



LCDIFx_DEBUG3 field descriptions

Field	Description
31–12 RSVD0	Reserved bits, write as 0.

Table continues on the next page...

LCDIFx_DEBUG3 field descriptions (continued)

Field	Description
11–10 CUR_REQ_ STATE	Read only view of the request state machine
9 MST_AVALID	Read only view of the mst_avalid signal issued by the AXI bus master
8–4 MST_ OUTSTANDING_ REQS	Read only view of the current outstanding requests issued by the AXI bus master
MST_WORDS	Read only view of the current bursts issued by the AXI bus master.

13.2.6.41 LCD Interface Debug4 (LCDIFx_DEBUG4)

The LCD interface debug register is for diagnostic use only.

Address: Base address + 280h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIFx_DEBUG5 field descriptions

Field	Description
MST_ADDRESS	Read only view of the AS channel address issued by the AXI bus master.

13.3 CMOS Sensor Interface (CSI)

13.3.1 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input.
- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bitreceive FIFO packing.
- 256 x 64 FIFO to store received image pixel data.
- Reveive FIFO overrun protection mechanism.

- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
- Support double bufferring two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).
- Supports simple deinterlacing of interlaced input.

13.3.2 External Signals

The table below describes the external signals for the CSI. The external signals are tied between the CSI module and an external CMOS sensor.

Table 13-5. CSI External Signals

Signal	Description	Pad	Mode	Direction

13.3.3 Clocks

The following table describes the clock sources for CSI. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 13-6. CSI Clocks

Clock name	Clock Root	Description
csi_hclk	MAIN_AXI_CLK_ROOT	Module clock
ipg_clk	MAIN_AXI_CLK_ROOT	Peripheral clock
ipg_clk_s	MAIN_AXI_CLK_ROOT	Peripheral access clock
ipg_clk_s_raw	MAIN_AXI_CLK_ROOT	Peripheral raw data clock

13.3.4 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI_DATA[9:2].

- To connect with one 10-bit sensor, the sensor data interface should connect to CSI_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI_DATA[15:0].
- To connect with two 8-bit sensors, the sensor data interfaces should connect to CSI_DATA[7:0] and CSI_DATA[15:8].

13.3.4.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the RxFIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF_LEVEL and DMA_REQ_EN_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the RxFIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA_TSF_DONE_FB1 or DMA_TSF_DONE_FB2 bit will be set in

CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA_REFLASH_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the externl memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF_LEVEL and DMA_REQ_EN_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA_TSF_DONE_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF_DMA_DONE_INTEN is enabled in CSICR1 register. The DMA_REFLASH_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

13.3.4.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

13.3.4.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

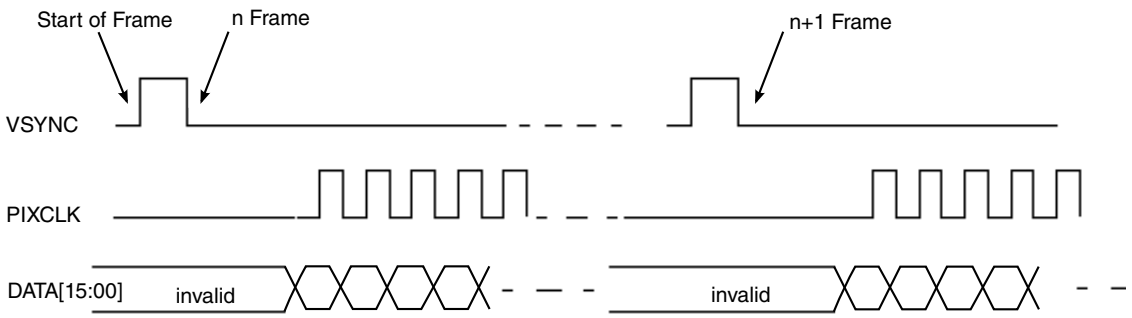

Figure 13-18. Non-Gated Clock Mode Timing Diagram

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 13-18 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

13.3.4.4 CCIR656 Interlace Mode

In CCIR656 mode, only the PIXCLK and CSI_DATA[13:6] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering-that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

Figure below describes the frame structure in PAL system, showing vertical and horizontal blanking.

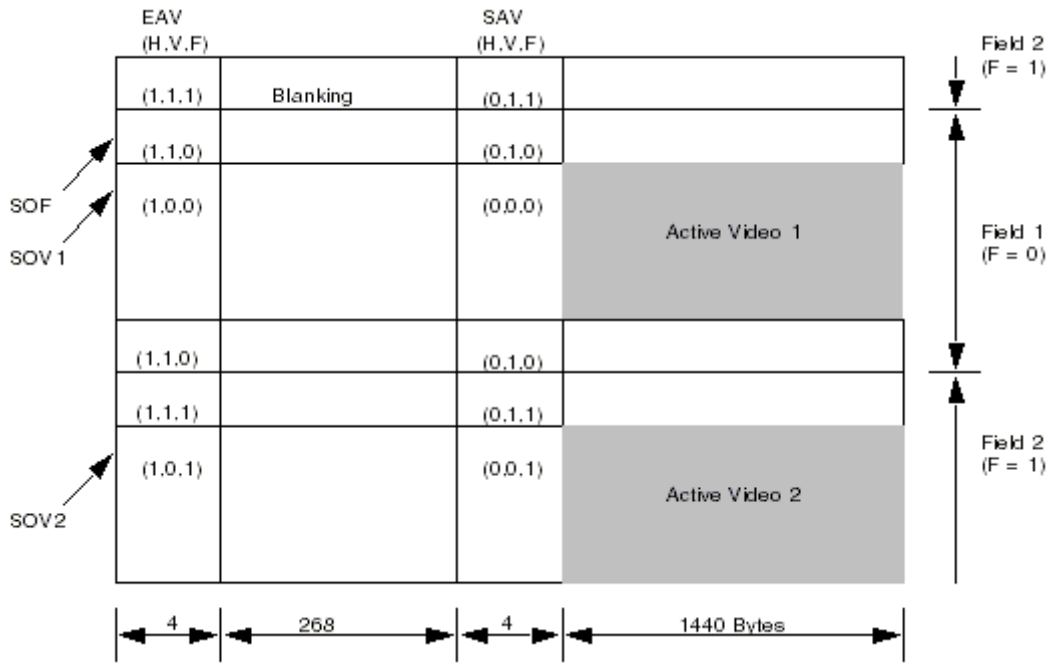

Figure 13-19. CCIR656 Interlace Mode (PAL)

Figure below describes the general timing for a single line, showing SAV and EAV.

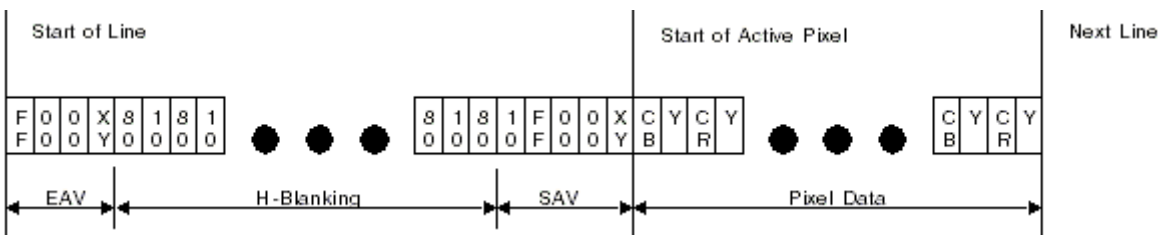

Figure 13-20. CCIR656 General Line Timing

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

Table 13-8. Coding for SAV and EAV

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
7 (MSB)	1	0	0	1
6	1	0	0	F
5	1	0	0	V
4	1	0	0	H

Table continues on the next page...

Table 13-8. Coding for SAV and EAV (continued)

Data Bit Number	1st Byte 0xFF	2nd Byte 0x00	3rd Byte 0x00	4th Byte 0xXY
3	1	0	0	P3
2	1	0	0	P2
1	1	0	0	P1
0	1	0	0	P0

Table 13-9. Codes with Protection bits for Error Detection/Correction

F	V	H	P3	P2	P1	P0

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

13.3.4.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

Figure below shows the typical flow of progressive mode.

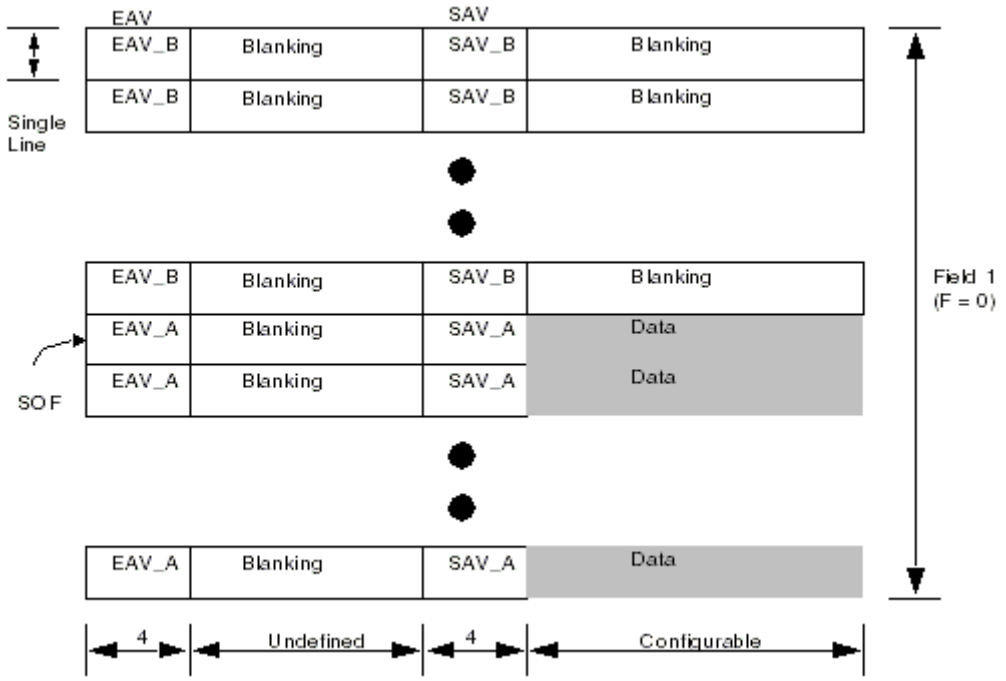

Figure 13-21. CCIR656 Progressive Mode (General Case)

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

13.3.4.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

13.3.5 Interrupt Generation

The information found here describes CSI events that generate interrupts.

13.3.5.1 Start Of Frame Interrupt (SOF_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

13.3.5.2 End Of Frame Interrupt (EOF_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

13.3.5.3 Change Of Field Interrupt (COF_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF_INT bit in the CSI Status Register (CSISTAT) before checking that F1_INT or F2_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

13.3.5.4 CCIR Error Interrupt (ECC_INT)

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC_INT status bit is set.

13.3.5.5 RxFIFO Full Interrupt (RxFF_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF_LEVEL in CSICR3.

13.3.5.6 Statistic FIFO Full Interrupt (STATFF_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF_LEVEL in CSICR3.

13.3.5.7 RxFIFO Overrun Interrupt (RFF_OR_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

13.3.5.8 Statistic FIFO Overrun Interrupt (SFF_OR_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

13.3.5.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

13.3.5.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB2)

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

13.3.5.11 Statistic FIFO DMA Transfer Done Interrupt (DMA_TSF_DONE_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

13.3.5.12 AHB Bus Response Error Interrupt (HRESP_ERR_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

13.3.6 Data Packing Style

Careful attention to endianess is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the PACK_DIR and the SWAP16_EN bit in CSI Control Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring PIXEL_BIT bit in CSI Control Register 1 (CSICR1) and TWO_8BIT_SENSOR bit in CSI Control Register3 (CSICR3). The input data is packed according to the setting of PACK_DIR bit. The packed data is stored in the RX FIFO according to the setting of the SWAP16_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit. For 16-bit data format, the data path can be a combination by two 8-bit sensors. One sensor is connected to the CSI_DATA[7:0]. The other sensor is connected to CSI_DATA[15:8].

13.3.6.1 RX FIFO Path

13.3.6.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the PACK_DIR bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as

P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data, from two sensors, is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0, where P0 and P1 are the two 8-bit data coming in time slot 0 (P0 is the first pixel of the sensor connected with CSI_DATA[7:0] and P1 is the first pixel of the sensor connected with CSI_DATA[15:8]). P2 and P3 are the two 8-bit data coming in time slot 1 (second pixels of the two sensors).

13.3.6.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, …
- 64-bit data before storage in the CSI RX FIFO (PACK_DIR bit = 1): RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bitdata in CSI RX FIFO (SWAP16_EN bit enabled): RG3GB3RG2GB2RG1GB1RG0GB0
- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

13.3.6.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the figure below.

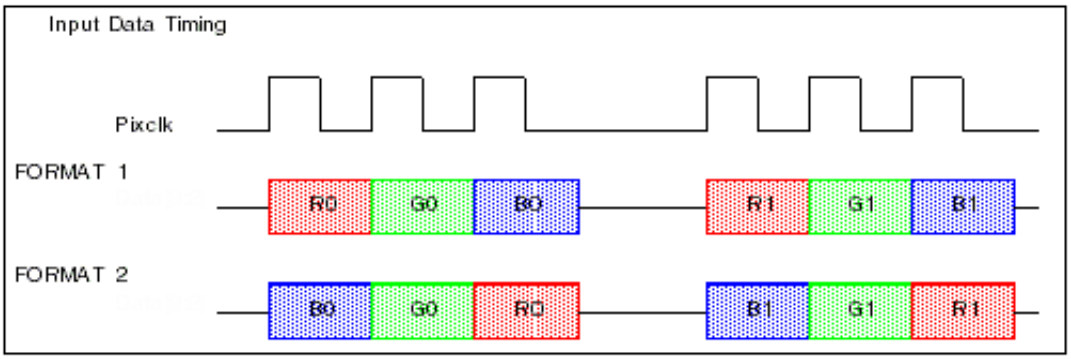

Figure 13-22. Sample Timing Diagram for RGB888 8 bits/cycle Data

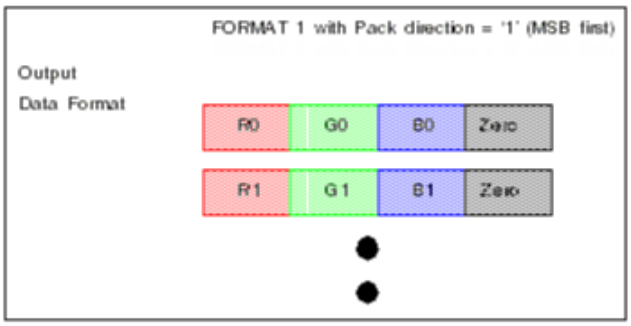
An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the figure below. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A_FORMAT_SEL in CSI_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.



FORMAT 1 with Pack direction = '1' (MSB first)
Output
Data Format

G0
B0
Zero
R1
G1
B1
Zero

13.3.6.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK_DIR and SWAP16_EN bits in the CSICR1 register have no effect on the input path. The PACK_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK_DIR bit = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

…

When the PACK_DIR bit = 0, the stat data is packed as:

First 32-bit GR

Second 32-bit: FB

...

13.3.7 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

CSI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3071_0000	CSI Control Register 1 (CSI_CSICR1)	32	R/W	4000_0800h	13.3.7.1/ 3641
3071_0004	CSI Control Register 2 (CSI_CSICR2)	32	R/W	0000_0000h	13.3.7.2/ 3645
3071_0008	CSI Control Register 3 (CSI_CSICR3)	32	R/W	0000_0000h	13.3.7.3/ 3647
3071_000C	CSI Statistic FIFO Register (CSI_CSISTATFIFO)	32	R	0000_0000h	13.3.7.4/ 3649

Table continues on the next page...

CSI memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3071_0010	CSI RX FIFO Register (CSI_CSIRFIFO)	32	R	0000_0000h	13.3.7.5/ 3649
3071_0014	CSI RX Count Register (CSI_CSIRXCNT)	32	R/W	0000_9600h	13.3.7.6/ 3650
3071_0018	CSI Status Register (CSI_CSISR)	32	R/W	0000_4000h	13.3.7.7/ 3651
3071_0020	CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)	32	R/W	0000_0000h	13.3.7.8/ 3654
3071_0024	CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)	32	R/W	0000_0000h	13.3.7.9/ 3654
3071_0028	CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)	32	R/W	0000_0000h	13.3.7.10/ 3655
3071_002C	CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_CSIDMASA_FB2)	32	R/W	0000_0000h	13.3.7.11/ 3656
3071_0030	CSI Frame Buffer Parameter Register (CSI_CSIFBUF_PARA)	32	R/W	0000_0000h	13.3.7.12/ 3656
3071_0034	CSI Image Parameter Register (CSI_CSIIMAG_PARA)	32	R/W	0000_0000h	13.3.7.13/ 3657

13.3.7.1 CSI Control Register 1 (CSI_CSICR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 3071_0000h base + 0h offset = 3071_0000h

CSI_CSICR1 field descriptions

Field	Description
31 SWAP16_EN	SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO. **NOTE:** Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122 **NOTE:** Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. **NOTE:** This only works when the CSI is in CCIR progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 PrP_IF_EN	CSI-PrP Interface Enable. This bit controls the CSI to PrP bus. When enabled the RxFIFO is detached from the AHB bus and connected to PrP. All CPU reads or DMA accesses to the RxFIFO register are ignored. All CSI interrupts are also masked. 0 CSI to PrP bus is disabled 1 CSI to PrP bus is enabled
27 VIDEO_MODE	Video mode select. This bit controls the video mode in CCIR mode and TV decoder input. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in CCIR interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 SFF_DMA_ DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable
20 FB2_DMA_ DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done.

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable
19 FB1_DMA_DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done. 0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt. 0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt. 0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt. 0 SOF interrupt disable 1 SOF interrupt enable
15–12 Reserved	This field is reserved. Reserved. This field is reserved.
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC. This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0. 0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	CCIR656 Interface Enable. This bit selects the type of interface used. When the CCIR656 timing decoder is enabled, it replaces the function of timing interface logic. 0 Traditional interface is selected. Timing interface logic is used to latch data. 1 CCIR656 interface is selected.
9 Reserved	This field is reserved. This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RXFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RXFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits. 0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO. 0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xBBBBAAAA in STAT FIFO. 1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xAAAABBBB in STAT FIFO.

Table continues on the next page...

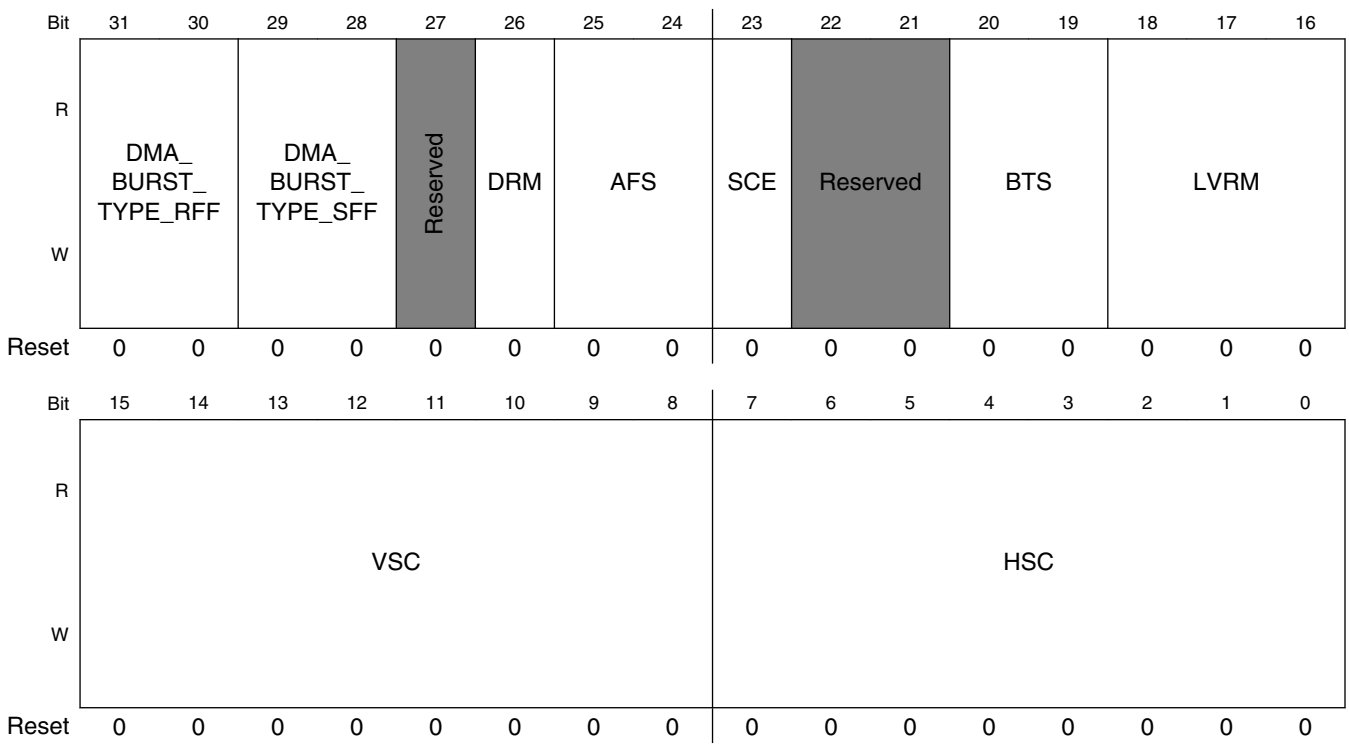
CSI_CSICR1 field descriptions (continued)

Field	Description
6 CLR_STATFIFO	Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF. The bit is restored to 0 automatically after finish. Normally reads 0.
5 CLR_RXFIFO	Asynchronous RXFIFO Clear. This bit clears the RXFIFO. This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored. Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that. The bit is restored to 0 automatically after finish. Normally reads 0.
4 GCLK_MODE	Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode. This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored. 0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored. 1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.
3 INV_DATA	Invert Data Input. This bit enables or disables internal inverters on the data lines. 0 CSI_D[7:0] data lines are directly applied to internal circuitry 1 CSI_D[7:0] data lines are inverted before applied to internal circuitry
2 INV_PCLK	Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module. 0 CSI_PIXCLK is directly applied to internal circuitry 1 CSI_PIXCLK is inverted before applied to internal circuitry
1 REDGE	Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data. 0 Pixel data is latched at the falling edge of CSI_PIXCLK 1 Pixel data is latched at the rising edge of CSI_PIXCLK
0 PIXEL_BIT	Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller. 0 8-bit data for each pixel 1 10-bit data for each pixel

13.3.7.2 CSI Control Register 2 (CSI_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 3071_0000h base + 4h offset = 3071_0004h



CSI_CSICR2 field descriptions

Field	Description
31–30 DMA_BURST_ TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_ TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

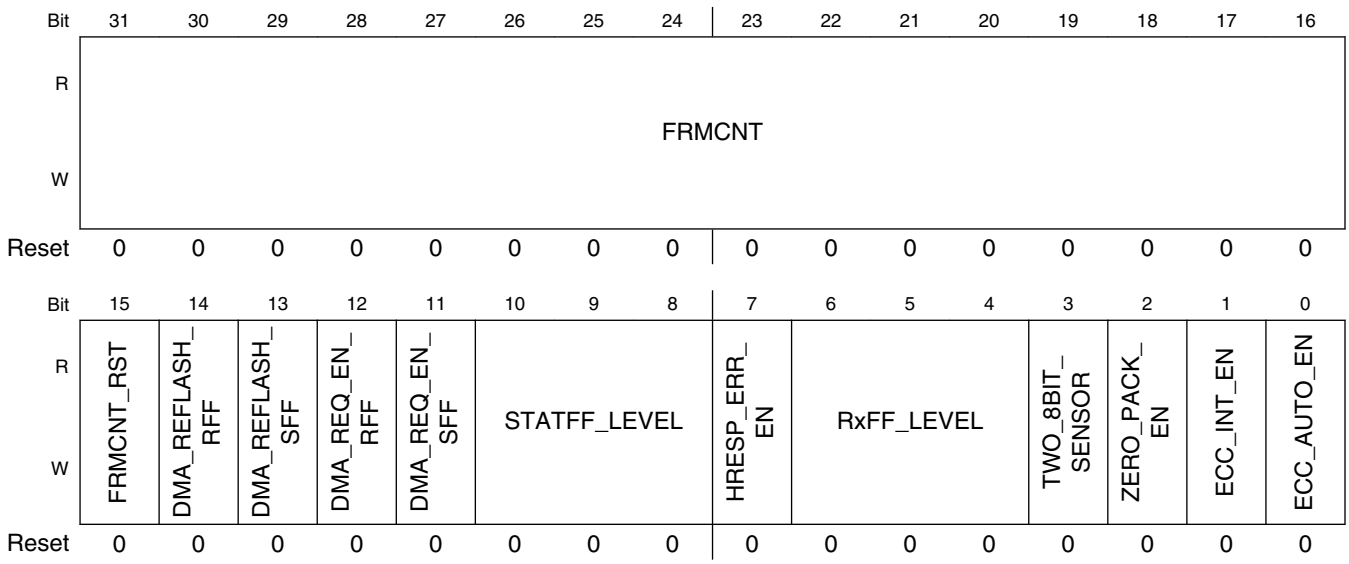
18–16 LVRM	Live View Resolution Mode. Selects the grid size used for live view resolution. 0 512 x 384 1 448 x 336 2 384 x 288 3 384 x 256 4 320 x 240 5 288 x 216 6 400 x 300
15–8 VSC	Vertical Skip Count. Contains the number of rows to skip. SCE must be 1, otherwise VSC is ignored. 0-255 Number of rows to skip minus 1
HSC	Horizontal Skip Count. Contains the number of pixels to skip. SCE must be 1, otherwise HSC is ignored. 0-255 Number of pixels to skip minus 1

13.3.7.3 CSI Control Register 3 (CSI_CSICR3)

This read/write register acts as an extension of the functionality of the CSI Control register 1, adding additional control and features.

Address: 3071_0000h base + 8h offset = 3071_0008h



CSI_CSICR3 field descriptions

Field	Description
31–16 FRMCNT	Frame Counter. This is a 16-bit Frame Counter (Wraps around automatically after reaching the maximum)
15 FRMCNT_RST	Frame Count Reset. Resets the Frame Counter. (Cleared automatically after reset is done) 0 Do not reset 1 Reset frame counter immediately
14 DMA_REFLASH_RFF	Reflash DMA Controller for RxFIFO. This bit reflash the embedded DMA controller for RxFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller
13 DMA_REFLASH_SFF	Reflash DMA Controller for STATFIFO. This bit reflash the embedded DMA controller for STATFIFO. It should be reflashed before the embedded DMA controller starts to work. (Cleared automatically after reflashing is done) 0 No reflashing 1 Reflash the embedded DMA controller

Table continues on the next page...

CSI_CSICR3 field descriptions (continued)

Field	Description
12 DMA_REQ_EN_RFF	DMA Request Enable for RxFIFO. This bit enables the dma request from RxFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
11 DMA_REQ_EN_SFF	DMA Request Enable for STATFIFO. This bit enables the dma request from STATFIFO to the embedded DMA controller. 0 Disable the dma request 1 Enable the dma request
10–8 STATFF_LEVEL	STATFIFO Full Level. When the number of data in STATFIFO reach this level, STATFIFO full interrupt is generated, or STATFIFO DMA request is sent. 000 4 Double words 001 8 Double words 010 12 Double words 011 16 Double words 100 24 Double words 101 32 Double words 110 48 Double words 111 64 Double words
7 HRESP_ERR_EN	Hresponse Error Enable. This bit enables the hresponse error interrupt. 0 Disable hresponse error interrupt 1 Enable hresponse error interrupt
6–4 RxFF_LEVEL	**RxFIFO Full Level**. When the number of data in RxFIFO reaches this level, a RxFIFO full interrupt is generated, or an RXFIFO DMA request is sent. 000 4 Double words 001 8 Double words 010 16 Double words 011 24 Double words 100 32 Double words 101 48 Double words 110 64 Double words 111 96 Double words
3 TWO_8BIT_SENSOR	Two 8-bit Sensor Mode. This bit indicates one 16-bit sensor or two 8-bit sensors are connected to the 16-bit data ports. This bit should be set if there is one 16-bit sensor or two 8-bit sensors are connected. This bit should be configured before activating or restarting the embedded DMA controller. 0 Only one sensor is connected. 1 Two 8-bit sensors are connected or one 16-bit sensor is connected.
2 ZERO_PACK_EN	Dummy Zero Packing Enable. This bit causes a dummy zero to be packed with every 3 incoming bytes, forming a 32-bit word. The dummy zero is always packed to the LSB position. This packing function is only available in 8-bit/pixel mode. 0 Zero packing disabled 1 Zero packing enabled

Table continues on the next page...

CSI_CSICR3 field descriptions (continued)

Field	Description
1 ECC_INT_EN	Error Detection Interrupt Enable. This bit enables and disables the error detection interrupt. This feature only works in CCIR interlace mode. 0 No interrupt is generated when error is detected. Only the status bit ECC_INT is set. 1 Interrupt is generated when error is detected.
0 ECC_AUTO_EN	Automatic Error Correction Enable. This bit enables and disables the automatic error correction. If an error occurs and error correction is disabled only the ECC_INT status bit is set. This feature only works in CCIR interlace mode. 0 Auto Error correction is disabled. 1 Auto Error correction is enabled.

13.3.7.4 CSI Statistic FIFO Register (CSI_CSISTATFIFO)

The StatFIFO is a read-only register containing statistic data from the sensor. Writing to this register has no effect.

Address: 3071_0000h base + Ch offset = 3071_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STAT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSISTATFIFO field descriptions

Field	Description
STAT	Static data from sensor

13.3.7.5 CSI RX FIFO Register (CSI_CSIRFIFO)

This read-only register contains received image data. Writing to this register has no effect.

Address: 3071_0000h base + 10h offset = 3071_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIRFIFO field descriptions

Field	Description
IMAGE	Received image data

13.3.7.6 CSI RX Count Register (CSI_CSIRXCNT)

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 3071_0000h base + 14h offset = 3071_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved										RXCNT

CSI_CSIRXCNT field descriptions

Field	Description
31–22 -	This field is reserved. Reserved. These bits are reserved and should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RXFIFO is updated each time the RXFIFO is read by CPU or DMA.This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

13.3.7.7 CSI Status Register (CSI_CSISR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits should function normally even if the corresponding interrupt enable bits are not enabled.

Address: 3071_0000h base + 18h offset = 3071_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CSISR field descriptions

Field	Description
31–29 -	Reserved. These bits are reserved and should read 0.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
26 DMA_FIELD1_DONE	When DMA field 0 is complete, this bit will be set to 1(clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1) 0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1) 0 RXFIFO has not overflowed. 1 RXFIFO has overflowed.
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 DMA_TSF_DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writting 1 or reflashing the StatFIFO dma controller in CSICR3.(Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO) 0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writting 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RXFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO) 0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1) 0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	CCIR Field 2 Interrupt Status. Indicates the presence of field 2 of video in CCIR mode. (Cleared automatically when current field does not match) **NOTE:** Only works in CCIR Interlace mode. 0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	CCIR Field 1 Interrupt Status. Indicates the presence of field 1 of video in CCIR mode. (Cleared automatically when current field does not match) **NOTE:** Only works in CCIR Interlace mode. 0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in CCIR Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1) 0 Video field has no change. 1 Change of video field is detected.
12–8 -	This field is reserved. Reserved. These bits are reserved and should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse error has been detected. (Cleared by writing 1) 0 No hresponse error. 1 Hresponse error is detected.
6–2 -	This field is reserved. Reserved. These bits are reserved and should read 0.
1 ECC_INT	CCIR Error Interrupt. This bit indicates an error has occurred. This only works in CCIR Interlace mode. (Cleared by writing 1) 0 No error detected 1 Error is detected in CCIR coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO) 0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

13.3.7.8 CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 20h offset = 3071_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DMA_START_ADDR_SFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	DMA_START_ADDR_SFF														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_STATFIFO field descriptions

Field	Description
31–2 DMA_START_ ADDR_SFF	DMA Start Address for STATFIFO. Indicates the start address to write data. The embedded DMA controller will read data from STATFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.3.7.9 CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)

This register provides the total transfer size for the embedded DMA controller of STATFIFO. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 24h offset = 3071_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DMA_TSF_SIZE_SFF																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMATS_STATFIFO field descriptions

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transfered by the embedded DMA controller. The size should be double words aligned.

13.3.7.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 28h offset = 3071_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_FB1 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB1	DMA Start Address in Frame Buffer1. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.3.7.11 CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_CSIDMASA_FB2)

This register provides the start address in the frame buffer2 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer2 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 2Ch offset = 3071_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DMA_START_ADDR_FB2														Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_FB2 field descriptions

Field	Description
31–2 DMA_START_ ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.3.7.12 CSI Frame Buffer Parameter Register (CSI_CSIFBUF_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 30h offset = 3071_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DEINTERLACE_STRIDE																FBUF_STRIDE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIFBUF_PARA field descriptions

Field	Description
31–16 DEINTERLACE_ STRIDE	DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. In normal line stride feature, only FBUF_STRIDE needs to be configured. FBUF_STRIDE	Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image.

13.3.7.13 CSI Image Parameter Register (CSI_CSIIMAG_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transfered in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 3071_0000h base + 34h offset = 3071_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMAGE_WIDTH																IMAGE_HEIGHT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

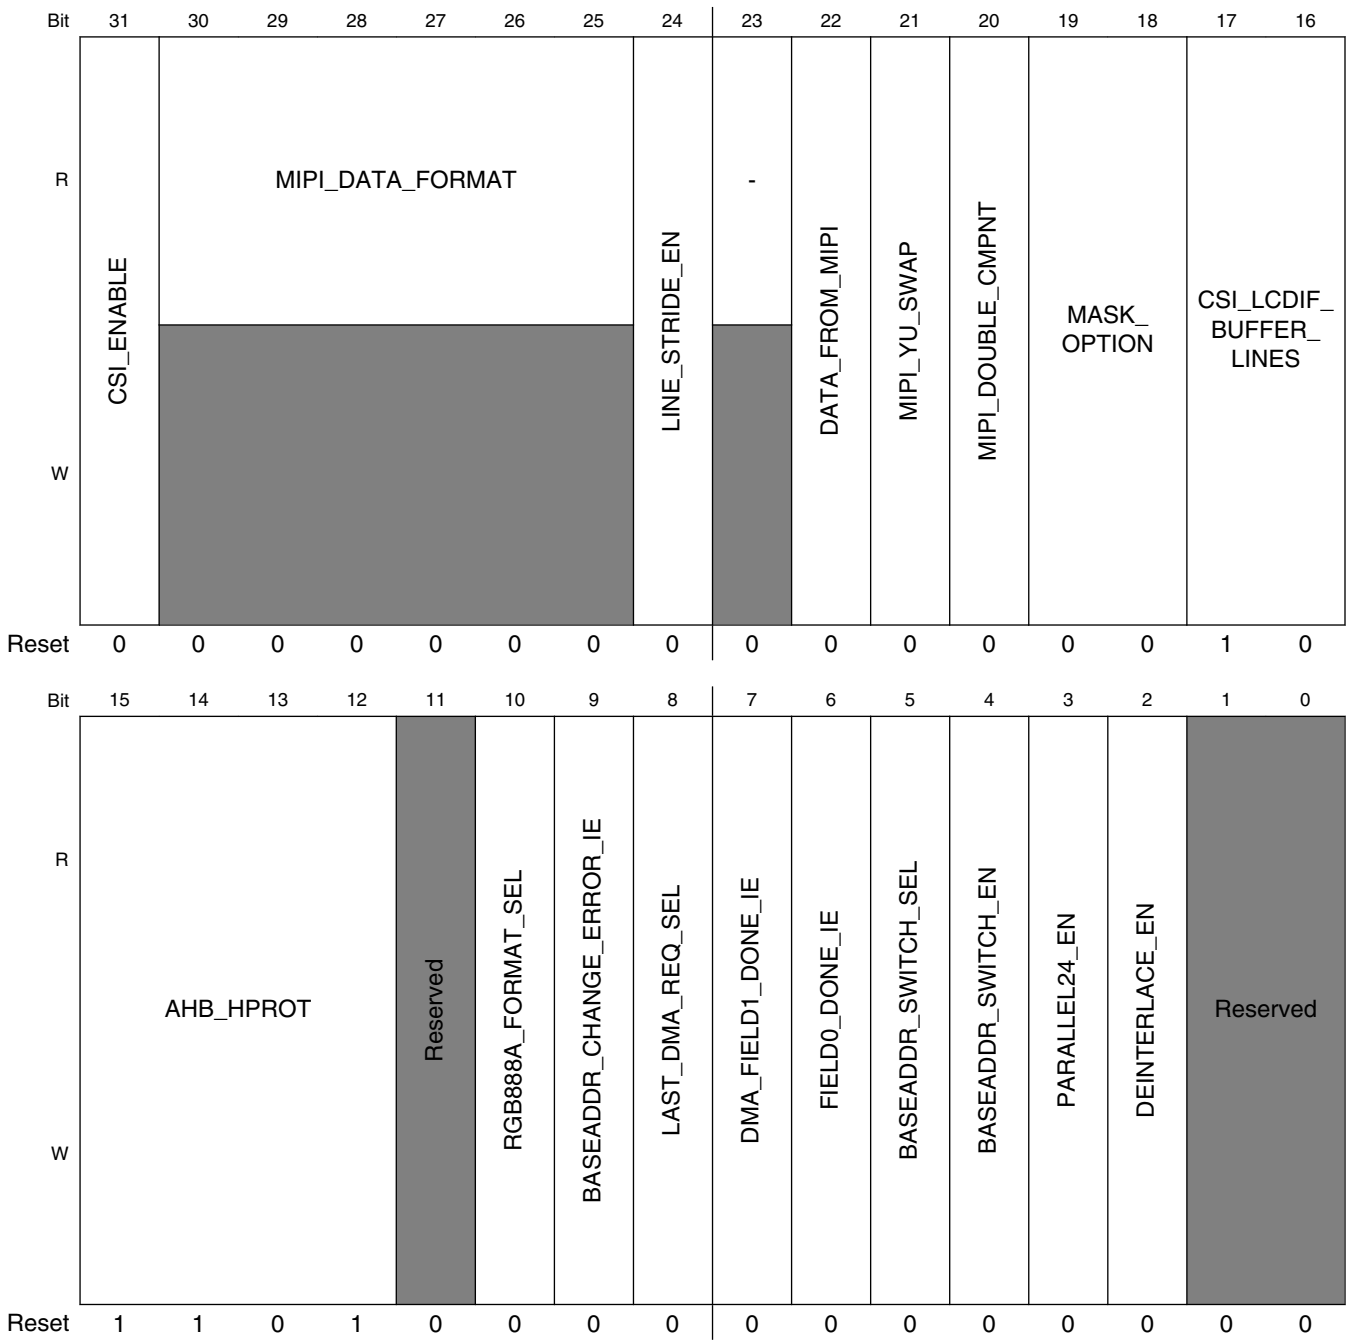
CSI_CSIIMAG_PARA field descriptions

Field	Description
31–16 IMAGE_WIDTH	Image Width. Indicates how many pixels in a line of the image from the sensor. If the input data from the sensor is 8-bit/pixel format, the IMAGE_WIDTH should be a multiple of 8 pixels. If the input data from the sensor is 10-bit/pixel or 16-bit/pixel format, the IMAGE_WIDTH should be a multiple of 2 pixels.
IMAGE_HEIGHT	Image Height. Indicates how many pixels in a column of the image from the sensor.

13.3.7.14 CSI Control Register 18 (CSI_CSICR18)

This read/write register acts as an extension of the functionality of the CSI Control register 1

Address: 3071_0000h base + 48h offset = 3071_0048h



CSI_CSICR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–25 MIPI_DATA_FORMAT	Image Data Format Generic Short Packet: 0x08 ~ 0x0F Embedded 8-bit non Image: 0x12 YUV420 (8-bit) 0x18 YUV420 (10-bit) 0x19 YUV420 (8-bit legacy) 0x1A YUV420 (8-bit CSPS) 0x1C YUV420 (10-bit CSPS) 0x1D YUV422 (8-bit) 0x1E YUV422 (10-bit) 0x1F RGB444 0x20 (Not support) RGB555 0x21 (Not support) RGB565 0x22 RGB666 0x23 RGB888 0x24 RAW6 0x28 RAW7 0x29 RAW8 0x2A RAW10 0x2B RAW12 0x2C RAW14 0x2D User defined 1 0x30 User defined 2 0x31 User defined 3 0x32 User defined 4 0x33 User defined 5 0x34 User defined 6 0x35 User defined 7 0x36 User defined 8 0x37
24 LINE_STRIDE_EN	When the line width are not the multiple of the burst length, assert this bit.
23 -	Reserved
22 DATA_FROM_MIPI	0 Data from parallel sensor 1 Data from MIPI
21 MIPI_YU_SWAP	It only works in MIPI CSI YUV422 double component mode.
20 MIPI_DOUBLE_CMPNT	Double component per clock cycle in YUV422 formats. 0 Single component per clock cycle

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
	(half pixel per clock cycle) 1 Double component per clock cycle (a pixel per clock cycle)
19–18 MASK_OPTION	These bits used to choose the method to mask the CSI input. 00 Writing to memory from first completely frame, when using this option, the CSI_ENABLE should be 1. 01 Writing to memory when CSI_ENABLE is 1. 02 Writing to memory from second completely frame, when using this option, the CSI_ENABLE should be 1. 03 Writing to memory when data comes in, not matter the CSI_ENABLE is 1 or 0.
17–16 CSI_LCDIF_ BUFFER_LINES	The number of lines are used in handshake mode with LCDIF. 00 4 lines 01 8 lines 02 16 lines 03 16 lines
15–12 AHB_HPROT	Hprot value in AHB bus protocol.
11 -	This field is reserved.
10 RGB888A_ FORMAT_SEL	Output is 32-bit format. 0 {8'h0, data[23:0]} 1 {data[23:0], 8'h0}
9 BASEADDR_ CHANGE_ ERROR_IE	Base address change error interrupt enable signal.
8 LAST_DMA_ REQ_SEL	Choosing the last DMA request condition. 0 fifo_full_level 1 hburst_length
7 DMA_FIELD1_ DONE_IE	When in interlace mode, field 1 done interrupt enable. 0 Interrupt disabled 1 Interrupt enabled
6 FIELD0_DONE_ IE	In interlace mode, fileld 0 means interrupt enabled. 0 Interrupt disabled 1 Interrupt enabled
5 BASEADDR_ SWITCH_SEL	CSI 2 base addresses switching method. When using this bit, BASEADDR_SWITCH_EN is 1. 0 Switching base address at the edge of the vsync 1 Switching base address at the edge of the first data of each frame
4 BASEADDR_ SWITCH_EN	When this bit is enabled, CSI DMA will switch the base address according to BASEADDR_SWITCH_SEL rather than atomically by DMA completed.

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
3 PARALLEL24_ EN	When input is parallel rgb888/yuv444 24bit, this bit can be enabled.
2 DEINTERLACE_ EN	This bit is used to select the output method When input is standard CCIR656 video. 0 Deinterlace disabled 1 Deinterlace enabled
-	This field is reserved. Reserved.

13.4 MIPI DSI Host Controller (MIPI_DSI)

13.4.1 Overview

13.4.1.1 Key features

The following list summarizes the key features of the MIPI DSI:

- Complies to MIPI DSI Standard Specification V1.01r11
  - Maximum resolution ranges up to SXGA+(1400 x 11050 @ 60 Hz, 24 bpp)
    - It should be decided on bandwidth between input clock (video clock) and output clock (D-PHY HS clock).
  - Supports 1, 2 data lanes
  - Supports pixel format: 16 bpp, 18 bpp packed, 18 bpp loosely packed (3 byte format), and 24bpp
- Interfaces
  - Complies with Protocol-to-PHY Interface (PPI) in 1.0 Gbps / 1.5 Gbps MIPI D-PHY
  - Supports RGB Interface for Video Image Input from general display controller
  - Supports S-i80 (Synchronous i80) Interface for Command Mode Image input from display controller
  - Supports PMS control interface for PLL to configure byte clock frequency
  - Supports Prescaler to generate escape clock from byte clock

13.4.1.2 Block diagram

13.4.2 External Signals

The following table describes the external signals of MIPI DSI:

Table 13-11. MIPI DSI External Signals

Signal	Description	Pad	Mode	Direction
MIPI_DSI_CLK_N	D-PHY Negative D-Phy differential clock line Receiver input	MIPI_DSI_CLK_N	No muxing	I
MIPI_DSI_CLK_P	D-PHY Positive D-Phy differential clock line Receiver input	MIPI_DSI_CLK_P	No muxing	I

13.4.3.4 Internal primary FIFOs

The following table describes configurable-sized primary FIFOs.

Table 13-12. Internal Primary FIFO List

Port	FIFO Type	Size	Description
Main display for RGB I/F and S-i80 I/F	Packet Header FIFO	3 Bytes X 128 depth	Packet header FIFO for main display
	Payload FIFO	4 Bytes X 2048 depth	Payload FIFO for main display image

Table continues on the next page...

Table 13-12. Internal Primary FIFO List (continued)

Port	FIFO Type	Size	Description
			(SRAM used)
Sub display for S-i80 I/F image data	Packet Header FIFO	3 Bytes X 4 depth	Packet header FIFO for S-i80 I/F sub display
	Payload FIFO	4 Bytes X 512 depth	Payload FIFO for S-i80 I/F sub display image (SRAM used)
Command for S-i80 I/F command	Packet Header FIFO	3 Bytes X 16 depth	Packet header FIFO for S-i80 I/F command packet
	Payload FIFO	4 Bytes X 16 depth	Payload FIFO for S-i80 I/F command long packet payload

13.4.3.5 Packet header arbitration

There are four-packet headers FIFOs for Tx, namely, main display, sub display, S-i80 INTERFACE command, and SFR FIFO. The main and sub display FIFO packet headers contain the image data, while the S-i80 INTERFACE command FIFO packet header contains the command packets. On the other hand, the SFR FIFO packet header contains command packets, sub display image data (in Video mode), and so on.

The packet header arbiter has a “Fixed priority” algorithm. Priority order is fixed as main display, sub display, S-i80 INTERFACE command, and SFR FIFO packet header.

In the Video mode, sub display and S-i80 INTERFACE command FIFO are not used. The SFR FIFO packet header checks if the main display FIFO is empty (no request) in not-active image region and then sends its request.

13.4.3.6 RxFIFO structure

To read the packets received via low power data receiving mode, RxFIFO acts like an SFR. RxFIFO is an asynchronous FIFO with ByteClk and PCLK domains as input clock and output clock domains respectively. The Rx data is synchronized to RxClk. RXBUF has four Rx Byte buffers for aligning byte to word.

The packet headers of all the packets stored in RXFIFO are word-aligned, that is, the first byte of a packet is always stored in LSB. For example, if a long packet has 7-byte payload, the last byte is filled with dummy byte and the next packet is stored in the next word, as shown in the following figure.

NOTE

CRC data is not stored in RXFIFO.

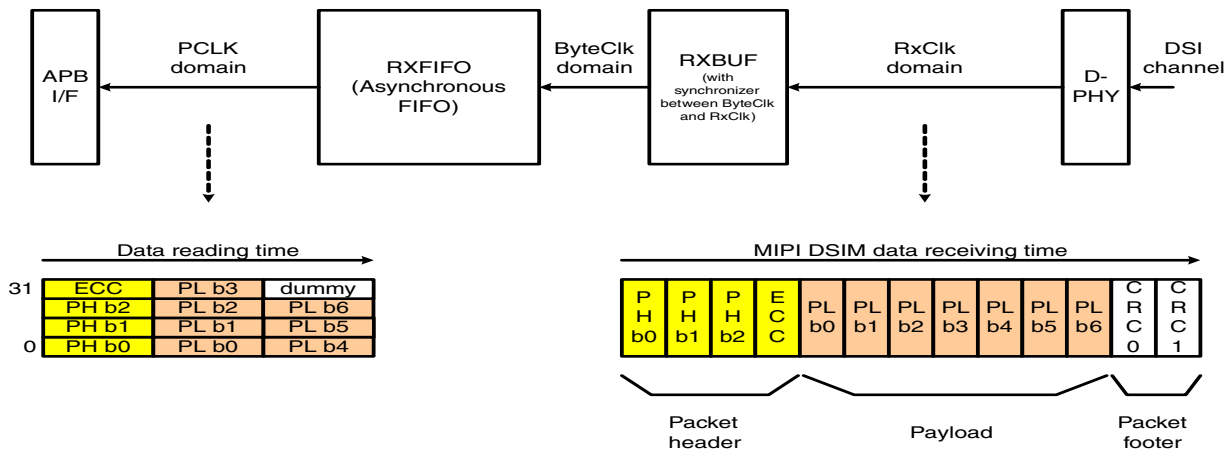

Figure 13-27. Rx Data Word Alignment

13.4.3.7 Interfaces and protocol

Display Controller-to-DSI Conceptual Signal Converting Diagram in Video Mode.

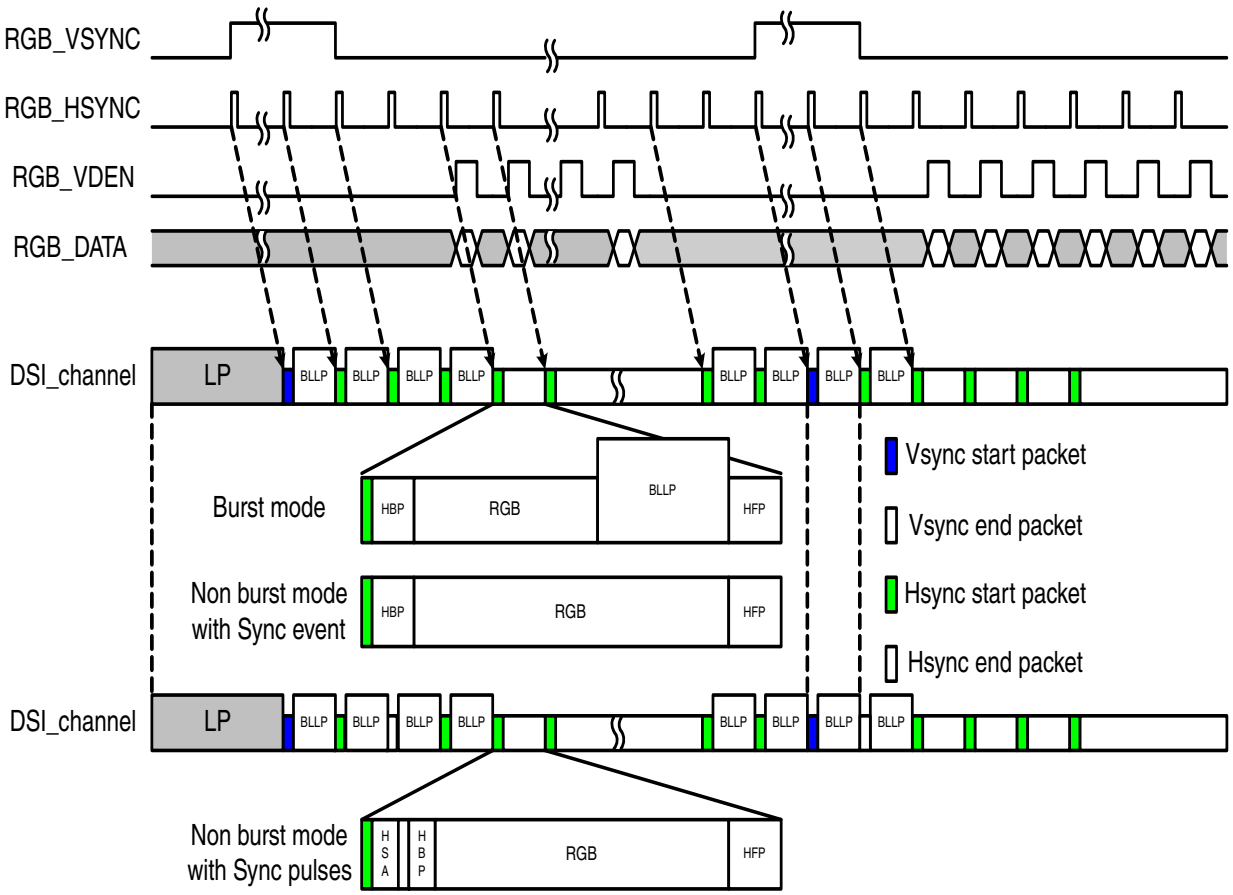

Figure 13-28. Signal Converting Diagram in Video Mode

13.4.3.8 Interface timing and protocol

13.4.3.8.1 Display controller interface

MIPI DSI Master has two-display controller interfaces, namely, RGB INTERFACE for main display and CPU INTERFACE (S-i80 INTERFACE) for main/ sub display. The Video mode uses RGB INTERFACE while the Command mode uses CPU INTERFACE.

The RGB image data is loaded on the data bus of RGB INTERFACE and S-i80 INTERFACE with the same order: RGB_VD[23:0] or SYS_VDOUT[23:0] is {R[7:0],G[7:0],B[7:0]}. Each byte aligns to the most significant bit. For instance, in the 12-bit mode, only three 4-bit values are valid as R, G, and B each, that is, data[23:20], data[15:12], and data[7:4]. The DSIM ignores rest of the bits.

13.4.3.8.2 RGB interface

Vsync, Hsync, and VDEN are active high signals. Among the three signals, Vsync and Hsync are pulse types that spend several video clocks. RGB_VD[23:0] is {R[7:0], G[7:0], B[7:0]}. All sync signals are synchronized to the rising edge of RGB_VCLK. The display controller sends minimum one horizontal line length of Vsync pulse, V back porch, and V front porch. Hsync pulse width should be longer than 1-byte clock cycle.

13.4.3.8.2.1 HSA disable mode

HSA mode specifies the Horizontal Sync Pulse area disable mode.

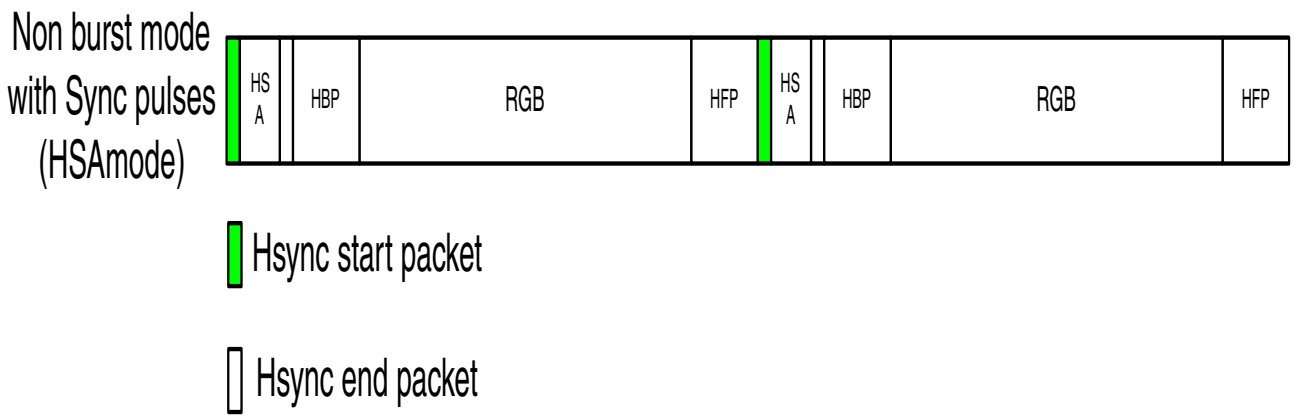

Figure 13-29. Block Timing Diagram of HSA Disable Mode (HSA Mode Reset : DSIM_CONFIG[20] = 0)

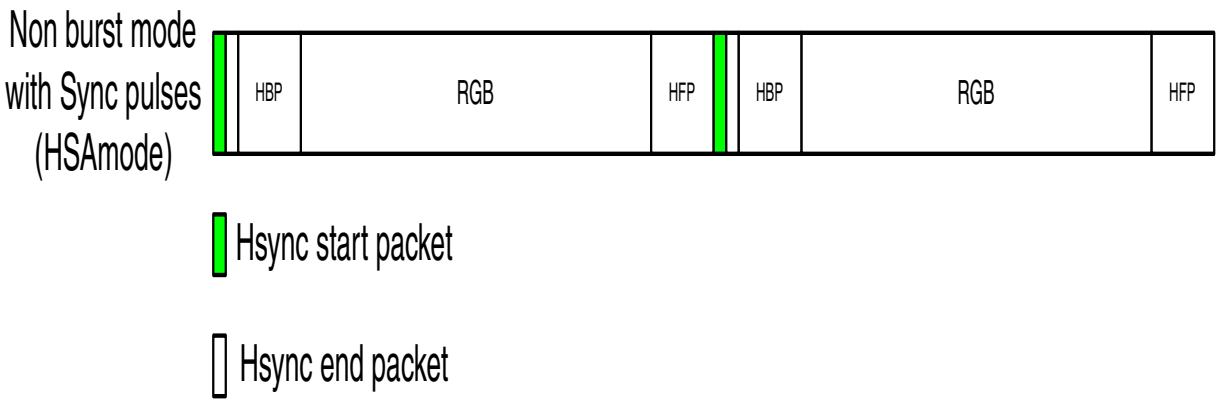

Figure 13-30. Block Timing Diagram of HSA Disable Mode (HSA Mode Reset : DSIM_CONFIG[20] = 1)

13.4.3.8.2.2 HBP disable mode

This is optional spec what is used only burst mode. HBP mode is Horizontal Back Porch disable mode.

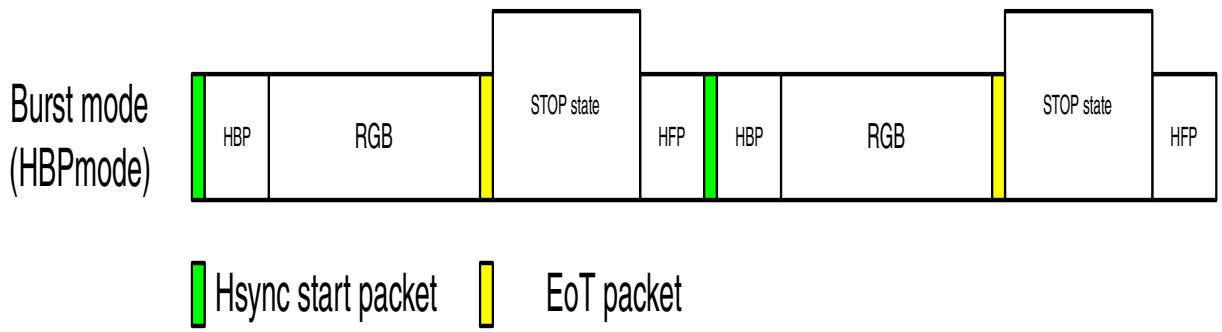

Figure 13-31. Block Timing Diagram of HBP Disable Mode (HBP Mode Reset : DSIM_CONFIG[21] = 0)

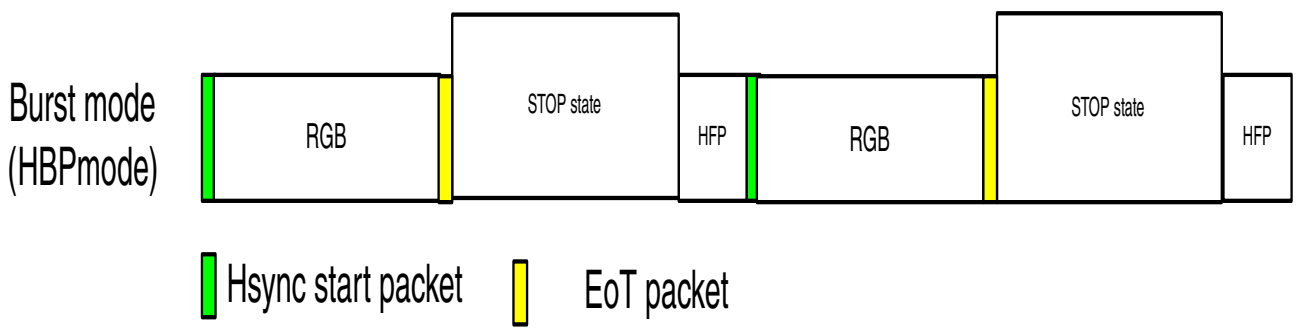
Figure 13-32. Block Timing Diagram of HBP Disable Mode (HBP Mode Set : DSIM_CONFIG[21] = 1)



13.4.3.8.2.3 HFP disable mode

This is optional spec what is used only burst mode. HFP mode is Horizontal Front Porch disable mode.

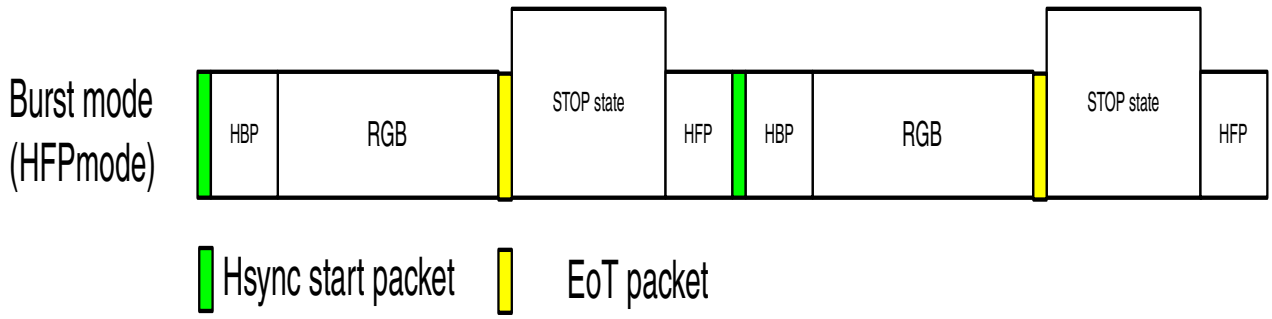


Figure 13-33. Block Timing Diagram of HFP Disable Mode (HFP Mode Set : DSIM_CONFIG[22] = 1)

13.4.3.8.2.4 HSE disable mode

HSE mode is Horizontal Sync End packet enable mode in Vsync pulse or Vporch area.

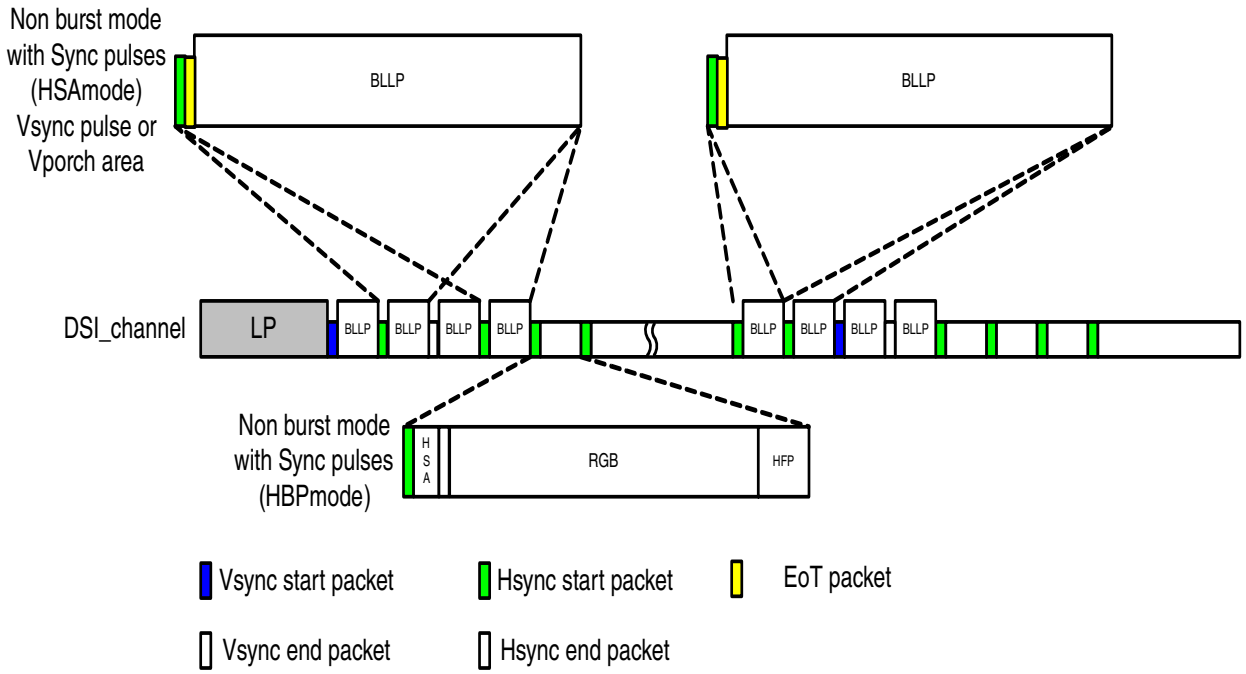

Figure 13-34. Block Timing Diagram of HSE Disable Mode (HSE Mode Reset : DSIM_CONFIG[23] = 0)

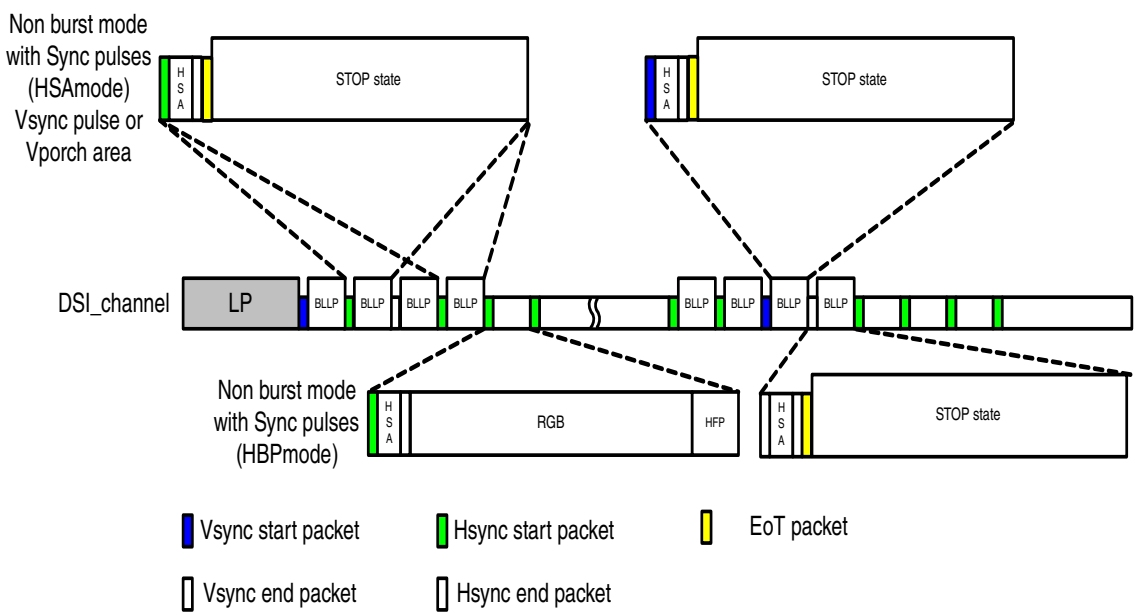

Figure 13-35. Block Timing Diagram of HSE Disable Mode (HSE Mode Reset : DSIM_CONFIG[23] = 1)

13.4.3.8.2.5 Transfer general data in video mode

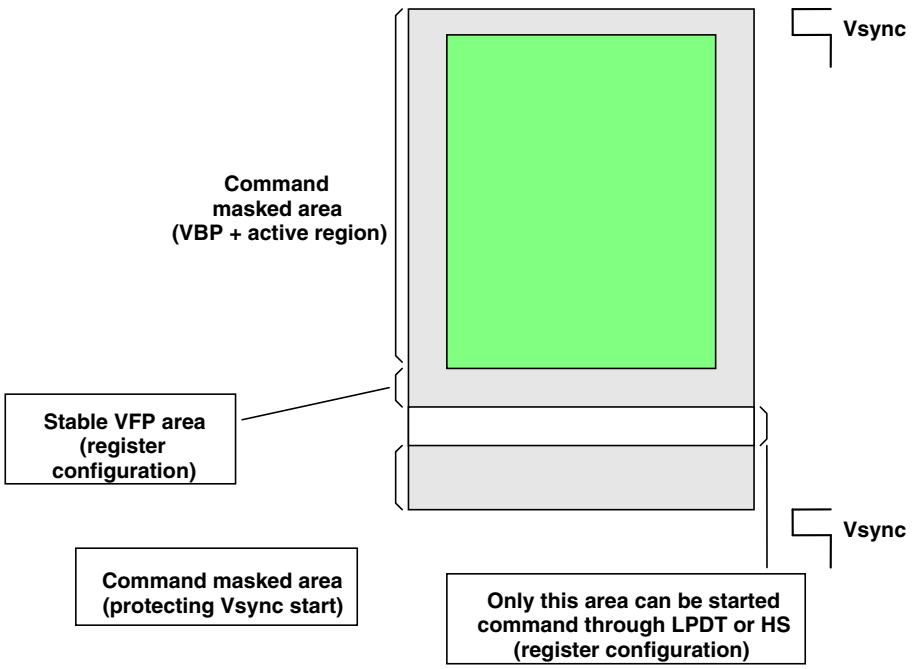

Figure 13-36. Stable VFP Area Before Command Transfer Allowing Area

MIPI DSIM Converts RGB Interface to Video Mode.

Vsync and Hsync packets are extremely important to protect image in Video mode. MIPI DSIM allows several lines in VFP area to transfer general data transfer. As shown in the figure above, the vertical front porch is divided into three areas, namely stable VFP area, command allowed area, and command masked area.

The register configures stable VFP area. Configuration boundary is 11'h000 ~ 11'h7FFF in DSIM_MVPORCH.

The register also configures the command allowed area. Configuration boundary is 4'h0 ~ 4'hF in DSIM_MVPORCH. Only this area is allowed to start "command transfer" through HS mode or LPDT. In LPDT, data transferring takes a long time to complete (approximately hundreds of microseconds or more). In this time, Hsync packet does not arrive due to LPDT long packet. MIPI DSIM comprises of big size FIFO for lost Hsync packet. After LPDT, MIPI DSIM transfers these Hsync packets immediately through HS mode.

To protect Vsync, command masked area is masked area. This area is calculated using LPDT bandwidth. For example, if EscClk is 10 MHz, the maximum long packet payload size is 1 KB and LPDT, LPDT transferring time is 824 µs (packet size: 1030 byte, LPDT maximum bandwidth: 10Mbps). If one line time is 20 µs, the line timing violation occurs in 42 lines. Therefore, command masked area is larger than 42 + α. This 'α' is transferring time of the violated Hsync packets.

Display controller should be configured in such a way that VFP lines are sum of stable VFP, command allowed area, and command masked area.

13.4.3.8.3 S-i80 interface

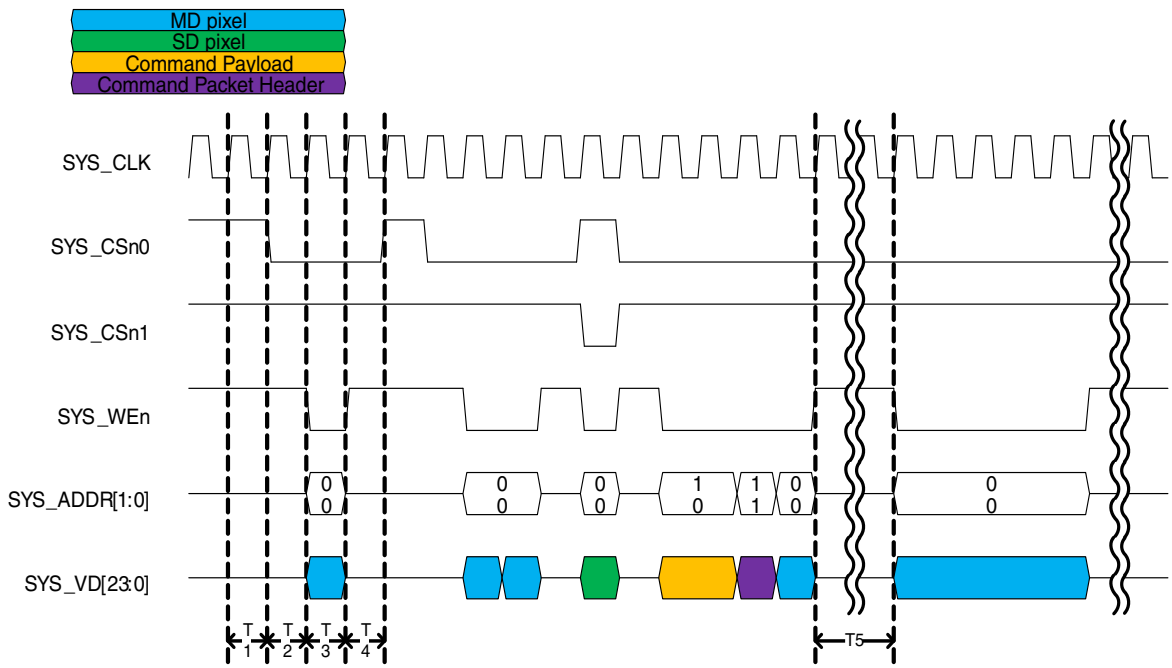

Figure 13-37. S-i80 I/F Timing Diagram

- T1 ≥ 1 clock cycle.
- T2 ≥ 0 clock cycle.
- T3 ≥ 1 clock cycle.
- T4 ≥ 0 clock cycle.
- T2 + T3 + T4 > 1 cycle of Byte clock
- T5 ≥ 10 clock cycles. (every horizontal blank period)

A display controller generates these signals with its internal clock: SYS_CS0 / CS1, SYS_WE, and SYS_VD. MIPI DSI master decodes the SYS_ADDR. The follwoing table describes the Command mode Interface address map.

Table 13-13. Command Mode Interface Address Map

SYS_ADDR[1:0]	Description
2'b00	Image data
2'b01	Reserved
2'b10	Payload data
2'b11	Packet Header

The following figure shows how MIPI DSI Master makes packet from the image data stream via S-i80 INTERFACE in Command mode. MIPI DSI master makes packet from the first line with DCS command "write_memory_start" and the other lines with DCS command "write_memory_continue".

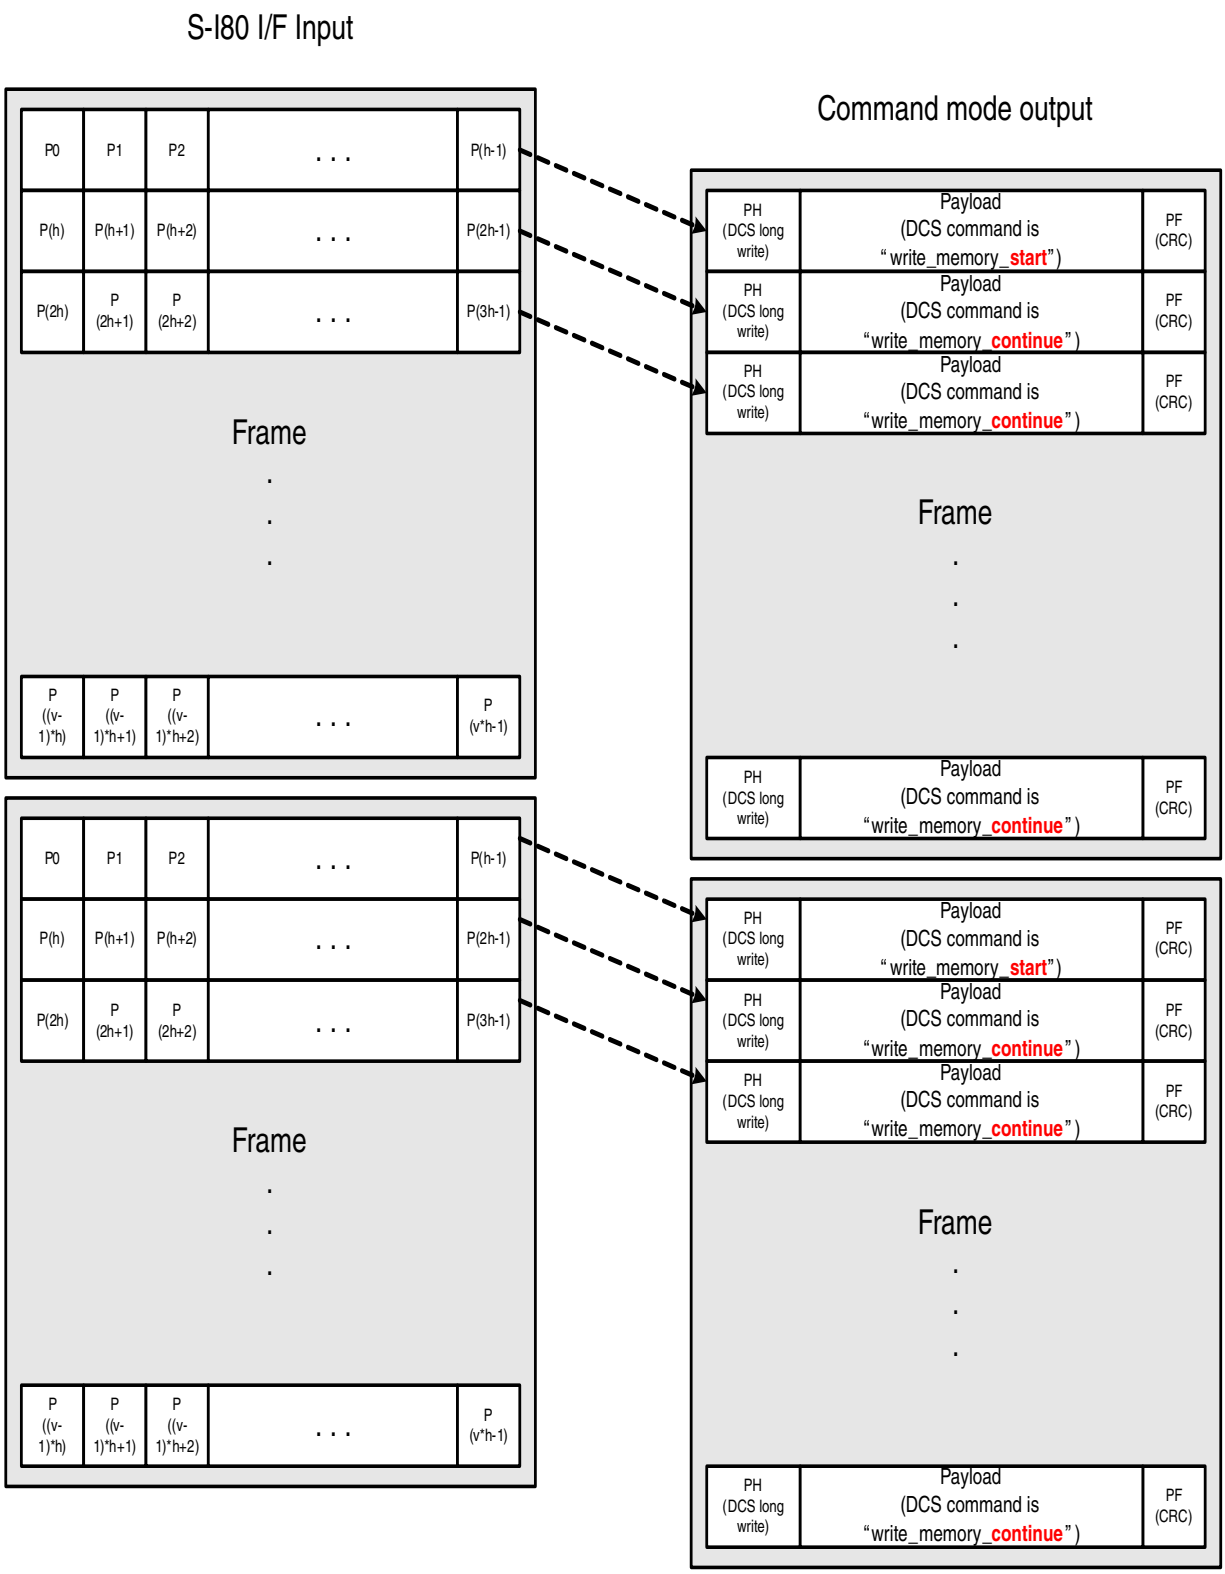

Figure 13-38. Packetizing for MIPI DSI Command Mode from S-i80 I/F

13.4.3.8.4 Relation between input transactions and DSI transactions

Table 13-14. Relation between Input Transactions and DSI Transactions

Input Interface	Input Transaction	DSI Transaction
RGB	RGB transaction	Specifies the RGB Packet
		888, 666, 666 (loosely packed), and 565 should be specified via register configuration.
RGB / S-i80	RGB / S-i80 Image Transaction	Specifies the Data type, that is, “DCS Long Write packet”. (DCS command is “memory write start/continue”.)
S-i80	S-i80 Command Transaction	Specifies any DSI packet. Bytes in S-i80 transaction should be the same bytes in DSI packets.
SFR	Header and Payload FIFO access	Specifies any DSI Packets. Bytes in APB transaction should be the same bytes in DSI packets.

13.4.3.8.5 PPI interface timing and protocol

13.4.3.8.5.1 Initialization after power-on / reset

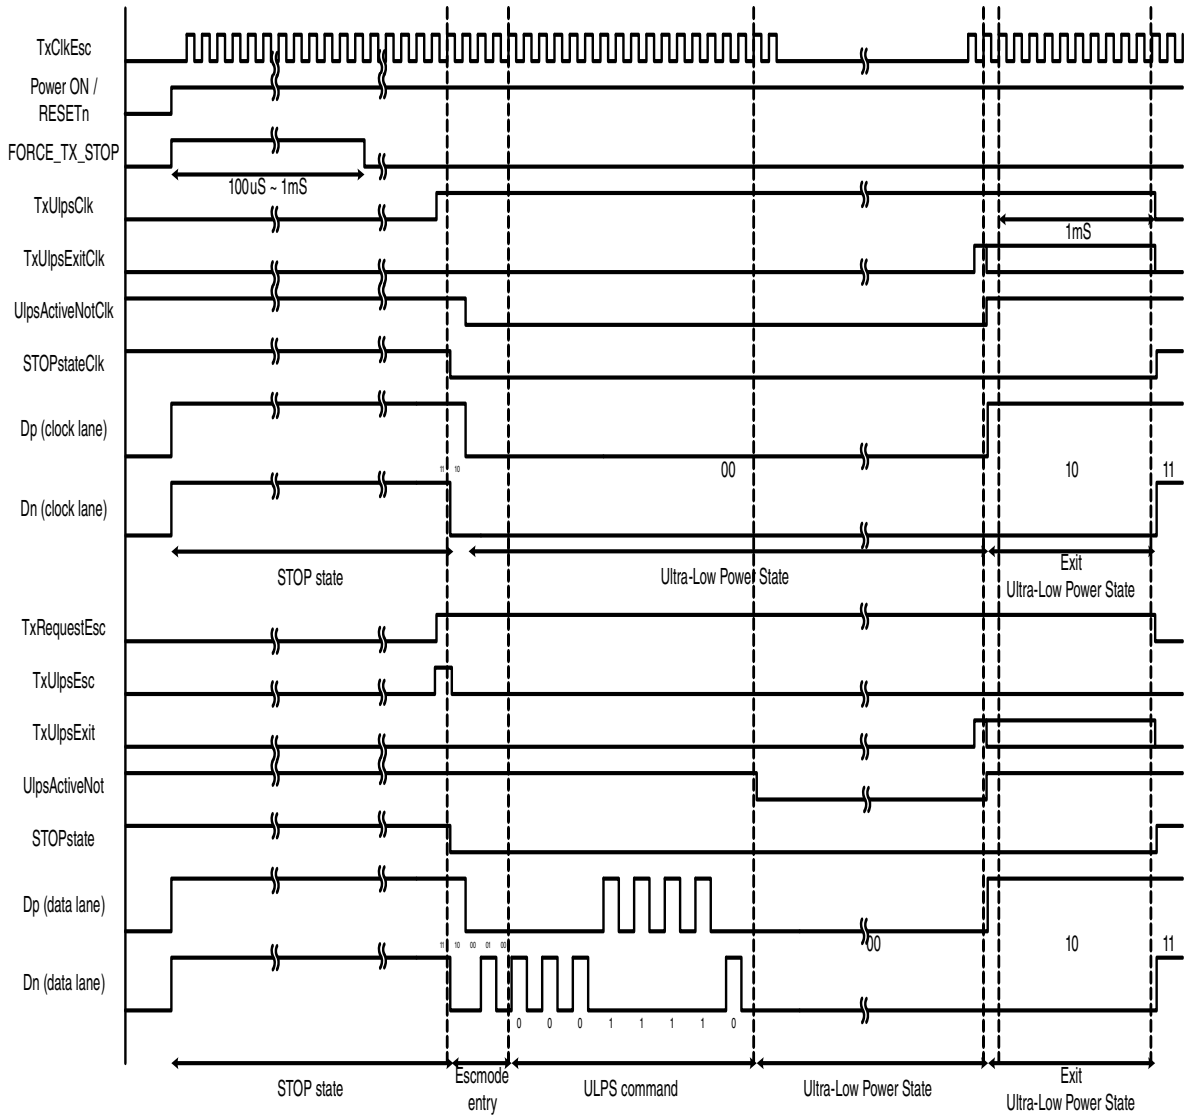

Figure 13-39. Timing Diagram of Initialization

13.4.3.8.5.2 High speed data transfer

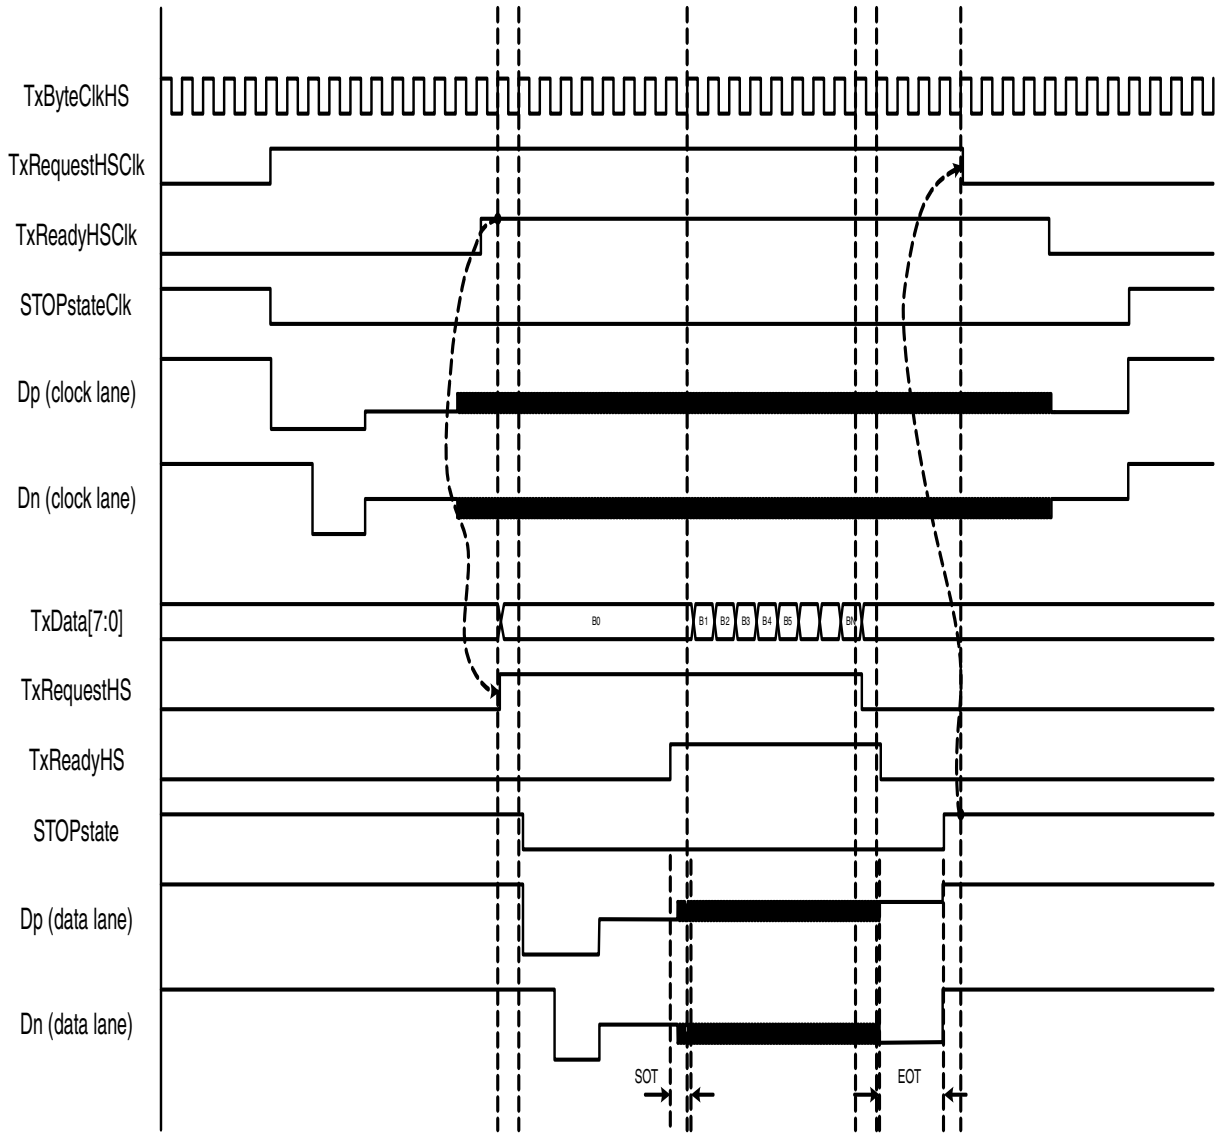

Figure 13-40. Timing Diagram of High Speed Data Transfer

13.4.3.8.5.3 Low power data transfer

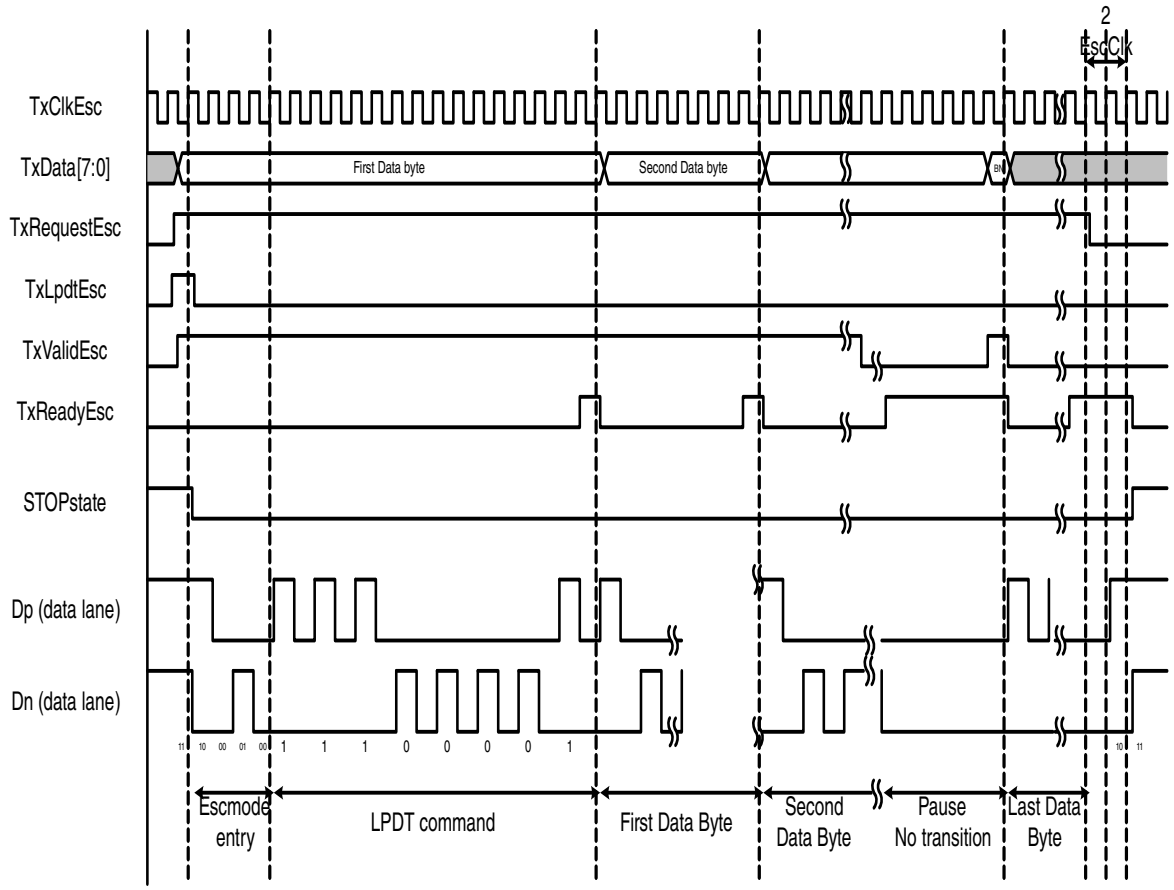

Figure 13-41. Timing Diagram of Low Power Data Transfer

13.4.3.8.5.4 Ultra-Low power state

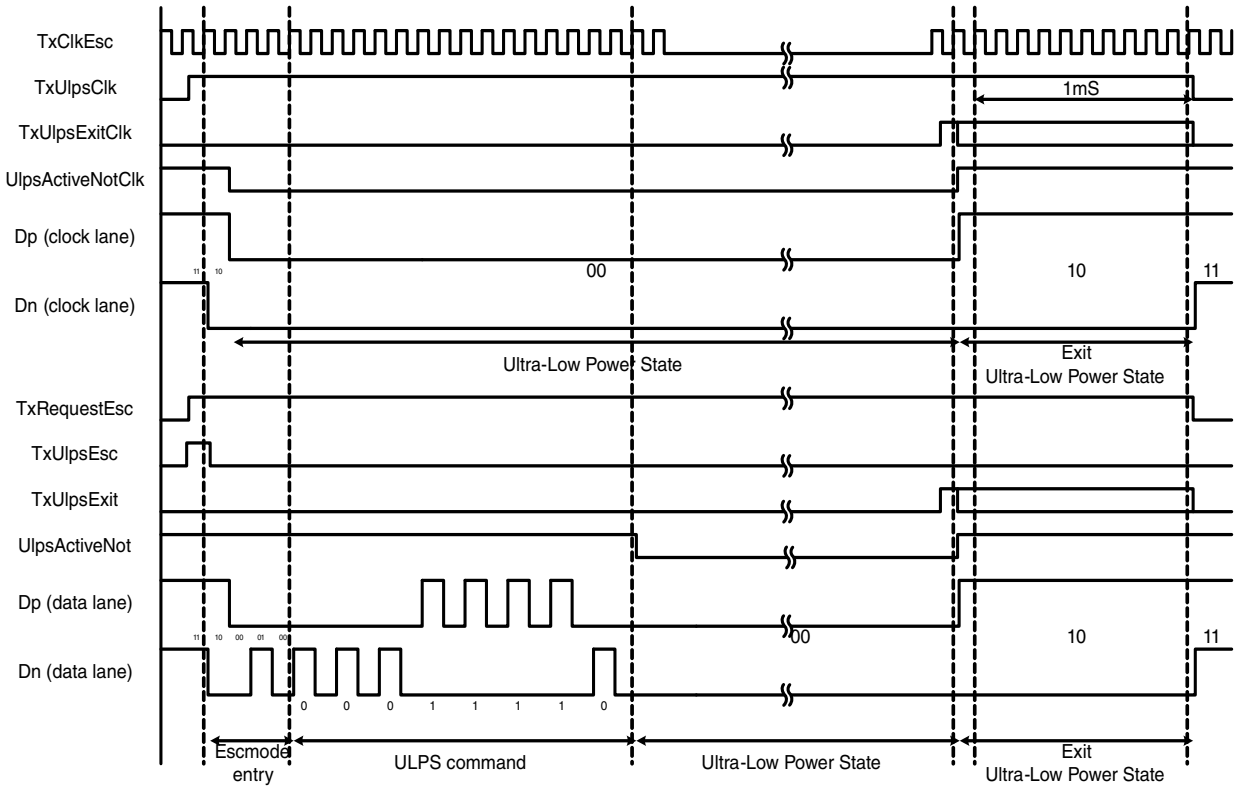

Figure 13-42. Timing Diagram of Ultra Low Power State

13.4.3.8.5.5 Trigger function

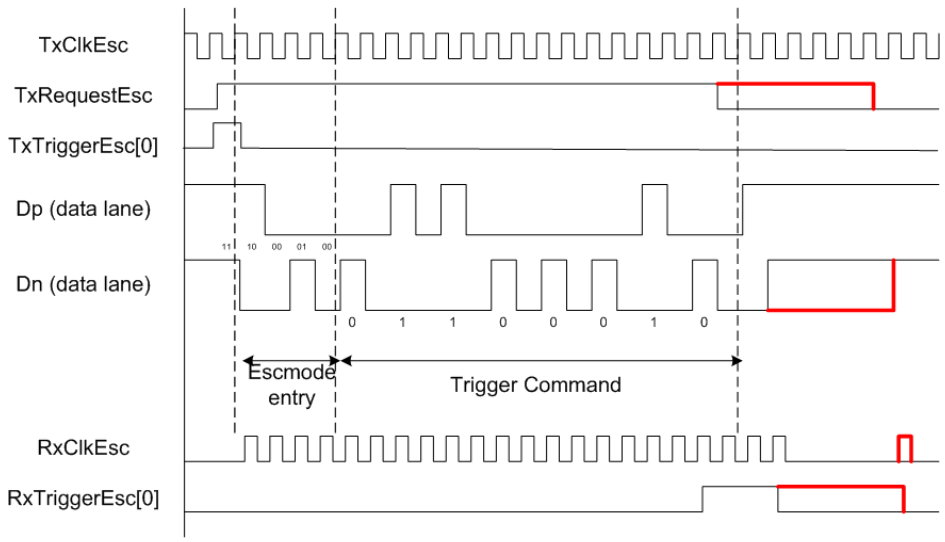

Figure 13-43. Diagram of Trigger Function “Remote Reset”

There are four types of trigger commands:

- 01100010 : remote reset – forward direction
- 01011101 : Tearing Effect – reverse direction
- 00100001 : Acknowledge – reverse direction
- 10100000 : Unknown

If DSI D-PHY received these signals, D-PHY indicates trigger function to protocol layer.

13.4.3.8.5.6 Turn-around and low power data receiving

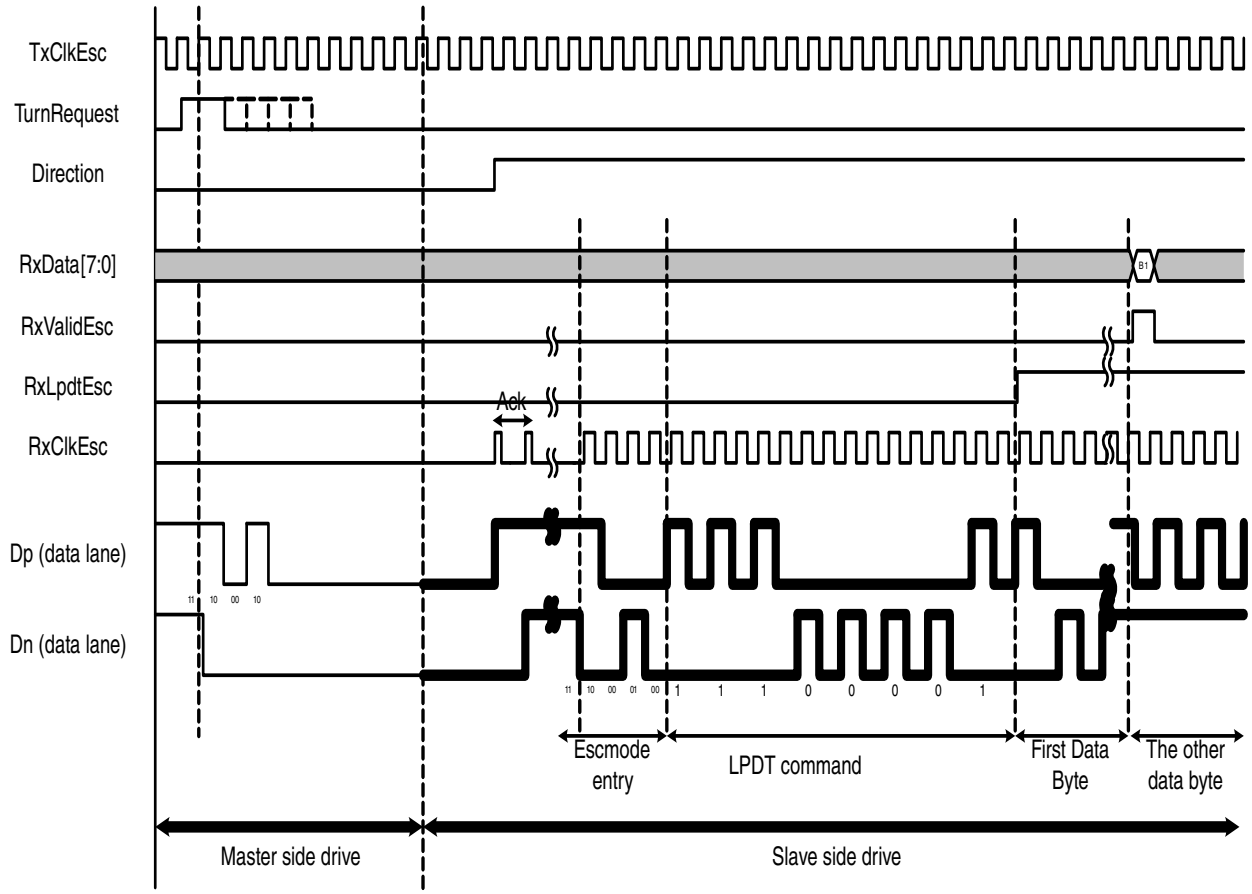

Figure 13-44. Timing Diagram of Bus-Turn-Around

13.4.3.8.5.7 TE signaling

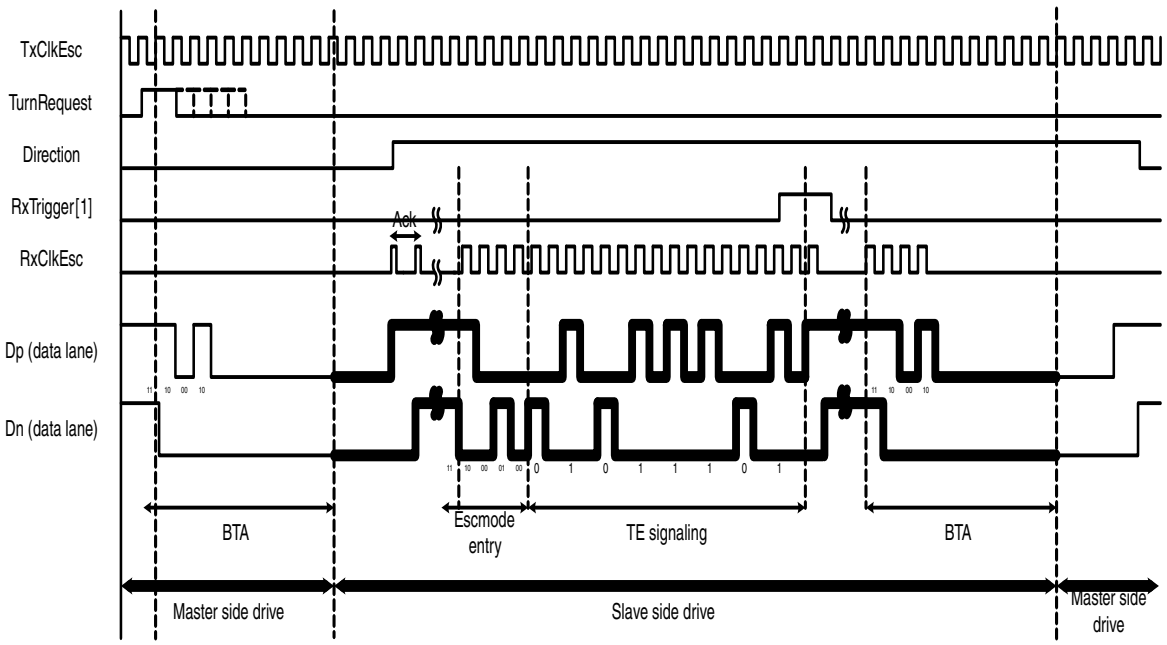

Figure 13-45. TE Signaling

13.4.3.9 Configuration

13.4.3.9.1 Video mode VS Command mode

MIPI DSI Master Block supports two modes, namely, Video mode and Command mode.

Command mode uses RGB interface and S-i80 interface. Mode can change via SFRs.

13.4.3.9.2 Dual display VS Single display

13.4.3.9.2.1 Dual display

MIPI DSI Master supports dual display configuration in Command mode only, that is, both main and sub display image should be transmitted via S-i80 INTERFACE.

13.4.3.9.2.2 Single display

For single display configuration, use video mode or command mode.

13.4.3.9.3 PLL

To transmit Image data, MIPI DSI Master Block needs high frequency clock (80 MHz ~ 1.5 GHz) generated by PLL.

To configure PLL, MIPI DSI Master comprises of SFRs and corresponding interface signals. PLL is embedded in PHY module. You should use other PLL in SoC if it meets the timing specification.

13.4.3.9.4 Buffer

In MIPI DSI standard specification, DSI Master sends image stream in burst mode. The image stream transmits in high-speed and bit-clock frequency. This mode allows the device to stay in stop state longer to reduce power consumption. For this mode, MIPI DSI Master has a line buffer to store one complete line and send it faster at the next line time.

13.4.3.10 Application Scenario

13.4.3.10.1 Display mode

13.4.3.10.1.1 Video mode

Video mode starting sequence:

1. Set RGB I/F in Display Controller (RGB888), also set Video mode at MIPI DSI Master
2. Configure all parameters for displaying image (define resolution, back porch, front porch, data lane number, HS clock frequency (byte clock), etc).
3. Start image transmission.

13.4.3.10.1.2 Command mode

Command mode starting sequence:

1. Set S-i80 I/F in Display Controller (RGB888), also set Command mode at MIPI DSI Master
2. Configure all parameters for displaying image.
3. Set the command at MIPI DSI registers using MIPI DCS.

4. S-i80 I/F is just used to transmit image data. The users have to read display peripheral status and write command through MIPI DSI registers.

13.4.3.10.2 Programming model

Table 13-15. Behavior Programming Each Case

No.	Mode	Case	Pseudo Code

1	Video	Initialize	1. reset or power on
			2. SFR_Write(Display Controller_registers, RGB I/F_888);
			3. SFR_Write(DSIM_CLKCNT,{16'h1000,Esc_prescaler}); //EscClk = ByteClk/Esc_prescaler;
			4. SFR_Write(DSIM_MDRESOL,{M_vert,M_horizon});
			5. SFR_Write(DSIM_MVPORCH,M_Vback);
			6. SFR_Write(DSIM_MHPORCH,{M_Hfront,M_Hback});
			7. SFR_Write(DSIM_MBLANK,{M_SBLLP,M_LBLLP});
			8. SFR_Write(DSIM_MSYNC,{M_VSA,M_HSA}); // In SyncEvent mode, Ignore it
			9. SFR_Write(DSIM_CONFIG,{HFPdismode, MainVC,MPix, SubVC,SPix,Sync_inform,BLLP,Burst, Videomode(1),NumofDatlane,Lane_EN); // set the value of each bit
			10. SFR_Write(DSIM_PLLCTRL, {4'h0, Freq_band,4'h8,PMS}); // PLL enable
			11. Wait for 100µS ~ 1mS using system timer after reset or power on. In this time, ForceSTOPstate at DSIM_CONFIG is assigned to D-PHY by default. 100µS ~ 1mS is not mendatory. Please see DSI slave spec
			12. SFR_Write(DSIM_CONFIG, ForceSTOPstate(0)); // disable
			13. While(~SFR_Read(DSIM_STATUS, StopstateClk, StopstateDat)); D-PHY & protocol layer(MIPI DSI Master block) in STOP state
			14. SFR_Write(DSIM_ESCMODE, TxUlps(1),TxUlpsClk(1)); D-PHY & protocol layer(MIPI DSI Master block) in ULPS In ULPS, User can turn off Byte/Esc clock for Low power estimation SFR_Write(DSIM_CLKCNT, ESCClk_EN(0), BytClk_En(0)); Or SFR_Write(DSIM_CLKCNT,ByteClk_EN(0),Lane_EscClkEn[4 :0](0));
			If user wants to turn on display, Turn on EscClk and
			15. SFR_Write(DSIM_ESCMODE, TxUlpsExit(1),TxUlpsClkExit(1));
			16. While(~SFR_Read(DSIM_STATUS, UlpsClk, UlpsDat));
			17. SFR_Write (DSIM_ESCMODE, TxUlpsExit (0), TxUlpsClkExit (0));
			18. Wait for about 1mS using system timer. 1mS is not mendatory, Just example. Please see DSI slave spec.
			19. SFR_Write (DSIM_ESCMODE, TxUlps (0),TxUlpsClk (0));
			20. While (~SFR_Read(DSIM_STATUS, StopstateClk, StopstateDat)); D-PHY & protocol layer (MIPI DSI Master block) in STOP state
			21. MIPI DSI Master is ready for HS/LP operation.

2	Video	HS Data Transfer	In Video mode, there is no pseudo code. After initializing, SFR_Write (Display Controller_register, START); If line image is full in line buffer, MIPI DSI master transmit data through long data packet. If user wants to send general command to display or transmit image to sub display from memory, user will have to set following sequence. 1. SFR_Write (DSIM_PAYLOAD,PAYLOAD_DATA);

Table continues on the next page...

Table 13-15. Behavior Programming Each Case (continued)

No.	Mode	Case	Pseudo Code
			2. SFR_Write (DSIM_PKTHDR,PKTHDR_DATA); If user wants to send command to Sub display, User shall set “Sub display Virtual Channel field” in Packet Header (PKTHDR[7:6]).
3	Video	LP Data Transfer	If user wants to send general command to display or transmit image to sub display from memory via LPDT, 1. SFR_Write (DSIM_ESCMODE, TxLpdt); 2. If DSIM transfer data in HS mode, DSIM will wait STOPstate and transfer mode change HS to LP. 3. Same way previous test scenario cases. If user wants to send command to Sub display, User shall set “Sub display Virtual Channel field” in Packet Header (PKTHDR[7:6]).
4	Video	ULPS	ULPS sequence is same the initialization process(test scenario #1) 13 ~20
5	Video	Trigger function	Follow the process : 1. SFR_Write (DSIM_ESCMODE, TxTriggerRst); 2. If DSI master state is not STOP state, DSIM will wait for LP stop mode and transmit trigger automatically
6	Video	BTA	There are two cases of BTA. One case is after transferring general read data packet or DCS command write(set_tear_on) and the other on is BTA_req bit setting by software. Previous case is automatically setting BTA. Next case is following sequence. If user reads the state or data of display panel, user will use BTA. 1. SFR_Write(DSIM_ESCMODE, BTA); 2. If DSIM transfer data, DSIM will wait STOPstate. 3. After BTA assert, DSIM release DSI channel. In reverse direction (DSI slave has DSI channel grant), all DSIM FIFO is flush and masked Video / SFR inputs. Only LPRX data input is unmasked. 4. If DSIS release DSI channel to DSIM, Int_BusTurnOver is generated. After ISR, DSIM can transfer data.

7	Command	Initialize	1. Reset or power on
			2. SFR_Write(Display Controller_registers, S-i80 I/F_888);
			3. SFR_Write(DSIM_CLKCNT,{16’h1000,Esc_prescaler});
			4. SFR_Write(DSIM_MDRESOL,{M_vert,M_horizon});
			5. SFR_Write(DSIM_SDRESOL,{S_vert,S_horizon});

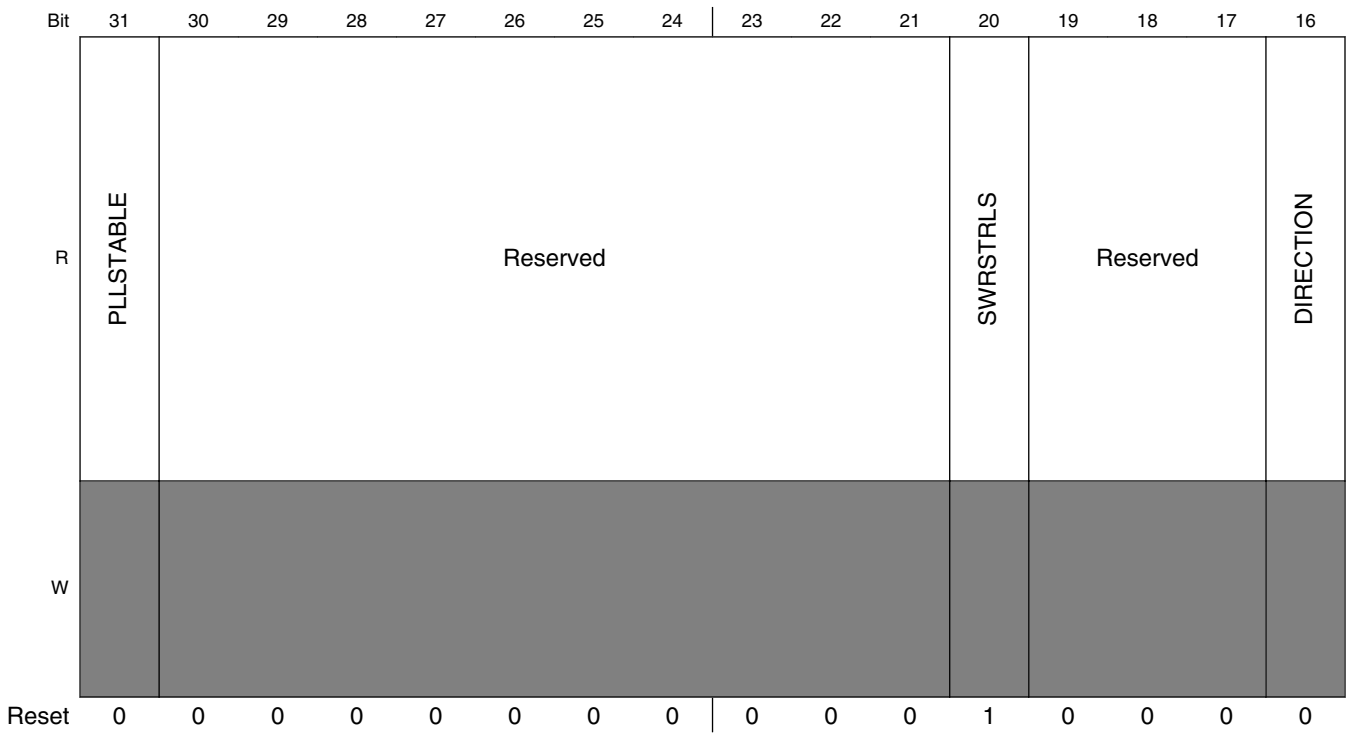
MIPI_DSI_VERSION field descriptions

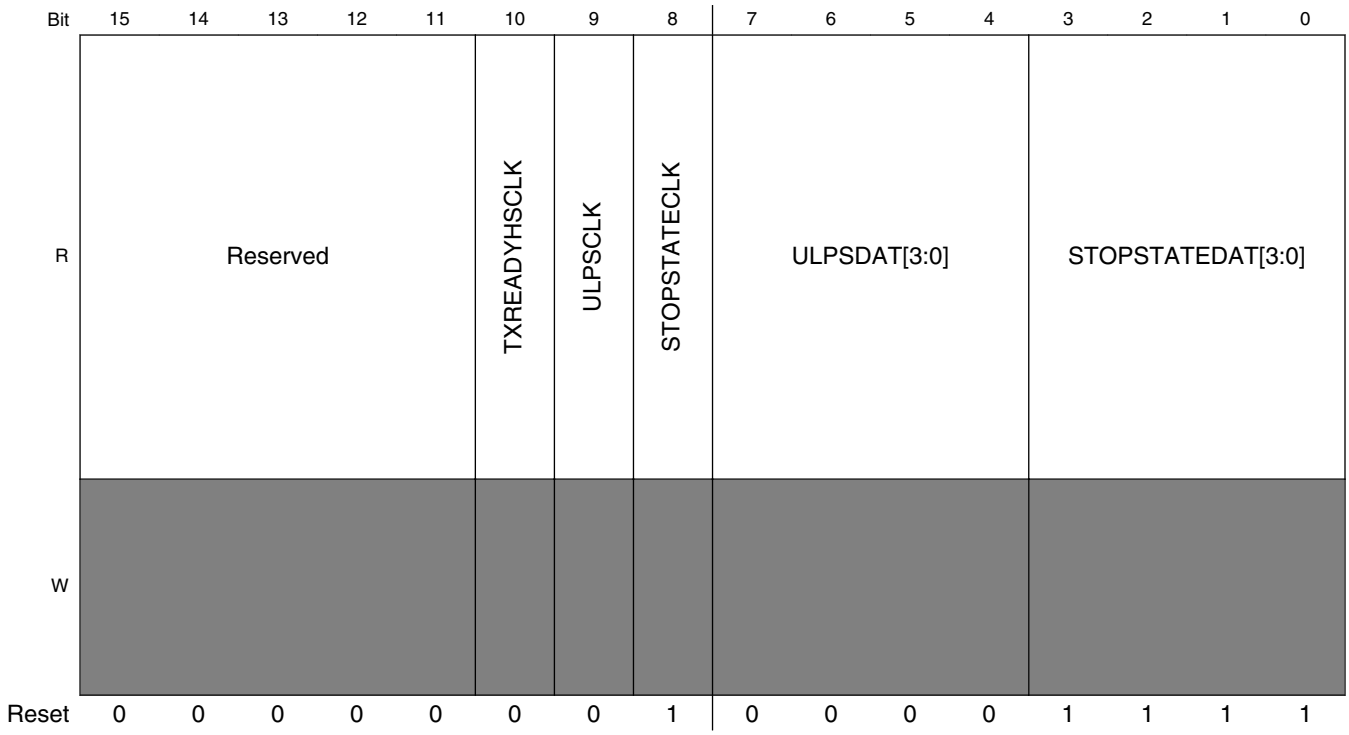
Field	Description
VERSION	Specifies the DSIM version information

13.4.4.2 MIPI_DSI_STATUS

This register reads and checks internal and interface status. It also checks FSM status, Line buffer status, current image line number, and so on.

Address: 3076_0000h base + 4h offset = 3076_0004h





MIPI_DSI_STATUS field descriptions

Field	Description
31 PLLSTABLE	D-PHY PLL generates stable byteclk.
30–21 Reserved	This field is reserved.
20 SWRSTRLS	Specifies the software reset status 0 Reset state 1 Release state
19–17 Reserved	This field is reserved.
16 DIRECTION	Specifies the data direction indicator 0 Forward direction 1 Backward direction
15–11 Reserved	This field is reserved.
10 TXREADYHSCLK	Specifies the HS clock ready at clock lane 0 Not ready for transmitting HS data at clock lane 1 Ready for transmitting HS data at clock lane
9 ULPSCLK	Specifies the ULPS indicator at clock lane 0 No ULPS in clock lane 1 ULPS in clock lane

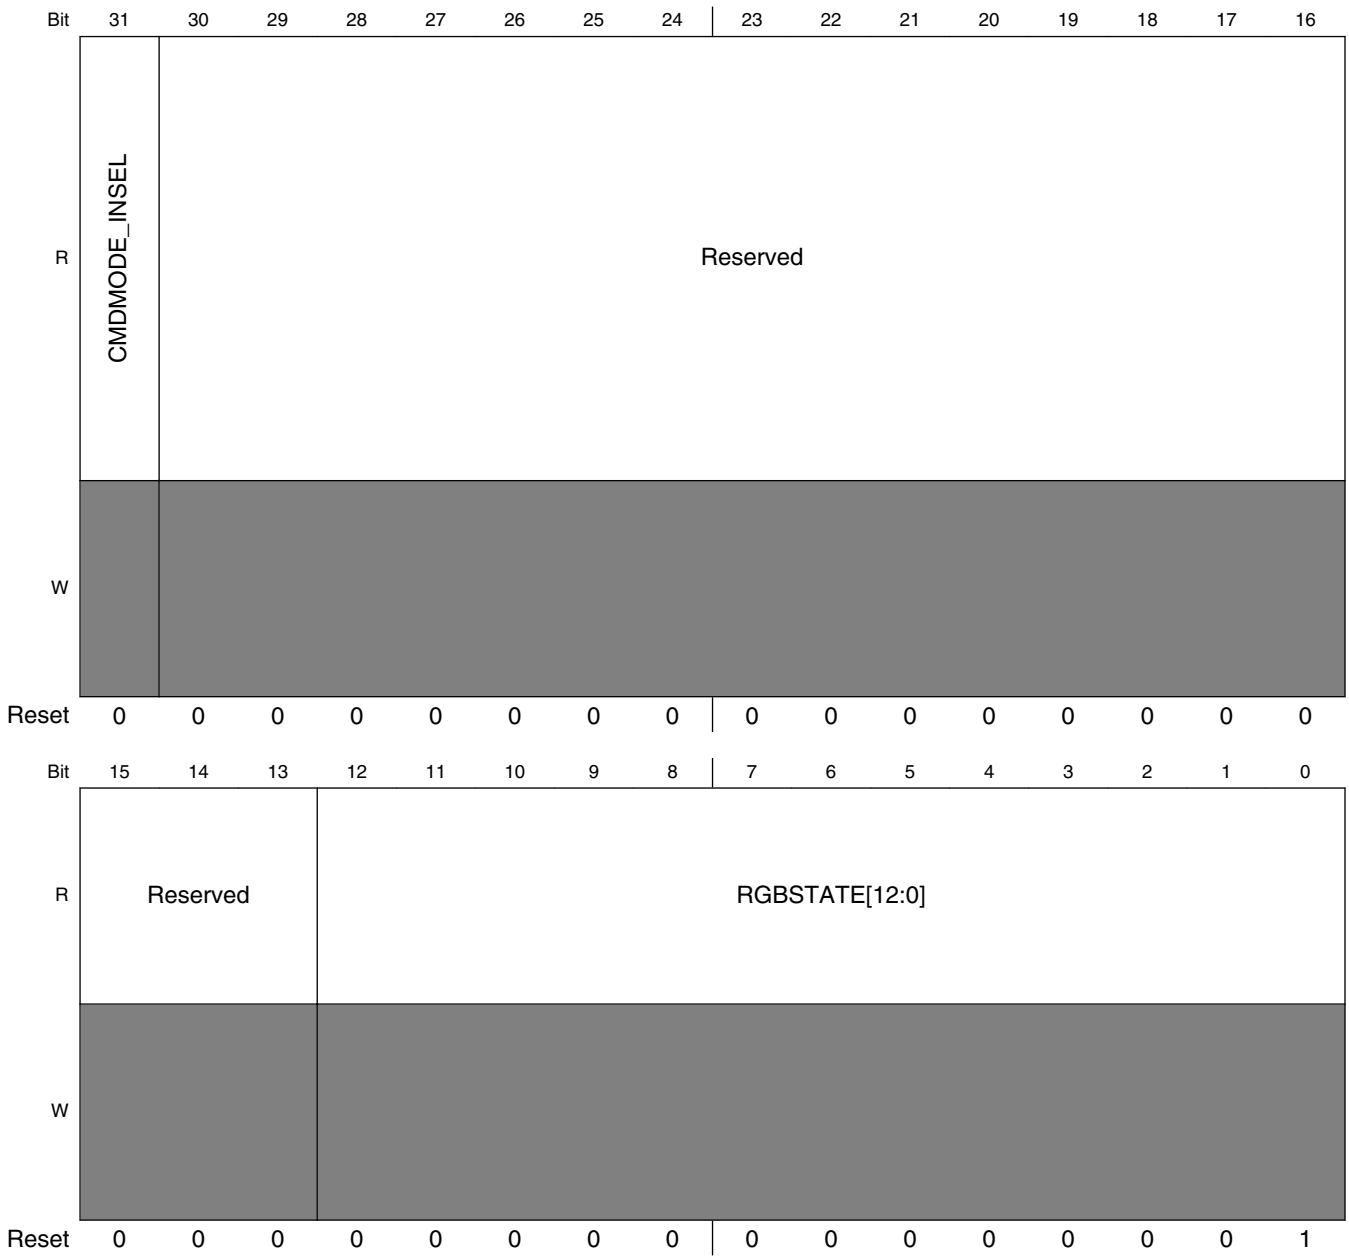
Table continues on the next page...

MIPI_DSI_STATUS field descriptions (continued)

Field	Description
8 STOPSTATECLK	Specifies the stop state indicator at clock lane 0 No stop state in clock lane 1 Stop state in clock lane
7–4 ULPSDAT[3:0]	Specifies the ULPS indicator at data lanes • UlpsDat[0]: Data lane 0 • UlpsDat[1]: Data lane 1 • UlpsDat[2]: Reserved • UlpsDat[3]: Reserved 0 No ULPS in each data lane 1 ULPS in each data lane
STOPSTATEDAT[3:0]	Specifies the stop state indicator at data lane • StopstateDat[0]: Data lane 0 • StopstateDat[1]: Data lane 1 • StopstateDat[2]: Reserved • StopstateDat[3]: Reserved

13.4.4.3 RGB Status Register (MIPI_DSI_RGB_STATUS)

Address: 3076_0000h base + 8h offset = 3076_0008h



MIPI_DSI_RGB_STATUS field descriptions

Field	Description
31 CMDMODE_ INSEL	Specifies the command mode input selection

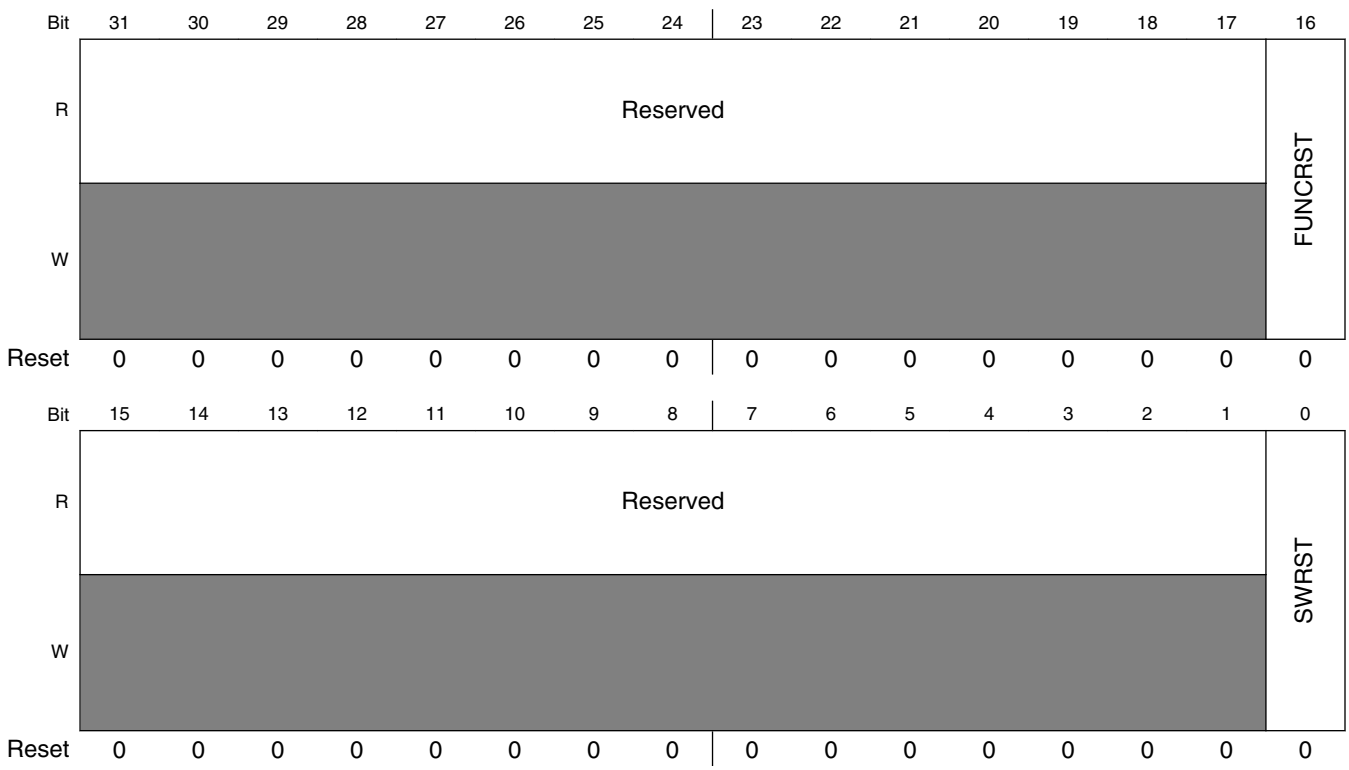
Table continues on the next page...

MIPI_DSI_RGB_STATUS field descriptions (continued)

Field	Description
	0 Using RGB video interface 1 Using S-i80 interface
30–13 Reserved	This field is reserved.
RGBSTATE[12:0]	Specifies the RGB packetize FSM status 0x0001 IDLE 0x0002 STOP 0x0004 VSYS 0x0008 VSE 0x0010 HSS 0x0020 HSA 0x0040 HSE 0x0080 HBP 0x0100 RGB 0x0200 NULL 0x0400 HFP 0x0800 EOT 0x1000 NHOLD

13.4.4.4 MIPI_DSI_SWRST

Address: 3076_0000h base + Ch offset = 3076_000Ch



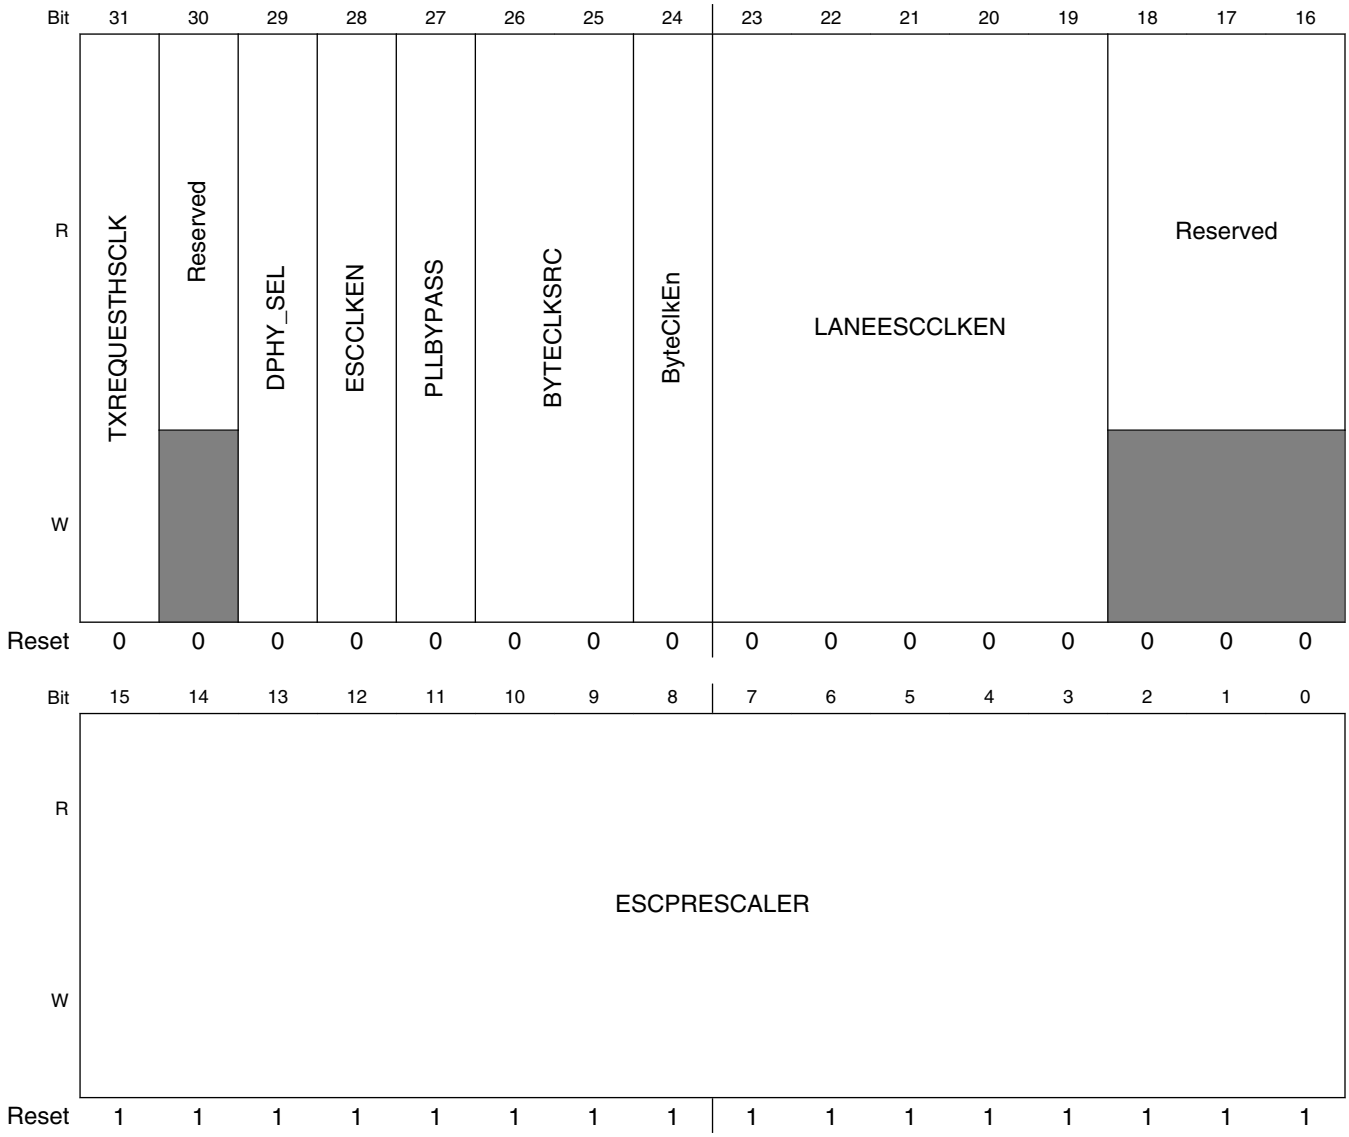
MIPI_DSI_SWRST field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 FUNCRST	Specifies the software reset (High active). "Function reset" resets all FF in MIPI DSIM (except SFRs: STATUS, RGB_STATUS, SWRST, CLKCTRL, TIMEOUT, CONFIG, ESCMODE[1], MDRESOL, MVPORCH, MHPORCH, MSYNC, INTMSK, SDRESOL, S3D_CTL, P3D_CTL, MIC_CTL, P3D_ON_MIC_OFF_HSA, P3D_OFF_MIC_ON_HSA, P3D_ON_MIC_ON_HSA, P3D_ON_MIC_OFF_HFP, P3D_OFF_MIC_ON_HFP, P3D_ON_MIC_ON_HFP, MULTI_PKT, FIFOTHLD, FIFOCTRL, [2], MEMACCHR, PLLCTRL, PLLTMR, PHYACCHR, and VERINFORM). 0 Standy 1 Reset
15–1 Reserved	This field is reserved.
0 SWRST	Specifies the software reset (High active). "Software reset" resets all FF in MIPI DSIM (except some SFRs: STATUS, SWRST, CLKCTRL, PLLCTRL, PLLTMR, PHYTUNE, and VERINFORM). 0 Standy 1 Reset

1. ForceStopstate, CmdLpdt, TxLpdt
2. nInitRx, nInitSfr, nInitI80, nInitSub, nInitMD

13.4.4.5 Clock Control Register (MIPI_DSI_CLKCTRL)

Address: 3076_0000h base + 10h offset = 3076_0010h



MIPI_DSI_CLKCTRL field descriptions

Field	Description
31 TXREQUESTHSCLK	Specifies the HS clock request for HS transfer at clock lane (Turn on HS clock)
30 Reserved	This field is reserved.
29 DPHY_SEL	D-PHY Select 0 1.5 Gbps D-PHY (default) 1 1 Gbps D-PHY

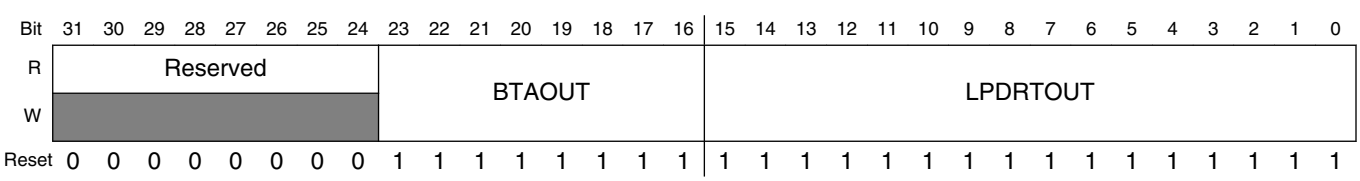
Table continues on the next page...

MIPI_DSI_CLKCTRL field descriptions (continued)

Field	Description
28 ESCCLKEN	Enables the escape clock generating prescaler 0 Disables 1 Enables
27 PLLBYPASS	Sets the PLLBypass signal connected to D-PHY module input for selecting clock source bit. This bit must be set to 0. 0 PLL output 1 External Serial clock
26–25 BYTECLKSRC	Selects byte clock source. (It must be 2'b00.) 00 = D-PHY PLL (default). PLL_out clock is used to generate ByteClk by dividing 8.
24 ByteClkEn	Enables byte clock 0 Disables 1 Enables
23–19 LANEESCCLKEN	Enables escape clock for D-phy lane • LaneEscClkEn[0] = Clock lane • LaneEscClkEn[1] = Data lane 0 • LaneEscClkEn[2] = Data lane 1 • LaneEscClkEn[3] = Reserved • LaneEscClkEn[4] = Reserved 0 Disables 1 Enables
18–16 Reserved	This field is reserved.
ESCPRESCALER	Specifies the escape clock prescaler value. The escape clock frequency range varies up to 20 MHz. **NOTE:** The requirement for BTA is that the Host Escclk frequency should range between 66.7 ~ 150% of the peripheral escape clock frequency. EscClk = ByteClk / (EscPrescaler)

13.4.4.6 MIPI_DSI_TIMEOUT

Address: 3076_0000h base + 14h offset = 3076_0014h



MIPI_DSI_TIMEOUT field descriptions

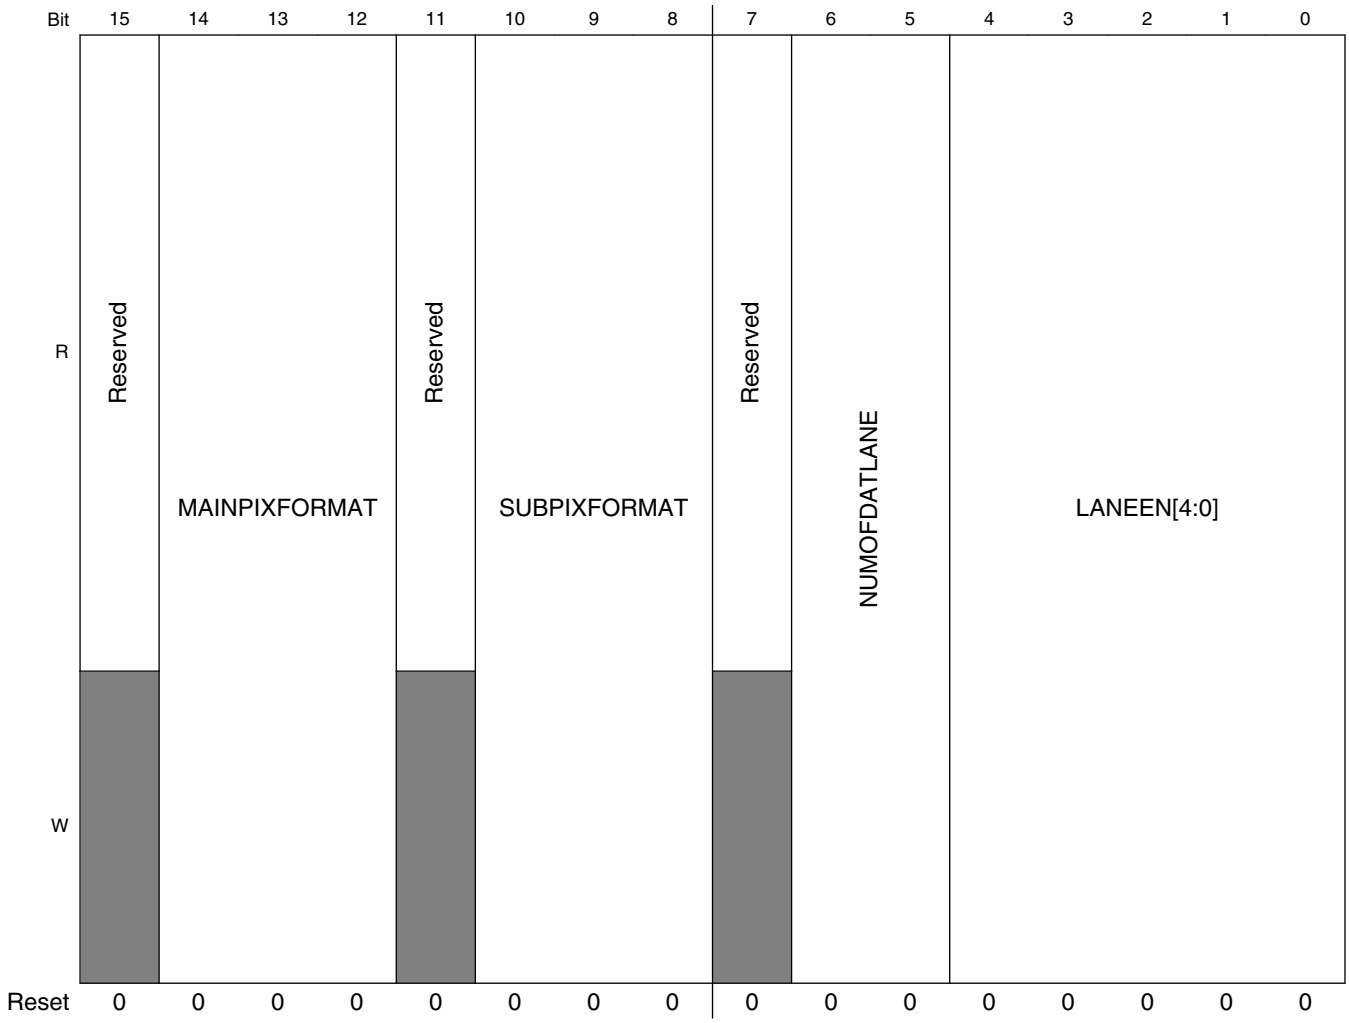
Field	Description
31–24 Reserved	This field is reserved.
23–16 BTAOUT	Specifies the timer for BTA. This register specifies time out from BTA request to change the direction with respect to Tx escape clock.
LPDRTOUT	Specifies the timer for LP Rx mode timeout. This register specifies time out on how long RxValid deasserts, after RxLpdt asserts with respect to Tx escape clock. RxValid specifies Rx data valid indicator. RxLpdt specifies an indicator that D-phy is under RxLpdt mode. RxValid and RxLpdt specifies signal from D-phy.

13.4.4.7 MIPI_DSI_CONFIG

This register configures MIPI DSI master such as data lane number, input interface, porch area, frame rate, BTA, LPDT, ULPS, and so on.

Address: 3076_0000h base + 18h offset = 3076_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NON_CONTINUOUS_CLOCK_LANE	CLKLANE_STOP_START	MFLUSH_VS	EOT_ R03	SYNCINFORM	BURSTMODE	VIDEOMODE	AUTOMODE	HSEDISABLEMODE	HFPDISABLEMODE	HBPDISABLEMODE	HSADISABLEMODE	MAINVC		SUBVC	
W						BURSTMODE										
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0



MIPI_DSI_CONFIG field descriptions

Field	Description
31 NON_ CONTINUOUS_ CLOCK_LANE	Non-continuous clock mode. This feature is D-PHY clock lane control DP / DN. The follwoing figure shows timing diagram of clock lane. Multi Packet register shows configuration of count values.

Table continues on the next page...

MIPI_DSI_CONFIG field descriptions (continued)

Field	Description
	 **Figure 13-46. Non-continuous Clock Lane Timing Diagram** 0 Disable (default) 1 Enable
30 CLKLANE_STOP_START	PHY clock lane On / Off for ESD. It is operated when first HBP to second HFP in every VSYNC. This feature not guarantees on Command mode. 0 Disable (default) 1 Enable
29 MFLUSH_VS	Auto flush of MD FIFO using Vsync pulse. It needs that Main display FIFO should be flushed for deleting garbage data. 0 Disable (default) 1 Enable
28 EOT_R03	Disables EoT packet in HS mode. 0 Enables EoT packet generation for V1.01r11 1 Disables EoT packet generation for V1.01r03
27 SYNCINFORM	Selects Sync Pulse or Event mode in Video mode In command mode, this bit is ignored. 0 Event mode (non burst, burst) 1 Pulse mode (non burst only)
26 BURSTMODE	Selects Burst mode in Video mode In Non-burst mode, RGB data area is filled with RGB data and Null packets, according to input bandwidth of RGB interface. In Burst mode, RGB data area is filled with RGB data only.

Table continues on the next page...

MIPI_DSI_CONFIG field descriptions (continued)

Field	Description
	In command mode, this bit is ignored. 0 Non-burst mode 1 Burst mode
25 VIDEOMODE	Specifies display configuration
24 AUTOMODE	Specifies auto vertical count mode In Video mode, the vertical line transition uses line counter configured by VSA, VBP, and Vertical resolution. If this bit is set to '1', the line counter does not use VSA and VBP registers. In command mode, this bit is ignored. 0 Configuration mode 1 Auto mode
23 HSEDISABLEMODE	In Vsync pulse and Vporch area, MIPI DSI master transfers only Hsync start packet to MIPI DSI slave at MIPI DSI spec 1.1r02. This bit transfers Hsync end packet in Vsync pulse and Vporch area (optional). In command mode, this bit is ignored. 0 Disables transfer 1 Enables transfer
22 HFPDISABLEMODE	Specifies HFP disable mode. If this bit set, DSI master ignores HFP area in Video mode. In command mode, this bit is ignored. 0 Enables 1 Disables
21 HBPDISABLEMODE	Specifies HBP disable mode. If this bit set, DSI master ignores HBP area in Video mode. In command mode, this bit is ignored. 0 Enables 1 Disables
20 HSADISABLEMODE	Specifies HSA disable mode. If this bit set, DSI master ignores HSA area in Video mode. In command mode, this bit is ignored. 0 Enables 1 Disables
19–18 MAINVC	Specifies virtual channel number for main display
17–16 SUBVC	Specifies virtual channel number for sub display
15 Reserved	This field is reserved.
14–12 MAINPIXFORMAT	Specifies pixel stream format for main display 000 3 bpp (for Command mode only) 001 8 bpp (for Command mode only) 010 12 bpp (for Command mode only)

Table continues on the next page...

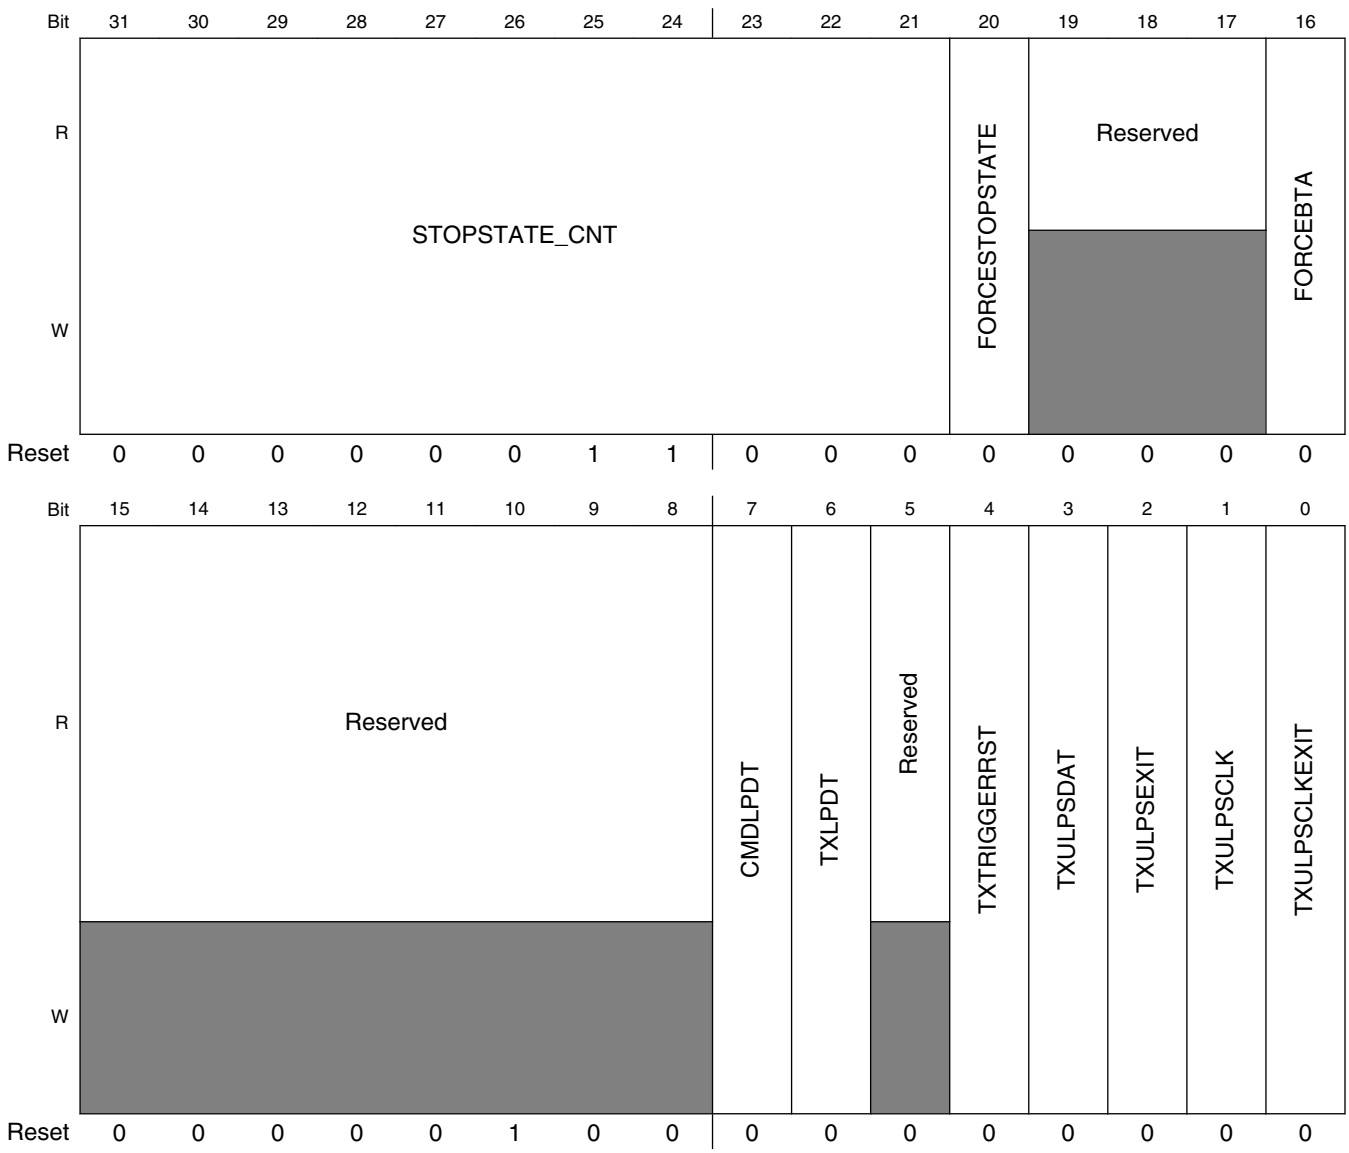
MIPI_DSI_CONFIG field descriptions (continued)

Field	Description
	011 16 bpp (for Command mode only) 100 16-bit RGB (565) (for Video mode only) 101 18-bit RGB (666: packed pixel stream) (for Video mode only) 110 18-bit RGB (666: loosely packed pixel stream) for Common 111 24-bit RGB (888) for common
11 Reserved	This field is reserved.
10–8 SUBPIXFORMAT	Specifies pixel stream format for main display 000 3 bpp (for Command mode only) 001 8 bpp (for Command mode only) 010 12 bpp (for Command mode only) 011 16 bpp (for Command mode only) 100 16-bit RGB (565) (for Video mode only) 101 18-bit RGB (666: packed pixel stream) (for Video mode only) 110 18-bit RGB (666: loosely packed pixel stream) for Common 111 24-bit RGB (888) for common
7 Reserved	This field is reserved.
6–5 NUMOFDATLANE	Sets the data lane number 00 Data lane 0 (1 data lane) 01 Data lane 0 ~ 1 (2 data lanes) 10 Reserved. 11 Reserved.
LANEEN[4:0]	Enables the lane. If Lane_EN is disabled, the lane ignores input and drives initial value through output port. • LaneEn[0] = Clock lane enabler • LaneEn[1] = Data lane 0 enabler • LaneEn[2] = Data lane 1 enabler • LaneEn[3] = Reserved • LaneEn[4] = Reserved

13.4.4.8 Escape Mode Register (MIPI_DSI_ESCMODE)

This register configures MIPI DSI master.

Address: 3076_0000h base + 1Ch offset = 3076_001Ch



MIPI_DSI_ESCMODE field descriptions

Field	Description
31–21 STOPSTATE_CNT	After transmitting read packet or write “set_tear_on” command, BTA requests to D-phy automatically. This counter value specifies the interval value between transmitting read packet (or write “set_tear_on” command) and BTA request. 11'h000 = 2 EscClk

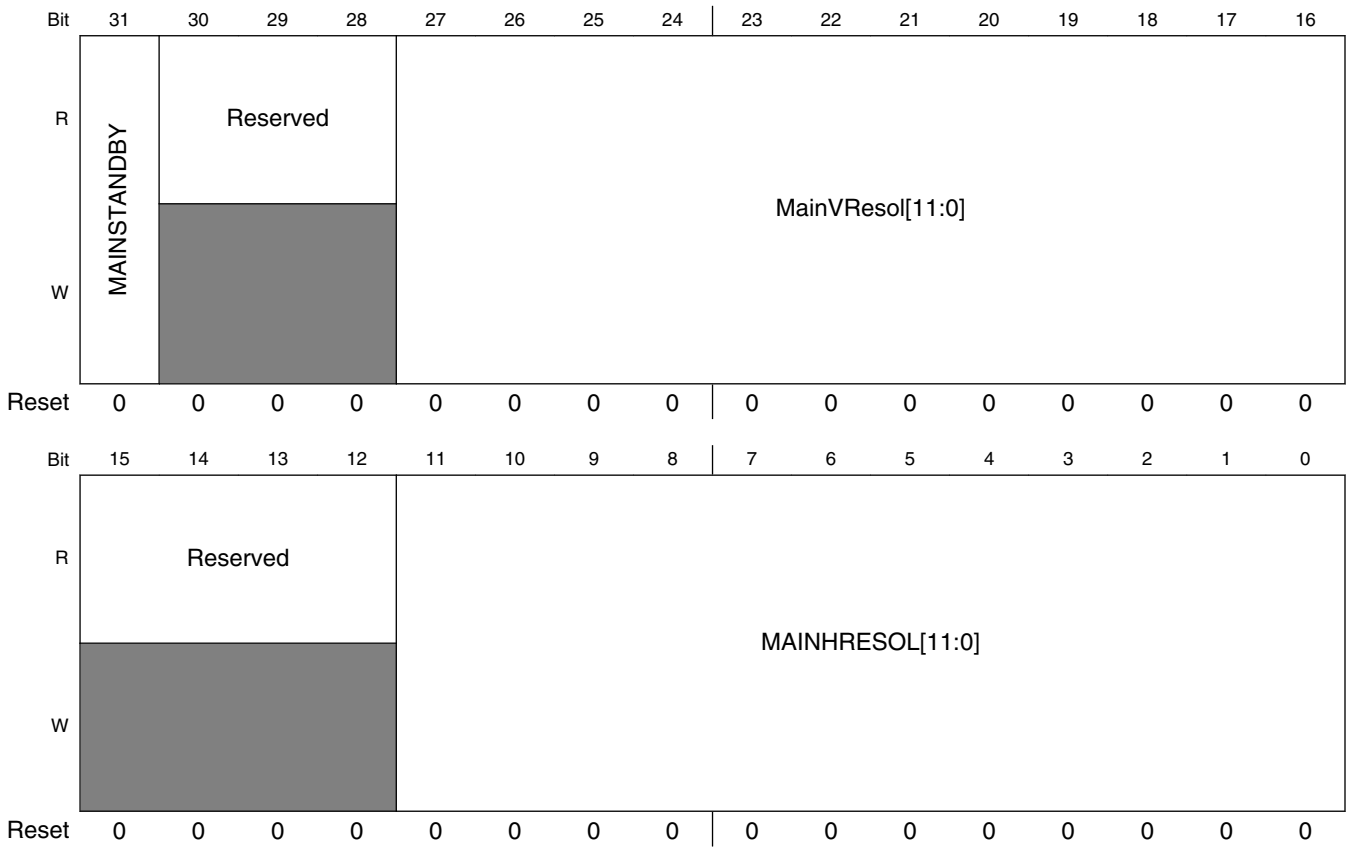
Table continues on the next page...

MIPI_DSI_ESCMODE field descriptions (continued)

Field	Description
	11'h001 = 2 EscClk + 1 EscClk ~ 11'h3FF = 2 EscClk + 1023 EscClk
20 FORCESTOPSTATE	Forces Stopstate for D-PHY
19–17 Reserved	This field is reserved.
16 FORCEBTA	Forces Bus Turn Around 1 = Sends the protocol layer request to D-PHY. MIPI DSI peripheral becomes master after BTA sequence. This bit clears automatically after receiving BTA acknowledge from MIPI DSI peripheral.
15–8 Reserved	This field is reserved.
7 CMDLPDT	Specifies LPDT transfers command in SFR FIFO 0 HS Mode 1 LP Mode
6 TXLPDT	Specifies data transmission in LP mode (all data transfer in LPDT) 0 HS Mode 1 LP Mode
5 Reserved	This field is reserved.
4 TXTRIGGERRST	Specifies remote reset trigger function. After trigger operation, these bits will be cleared automatically.
3 TXULPSDAT	Specifies ULPS request for data lane. Manually clears after ULPS exit.
2 TXULPSEXIT	Specifies ULPS exit request for data lane. Manually clears after ULPS exit.
1 TXULPSCLK	Specifies ULPS request for clock lane. Manually clears after ULPS exit.
0 TXULPSCLKEXIT	Specifies ULPS exit request for clock lane. Manually clears after ULPS exit.

13.4.4.9 Main Display Image Resolution Register (MIPI_DSI_MDRESOL)

Address: 3076_0000h base + 20h offset = 3076_0020h



MIPI_DSI_MDRESOL field descriptions

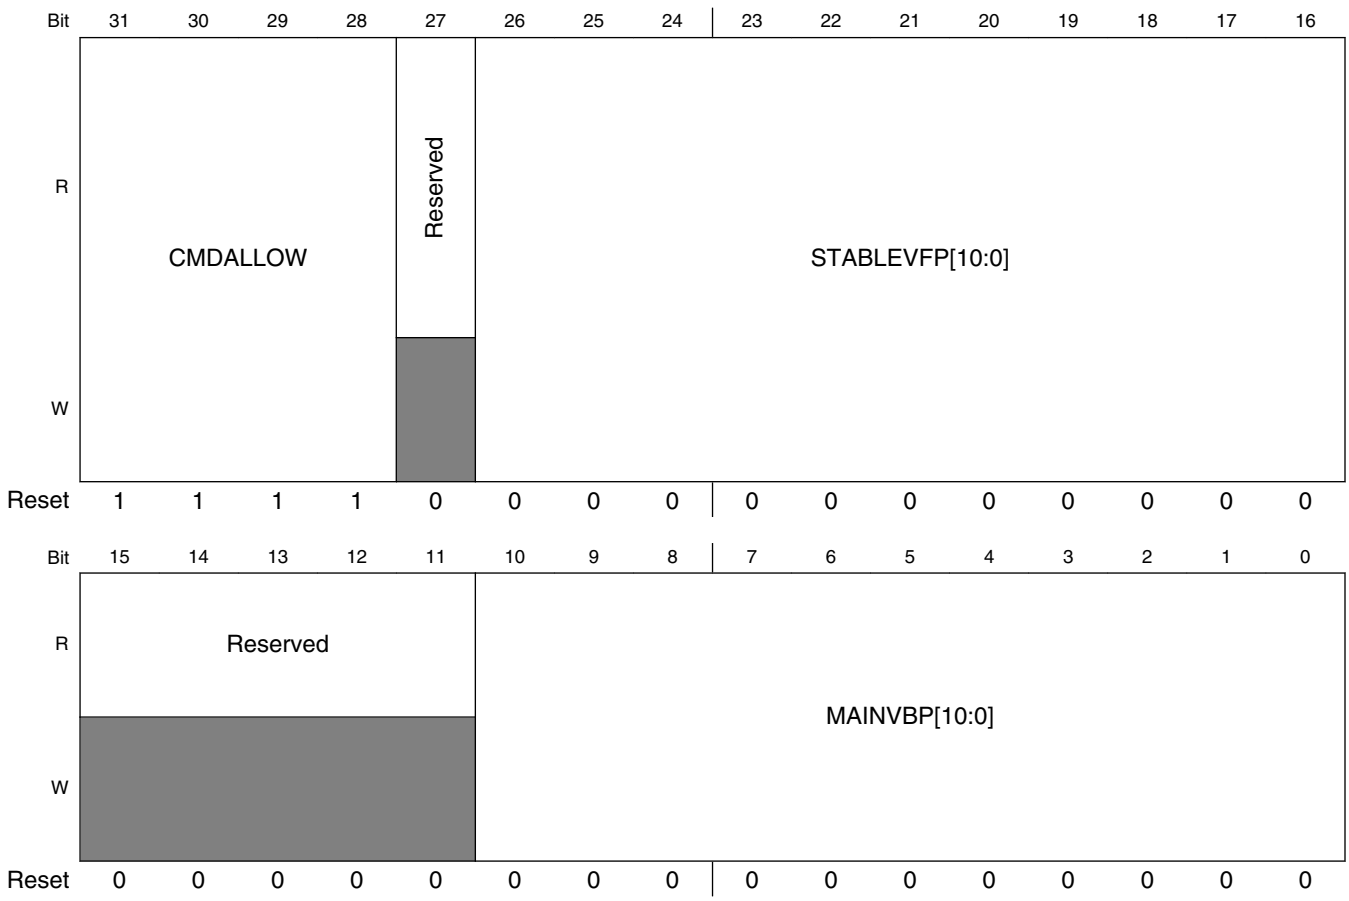
Field	Description
31 MAINSTANDBY	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. Standby should be set after configuration (resolution, reqtype, pixelform, and so on) is set for command mode. In Video mode, if this bit value is 0, data is not transferred. 0 Not ready 1 Standby
30–28 Reserved	This field is reserved.
27–16 MainVResol[11:0]	Specifies Vertical resolution (1 ~ 2047)
15–12 Reserved	This field is reserved.
MAINHRESOL[11:0]	Specifies Horizontal resolution (1 ~ 2047)

13.4.4.10 Main Display VPORCH Register (MIPI_DSI_MVPORCH)

NOTE

Transfers command packets after Stable VFP area. Display controller VFP lines should be set based on sum of these values: Stable VFP, command allowing area and command masked area. See the section for transferring general data in Video mode.

Address: 3076_0000h base + 24h offset = 3076_0024h



MIPI_DSI_MVPORCH field descriptions

Field	Description
31–28 CMDALLOW	Specifies the number of horizontal lines, where command packet transmission is allowed after Stable VFP period. For more information, see Figure 13-36.
27 Reserved	This field is reserved.

Table continues on the next page...

MIPI_DSI_MVPORCH field descriptions (continued)

Field	Description
26–16 STABLEVFP[10:0]	Specifies the number of horizontal lines, where command packet transmission is not allowed after end of active region. For more information, see Figure 13-36.. **NOTE:** In Command mode, these bits are ignored.
15–11 Reserved	This field is reserved.
MAINVBP[10:0]	Specifies vertical back porch width for Video mode (line count). In Command mode, these bits are ignored.

13.4.4.11 MIPI_DSI_MHPORCH

Address: 3076_0000h base + 28h offset = 3076_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MIPI_DSI_MHPORCH field descriptions

Field	Description
31–16 MAINHFP[15:0]	Specifies the horizontal front porch width for Video mode. HFP is specified using blank packet. These bits specify the word counts for blank packet in HFP. In Command mode, these bits are ignored.
MAINHBP[15:0]	Specifies the horizontal back porch width for Video mode. HBP is specified using blank packet. These bits specify the word counts for blank packet in HBP. In Command mode, these bits are ignored.

13.4.4.12 MIPI_DSI_MSYNC

Address: 3076_0000h base + 2Ch offset = 3076_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

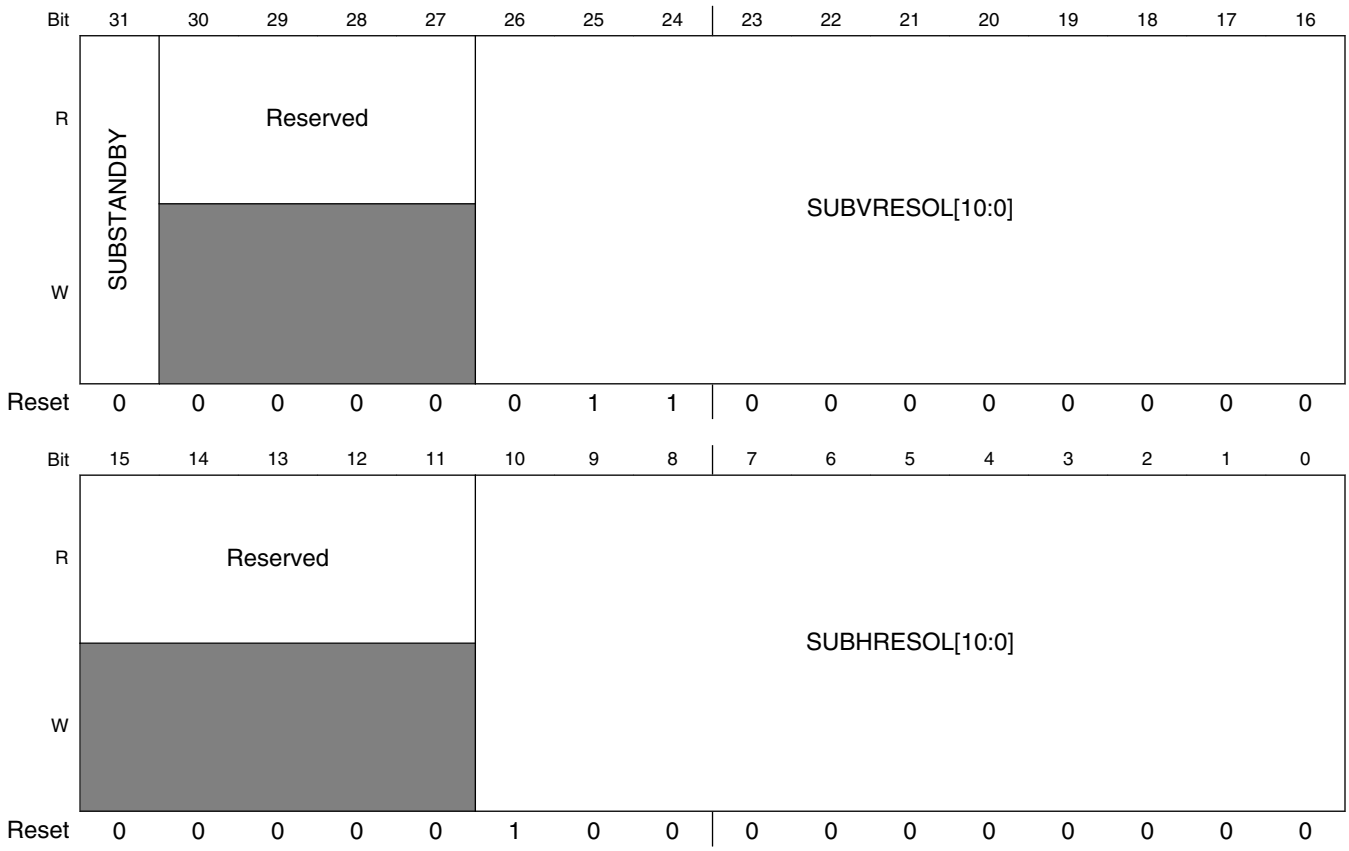
MIPI_DSI_MSYNC field descriptions

Field	Description
31–22 MAINVSA[9:0]	Specifies the vertical sync pulse width for Video mode (Line count). In command mode, these bits are ignored.
21–16 Reserved	This field is reserved.
MAINHSA[15:0]	Specifies the horizontal sync pulse width for Video mode. HSA is specified using blank packet. These bits specify word counts for blank packet in HSA. In command mode, these bits are ignored.

13.4.4.13 Sub Display Image Resolution Register (MIPI_DSI_SDRESOL)

Address: 3076_0000h base + 30h offset = 3076_0030h



MIPI_DSI_SDRESOL field descriptions

Field	Description
31 SUBSTANDBY	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. Standby should be set after configuration (resolution, reqtype, pixelform, and so on) is set for command mode. In Video mode, this bit is ignored. 0 Not ready 1 Standby
30–27 Reserved	This field is reserved.
26–16 SUBVRESOL[10:0]	Specifies the Vertical resolution (1 ~ 1024)
15–11 Reserved	This field is reserved.
SUBHRESOL[10:0]	Specifies the Horizontal resolution (1 ~ 1024)

13.4.4.14 Interrupt Source Register (MIPI_DSI_INTSRC)

This register identifies interrupt sources.

Internal block error, data transmit interrupt, inter-layer (D_PHY) error, etc.

The bits are set even if they are masked off by DSIM_INTMSK_REG.

Write ‘1’ to clear the Interrupt.

Address: 3076_0000h base + 34h offset = 3076_0034h

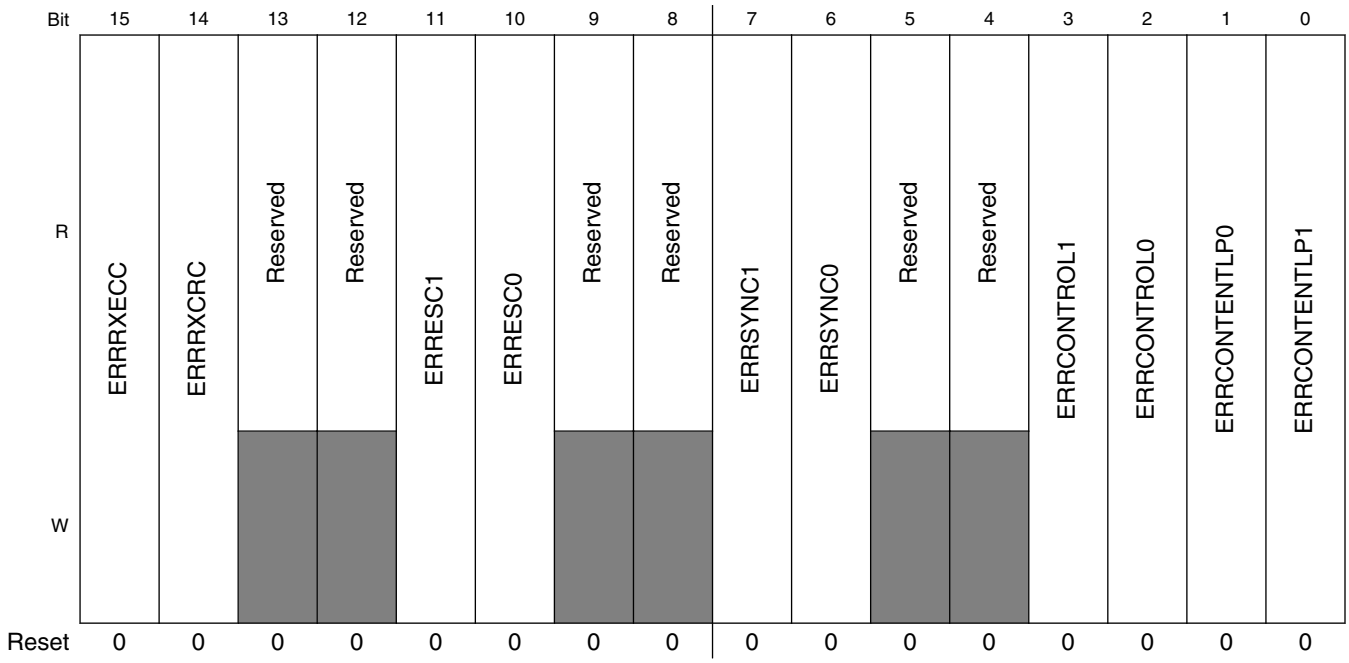
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



MIPI_DSI_INTSRC field descriptions

Field	Description
31 PLLSTABLE	Indicates that D-phy PLL is stable.
30 SWRSTRELEASE	Releases the software reset.
29 SFRPLFIFOEMPTY	Specifies the SFR payload FIFO empty.
28 SFRPHFIFOEMPTY	Specifies the SFR Packet Header FIFO emtpy
27 SYNCOVERRIDE	Indicates that other DSI command transfer have overridden sync timing.
26 Reserved	This field is reserved.
25 BUSTURNOVER	Indicates when bus grant turns over from DSI slave to DSI master.
24 FRAMEDONE	Indicates when MIPI DSIM transfers the whole image frame. **NOTE:** If Hsync is not received during two line times, internal timer is timed out and this bit is flagged.
23–22 Reserved	This field is reserved.
21 LPDRTOUT	Specifies the LP Rx timeout. See time out register (0x10).
20 TATOUT	Turns around Acknowledge Timeout. See time out register (0x10).
19 Reserved	This field is reserved.

Table continues on the next page...

MIPI_DSI_INTSRC field descriptions (continued)

Field	Description
18 RXDATDONE	Completes receiving data
17 RXTE	Receives TE Rx trigger
16 RXACK	Receives ACK Rx trigger
15 ERRRXECC	Specifies the ECC multi bit error in LPDR
14 ERRRXCRC	Specifies the CRC error in LPDR
13 Reserved	This field is reserved.
12 Reserved	This field is reserved.
11 ERRESC1	Specifies the escape mode entry error lane 1. For more information, refer to standard D-PHY specification.
10 ERRESC0	Specifies the escape mode entry error lane 0. For more information, refer to standard D-PHY specification.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 ERRSYNC1	Specifies the LPDT Sync Error lane1. For more information, refer to standard D-PHY specification.
6 ERRSYNC0	Specifies the LPDT Sync Error lane0. For more information, refer to standard D-PHY specification.
5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
3 ERRCONTROL1	Controls Error lane1. For more information, refer to standard D-PHY specification.
2 ERRCONTROL0	Controls Error lane0. For more information, refer to standard D-PHY specification.
1 ERRCONTENTLP0	Specifies the LP0 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, refer to standard D-PHY specification.
0 ERRCONTENTLP1	Specifies the LP1 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, refer to standard D-PHY specification.

13.4.4.15 Interrupt Mask Register (MIPI_DSI_INTMSK)

This register masks interrupt sources.

Address: 3076_0000h base + 38h offset = 3076_0038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MIPI_DSI_INTMSK field descriptions

Field	Description
31 MSKPLLSTABLE	Indicates that D-PHY PLL is stable.
30 MSKSWRSTRELEASE	Releases software reset.
29 MSKSFRPLFIFOEMPTY	Empties SFR payload FIFO.
28 MSKSFRPHFIFOEMPTY	Interrupt Mask for SFR packet header FIFO empty
27 MSKSYNCOVERRIDE	Indicates that other DSI command transfer have overridden sync timing.
26 Reserved	This field is reserved.
25 MSKBUSTURNOVER	Indicates when bus grant turns over from DSI slave to DSI master.
24 MSKFRAMEDONE	Indicates when MIPI DSIM transfers whole image frame.
23–22 Reserved	This field is reserved.
21 MSKLPDRTOUT	Specifies LP Rx timeout. See time out register (0x10).
20 MSKTATOUT	Specifies turnaround acknowledge timeout. See time out register (0x10)
19 Reserved	This field is reserved.

Table continues on the next page...

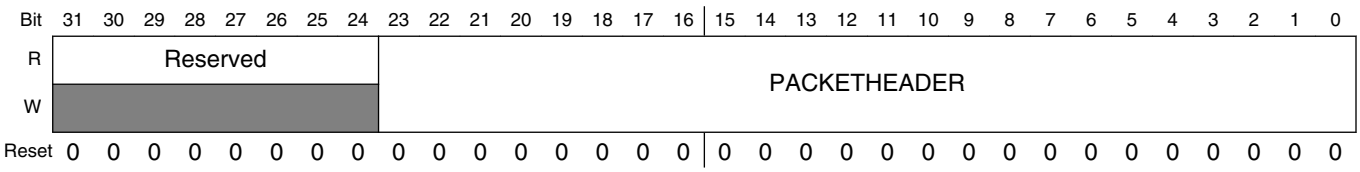
MIPI_DSI_INTMSK field descriptions (continued)

Field	Description
18 MSKRXDATDONE	Specifies completion of data receiving
17 MSKRXTE	Specifies receipt of TE Rx trigger
16 MSKRXACK	Specifies receipt of ACK Rx trigger
15 MSKRXECC	Specifies ECC multibit error in LPDR
14 MSKRXCRC	Specifies CRC error in LPDR
13 Reserved	This field is reserved.
12 Reserved	This field is reserved.
11 MSKESC1	Specifies escape mode entry error in lane1. For more information, refer to standard D-PHY specification.
10 MSKESC0	Specifies escape mode entry error in lane0. For more information, refer to standard D-PHY specification.
9 Reserved	This field is reserved.
8 Reserved	This field is reserved.
7 MSKSYNC1	Specifies LPDT sync error in lane1. For more information, refer to standard D-PHY specification.
6 MSKSYNC0	Specifies LPDT sync error in lane0. For more information, refer to standard D-PHY specification.
5 Reserved	This field is reserved.
4 Reserved	This field is reserved.
3 MSKCONTROL1	Controls error in lane1. For more information, refer to standard D-PHY specification.
2 MSKCONTROL0	Controls error in lane0. For more information, refer to standard D-PHY specification.
1 MSKCONTENTLP0	Specifies LP0 contention error. For more information, refer to standard D-PHY specification.
0 MSKCONTENTLP1	Specifies LP1 contention error. For more information, refer to standard D-PHY specification.

13.4.4.16 Packet Header FIFO Register (MIPI_DSI_PKTHDR)

This register is the FIFO for packet header to send DSI packets.

Address: 3076_0000h base + 3Ch offset = 3076_003Ch



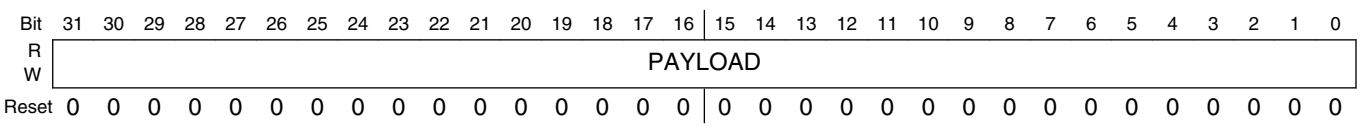
MIPI_DSI_PKTHDR field descriptions

Field	Description
31–24 Reserved	This field is reserved.
PACKETHEADER	Writes the packet header of Tx packet. • [7:0] = DI • [15:8] = Dat0 (Word Count lower byte for long packet) • [23:16] = Dat1 (Word Count upper byte for long packet)

13.4.4.17 Payload FIFO Register (MIPI_DSI_PAYLOAD)

This register is the FIFO for packet header to send DSI packets.

Address: 3076_0000h base + 40h offset = 3076_0040h



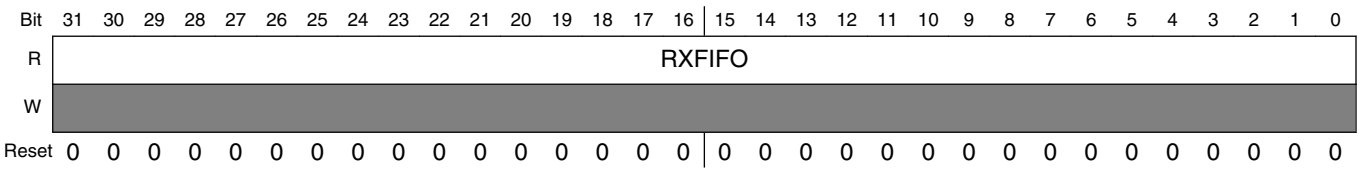
MIPI_DSI_PAYLOAD field descriptions

Field	Description
PAYLOAD	Writes the Payload of Tx packet

13.4.4.18 Payload FIFO Register (MIPI_DSI_RXFIFO)

This register is the gate of FIFO read.

Address: 3076_0000h base + 44h offset = 3076_0044h

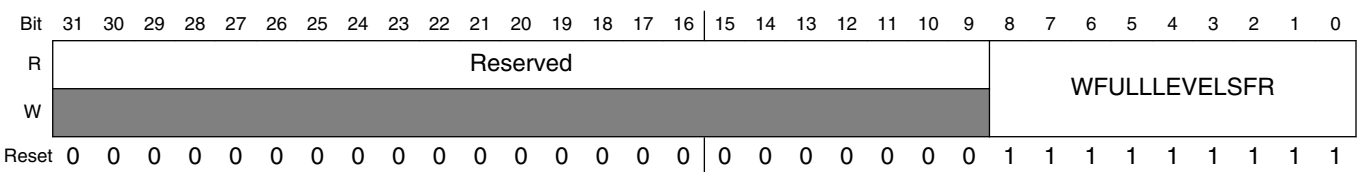


MIPI_DSI_RXFIFO field descriptions

Field	Description
RXFIFO	In the Rx mode, you can read Rx data through this register. **NOTE:** The CRC in packet is not stored in RxFIFO.

13.4.4.19 FIFO Threshold Level Register (MIPI_DSI_FIFOTHLD)

Address: 3076_0000h base + 48h offset = 3076_0048h



MIPI_DSI_FIFOTHLD field descriptions

Field	Description
31–9 Reserved	This field is reserved.
WFULLLEVELSFR	Almost full level of SFR payload FIFO

13.4.4.20 FIFO Status and Control Register (MIPI_DSI_FIFOCTRL)

Address: 3076_0000h base + 4Ch offset = 3076_004Ch

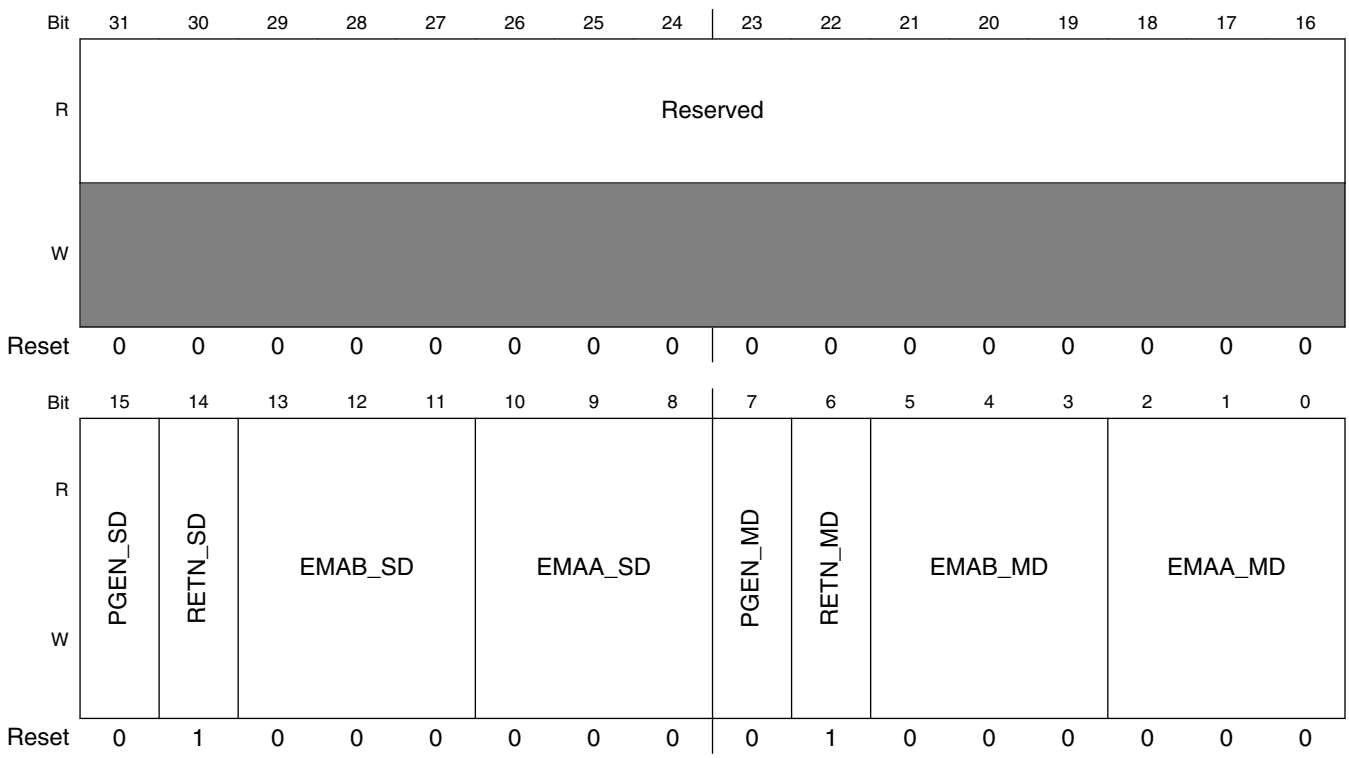
0 NINITMAIN	MD FIFO write point initialize

13.4.4.21 FIFO Memory AC Characteristic Register (MIPI_DSI_MEMACCHR)

NOTE

In current design, these memory port controls were disabled. User can ignore the function of this register.

Address: 3076_0000h base + 50h offset = 3076_0050h



MIPI_DSI_MEMACCHR field descriptions

Field	Description
31–16 Reserved	This field is reserved.

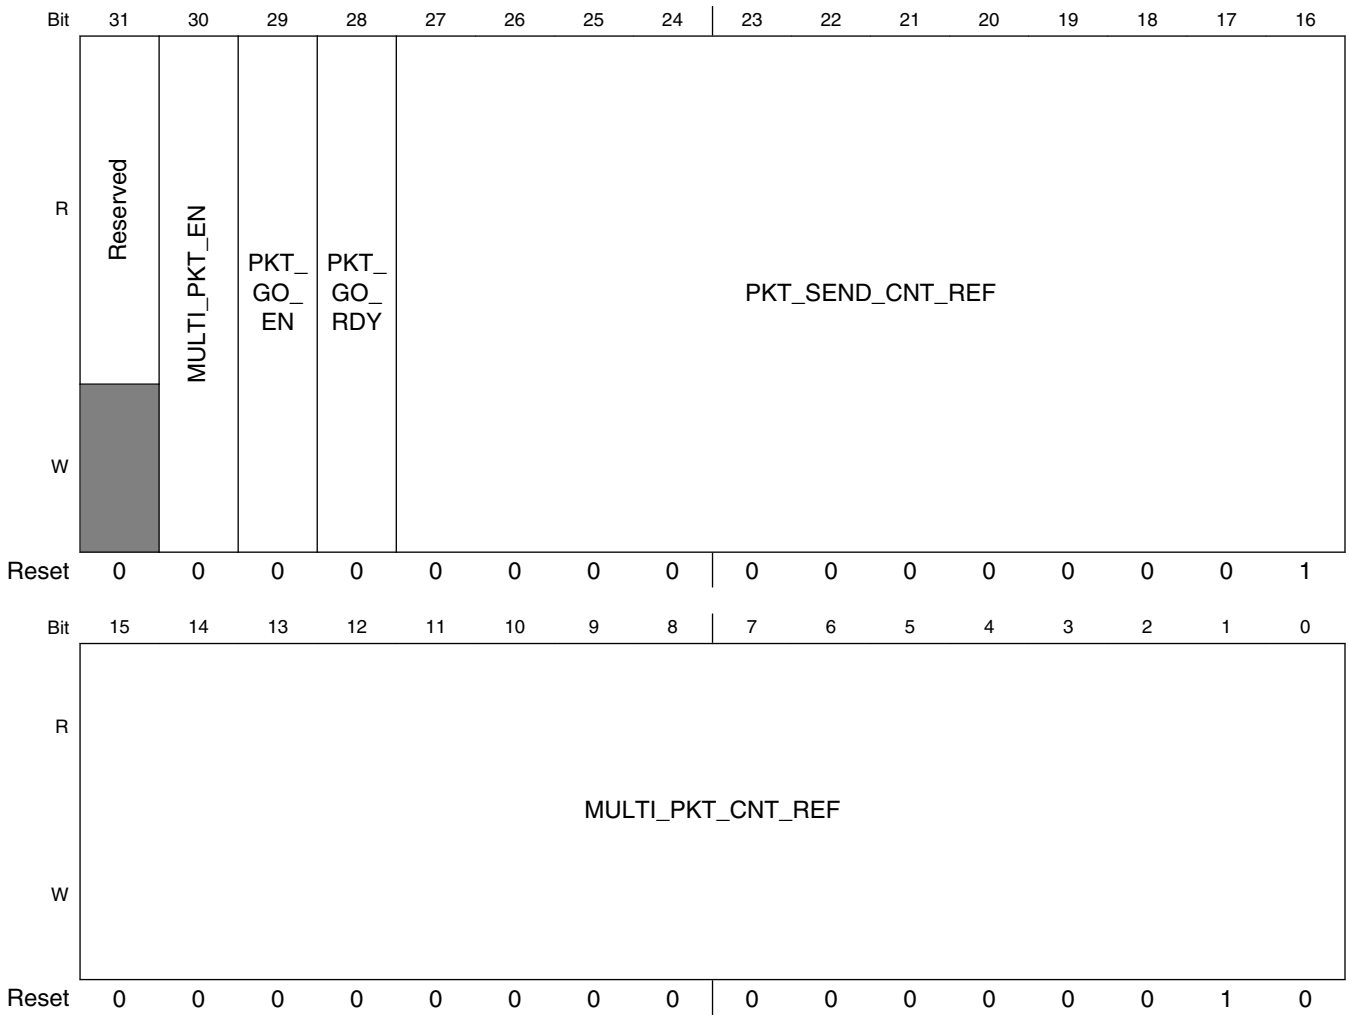
Table continues on the next page...

MIPI_DSI_MEMACCHR field descriptions (continued)

Field	Description
15 PGEN_SD	Sub display FIFO memory power gating
14 RETN_SD	Sub display FIFO memory Retention
13–11 EMAB_SD	Sub display FIFO memory B port margin adjustment
10–8 EMAA_SD	Sub display FIFO memory A port margin adjustment
7 PGEN_MD	Main display FIFO memory power gating
6 RETN_MD	Main display FIFO memory Retention
5–3 EMAB_MD	Main display FIFO memory B port margin adjustment
EMAA_MD	Main display FIFO memory A port margin adjustment

13.4.4.22 MIPI_DSI_MULTI_PKT

Address: 3076_0000h base + 78h offset = 3076_0078h



MIPI_DSI_MULTI_PKT field descriptions

Field	Description
31 Reserved	This field is reserved.
30 MULTI_PKT_EN	Specifies the send multi command packets on single transmission. Multi command packet can transfer by only HS mode. 0 Send single command packet 1 Send multi command packets
29 PKT_GO_EN	Specifies the send command packet(s) per frame enable . Packet go can transfer by only HS mode.

Table continues on the next page...

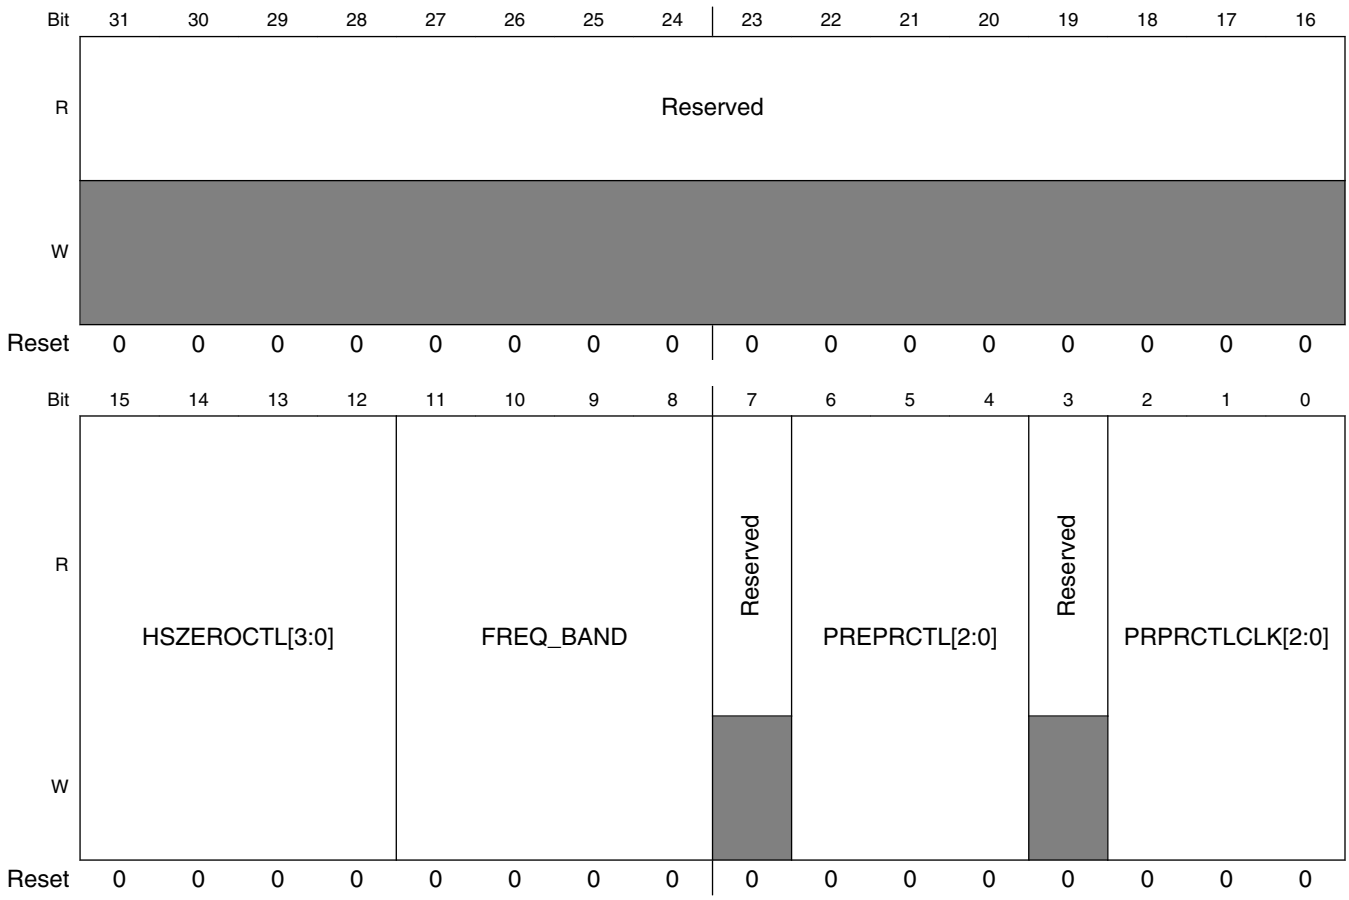
MIPI_DSI_MULTI_PKT field descriptions (continued)

Field	Description
	0 Send command packet(s) during every VFP 1 Send command packet(s) during 1frame VFP
28 PKT_GO_RDY	Specifies the send command packet(s) on this frame VFP. If packet transferred or PKT_Go_EN is disabled, this bit goes to 1'b0.
27–16 PKT_SEND_ CNT_REF	Specifies the command packet(s) send point indicator. That value is 1H time + D-PHY LP-HS-LP latency by ByteCLK. Do not use '0'.
MULTI_PKT_ CNT_REF	Specifies the number of packets on single transmission. Do not use '0' and '1'. 0 and 1 are same as '2'

13.4.4.23 1 Gbps D-PHY PLL Control Register (MIPI_DSI_PLLCTRL_1G)

This register configures 1Gbps D-PHY PLL control, D-PHY, clock range indication, and so on.

Address: 3076_0000h base + 90h offset = 3076_0090h



MIPI_DSI_PLLCTRL_1G field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–12 HSZEROCTL[3:0]	1 Gbps D-PHY HS-Zero driving timing control.
11–8 FREQ_BAND	1 Gbps D-PHY Timing control for D-PHY global operation timing.
7 Reserved	This field is reserved.

Table continues on the next page...

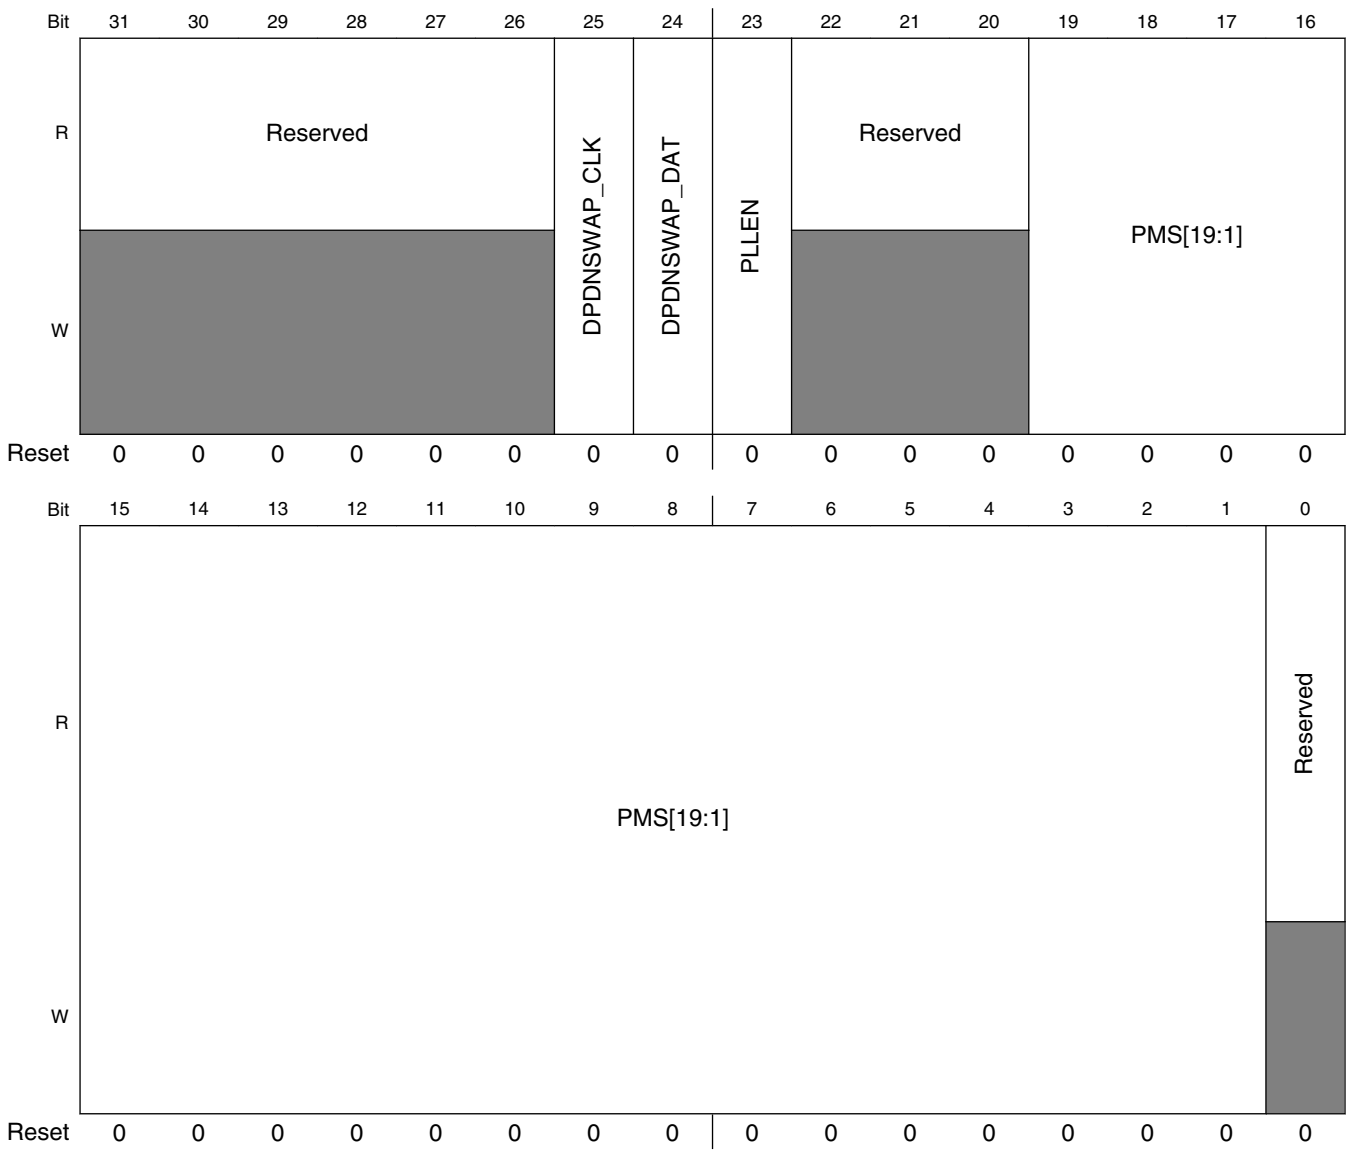
MIPI_DSI_PLLCTRL_1G field descriptions (continued)

Field	Description
6–4 PREPRCTL[2:0]	1 Gbps D-PHY PLL Tclk-prepare and Ths-prepare driving control.
3 Reserved	This field is reserved.
PRPRCTLCLK[2:0]	1 Gbps D-PHY PLL Ths-prepare driving time control

13.4.4.24 PLL Control register (MIPI_DSI_PLLCTRL)

This register configures PLL control, D-PHY, clock range indication, and so on.

Address: 3076_0000h base + 94h offset = 3076_0094h



MIPI_DSI_PLLCTRL field descriptions

Field	Description
31–26 Reserved	This field is reserved.

Table continues on the next page...

MIPI_DSI_PLLCTRL field descriptions (continued)

Field	Description
25 DPDNSWAP_CLK	Swaps Dp / Dn channel of clock lane. If this bit is set, Dp and Dn channel swap each other.
24 DPDNSWAP_DAT	Swaps Dp / Dn channel of Data lanes. If this bit is set, Dp and Dn channel swap each other.
23 PLLEN	Enables PLL
22–20 Reserved	This field is reserved.
19–1 PMS[19:1]	Specifies the PLL PMS value
0 Reserved	This field is reserved.

13.4.4.25 PLL Control Register 1 (MIPI_DSI_PLLCTRL1)

This register configures D-PHY PLL control (M_PLLCTL[31:0]).

Address: 3076_0000h base + 98h offset = 3076_0098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13.5 MIPI CSI2 Host Controller (MIPI_CSI2)

13.5.1 Overview

The CSI-2 Host Controller is a digital core that implements all protocol functions defined in the MIPI CSI-2 Specification, providing an interface between the System and the MIPI D-PHY, allowing the communication with a MIPI CSI-2 compliant Camera Sensor.

13.5.1.1 Features

The following list summarizes the key features of the MIPI CSI2:

- Compliant to MIPI D-phy standard specification V1.1
  - Compliant to previous version of Samsung D-phy
- Compliant to MIPI CSI2 Standard Specification V1.01r06
- Support primary and secondary Image format
  - YUV420, YUV420 (Legacy), YUV420 (CSPS), YUV422 of 8-bits and 10-bits
  - RGB565, RGB666, RGB888
  - RAW6, RAW7, RAW8, RAW10, RAW12, RAW14
  - Compressed format: 10-6-10, 10-7-10, 10-8-10, 14-10-14
  - All of user defined byte-based Data packet
- Support embedded byte-based non-Image data packet and generic short packets
- Support interleave mode using Virtual channel
- Support up to two D-PHY Rx Data Lanes
- Interfaces
  - Compatible to PPI (Protocol-to-PHY Interface) in MIPI D-PHY Specification
  - Image output data bus width: 32 bit
  - Support four channel virtual channels or data interleave
- Memory

Non-image memory

- 8 KB SRAM for asynchronous clock domain
- This memory can store maximum 4 KB of non-image data per frame.

Image Memory

- 1KB SRAM for image memory
- This memory works as buffering for the difference of input / output bandwidth

- Pixel clock can be gated when no ppi data is coming.

13.5.1.2 Block diagram

13.5.1.2.1 Block diagram of camera system with CSIS V3.3

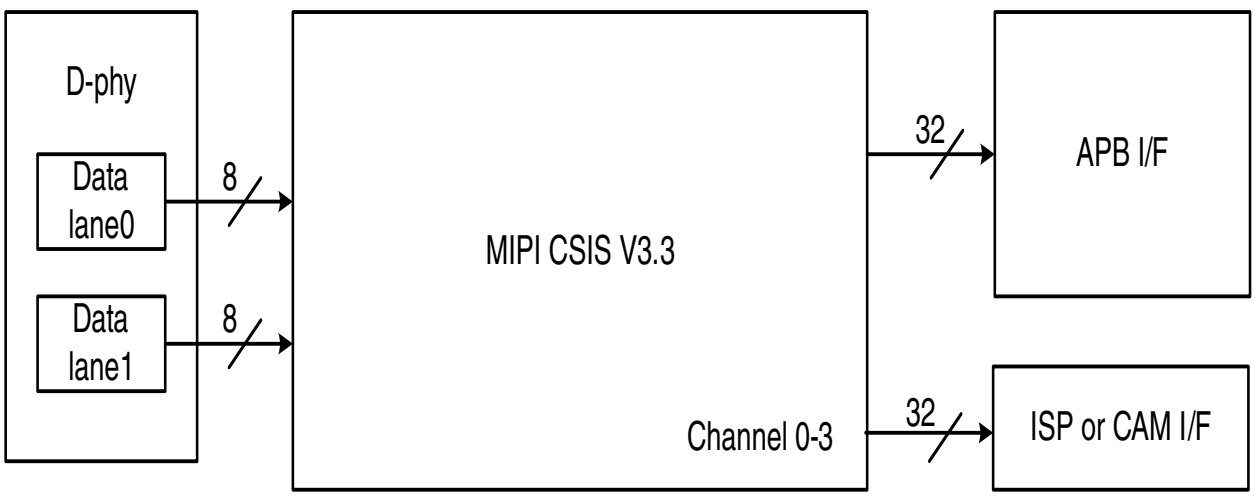

Figure 13-47. Block Diagram of Camera System with CSIS V3.3

13.5.1.2.2 MIPI CSI Slave and D-PHY I/F block diagram

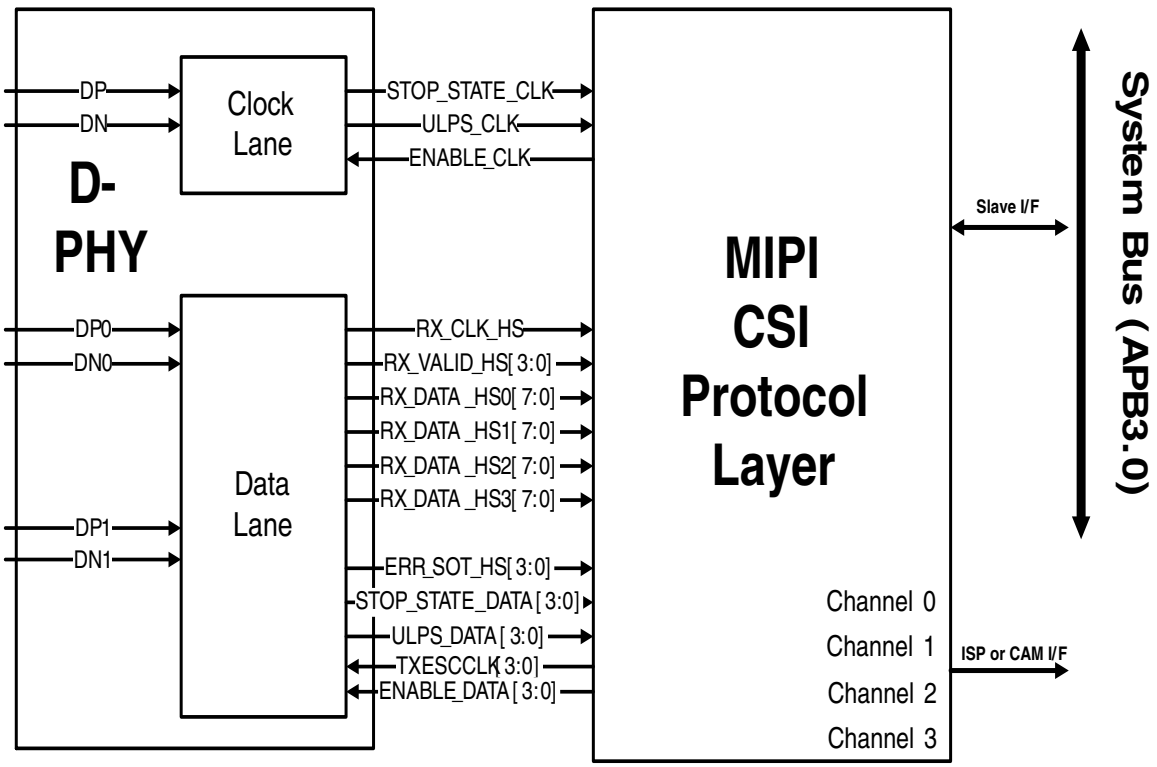

Figure 13-48. PPI I/F Block Diagram

13.5.1.2.3 MIPI CSI Slave block diagram

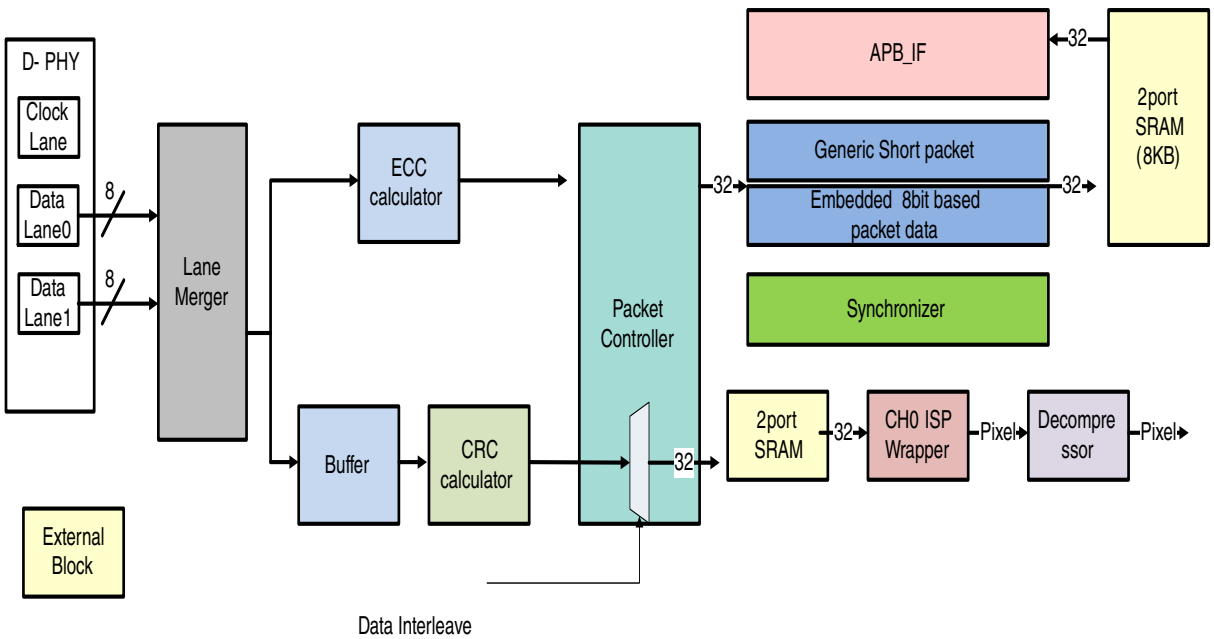

Figure 13-49. Block Diagram of CSIS V3.3 Slave Module

13.5.1.3 Internal memories

There are some configurable-sized Memories. The following table describes these Memories.

Table 13-16. Internal Memory List

Usage	Memory Type	Size	Description
Generic data	2 port SRAM	8 KB (2048 X 32 bits)	Store the Embedded data or Generic data (This memory can be split several memories and then need mux for those memories)
Image data	2 port SRAM	1 KB (256 x 32 bits)	Store the Image data of Virtual Channel

There is the timing diagram for read memory in the following figure. If the mux for the split memories is needed, register for storing the address is necessary, because the RDATA of memory is prepared at one clock later when the REN and RADDR are accepted.

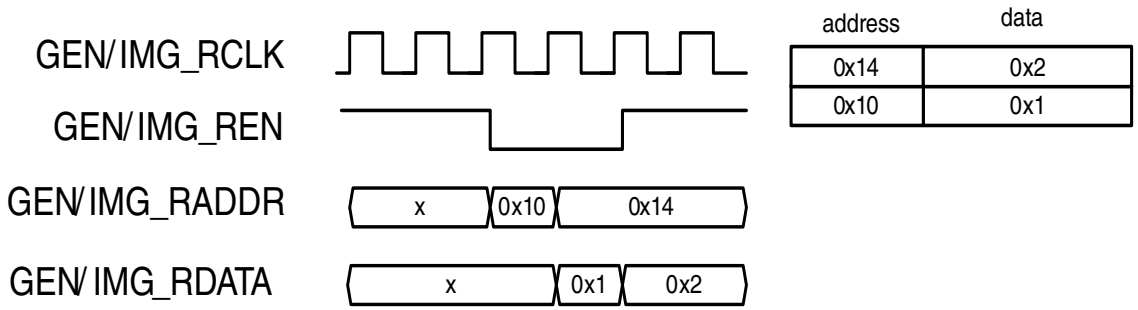

Figure 13-50. Timing Diagram of Read Memory

13.5.2 External Signals

The following table describes the external signals of MIPI CSI:

Table 13-17. MIPI CSI External Signals

Signal	Description	Pad	Mode	Direction
MIPI_CSI_CLK_N	D-PHY Negative D-Phy differential clock line Receiver input	MIPI_CSI_CLK_N	No muxing	I
MIPI_CSI_CLK_P	D-PHY Positive D-Phy differential clock line Receiver input	MIPI_CSI_CLK_P	No muxing	I
MIPI_CSI_D0_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_CSI_D0_N	No muxing	I
MIPI_CSI_D0_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_CSI_D0_P	No muxing	I
MIPI_CSI_D1_N	D-PHY Negative D-Phy differential data line Receiver input	MIPI_CSI_D1_N	No muxing	I
MIPI_CSI_D1_P	D-PHY Positive D-Phy differential data line Receiver input	MIPI_CSI_D1_P	No muxing	I

13.5.3 Functional Description

13.5.3.1 Interface and protocol

13.5.3.1.1 D-PHY layer FSM

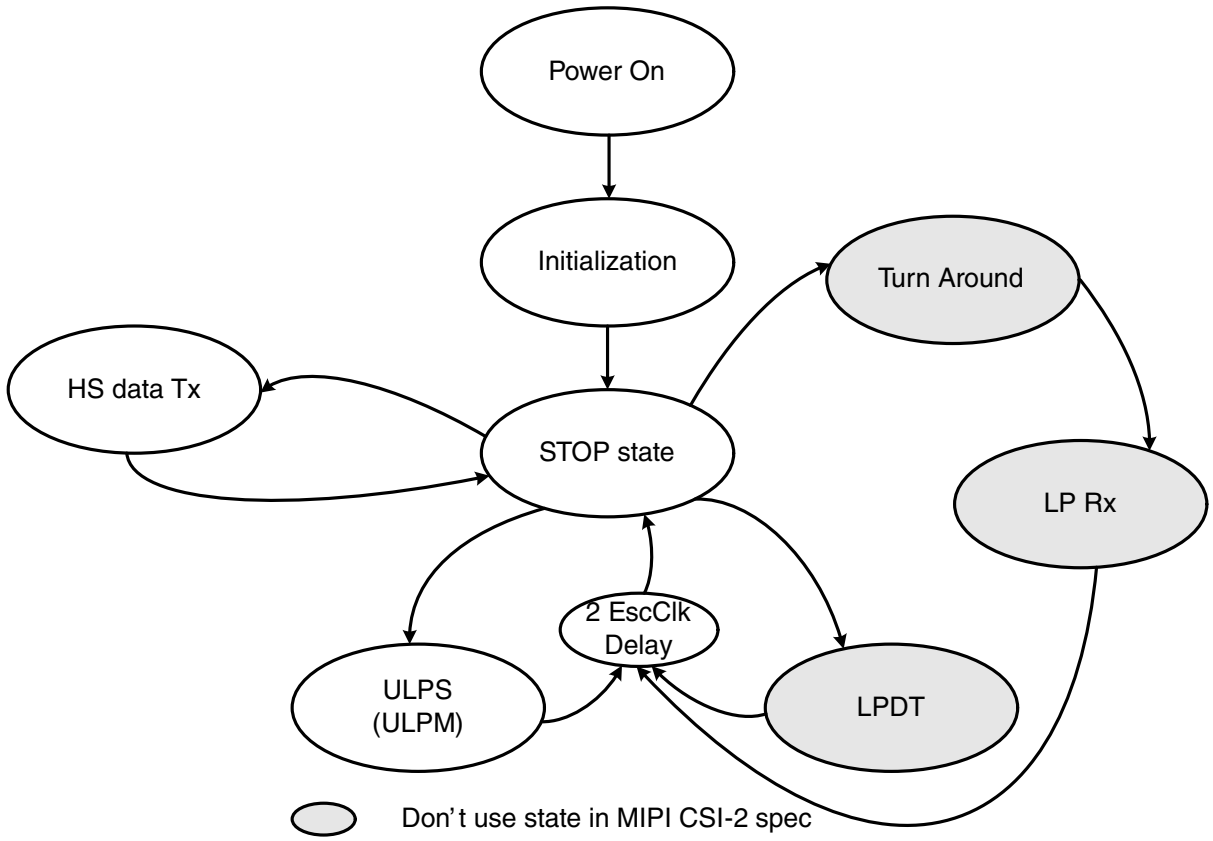

Figure 13-51. D-PHY Finite State Machine

CSIS V3.3 system supports HSDT (High Speed Data Transfer) and ULPS (ULPM–Utra-Low Power State or Mode) only. There is no trigger function, LPDT, and BTA.

13.5.3.1.2 Interface timing and protocol

13.5.3.1.2.1 PPI interface timing and protocol

CSIS V3.3 supports HSDT and ULPM.

13.5.3.1.2.1.1 High speed data transfer

In the following figure, the upper five signals are related with clock lane and the lower six signals are related with data lane. Dp and Dn of upper signals are D-phy channel of clock lane. BYTE_CLK is generated clock in the D-PHY. Dp and Dn of lower signals are

Data lane. Another signals of lower are Phy Status signals. STOPstate (and STOPstateClk) indicates that differential channel state of D-phy is LP11 (the voltage level of Dp and Dn is 1.2 V)

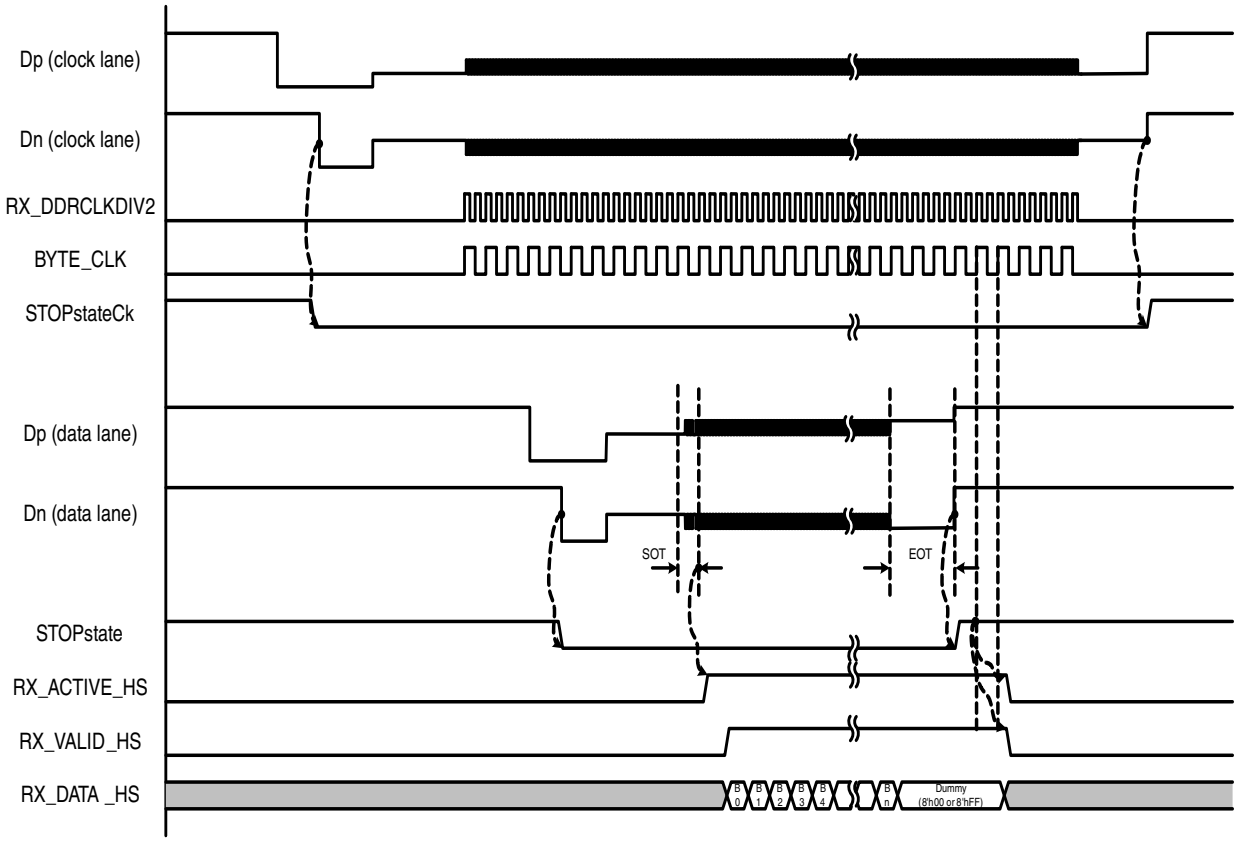

Figure 13-52. Timing Diagram of High Speed Data Transfer

13.5.3.1.2.1.2 Ultra-low power mode

In the following figure, UlpsActiveNot* and STOPstate* is in PPI. ULPS command generated by D- PHY Tx is only for D-PHY Rx, it is decoded by D-PHY Rx and transferred to Link with Ulps data.

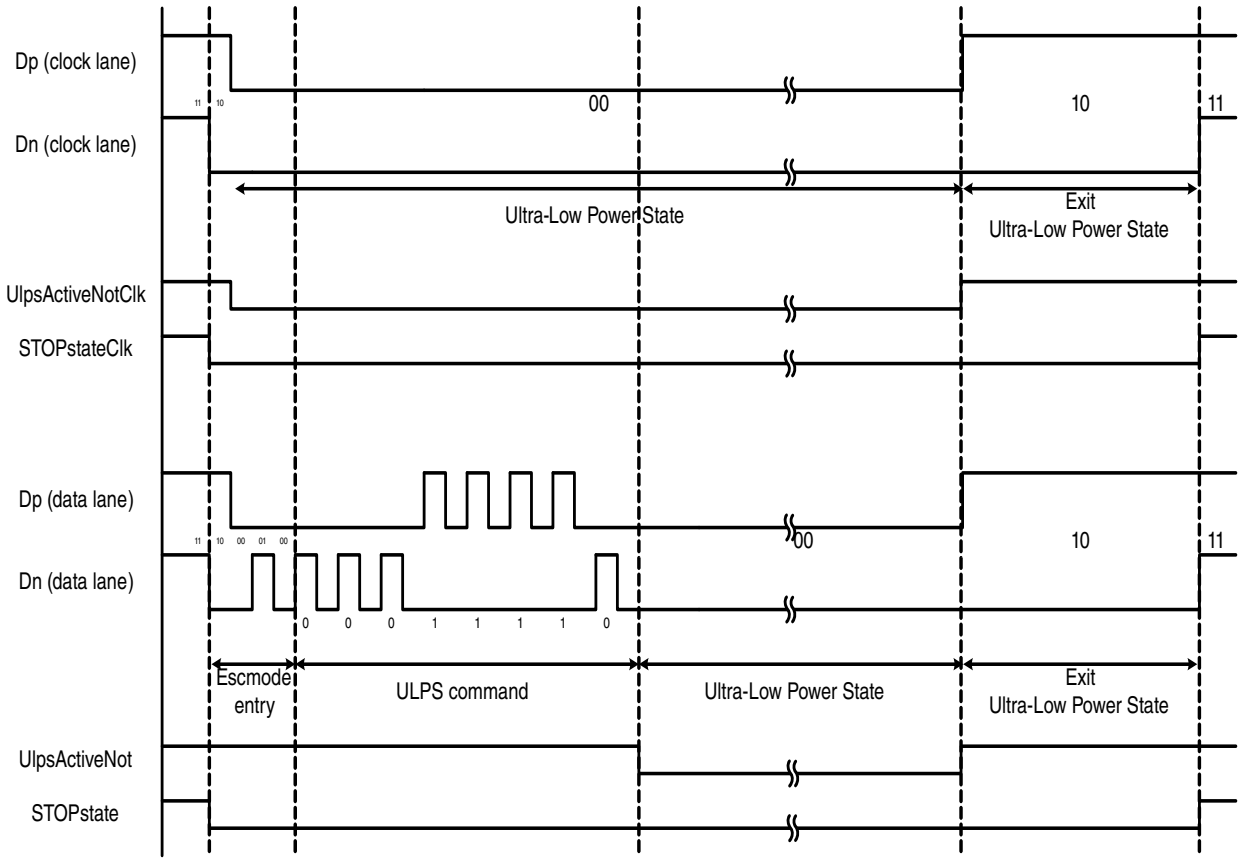

Figure 13-53. Timing Diagram of Ultra Low Power Mode

13.5.3.1.2.2 ISP (CAM I/F) interface

CSIS V3.3 has output signals, which are PIX_CLK, VVALID, HVALID, BVALID, DATA , StopReqEn, and input signal which is StopReq. PIX_CLK is output pixel clock what is generated from PCLK or EXTCLK (WRAP_CLK). VVALID is vertical sync signal. HVALID is horizontal sync signal. BVALID indicates the valid number of bytes, which is only used in User Defined type. DATA is image data bus. DATA bus width is dependent on Image format. Maximum bus width is 24 bits, which is RGB888. The following figure describes the output protocol of MIPI CSIS. All signal s are synchronized with the rising edge of PIX_CLK.

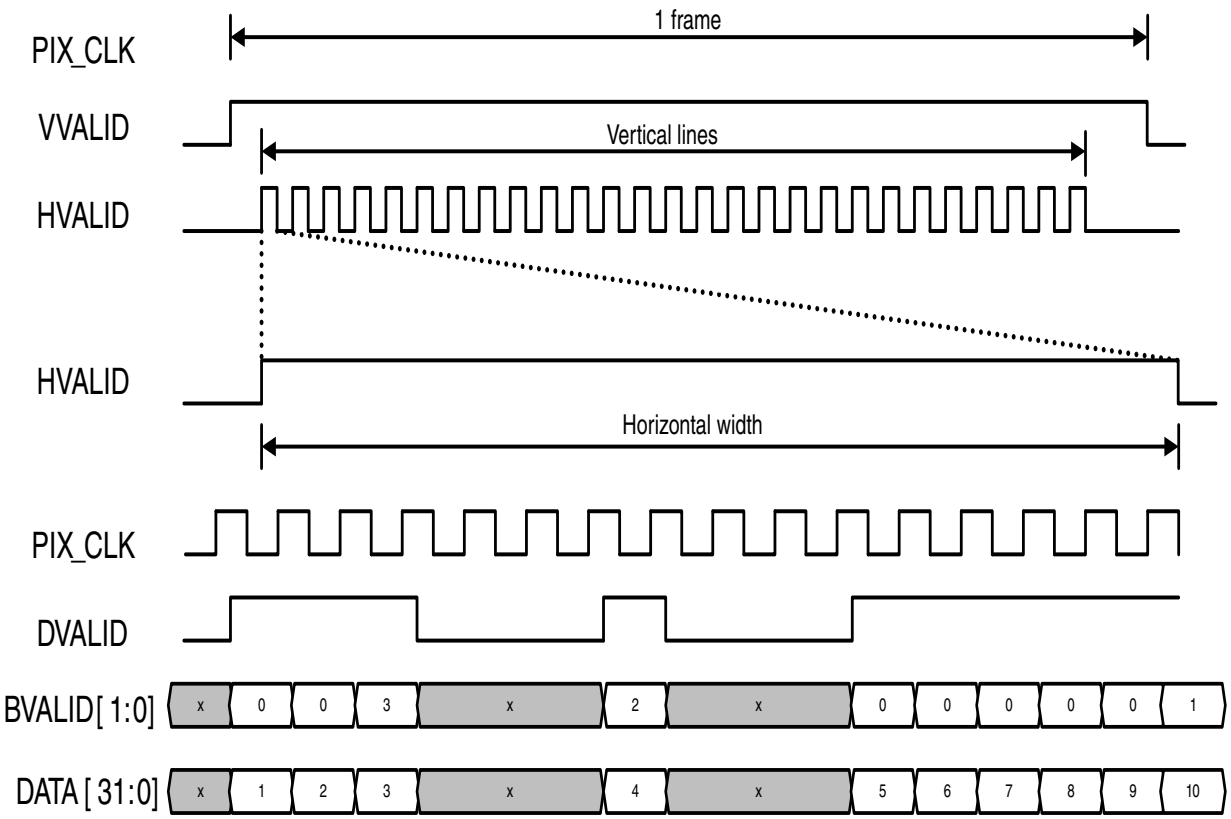

Figure 13-54. Output Protocol of ISP Wrapper of CSIS V3.3

The following figure describes timing diagram of ISP wrapper output protocol.

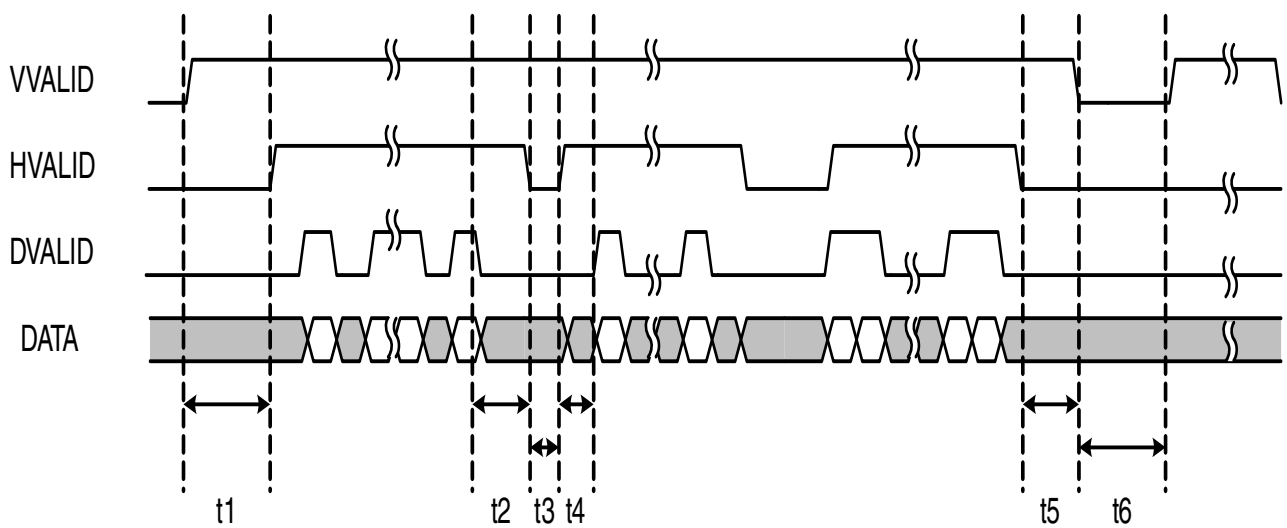

Figure 13-55. Timing Diagram of ISP Wrapper Output Protocol

The following table is a timing table of output protocol.

Table 13-18. Description of Output Protocol

	Description	Minimum Cycle of Pixel Clock	Maximum Cycle of Pixel clock
t1	Interval between rising of VVALID and first rising of HVALID	Vsync_SIntv + 1 (1 ~ 64)	—
t2	Interval between last falling of DVALID and falling of HVALID	Hsync_LIntv + 1 (1 ~ 6 4)	—
t3	Interval between falling of HVALID and rising of next HVALID	1	—
t4	Interval between rising of HVALID and first rising of DVALID	0	—
t5	Interval between last falling of HVALID and falling of VVALID	Vsync_EIntv (0 ~ 4095)	—
t6	Interval between falling of VVALID and rising of next VVALID	1	—

13.5.3.1.2.2.1 Handshaking with back pressure

In the following figure, there are handshaking signals which are StopReqEn and StopReq to stall data flow when the Post-IP needs more clock cycles to process its computation. The handshaking is called as back pressure interface.

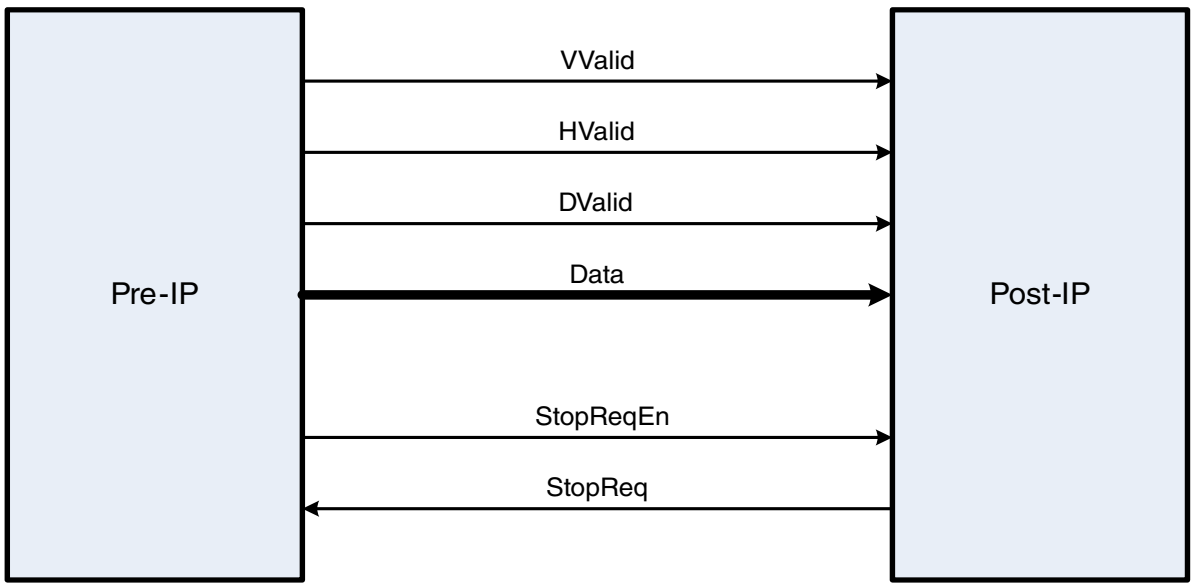

Figure 13-56. Interface between Two IPs

Under the stoppable condition (StopReqEn and StopReq = 1), sync signals (VVALID, HVALID, DVALID, and BVALID) are not changed. Only after releasing of the stoppable condition, sync signals can be changed. In the following figure, (b) shows that StopReq is ignored when StopReqEn is not active. StopReqEn is high when the room of memory is greater than IMG_MEM_FULL_GAP, because of the delay of full signal propagation, IMG_MEM_FULL_GAP must not be set under 4 to avoid memory overflow.

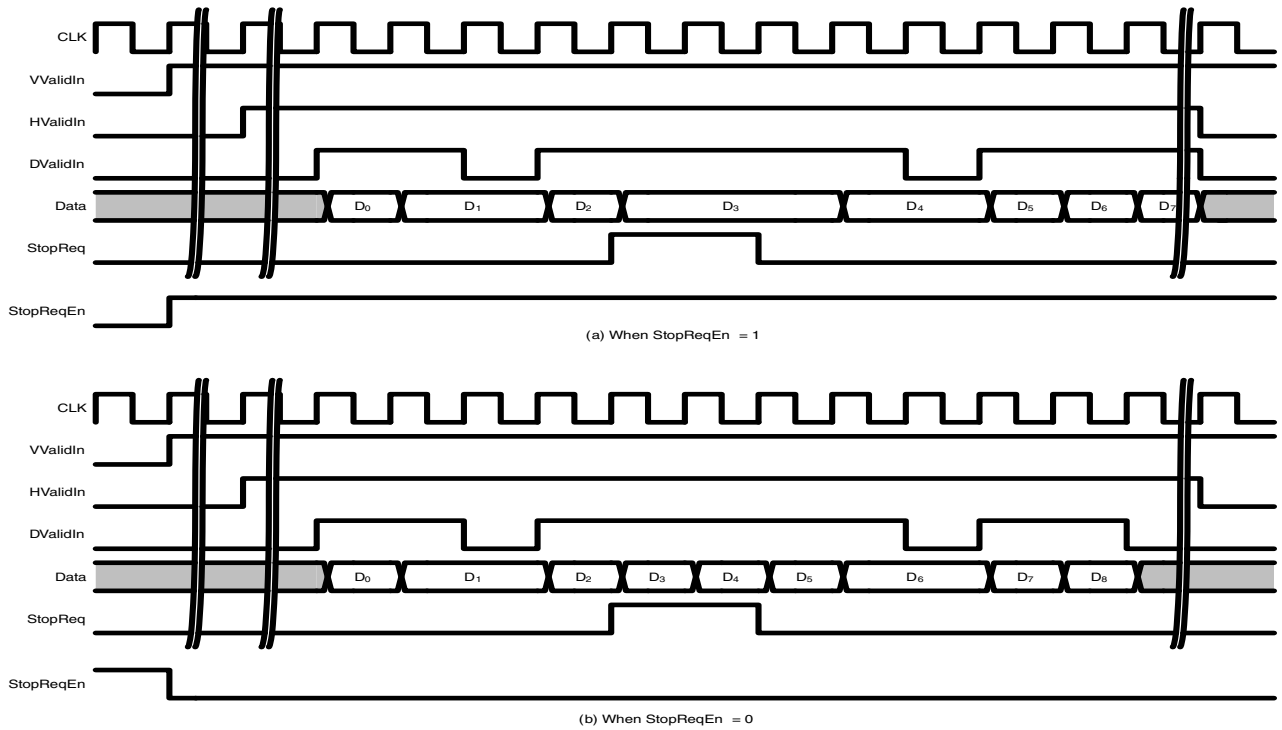

Figure 13-57. Timing Diagram According to StopReqEn and StopReq

13.5.3.1.2.2.2 Normal Data alignment in output Data bus

The following figure describes data alignment of RGB formats.

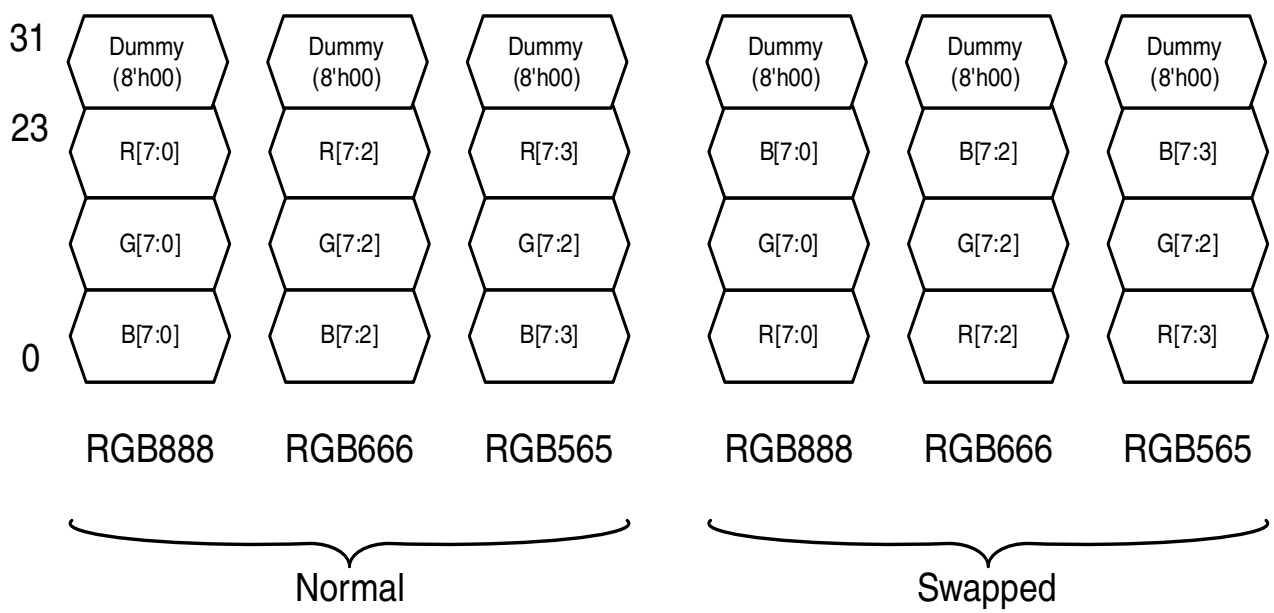

Figure 13-58. RGB Data Alignment

The following figure describes data alignment of RAW and YUV formats.

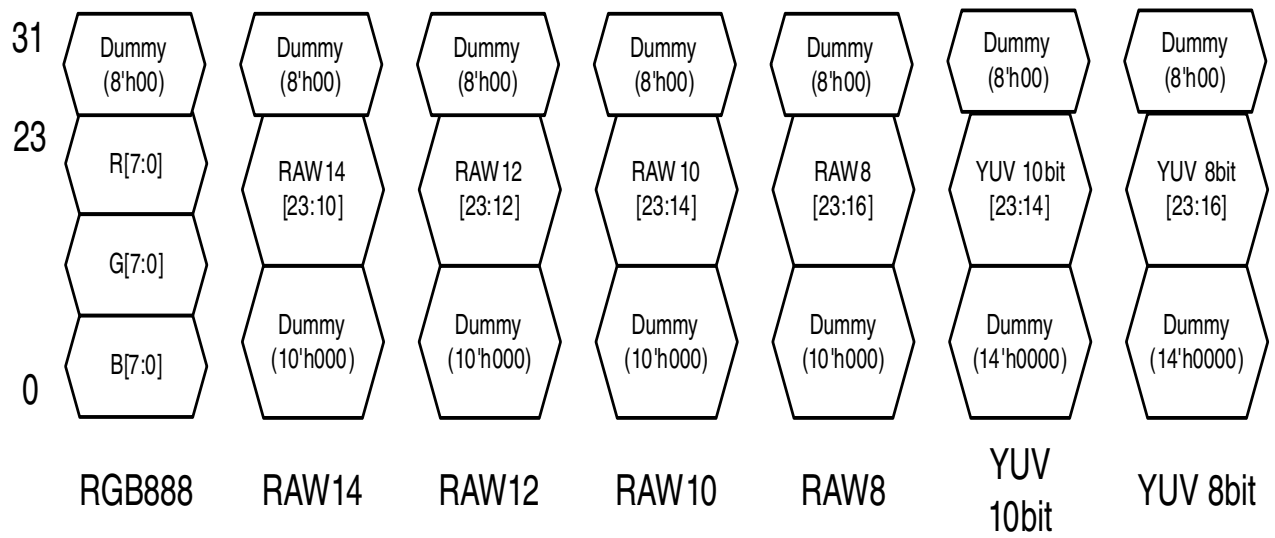

Figure 13-59. RAW and YUV Data Alignment

The following table describes present of each bit in image data bus.

Table 13-19. MIPI CSIS Output Format in Bus

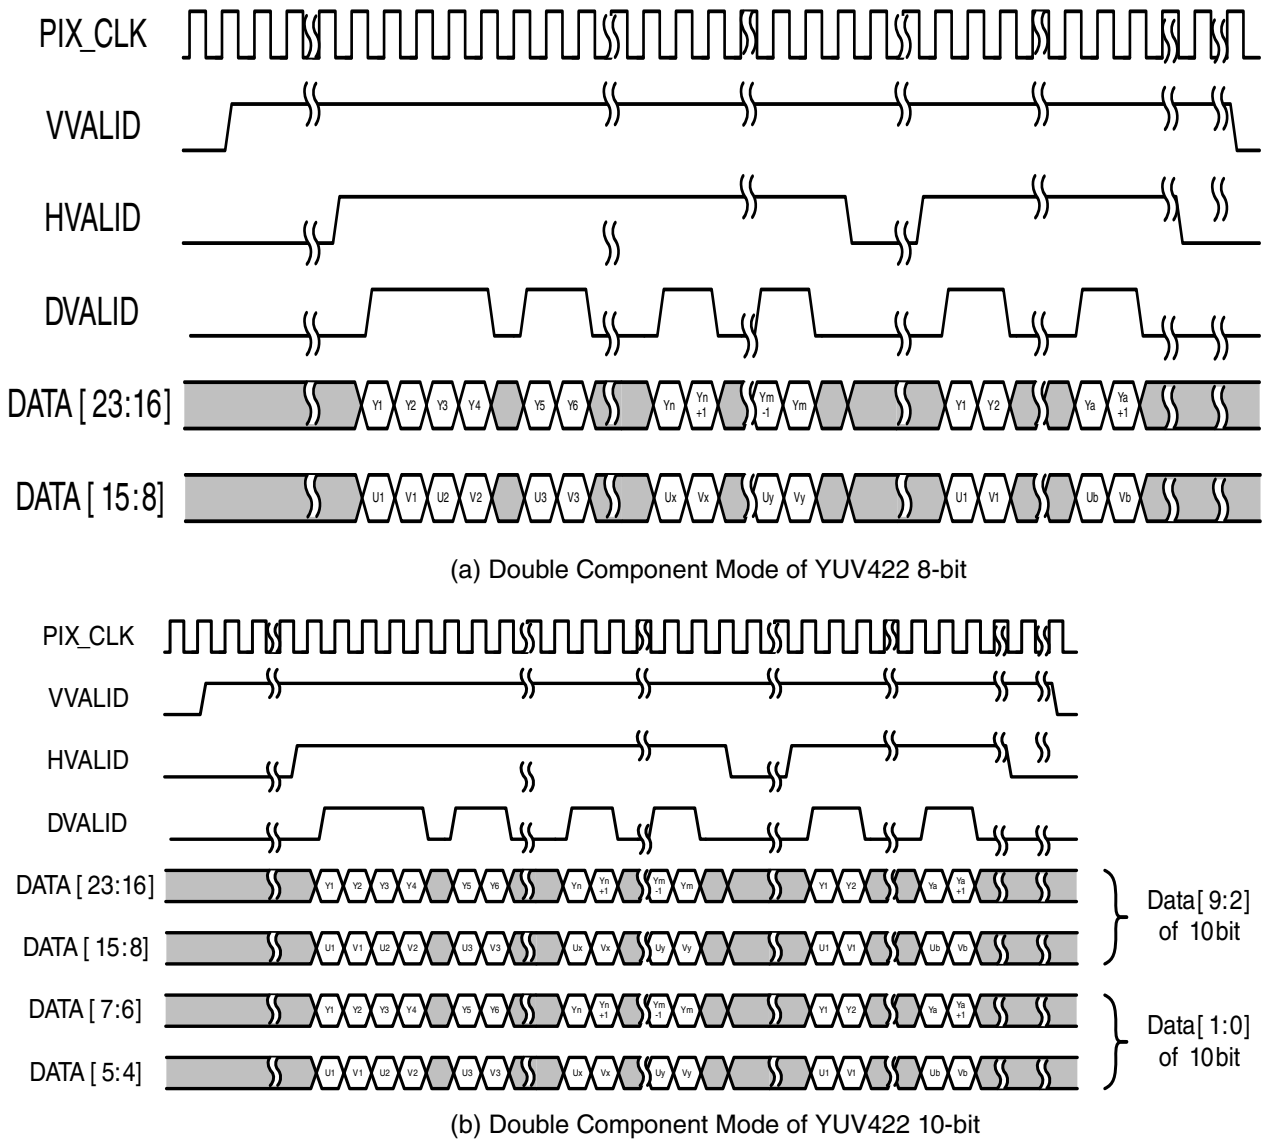

Figure 13-60. Waveform of Double Component Mode

13.5.3.2 Configuration

13.5.3.2.1 Image resolution

MIPI CSI Slave block needs the configuration of Image resolution to measure Hsync pulse length exactly and detect frame end.

Vertical resolution register has 16 bits (16'h0001 ~ 16'hFFFF).

Horizontal resolution register has 16 bits (16'h0001 ~ 16'hFFFF).

13.5.3.2.2 Image data format

In CSIS V3.3, Image data format can be configured for transferring image data to ISP or CAM I/F.

13.5.3.2.2.1 YUV format

MIPI CSI2 supports YUV formats: YUV420 8-bit, YUV420 10-bit, YUV420 Legacy, YUV420 8-bit Chroma Shifted Pixel Sampling, YUV420 10-bit Chroma Shifted Pixel Sampling, YUV422 8-bit, and YUV422 10-bit.

The following table describes Data type of YUV packets.

Table 13-22. Data Type of YUV Packets

Data Type	Description
0x18	YUV420 8-bit
0x19	YUV420 10-bit
0x1A	Legacy YUV420 8-bit
0x1B	Reserved
0x1C	YUV420 8-bit CSPS (Chroma Shifted Pixel Sampling)
0x1D	YUV420 10-bit CSPS (Chroma Shifted Pixel Sampling)
0x1E	YUV422 8-bit
0x1F	YUV422 10-bit

13.5.3.2.2.2 RGB format

MIPI CSI2 supports RGB formats: RGB444, RGB555, RGB565, RGB666, and RGB888.

The following table describes data type of RGB packets.

Table 13-23. Data Type of RGB Packets

Data Type	Description
0x20	RGB444 (not support)
0x21	RGB555 (not support)
0x22	RGB565
0x23	RGB666
0x24	RGB888
0x25	Reserved
0x26	
0x27	

13.5.3.2.2.3 RAW format (Bayer RGB)

MIPI CSI2 supports RAW formats: RAW6, RAW7, RAW8, RAW10, RAW12, and RAW14.

The following table describes data type of RAW packets.

Table 13-24. Data Type of RAW Packets

Data Type	Description
0x28	RAW6
0x29	RAW7
0x2A	RAW8
0x2B	RAW10
0x2C	RAW12
0x2D	RAW14
0x2E	Reserved
0x2F	

13.5.3.2.2.4 User defined Byte-based format

CSIS V3.3 supports eight formats of user defined Byte-based data packet.

The following table describes data type of user defined packets.

Table 13-25. Data Type of RAW Packets

Data Type	Description
0x30	User defined Byte-based packet 1
0x31	User defined Byte-based packet 2
0x32	User defined Byte-based packet 3
0x33	User defined Byte-based packet 4
0x34	User defined Byte-based packet 5
0x35	User defined Byte-based packet 6
0x36	User defined Byte-based packet 7
0x37	User defined Byte-based packet 8

13.5.3.2.2.5 Generic format

CSIS V3.3 supports Generic Short and Long data type packet through only Virtual Channel 0. For the lower size and the Generic type data is not used frequently, it is limited that only the VC 0 supports the Generic format packet.

The intention of the Generic Short Packet data is to provide timing information for the opening / closing of shutters, triggering of flashes, etc. And the Embedded 8-bit contains the additional information of the picture frame.

All the Generic type data in a frame is stored at the SRAM and system is required to pop the data. For the double buffering, the embedded data can be used up to the half of SRAM size (EX: If SRAM is 8 KB allocated for the generic data type then each frame can use up to 4 KB generic data).

Table 13-26. Generic Short / Long Data Type

Data Type	Description
0x08	Generic Short Packet Code 1
0x09	Generic Short Packet Code 2
0x0A	Generic Short Packet Code 3
0x0B	Generic Short Packet Code 4
0x0C	Generic Short Packet Code 5
0x0D	Generic Short Packet Code 6
0x0E	Generic Short Packet Code 7
0x0F	Generic Short Packet Code 8
0x12	Embedded 8-bit non Image data (Generic long type)

13.5.3.2.2.6 Null and blanking data

For both the null and blanking data types CSIS V3.3 ignore the content of the packet payload data.

Table 13-27. Null and Blanking Data Type

Data Type	Description
0x10	Null
0x11	Blanking Data

13.5.3.3 User defined packet format

The User Defined Data Type values can be used to transmit arbitrary byte-based data, such as JPEG and 1226 MPEG4 data over the CSI-2 bus.

The packet data size in bits can be divisible by 8. For example, whole number of bytes can be transmitted.

For User Defined data:

- The frame is transmitted as a sequence of arbitrary sized packets.
- The packet size is vary from packet to packet.
- The packet spacing is vary between packets.

13.5.3.3.1 ISP / CAM I/F for user defined packet

For supporting user defined packet, MIPI CSIS puts out more signals: 2 bits of byte validation.

Byte validation signal indicates what is valid byte in data of word size. In the following figure, n is 0, 1, 2, or 3.

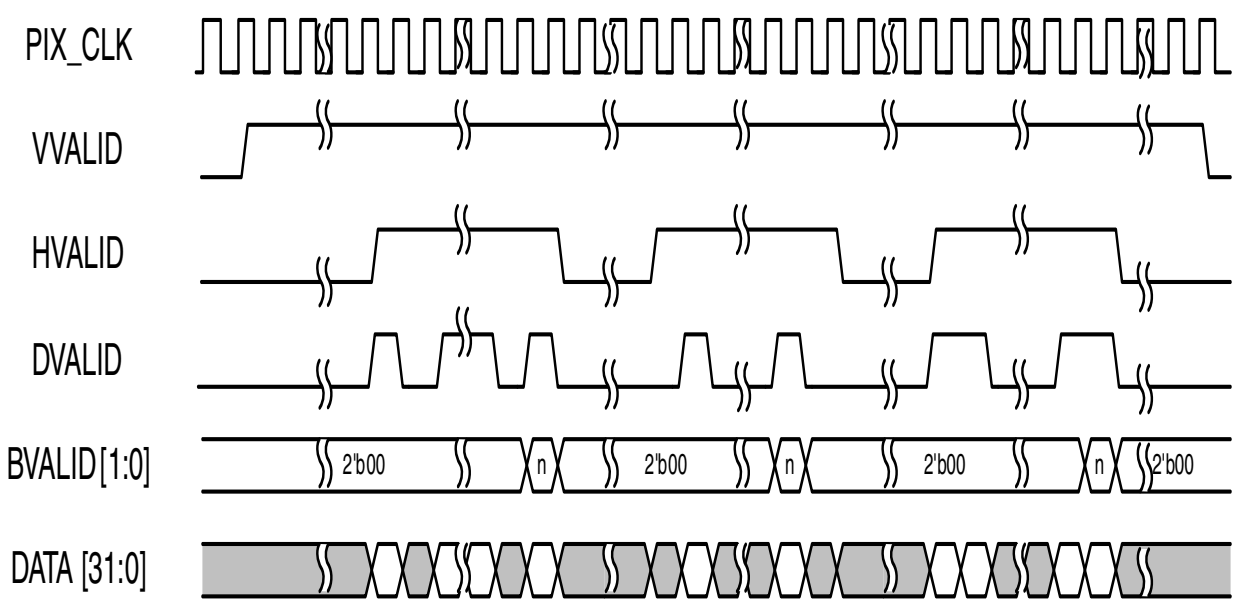

Figure 13-61. Output Protocol of CSIS V3.3 in User Defined Format

The following table describes BVALID in detail.

Table 13-28. Description Table of BVALID[1:0]

BVALID[1:0]	Description
2'b00	All bytes in data bus are valid.
2'b01	Only byte 0 is valid.
2'b10	2 bytes from LSB are valid.
2'b11	3 bytes from LSB are valid.

13.5.3.3.2 Pixel clock of ISP wrapper for user defined packet

Since CSIS V3.3, Byteclk is not used for Pixel clock even in the user defined format.

13.5.3.4 Decompressor for Bayer RGB

In Annex E of MIPI CSI-2 standard spec, compress formula is described. CSIS V3.3 can support 6 / 7 / 8-to-10 formats and 10-to-14 formats.

There are two types of determining predictor to decompress which are Simple and Advanced method (Refer 5.2 and 5.8's decomp_predict field). The Simple method is intended to minimize processing power and it is typically used with 8-10, 7-10 schemes. The Advanced method is more complex and provide slightly better quality, so it is usually used with 6-10 and 10-14 schemes. CSIS V3.3 can support both method at 6 / 7-10, 10-14 schemes, and only simple method at 8-10 scheme.

The following figure describes the block diagram of Decompressor logic in CSIS V3.3.

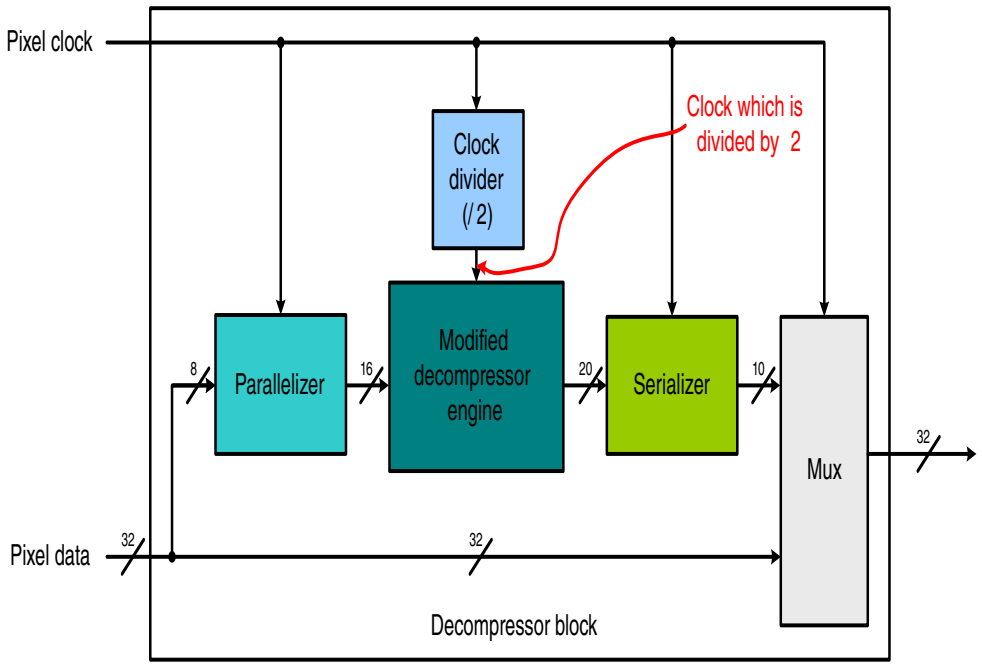

Figure 13-62. Block Diagram of Decompressor

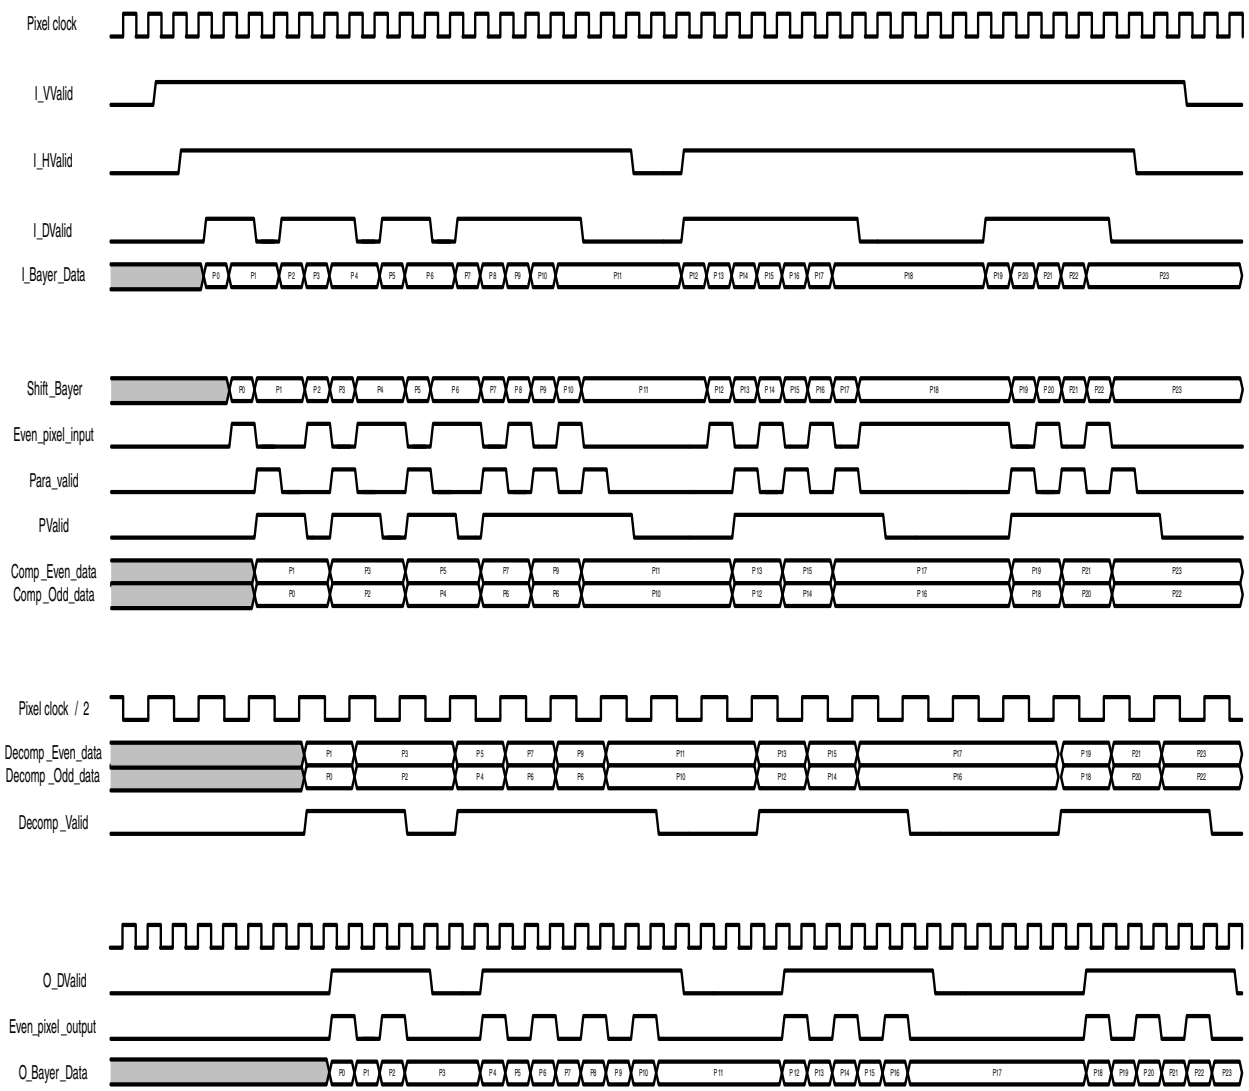
Decompressor engine was made by SysLSI Image team. It was modified for using Dvalid. Another logic of Decompressor was designed for processing two pixel per clock because of decompressor engine.

When camera module can send compressed Bayer RGB, user can be set CSIS_CTRL and CSIS_CONFIG registers. Turn the Decompress enable and format in CSIS_CTRL register on. And then set the compressed format (RAW6, 7, 8) before turning camera module on.

The following table is an example of wave of decompressor.

Figure 13-63. Waveform of Decompressor



1st group Figure 13-62 of is input signals of Decompressor. 2nd group of Figure 13-63 is signals of parallelizer of Decompressor. 3rd group of Figure 13-63 is output of Decompressor engine. The other group is output of Decompressor.

13.5.3.5 Interrupt

CSIS V3.3 has many interrupts for checking status, indicating error case and receiving generic data.

13.5.3.5.1 Odd_Before / Odd_After / Even_Before / Even_After

These interrupts are related with generic and embedded data.

Odd_Before and Odd_After interrupts are generated in odd frame. Even_Before and Even_After interrupts are generated in even frame. Odd_Before and Even_Before interrupts are generated when Generic Short packet or Embedded 8-bit based packet is received before image data (Vertical Back porch area).

13.5.3.6 Synchronization short packet data type

Image Frame begins with a Frame Start and finishes with a Frame End packet. With these Frame synch packet, CSIS V3.3 generate Vertical Sync signal (VVALID). The Line synchronization packet (Line Start and Line End) generate Horizontal Sync signal (HVALID). But it can be generated by image data packet so that CSIS V3.3 does not support the Line Synchronization packets (0x02 ~ 0x03) and ignore it if it is received.

Table 13-29. Synchronization Short Packet Data Type

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Not support)
0x03	Line End Code (Not support)
0x04 to 0x07	Reserved

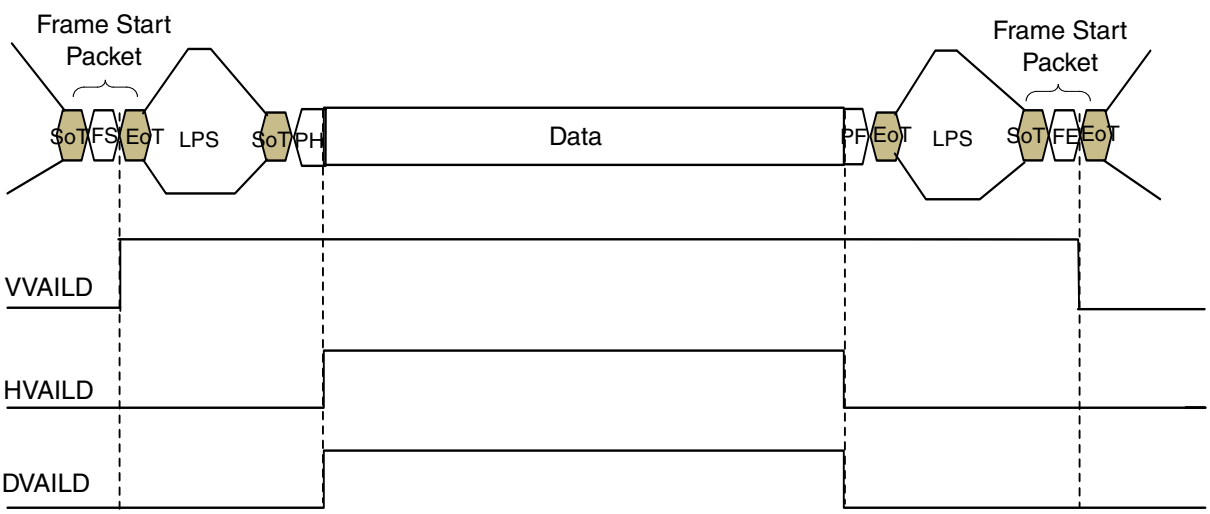


Figure 13-64. Synchronization Example

13.5.3.7 Clock gating for Pixel clock in the idle state

Since CSIS V3.3, it gates the Pixel clock when the target Channel is in idle state. In the following figure , the CLK_GATE signal is triggered at negative edge of pixel clock. The CLOCK_OPEN signal is from VVALID in the Packet Controller. So, Gated pixel clock is alive during the whole frame. The CLOCK_CLOSE signal is set when the O_VVALID of ISP wrapper set to zero, then GATE_FSM generate trail clock for flushing of the F/F in the ISP or CAM. After generating all the trail clocks, the GATE_PIXEL_CLOCK is closed. If the CLOCK_OPEN is set during the TRAIL_CLK state then it quit the state and enters the open state immediately.

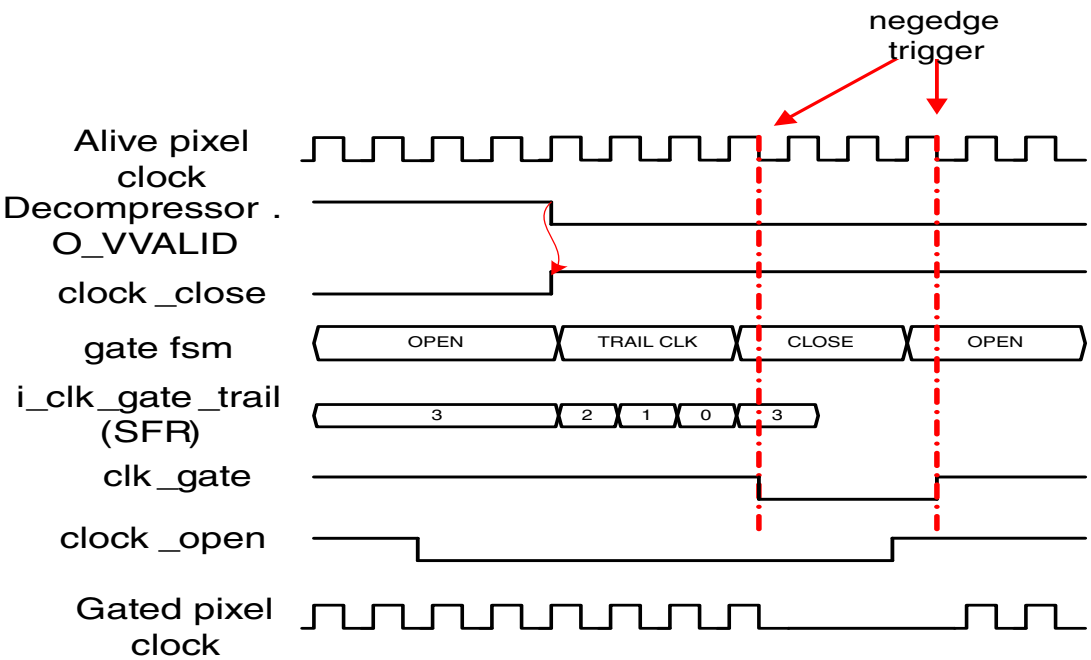

Figure 13-65. Pixel Clock Gating Timing

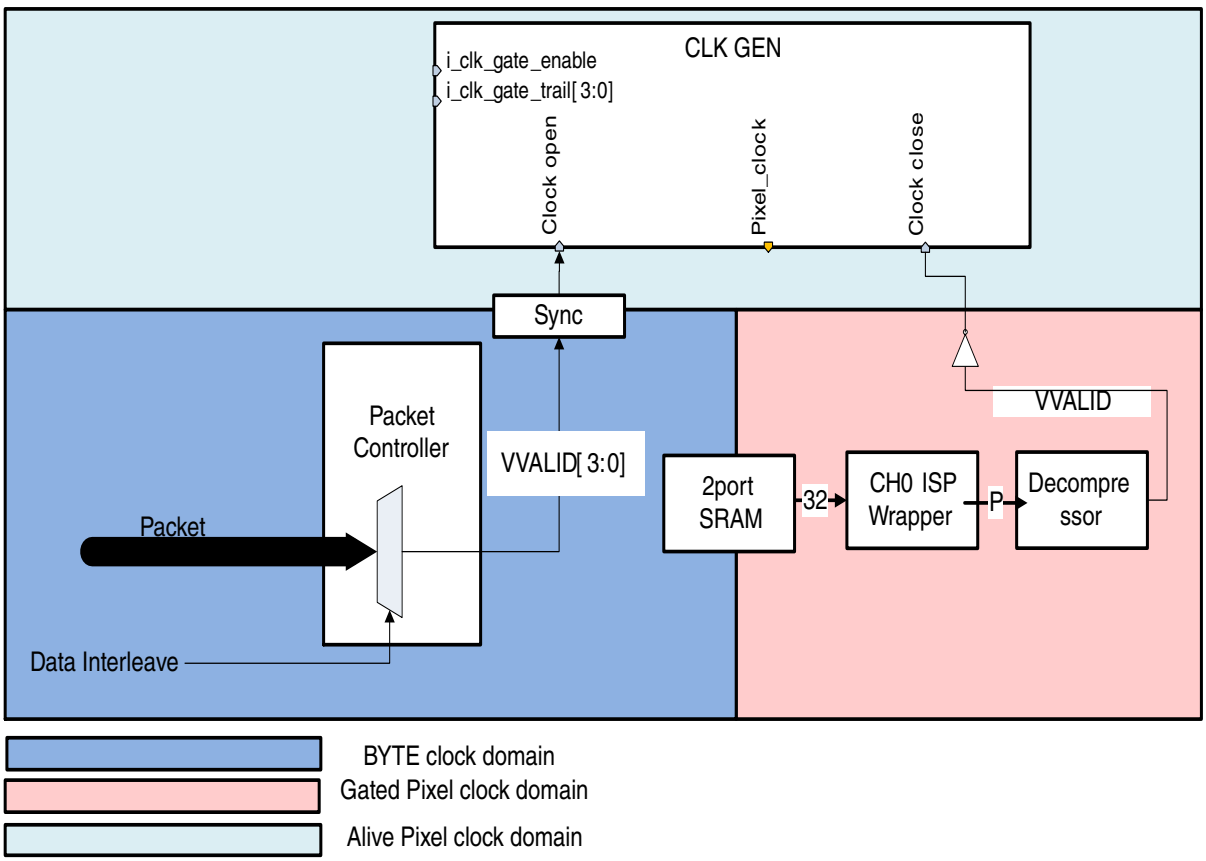

Figure 13-66. Clock Gating Block

13.5.3.8 Shadow update

The configurations related to ISP registers (which are dataformat, vci, resolution and so on.) cannot be varied during the run-time. So they are updated by programming 'UPDATE_SHADOW' (in CSIS_CMN_CTRL register) in idle state. The scheme describes in the following figure.

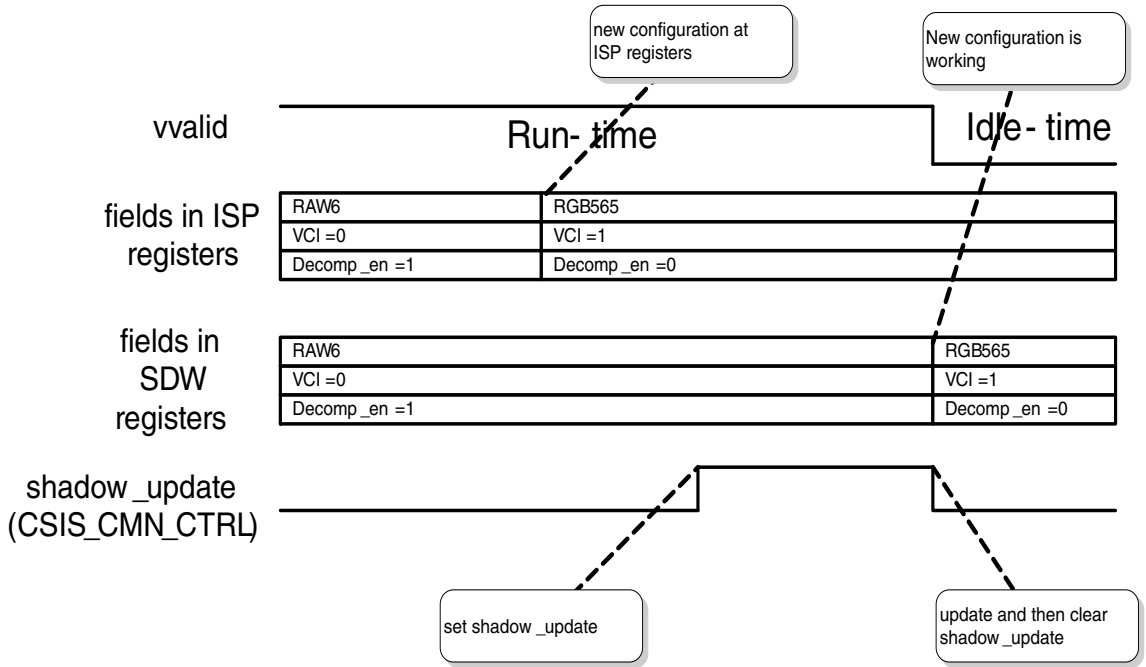

Figure 13-67. Operation of SHADOW_UPDATE

If the frame interleaving scheme(interleave_mode in CSIS_CMN_CTRL = 2 or 3) is used then the instance of entering IDLE_STATE at each ISP channels may be different. In this case, updating shadow registers can be delayed until that all ISP channels are in idle state by setting UPDATE_SHADOW_CTRL.

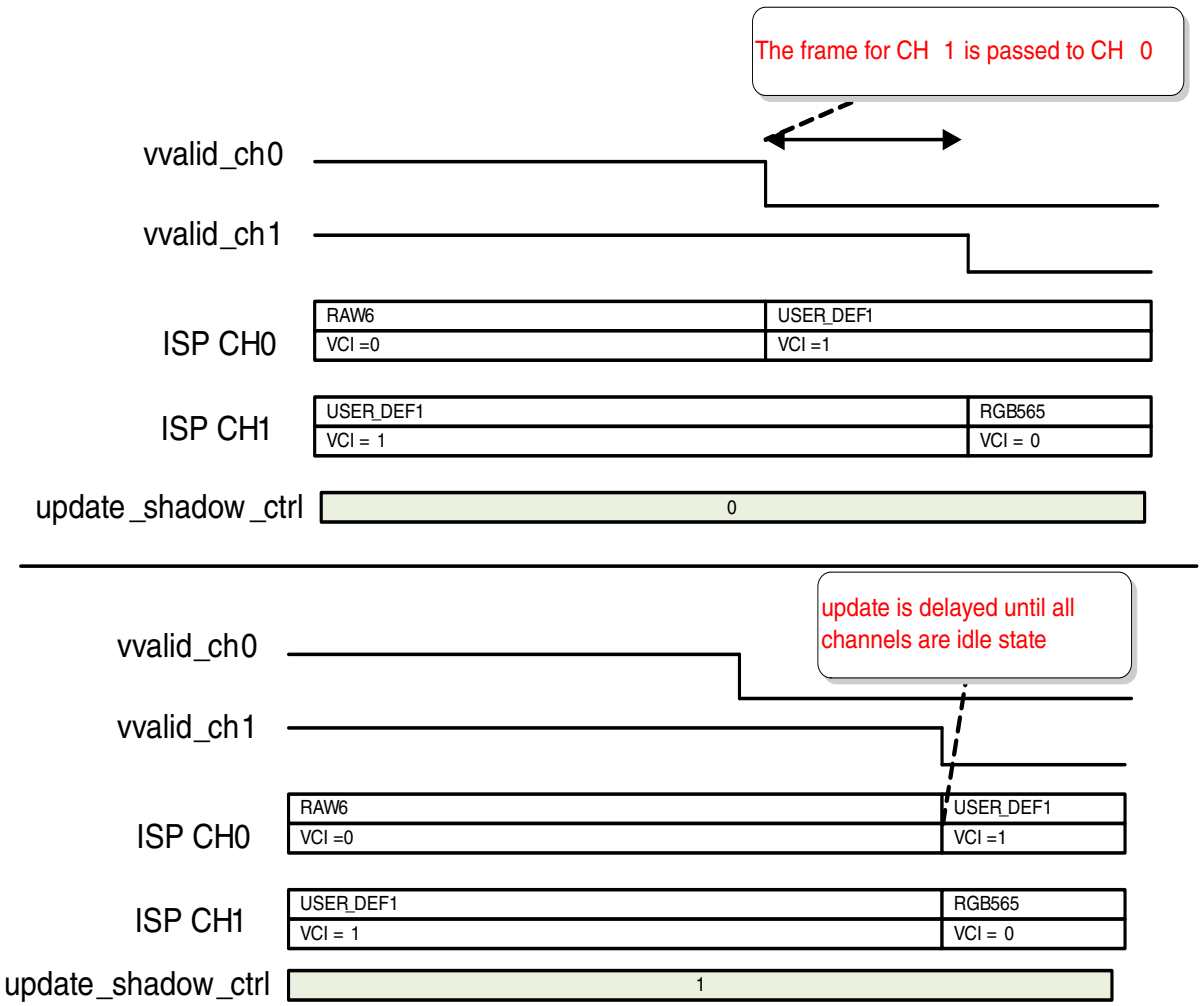

Figure 13-68. Operation of SHADOW_UPDATE_CTRL

13.5.3.9 Guide of MEM_FULL_GAP

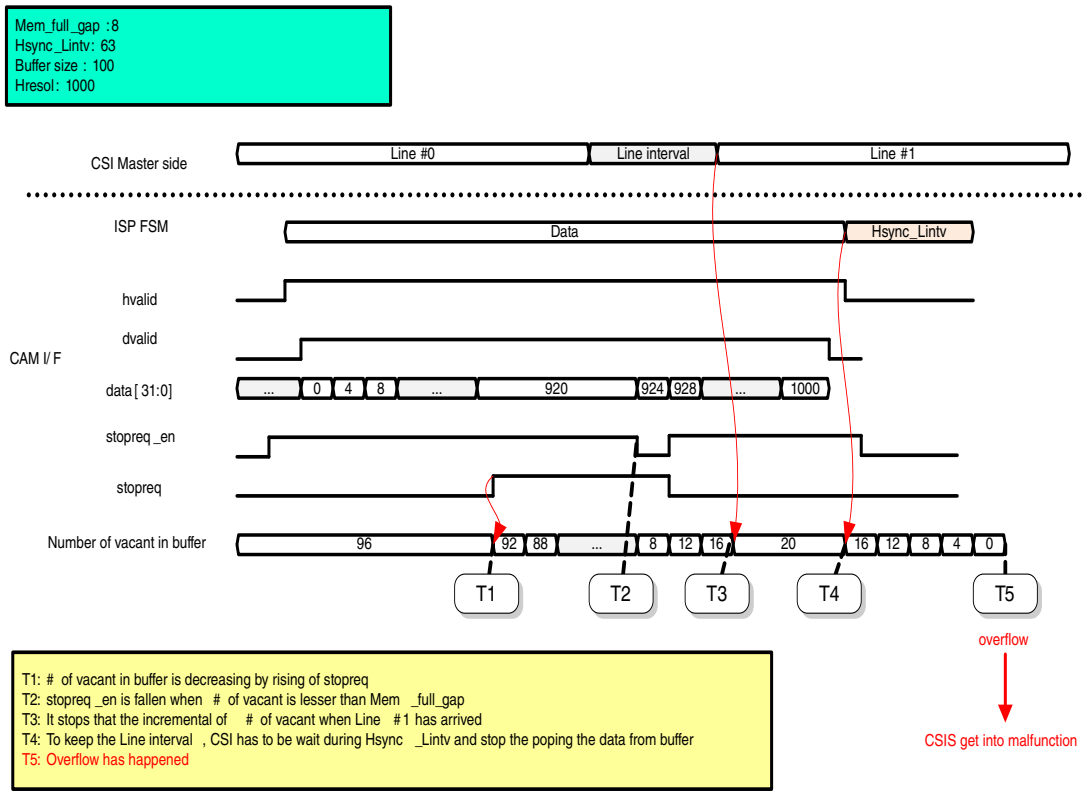

Figure 13-69. Relation Between MEM_FULL_GAP and Sync Interval

Related with Handshaking with back pressure, MEM_FULL_GAP in ISP configuration register should be set carefully because CSIS will be in malfunction if overflow has happened. MEM_FULL_GAP plays a role of preventing buffer overflow by poping out data from the buffer when the empty room of the buffer is lesser than the number of MEM_FULL_GAP. In the HSYNC_LINTV state, it is stopped to pop out data from the buffer. So, the minimum value of the MEM_FULL_GAP should be greater than the amount of data stored during the HSYNC_LINTV state. The related formula is following:

MEM_FULL_GAP ≥ (HSYNC_LINTV + 1) * Pixel clock period / Byte clock period + 8

NOTE

Propagation delay factor

For example:

Condition: HSYNC_LINTV = 31, Pixel clock = 666 MHz, Byte clock = 250 MHz MEM FULL_GAP: (31 + 1) * (1 / 666) / (1 / 250) = 12

'Don't stop last line' plays a role of preventing abnormal operation by ignoring stop request when the last line is transferred. So, do not change the 'Do not stop last line' values (default = 4'b1111) except for debugging.

13.5.3.10 Clock Specification

MIPI CSI may have three clock sources: RX_BYTE_CLK_HS0, I_PCLK, and I_WRAP_CLK.

I_PCLK	PCLK is system clock generated by general processor PLL.
RX_BYTE_CLK_HS0	This signal comes from data lane 0 of D-phy.
I_WRAP_CLK	I_WRAP_CLK is external clock for pixel clock what is for using ISP or CAM I/F.
I_DTLPCLK	D-phy Scan Test clock which is needed at 45 nm process (since 32 nm D-PHY has its own Test clock).

13.5.3.10.1 Clock domain

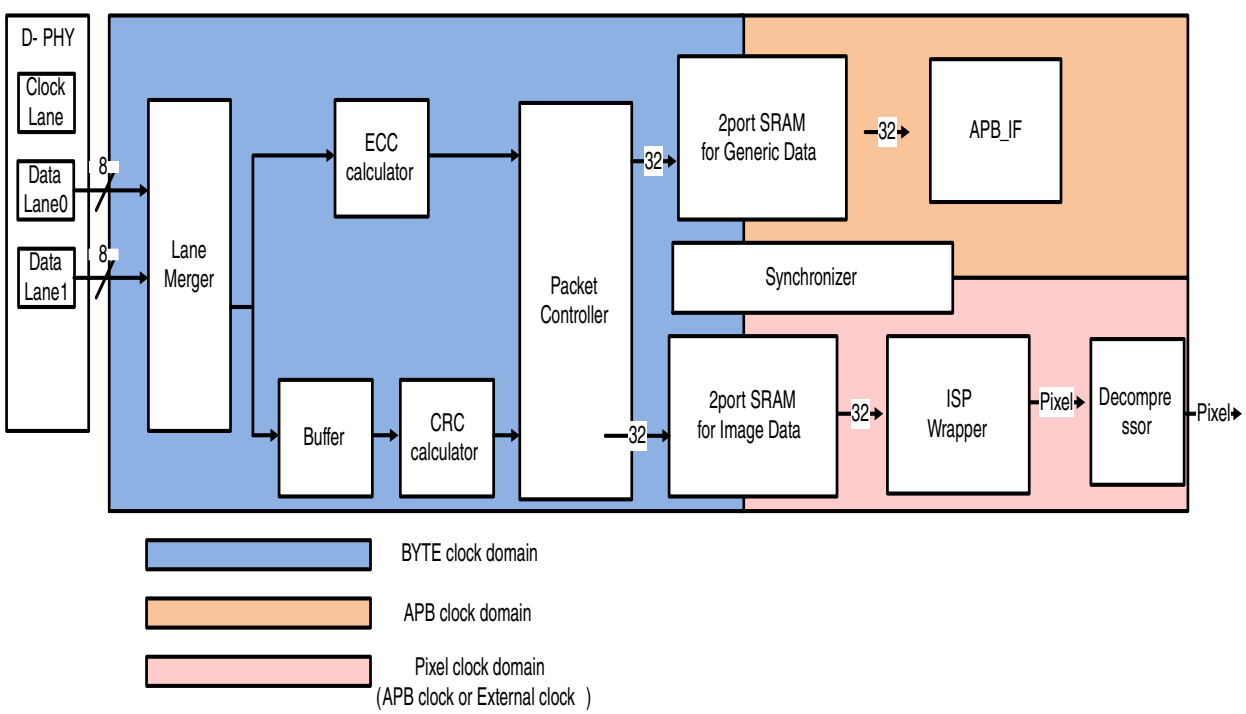

Figure 13-70. Bock Diagram of Clock Domain

Three number of clock domain of CSIS V3.3 is:

- BYTE clock (RX_BYTE_CLK_HS0)
- External clock (I_WRAP_CLK)
- APB clock (I_PCLK)

Pixel clock uses one of those clocks (Wrapper, APB), since CSIS V3.3 does not use BYTE clock for Pixel clock in the User defined data type.

The relationship between input and output bandwidth is that the output bandwidth should be faster than input bandwidth. There is an equation of previous relationship.

(freq. of RX_BYTE_CLK_HS) * (number of data lane) * 8 bits ≤ (freq. of Pixel clock) * (bitwidth of image format)

13.5.3.11 Interface Signals

13.5.3.11.1 Reset and clock signal

Table 13-30. Variation of Clock and Reset

Clock and Reset	Frequency	Clock Generator	Usage
I_PRESETn	—	—	Global Asynchronous reset
I_PCLK	—	System controller	Main control clock (system dependent)
RX_BYTE_CLK_HS0	up to 187.5 MHz (1.5 G) 125 MHz (1 G)	Data lane 0 of D-phy	MIPI CSI processes data with ByteCLK
I_WRAP_CLK	up to 200 MHz	External clock source	Output pixel clock
I_DTLPCLK	up to 200 MHz	External test device	For D-phy scan test mode

13.5.3.11.2 PPI (PHY-Protocol Interface) signals

BandCtrl and HSzeroCtl signals of following table are additional signals for D-phy timing configuration.The other PPI signals in the following table are compatible with MIPI D-phy spec.

Table 13-31. Protocol-to-Phy Interface Signal List

Signal	I/O	Description
Clock lane		
STOP_STATE_CLK	I	Stop state indicator (active high)
ULPS_CLK	I	ULPS state indicator (active low)
ENABLE_CLK	O	Clock lane enabler
Data lane (lane0 ~ 1 common, % = 0 and 1)		

Table continues on the next page...

Table 13-31. Protocol-to-Phy Interface Signal List (continued)

Signal	I/O	Description
RX_BYTE_CLK_HS0	I	Byte Clock
RX_VALID_HS%	I	Received Data is valid.
RX_DATA_HS%[7:0]	I	Data bus for HS transfer
STOP_STATE %	I	Stop state indicator (active high)
ULPS_DAT%	I	ULPS state indicator (active low)
ERR_SOT_HS%	I	Error flag of Start of transmission in HS mode.
ENABLE_D%	O	Data lane enabler
D-Sphy test		
I_DPHY_TESTMODE	I	D-phy test mode
I_DTLPCLK	I	D-phy Test clock
TXESCCLK%	O	Escape mode clock for D-phy test
D-phy config		
O_HS_SETTLE[7:0]	O	Configuration for tuning HS settle time
O_S_CLKSETTLECTRL[1:0]	O	Configuration for D-phy control
O_B_DPHYCTRL[63:0]	O	Configuration for D-phy ac characteristics
O_S_DPHYCTRL[63:0]	O	Configuration for D-phy ac characteristics
O_S_DPDN_SWAP_CLK	O	Swapping Dp and Dn channel of clock lane in D-phy.
O_S_DPDN_SWAP_DAT	O	Swapping Dp and Dn channel of data lanes in D-phy.

13.5.3.11.3 AMBA signal

Table 13-32. APB slave Interface signal list

Signal	I/O	Description
APB Slave		
I_PCLK	I	Main system clock
I_PRESETn	I	Main system reset
I_PADDR[31:0]	I	System address
I_PSEL	I	Module select strobe
I_PWRITE	I	Write strobe
I_PENABLE	I	Enable strobe
I_PWDATA[31:0]	I	Write data to slave module
O_PREADY	O	Slave module is ready (but tied high: always ready).
O_PSLVERR	O	Slave module with error
O_PRDATA[31:0]	O	Read data from slave module

13.5.3.11.4 Image signal

Image output signals are duplicated for output channel 1 to 3.

Table 13-33. Image Output Interface Signal List

Signal	I/O	Description
ISP or CAM I/F		
O_P IX C LK[0]	O	Pixel clock for ISP or CAM I/F This is pixel clock for transferring image date to ISP or CAM I/F. The default clock of this is PCLK. If user wants to assign another clock, Set the WCLK_SRC of CSIS_CNFG register. The relationship of bandwidth between input and output is that output bandwidth should be faster than input bandwidth. The frequency of this clock is determined as following equation. (# of data lane) * (frequency of RX_BYTE_CLK_HS) ≤ (bitwidths of image format) * (frequency of PIXCLK). O_PIX_CLK[0] are worked when the corresponding channels are used
O_VVALID [0]	O	Vertical sync (level) O_VVALID[0] is worked when the corresponding channels are used.
O_HVALID [0]	O	Horizontal sync (level) O_HVALID[0] is worked when the corresponding channels are used.
O_DVALID [0]	O	Data valid O_DVALID[0] is worked when the corresponding channels are used.
O_BVALID[1:0]	O	Byte valid O_BVALID[1:0] is worked when the corresponding channels are used.
O_DATA[31:0]	O	Pixel data O_DATA[31:0] is worked when the corresponding channels are used.

13.5.3.11.5 Sideband signal

Table 13-34. Image Sideband signal list

Signal	I/O	Description
Interrupt		
O_ INT_CSI S	O	Interrupt request signal
I_ INTGEN_SEL	I	Interrupt type selection signal: • 0: Pulse interrupt generation • 1: Level interrupt generation
External clock source		
I_W RAP_ CLK	I	External clock input for wrapper

13.5.3.11.6 Memory I/F

Table 13-35. Memory I/F

Signal	I/O	Description
Memory for Generic data		

Table continues on the next page...

Table 13-35. Memory I/F (continued)

Signal	I/O	Description
O_GEN_MEM_WCLK	O	Write clock (ByteClk)
O_GEN_MEM_WEN	O	Generic data Write enable strobe
O_GEN_MEM_WADDR[10:0]	O	Generic data Write Address
O_GEN_MEM_WDATA[31:0]	O	Generic data Write Data bus
O_GEN_MEM_RCLK	O	Read clock (PCLK)
O_GEN_MEM_RADDR[10:0]	O	Generic data Read Address
O_GEN_MEM_REN	O	Generic data Read enable strobe
I_GEN_MEM_RDATA[31:0]	I	Generic data Read Data bus
Memory for Image data		
O_IMG_MEM_WCLK	O	Write clock (ByteClk)
O_IMG_MEM_WEN	O	Image data Write enable strobe
O_IMG_MEM_WADDR[7:0]	O	Image data Write Address
O_IMG_MEM_WDATA[32:0]	O	Image data Write Data bus
O_IMG_MEM_RCLK	O	Read clock (PIXCLK)
O_IMG_MEM_RADDR[7:0]	O	Image data Read Address
O_IMG_MEM_REN	O	Image data Read enable strobe
I_IMG_MEM_RDATA[32:0]	I	Image data Read Data bus

13.5.3.11.7 Test signal

Table 13-36. Test Related Signal List

Signal	I/O	Description
I_ STMODE	I	Scan Test mode
I_ TCLK_WRAP	I	Scan Test Clock for WRAP clock domain This port is used for testing SCAN at the speed of WRAP clock. If user uses only 1 SCAN test net, this port should be connected to TCLK which is SCAN test clock.
I_ TCLK_WRAP_HALF	I	Scan Test Clock for WRAP / 2 clock domain This port is used for testing SCAN at the half speed of WRAP clock. If user uses only 1 SCAN test net, this port should be connected to TCLK which is SCAN test clock.
I_ TCLK_BYTE	I	Scan Test Clock for BYTE clock domain This port is used for testing SCAN at the speed of BYTE clock. If user uses only 1 SCAN test net, this port should be connected to TCLK which is SCAN test clock.

13.5.3.12 Application Scenario

13.5.3.12.1 Programming model

Table 13-37. Behavior Programming in Each Case

No.	Pseudo Code	Description
Initialize		
1	APB_WRITE(CSIS_INT R_ MSK, -)	Set Interrupt Mask
2	APB_WRITE(DPHY _B CTRL_ L , -)	Set DPHYBCTRL LSB
3	APB_WRITE(DPHY _B CTRL_ H , -)	Set DPHYBCTRL MSB
4	APB_WRITE(DPHY _CMN_ CTRL, 0x11)	Set DPHY HSSETTLE
5	APB_WRITE(ISP _ CONFIG_CH0 , -)	Set ISP_CH0 configuration
6	APB_WRITE(ISP_RESOL_CH0 , -)	Set ISP_CH0 resolution
7	APB_WRITE(ISP _ SYNC_CH0 , -)	Set ISP_CH0 sync
8	APB_WRITE(ISP_CONFIG _CH1, -)	Set ISP_CH1 configuration
9	APB_WRITE(ISP_RESOL _CH1, -)	Set ISP_CH1 resolution
10	APB_WRITE(ISP_SYNC _CH 1 , -)	Set ISP_CH1 sync
11	APB_WRITE(CSIS_CLK_CTRL, -)	Set CSIS clock control
12	APB_WRITE(CSIS_CMN_CTRL, -)	Set CSIS common control (enable CSI)
Run in Data transfer		

13.5.3.12.2 Enable decompressor

Table 13-38. Config CH0 with RAW10 Decomp-en (10 - 14 Decompressor)

No.	Pseudo Code	Description
Initialize		
1	APB_WRITE (ISP_RESOL_CH0, 0x0280_01E0)	Set CH0 Resol (640x480)
2	APB_WRITE (ISP_CONFIG_CH0, 0x0800_03AC)	Set CH0 Config (RAW10, VC:0, Fullgap:8, advanced predict decomp enabled)
3	APB_WRITE (CSIS_CMN_CTRL, 0x0001_0F01)	Set CSIS CMN CTRL (enable system, 4lane, VCI and DT interleave, ISP0 update)
Run in Data transfer		

13.5.4 Register

MIPI_CSI2 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3075_0004	CSIS Common Control (MIPI_CSI2_CSIS_CMN_CTRL)	32	R/W	0000_0000h	13.5.4.1/ 3772
3075_0008	CSIS Clock gate Control (MIPI_CSI2_CSIS_CLK_CTRL)	32	R/W	0000_00F0h	13.5.4.2/ 3774

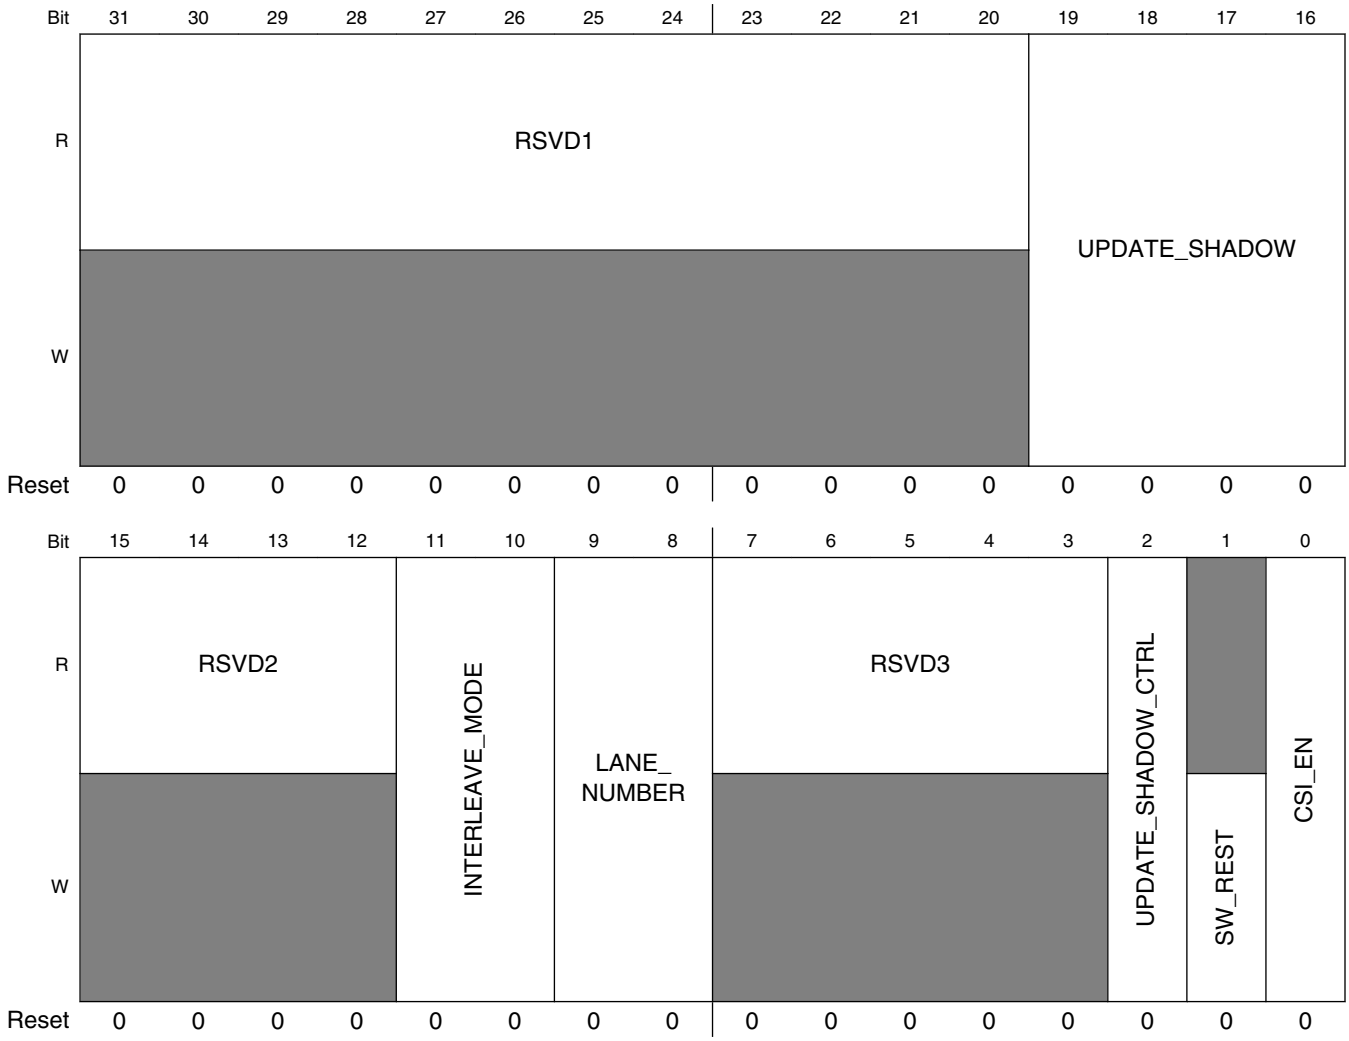
3075_0084	Shadow Resolution register of CH0 (MIPI_CSI2_SDW_RESOL_CH0)	32	R	0800_0800h	13.5.4.15/ 3790
3075_0088	Shadow SYNC register of CH0 (MIPI_CSI2_SDW_SYNC_CH0)	32	R/W	0000_0000h	13.5.4.16/ 3790
3075_00C0	Debug Control register (MIPI_CSI2_DBG_CTRL)	32	R/W	0000_0F00h	13.5.4.17/ 3791
3075_00C4	Debug Interrupt Mask (MIPI_CSI2_DBG_INTR_MSK)	32	R/W	0000_0000h	13.5.4.18/ 3792
3075_00C8	Debug Interrupt Mask (MIPI_CSI2_DBG_INTR_SRC)	32	R/W	0000_0000h	13.5.4.19/ 3794
3075_2000	Non Image Data (MIPI_CSI2_NON_IMG_DATA)	32	R/W	Undefined	13.5.4.20/ 3795

13.5.4.1 CSIS Common Control (MIPI_CSI2_CSIS_CMN_CTRL)

Address: 3075_0000h base + 4h offset = 3075_0004h



MIPI_CSI2_CSIS_CMN_CTRL field descriptions

Field	Description
31–20 RSVD1	Reserved Read as zero, do not modify.
19–16 UPDATE_ SHADOW	Strobe of updating shadow registers After configuration, user has to set this bit for updating shadow registers. This bit is cleared automatically after updating shadow registers. Bit 19, 18, 17 is reserved. Bit 16 set for CH0. 0 Default 1 Update the shadow registers

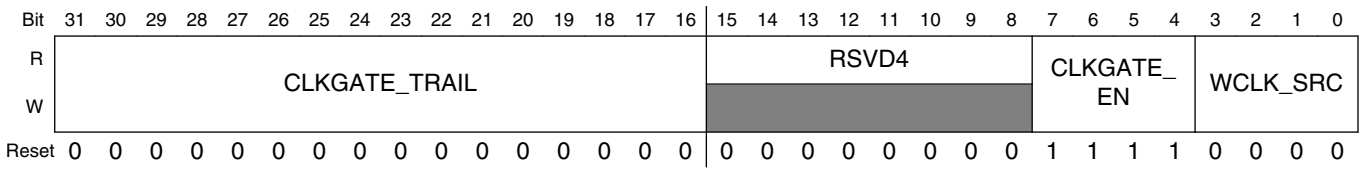
Table continues on the next page...

MIPI_CSI2_CSIS_CMN_CTRL field descriptions (continued)

Field	Description
15–12 RSVD2	Reserved Read as zero, do not modify.
11–10 INTERLEAVE_ MODE	Select Interleave mode, VC (Virtual channel) and DT (Data type) 11 VC and DT 10 VC only 01 DT only 00 CH0 only, no data interleave
9–8 LANE_NUMBER	Number of data lane 00 1 data lane 01 2 data lane 10 Reserved 11 Reserved
7–3 RSVD3	Reserved Read as zero, do not modify.
2 UPDATE_ SHADOW_CTRL	Update Shadow Control Enable this reg is recommended when interleave_mode is 2 or 3. 0 Disable (default) 1 Enable
1 SW_REST	Software Reset All writable registers in CSI2 go back to initial state. After this bit is active for three cycles, this bit will be deasserted automatically. **NOTE:** Almost MIPI CSI2 block uses “ByteClk” from D-phy. This “ByteClk” is not continuous clock. User has to assert software reset when Camera module is turned off. 0 Ready 1 Reset
0 CSI_EN	MIPI CSI2 system enable 0 Disable 1 Enable

13.5.4.2 CSIS Clock gate Control (MIPI_CSI2_CSIS_CLK_CTRL)

Address: 3075_0000h base + 8h offset = 3075_0008h

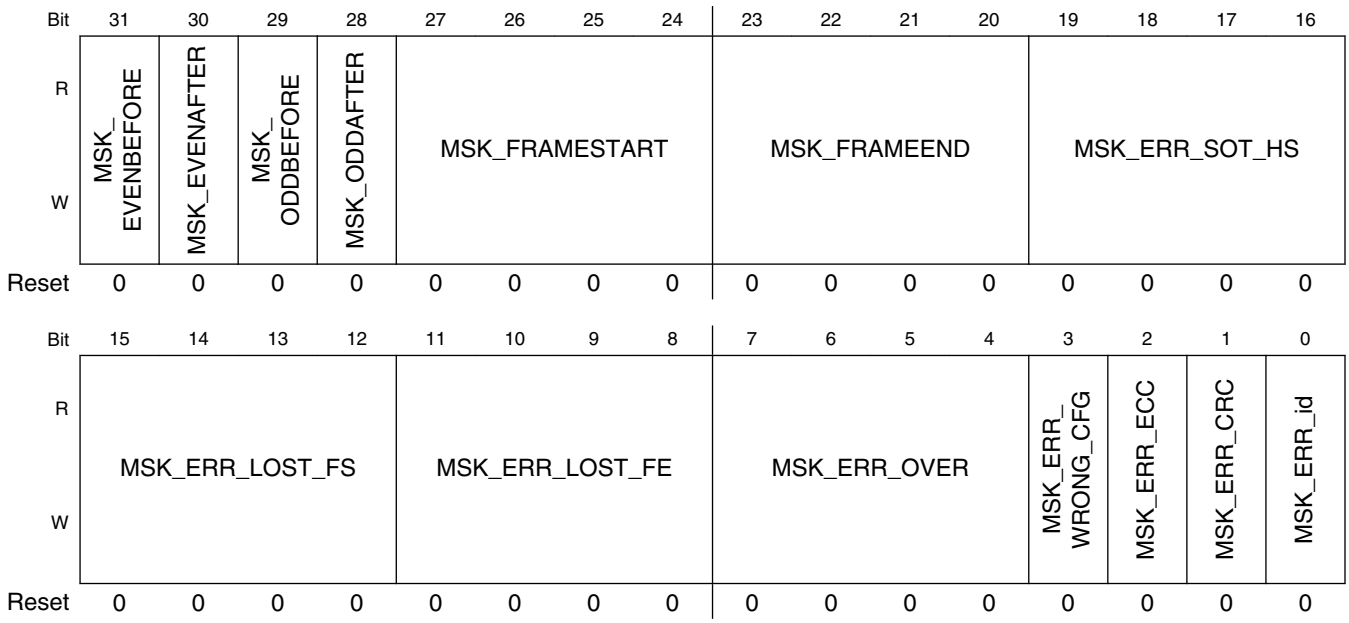


MIPI_CSI2_CSIS_CLK_CTRL field descriptions

Field	Description
31–16 CLKGATE_TRAIL	0 ~ 15 (1~16 Trailing clocks) [31:28], [27:24], [23:20] Reserved; [19:16] CH0. Trailing clocks are used for poping the F/F of ISP or CAM.
15–8 RSVD4	Reserved Read as zero, do not modify.
7–4 CLKGATE_EN	Bit 7, 6, 5 is reserved, bit 4 set for CH0. 0 Pixel clock is always alive. 1 Pixel clock is alive during the interval of frame.
WCLK_SRC	Pixel Clock Source This bit determines source of Pixel clock, which is clock of transferring image data to ISP or CAM I/F. Bit3, 2, 1 is reserved, bit0 set for CH0. 0 PCLK 1 EXTCLK (WRAP_CLK)

13.5.4.3 CSIS Interrupt Mask (MIPI_CSI2_CSIS_INT_MSK)

Address: 3075_0000h base + 10h offset = 3075_0010h



MIPI_CSI2_CSIS_INT_MSK field descriptions

Field	Description
31 MSK_ EVENBEFORE	Non Image data are received at Even frame and Before Image. 0 Disable (masked) 1 Enable (unmasked)
30 MSK_ EVENAFTER	Non Image data are received at Even frame and After Image. 0 Disable (masked) 1 Enable (unmasked)
29 MSK_ ODDBEFORE	Non Image data are received at Odd frame and Before Image. 0 Disable (masked) 1 Enable (unmasked)
28 MSK_ ODDAFTER	Non Image data are received at Odd frame and After Image. 0 Disable (masked) 1 Enable (unmasked)
27–24 MSK_ FRAMESTART	FS packet is received, [CH3,CH2,CH1,CH0] 0 Disable (masked) 1 Enable (unmasked)

Table continues on the next page...

MIPI_CSI2_CSIS_INT_MSK field descriptions (continued)

Field	Description
23–20 MSK_ FRAMEEND	FE packet is received, [CH3,CH2,CH1,CH0] 0 Disable (masked) 1 Enable (unmasked)
19–16 MSK_ERR_ SOT_HS	Start of transmission error [reserved, reserved, Lane1, Lane0] 0 Disable (masked) 1 Enable (unmasked)
15–12 MSK_ERR_ LOST_FS	Lost of Frame Start packet, [CH3,CH2,CH1,CH0] 0 Disable (masked) 1 Enable (unmasked)
11–8 MSK_ERR_ LOST_FE	Lost of Frame End packet, [CH3,CH2,CH1,CH0] 0 Disable (masked) 1 Enable (unmasked)
7–4 MSK_ERR_ OVER	Image FIFO overflow interrupt, [CH3,CH2,CH1,CH0] 0 Disable (masked) 1 Enable (unmasked)
3 MSK_ERR_ WRONG_CFG	Wrong configuration 0 Disable (masked) 1 Enable (unmasked)
2 MSK_ERR_ECC	ECC Error 0 Disable (masked) 1 Enable (unmasked)
1 MSK_ERR_CRC	CRC Error 0 Disable (masked) 1 Enable (unmasked)
0 MSK_ERR_id	Unknown ID Error 0 Disable (masked) 1 Enable (unmasked)

13.5.4.4 CSIS Interrupt Source (MIPI_CSI2_CSIS_INT_SRC)

Address: 3075_0000h base + 14h offset = 3075_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	EVENBEFORE	EVENAFTER	ODDBEFORE	ODDAFTER	FRAMESTART				FRAMEEND				ERR_SOT_HS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ERR_LOST_FS				ERR_LOST_FE				ERR_OVER				ERR_WRONG_CFG	ERR_ECC	ERR_CRC	ERR_ID
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MIPI_CSI2_CSIS_INT_SRC field descriptions

Field	Description
31 EVENBEFORE	Non Image data are received at Even frame and Before Image.
30 EVENAFTER	Non Image data are received at Even frame and After Image.
29 ODDBEFORE	Non Image data are received at Odd frame and Before Image.
28 ODDAFTER	Non Image data are received at Odd frame and After Image.
27–24 FRAMESTART	FS packet is received, [CH3,CH2,CH1,CH0]
23–20 FRAMEEND	FE packet is received, [CH3,CH2,CH1,CH0]
19–16 ERR_SOT_HS	Start of transmission error, [reserved, reserved, Lane1 , Lane0]
15–12 ERR_LOST_FS	Indication of lost of Frame Start packet, [CH3,CH2,CH1,CH0]
11–8 ERR_LOST_FE	Indication of lost of Frame End packet, [CH3,CH2,CH1,CH0]
7–4 ERR_OVER	Overflow is caused in image FIFO, [CH3,CH2,CH1,CH0] Outer bandwidth has to be faster than imputer bandwidth. But image FIFO can be overflow because of user's fault. There are two ways for preventing overflow. 1. Tune output pixel clock faster than current

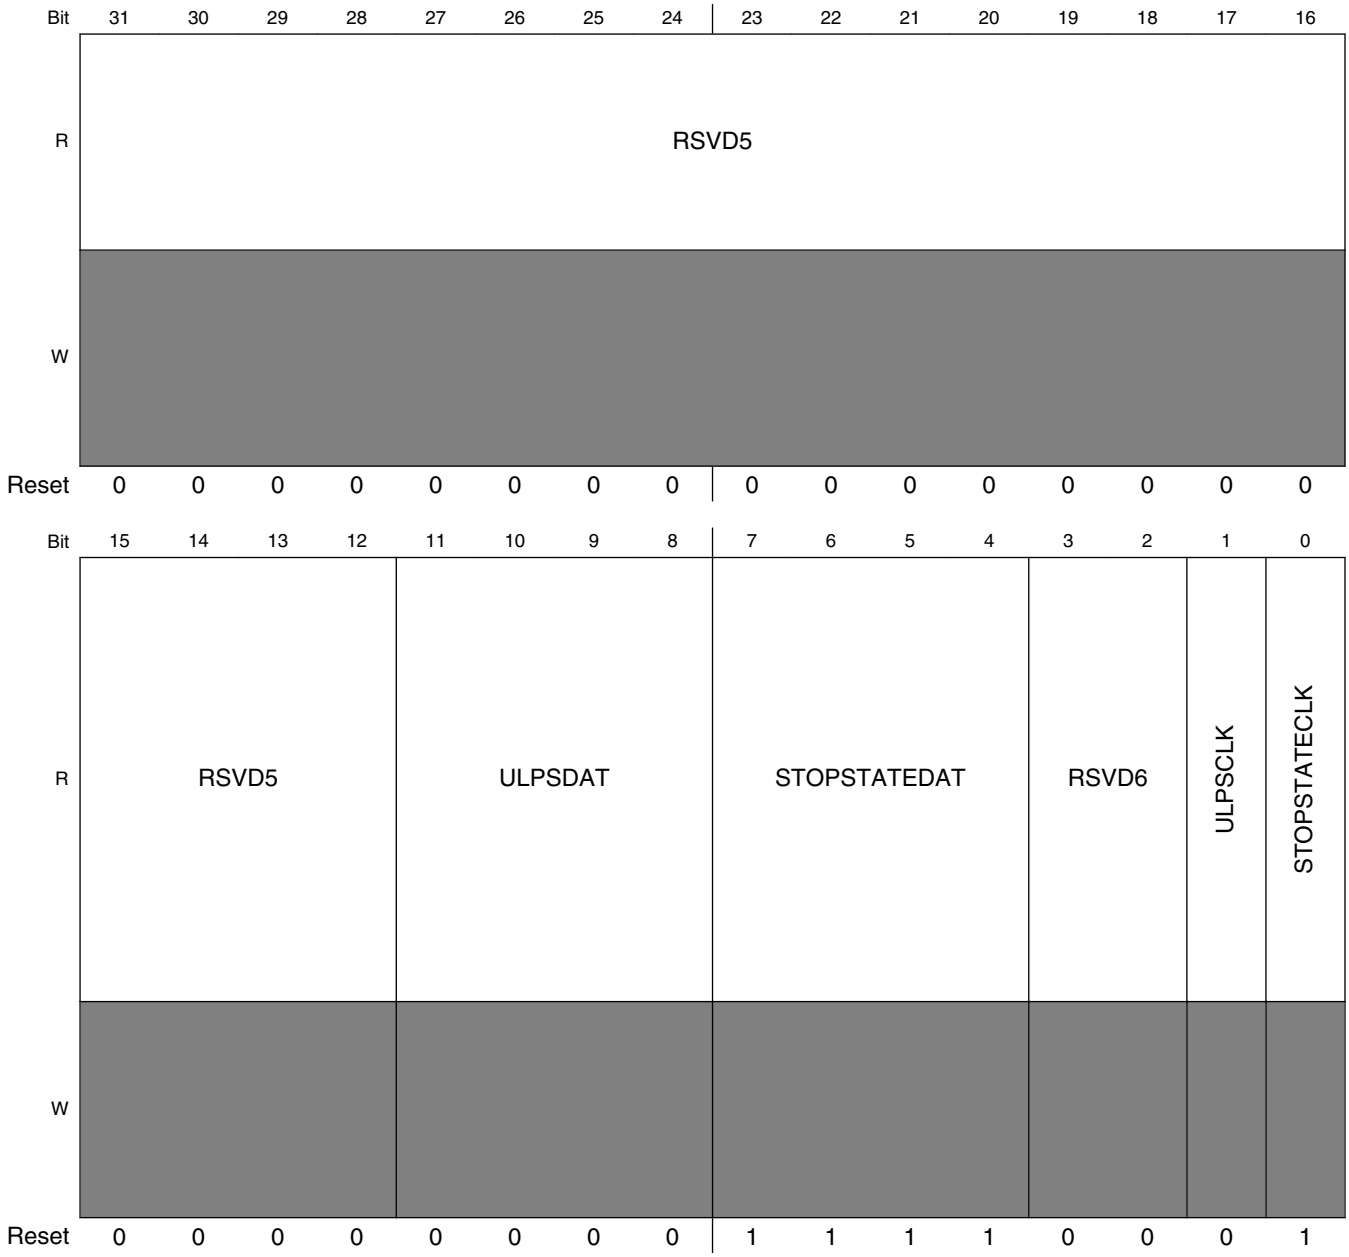
Table continues on the next page...

MIPI_CSI2_CSIS_INT_SRC field descriptions (continued)

Field	Description
	2. Tune input byte clock slowr than current First case: WCLK_SRC in CSIS_CTRL register can be set 1, and then assign faster clock Second case: user can set register in camera module through I^2C channel. When this interrupt is generated, 1. Turn camera off 2. Assert software reset, if you didn't assert software reset, MIPI CSIS could not receive any more data. 3. Tune the clock frequency and re-configure all related registers MIPI CSIS module is ready for operating.
3 ERR_WRONG_CFG	Wrong Configuration The received packet is not decoded at any channels of ISP (due to wrong data type or virtual channel ID)
2 ERR_ECC	ECC Error
1 ERR_CRC	CRC Error
0 ERR_ID	Unknown ID Error

13.5.4.5 D-PHY Status (MIPI_CSI2_DPHY_STATUS)

Address: 3075_0000h base + 20h offset = 3075_0020h



MIPI_CSI2_DPHY_STATUS field descriptions

Field	Description
31–12 RSVD5	Reserved Read as zero, do not modify.
11–8 ULPSDAT	Data lane [3:0] is in ULPS.

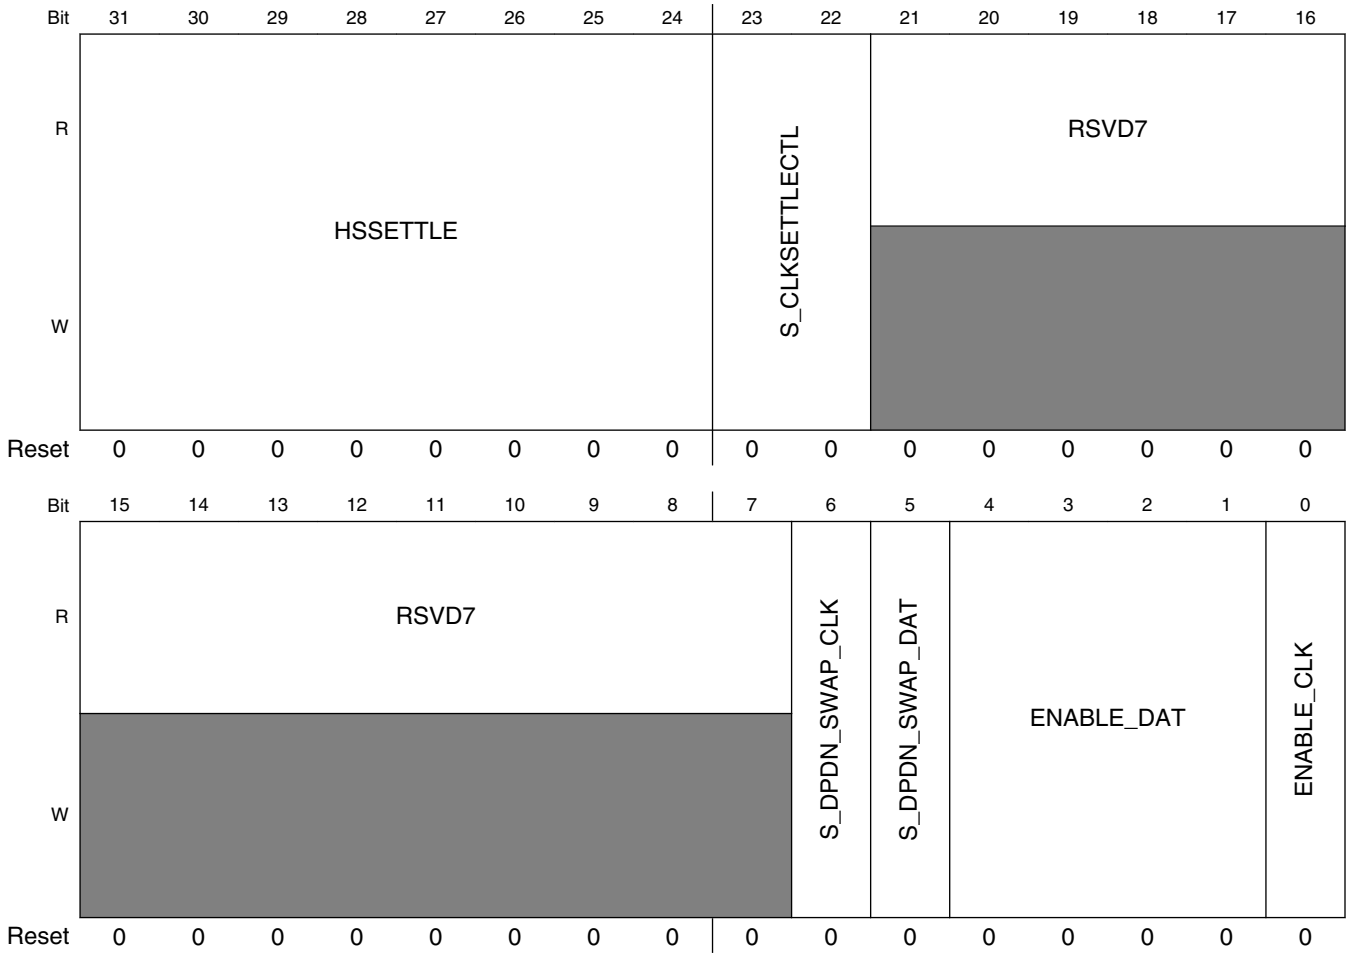
Table continues on the next page...

MIPI_CSI2_DPHY_STATUS field descriptions (continued)

Field	Description
	[11]: Reserved [10]: Reserved [9]: Data lane 1 [8]: Dsata lane 0 0 Not ULPS 1 ULPS —
7–4 STOPSTATEDAT	Data lane [3:0] is in Stop State. [7]: Reserved [6]: Reserved [5]: Data lane 1 [4]: Data lane 0 0 Not Stop state 1 Stop state
3–2 RSVD6	Reserved Read as zero, do not modify.
1 ULPSCLK	Clock lane is in ULPS. 0 Not ULPS 1 ULPS
0 STOPSTATECLK	Clock lane is in Stop state. 0 Not Stop state 1 Stop state

13.5.4.6 D-PHY Common Control (MIPI_CSI2_DPHY_CMN_CTRL)

Address: 3075_0000h base + 24h offset = 3075_0024h



MIPI_CSI2_DPHY_CMN_CTRL field descriptions

Field	Description
31–24 HSSETTLE	HS-RX settle time control register
23–22 S_ CLKSETTLECTL	D-PHY control register is for standard spec v0.9 of MIPI CSI2.
21–7 RSVD7	Reserved Read as zero, do not modify.
6 S_DPDN_ SWAP_CLK	Swapping Dp and Dn channel of clock lane. 0 Default 1 Swapped

Table continues on the next page...

MIPI_CSI2_DPHY_CMN_CTRL field descriptions (continued)

Field	Description
5 S_DPDN_ SWAP_DAT	Swapping Dp and Dn channel of data lanes. 0 Default 1 Swapped
4–1 ENABLE_DAT	D-PHY enable [3]: Reserved [2]: Reserved [1]: Data lane 1 [0]: Data lane 0 0 Disable 1 Enable
0 ENABLE_CLK	D-PHY clock lane enable 0 Disable 1 Enable

13.5.4.7 D-PHY Master and Slave Control register low (MIPI_CSI2_DPHY_BCTRL_L)

Address: 3075_0000h base + 30h offset = 3075_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13.6 Pixel Pipeline (PXP)

13.6.1 Overview

This document describes the micro-architecture for the Pixel Processing Pipeline used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder.

It is used to minimize the memory footprint required for the display pipeline and provide an area and performance optimized to both SDRAM-less and SRAM-based systems.

The PXP integrates of several independent processing stages into a cohesive strategy to create flexible pixel pipeline.

The PXP combines scaling, color space conversion (or CSC), alpha-blending, secondary color space conversion (or CSC2), pixel conversion lookup memory table (or LUT) ,rotation , dithering and waveform processing into a single processing engine, as shown in Figure 13-71. By integrating multiple blocks, a few intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity.

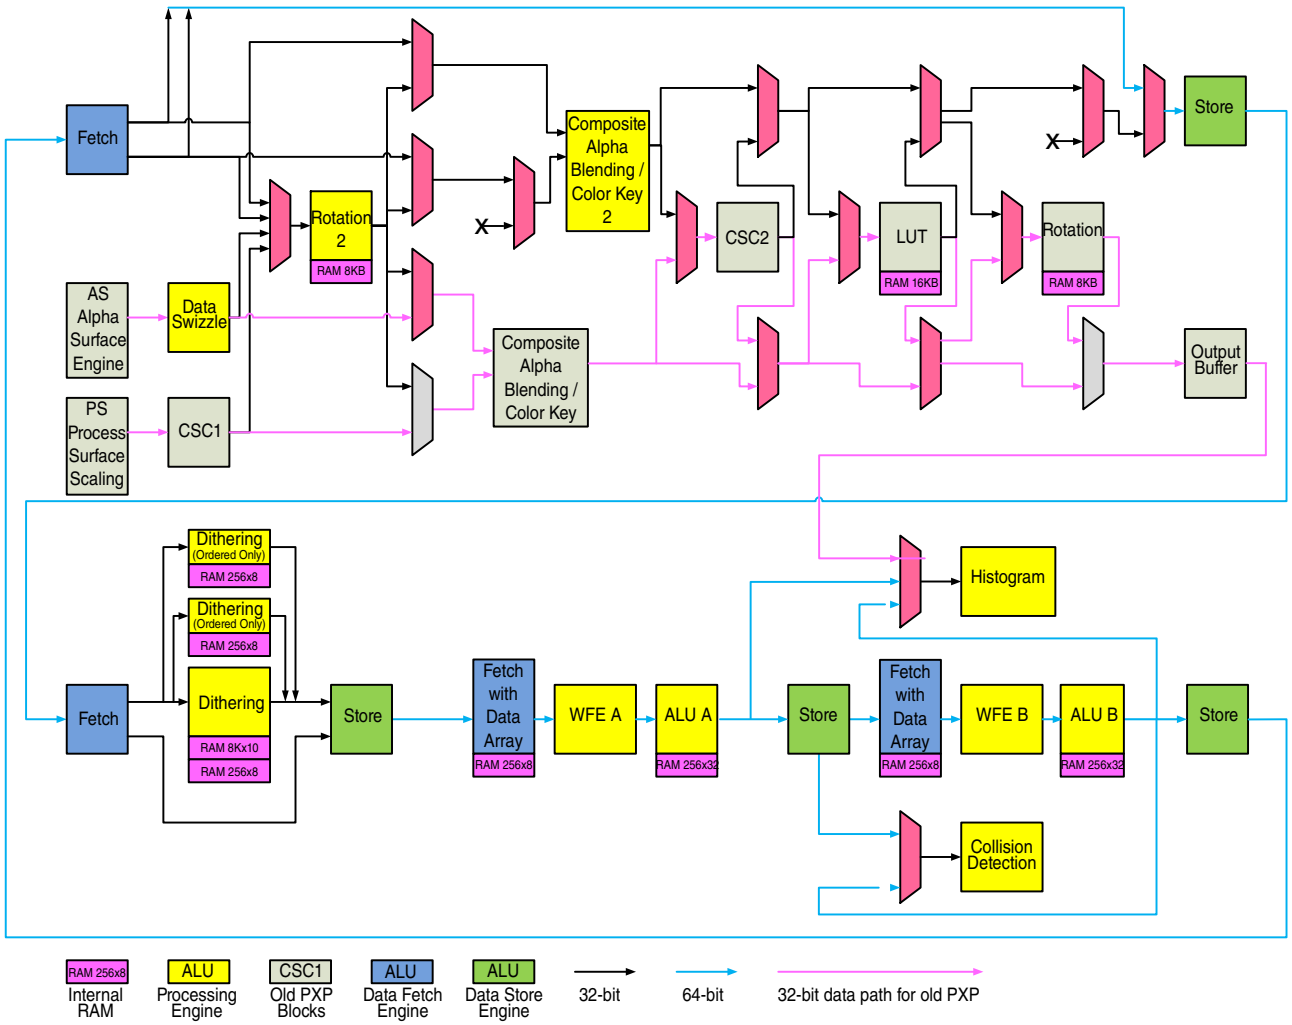

Figure 13-71. PXP Architecture

13.6.2 Clocks

The following table describes the clock sources for PXP. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 13-39. PXP Clocks

Clock name	Clock Root	Description
clk	pxp_axi_clk_root	PXP clock

13.6.3 Top-level architecture

The PXP consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction , input and/or output rotation, dithering and waveform processing. It is also capable of fetching data from and storing data to memory.

The legacy blocks operate within the requirements of the legacy PXP architecture, and perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The legacy pipeline operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order. The dither blocks and the waveform processing engines (WFE) will operate in a scan line format based on the active size. The input fetch and store engines can work on either on a block by block basis or in the scan line format.

Figure 13-71 shows the high-level architecture of the scaling, color space conversion, blending, pixel correction , rotation engines, dithering, waveform processing, histogram along with four sets of fetch and store engines. The Alpha Surface Engine fetches one RGB graphics plane alpha surface (AS). The scaling engine fetches a single processed surface (PS), which can be blended with the AS surface. The scaling engine also supports an alpha channel for the PS image. Although the legacy PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS are inclusive within the output buffer.

Figure 13-72 represents a sample output buffer configuration with both an AS and PS included. The alignment of each AS and PS within the output buffer can be at any arbitrary pixel locations. For example, the PS has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS is bounded by the LRC of the output buffer, 15,15 for this example.

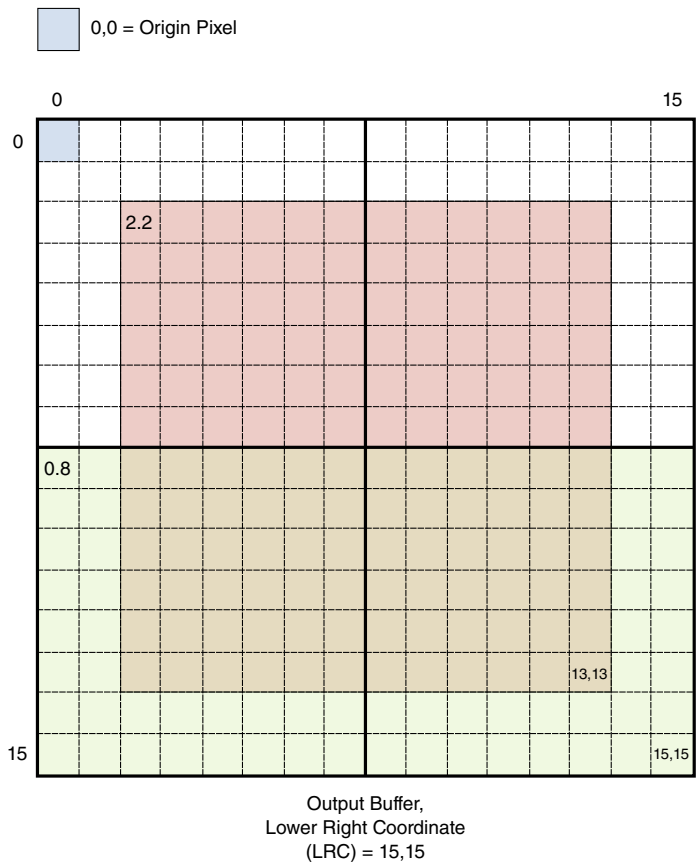

Figure 13-72. Sample output buffer configuration

The AS engine supports RGB pixel formats, and the PS engine supports ARGB, RGB, YUV, and YCbCr pixel formats. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There are two rotate engines in the PXP pipeline. Rotation can occur after image composition, at the output of the PS engine, or both. In the first scenario, all the data produced by the AS and PS engines is rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces. The Rotate engine at the input can also be used with the input fetch engine. For this, the fetch engine needs to be programmed in the blok mode to fetch a block of size 8x8. The CSC2 unit can convert to any RGB, YUV, or YCbCr color spaces for final output. Pixels can be corrected using a programmable LUT resource to achieve any desired pixels effects. For detailed information, please refer to Output Modes to RGBW4444CFA. The dither engine supports 3 dithering modes in addition to the standard quantization and pass-through modes. The dithering algorithms supported are: Ordered, Floyd-Steinberg and Atkinson. The WFE is a programmable engine that can be programed as required to process each pixel and pixel meta data. The Histogram sub-block collects statistics about the pixel data passing through it that is

useful to the EPDC in waveform selection and displaying the frame. The Histogram also contains mask and comparison functionality that can be used for collision detection and reporting of the collided area within an update area.

The PXP also supports two parallel image processing paths. The legacy flow can operate in parallel with the input fetch engine or the dithering or waveform processing engines. Please refer to HW_PXP_CTRL and HW_PXP_CTRL2 for details on how to enable each of the individual data flows. In addition to this, the CSC, Rotation 1 and LUT engines can be used as either part of the legacy flow or as a part of the second parallel data flow. These blocks can work in the scan line format or in block format. There are two separate blending engines for each flow.

13.6.3.1 Processing Details

The legacy PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.

This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed. The new architecture has four sets of fetch and store engines to enable parallel image processing and the ability to use only parts of the block like the dithering, or WFE or parts of the legacy flow.

Since the output of the rotation block must be NxN pixel blocks in scan order, the entire legacy pipeline will operate on NxN pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

Legacy Processing Pipeline

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset x, y. When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. Then, the CSC2 module can convert the

resulting pixels back into the YUV output color space. If the final output color space is YUV and there is no compositing required (AS not present, for example), then both the CSC units can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, LUT, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported. The two CSC units in the overall pixel data path must be used to achieve the desired source frame compositing and output pixel formatting.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel processing pipeline use the SRAM to maintain the double buffer block intermediate buffer.

The New Processing Pipelines

The input fetch and store engines can work in either block mode or in scan line format. As they can work with the rotate1 engine, they were designed to support blocks of size 8x8. The dither and WFE fetch and store eingines work in scan line format. The WFE fetch engines have internal memory of 32 words where each word is 64 bits. The store engines can co-ordinate data flow through the pipeline to the next fetch engine by either using the handshake mode or the bypass mode. In the handshake mode, the store engine of the previous stage writes to the memory and signals the next stage fetch engine that the programmed number of lines are ready to be fetched. In the bypass mode, the store engine sends data to the next stage fetch engine through standard handshake protocol followed by the legacy modules.

The input fetch engine has another alpha blender/color key module connected to it. Along with that, the muxes can be programed to use the rotate1 engine, the LUT and the CSC2 engine.

13.6.3.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.

The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC2 module can by bypassed or enabled to convert pixels to any output color space. In the case of processing RGB pixels in the PS engine, the CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provide a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

13.6.3.3 Decimation Image Scaling

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

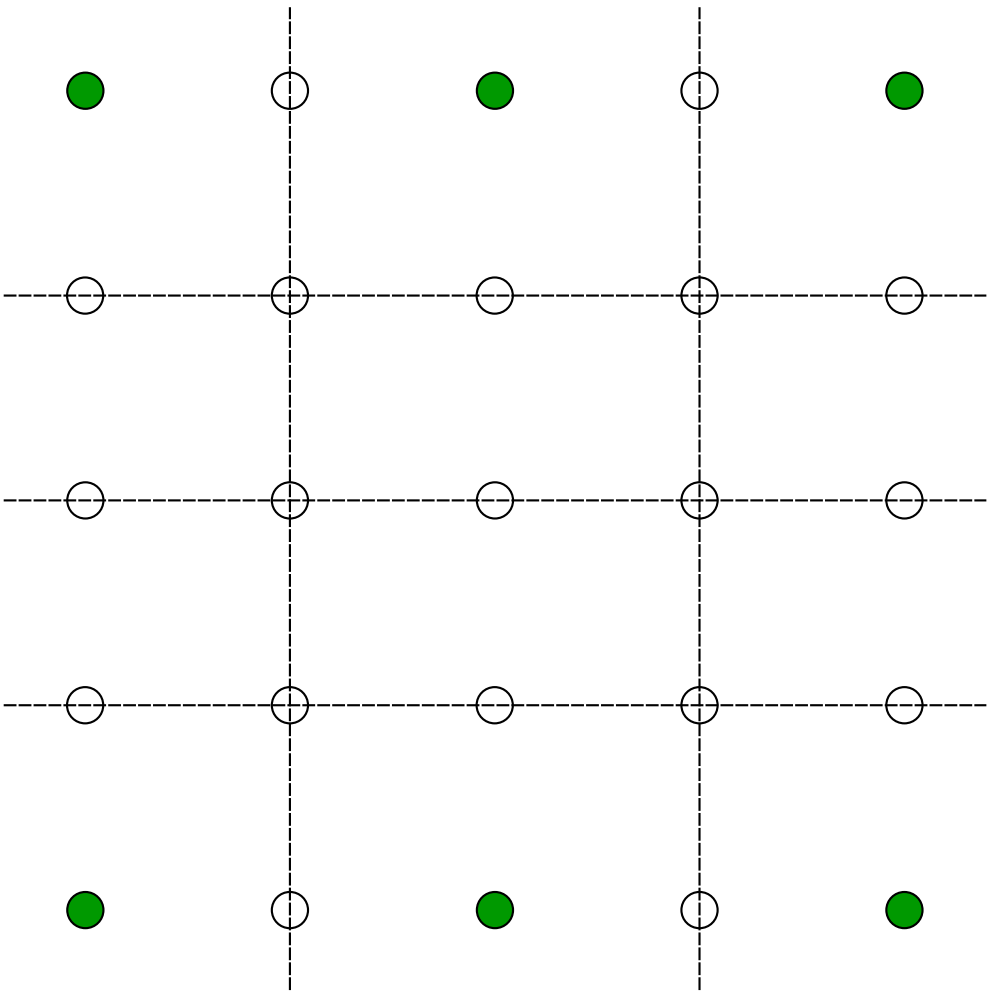

Figure 13-73. RGB decimation X /2, Y /4

Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

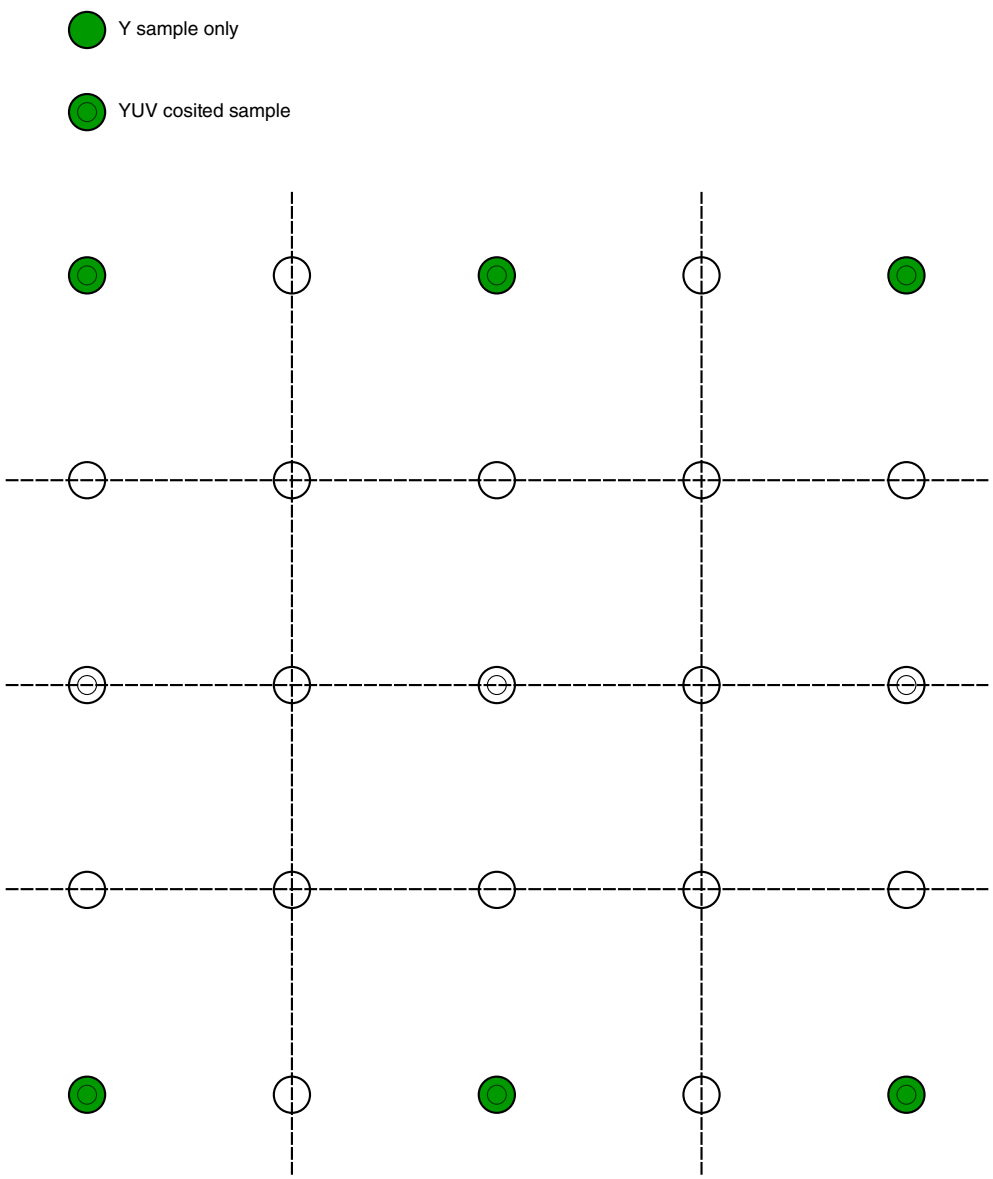

Figure 13-74. YUV420 decimation X /2, Y /4

13.6.3.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG_CSC1_COEF0[YCBCR_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	pixel0	pixel1	average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

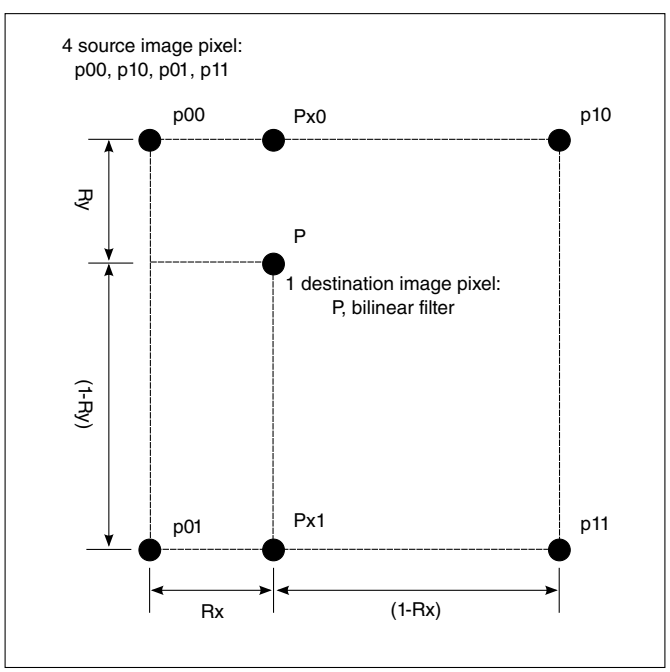

Figure 13-75. Output Pixel Value

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

Px0 = p00*(1-Rx) + p10*Rx

Px1 = p01*(1-Rx) + p11*Rx

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

P = Px0*(1-Ry) + Px1*Ry

13.6.3.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

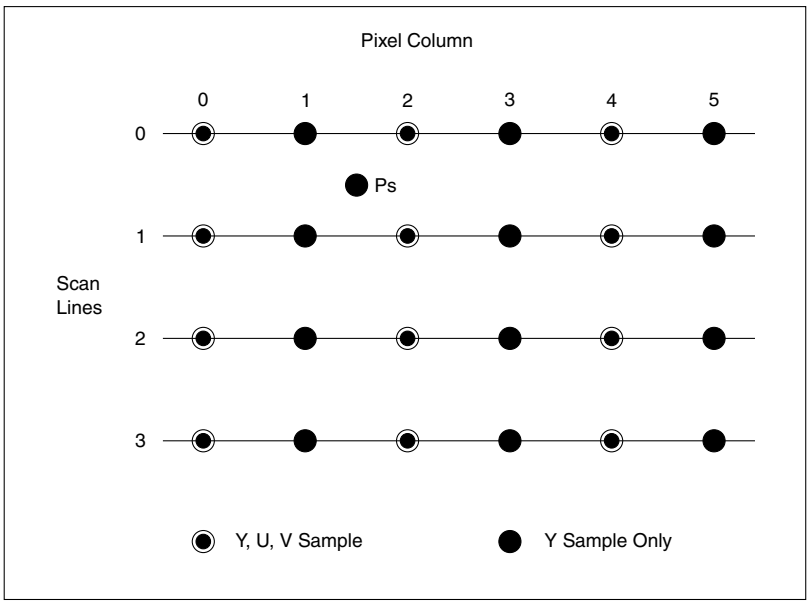

Figure 13-76. YUV Sample Positioning, 4:2:2

Consider the scaled output pixel Ps (pixel scaled) which has an accumulated step function of X=1.5 and Y=0.5. The remainder for the step function is Rx = 0.5 and Ry = 0.5. Or, the sub pixel position of output pixel Ps is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of Ps is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for Ps.

For the U and V components of Ps, there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is Ry=0.5 (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of X=1.5 has a remainder Rx=0.75. Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at Ps.

13.6.3.6 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain ¼ the data that the luma frame buffers store.

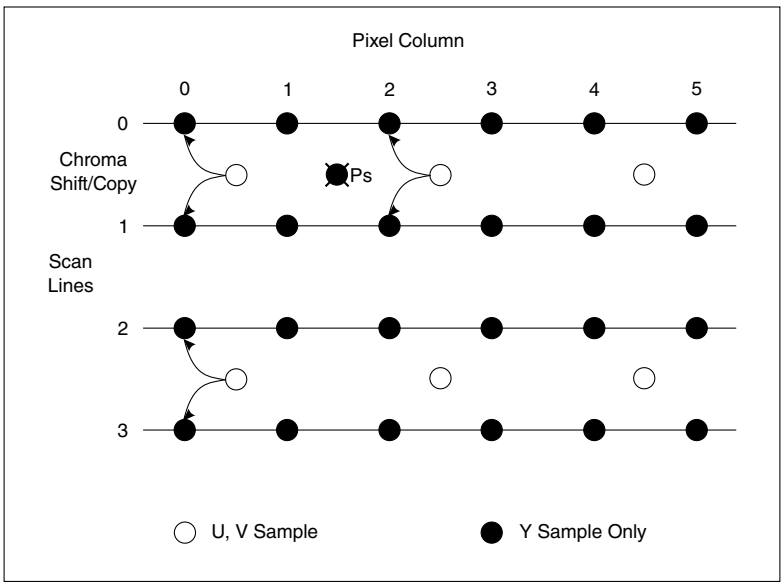

Figure 13-77. YUV Sample Positioning, 4:2:0

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel Ps.

1. All chroma samples from the input source image are shifted left and up by ½ a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel Ps in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].

For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.

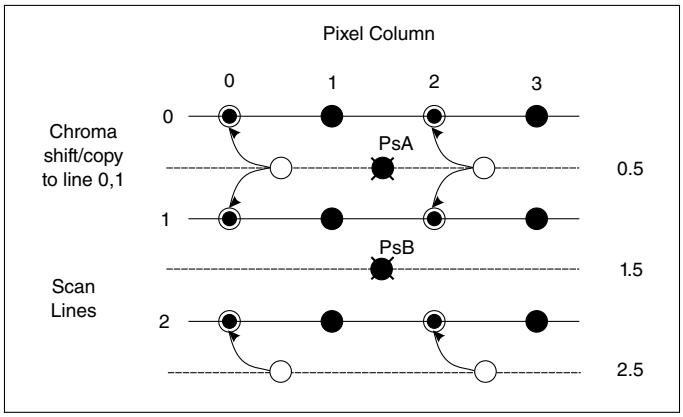

Figure 13-78. Scaled Chroma Computation Examples

The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

13.6.3.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.

Then each color component is passed to the scaling engine and each component is treated in the same manor. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manor.

13.6.3.8 Color Space Conversion (CSC)

There are two modules in the PXP to convert pixels between color spaces. They are referred to as CSC1 and CSC2 (for lack of a better naming convention).

CSC1 exists after the scaling unit and is dedicated to converting from YUV to RGB. CSC2 is a full duplex color space converter in that is can convert into either RGB or YUV (or YCbCr) color spaces depending on the desired output pixel format. All coefficients are programmed as two's compliment numbers and both CSC units can be bypassed if CSC is not desired at either position of these CSC units in the pixel data path.

13.6.3.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr -> RGB conversion. The constants will be stored in the PXP control registers as two's compliment values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

R = C0(Y+Yoffset) + C1(V+UVoffset)

G = C0(Y+Yoffset) + C3(U+UVoffset) + C2(V+UVoffset)

B = C0(Y+Yoffset) + C4(U+UVoffset)

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

13.6.3.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

13.6.3.11 CSC2 operation

The CSC2 module receives pixels in any color space and can convert the pixels into any of RGB, YUV, or YCbCr color spaces.

All coefficients are programmable and in the two's compliment notation. The output pixels are passed onto the LUT and rotation engine for further processing.

The following equations indicate the CSC2 modules ALU architecture.

Selecting RGB output in REG_CSC2_CTRL[CSC_MODE] configures the ALU in the following manor:

R = A1(Y-D1) + A2(U-D2) + A3(V-D3)

G = B1(Y-D1) + B2(U-D2) + B3(V-D3)

B = C1(Y-D1) + C2(U-D2) + C3(V-D3)

Selecting YUV output configures the ALU in the alternate manor:

Y = A1*R + A2*G + A3*B + D1

U = B1*R + B2*G + B3*B + D2

V = C1*R + C2*G + C3*B + D3

Saturation of each color channel is checked and corrected for excursions outside the nominal color space. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

NOTE

CSC2 may not be able to perform RGB to YCbCr or RGB to YUV conversion correctly. Only the Y conversion may be correct. In that case, conversion for CbCr and UV components

may require alternate chip resources either from GPU, IPU, or CPU if applicable.

13.6.3.12 Alpha Blending/Color Key

There are two alpha blending/color key engines in the new PXP. Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes. For the second alpha blending engine, the fetch engine should be programmed to fetch data in the RGB format. You can either use the 2 fetch channels or use either fetch channel with the PS.

Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion.

All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS or fetch data channels source pixels.

13.6.3.13 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel.

An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the REG_AS_CTRL[ALPHA] and REG_AS_CTRL[ALPHA_CTRL] register fields. If REG_AS_CTRL[ALPHA_CTRL] = ALPHA_OVERRIDE , the alpha value for the pixel is taken from the REG_AS_CTRL[ALPHA] . This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If REG_AS_CTRL[ALPHA_CTRL] = ALPHA_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

Gá = PIO programmed global alpha (8-bit value).

Eá = Embedded alpha associated with AS pixel.

á = Gá * Eá + 0x80

The result for the red channel as an example:

R[7:0] = (á * PS.r) + ((1 - á) * AS.r)

When á is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if á is 0x00 for a given pixel, PS will be loaded as the output pixel.

REG_AS_CTRL[ALPHA_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

13.6.3.14 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur. Conversely, if PS is within the AS color key range, then PS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:

CK0.r.low <= PS.r <= CK0.r.high

CK0.g.low <= PS.g <= CK0.g.high

CK0.b.low <= PS.b <= CK0.b.high

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

13.6.3.15 LUT

The lookup table (LUT) is used to modify pixels in a manner that is not linear and that cannot be achieved by the color space conversion modules.

Nonlinear response to the input pixels can be achieved based on how the lookup table is programmed.

Programming of the direct access LUT table can be facilitated by single PIO register writes or DMA access. For efficient loading of the LUT, DMA access should be used.

13.6.3.16 Lookup Modes

The LUT has four lookup modes. The lookup modes determine how the src_pixel is used to address the LUT memory.

The four lookup modes are:

1. DIRECT_Y8
2. DIRECT_RGB444
3. DIRECT_RGB454
4. CACHE_RGB565

The DIRECT modes access the LUT memory as a monolithic SRAM. The CACHE_RGB565 will access the memory as a 2-way set associative cache.

13.6.3.17 DIRECT_Y8

DIRECT_Y8 is used for a 256-byte lookup. In DIRECT_Y8, the most significant byte of the pixel is used to address the LUT entry.

This byte reflects the Y/R channel of the pixel data path. Luma, or monochrome, transformations are possible with this lookup mode. The address is generated as: src_pixel[23:16]. In DIRECT_Y8 operation, the memory is byte addressable.

13.6.3.18 DIRECT_RGB444

DIRECT_RGB444 is used for a 8KB (4K pixel) RGB444 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. To take advantage of the full 16KBmemory, the REG_LUT_CTRL[SEL_8KB] bit can be used to select the upper or lower 8KB memory, thus facilitating the use of 2 separate 444 LUT tables. In DIRECT_RGB444, the src_pixel is RGB/YUV[23;0] data is used to generate the lookup address. The address is generated as: {R/Y[23:20],G/U[15:12],B/V[7:4]}. In DIRECT_RGB444, the memory is pixel (2 byte) addressable.

13.6.3.19 DIRECT_RGB454

DIRECT_RGB454 is used for a 16KB (8K pixel) RGB454 to RGB565 lookup.

Pixel formats that are in the YUV color space at the position of the LUT in the PXP data path can also be converted. In DIRECT_RGB454, the src_pixel is RGB/YUV[23;0] data is used to generate the lookup address. The address is generated as: {R/Y[23:20],G/U[15:11],B/V[7:4]}. In DIRECT_RGB454, the memory is pixel (2 byte) addressable.

13.6.3.20 CACHE_RGB565

The CACHE_RGB565 lookup is used for a 128KB (65K pixel) RGB/YUV565 to RGB/YUV565 lookup.

The 128KB memory requirement is too costly from an area perspective to implement a complete lookup table in the LUT's on chip memory. For this reason, a LRU (least recently used) 16KB 2-way set associative cache has been implemented to reference the full 128KB lookup table stored in external memory.

The 2-way set associative cache is organized in the following way:

- 16KB total data storage
- 512 entries split between 256 ways
- 6 pixels/entry cache line

Cache efficiency is very critical. For a cache miss, the PXP will be stalled until the cache line can be filled. For a 32 bit DDR memory interface, the latency can be calculated as follows:

cycles latency for read command through DDR controller + CAS Latency + # burst cycles for read data to be returned + # cycles latency for data through DDR controller to LUT + 1 cycle for cache access of new data

The src_pixel is RGB[23:0] data used to generate the lookup address. To improve the cache efficiency the RGB/YUV565 address and the lookup table must be formatted in the following way:

Address: A[15:0] = $R_7G_7G_6B_7$ $R_6G_5B_6$ $R_5G_4B_5$ $R_4G_3B_4$ $R_3G_2B_3$

The address is organized as follows:

- A[15:12] tag address, used to compare a hit between cache ways
- A[11:4] index address, used to select cache set (i.e. row of memory)
- A[3:0] block address, used to select Pixel in the cache line

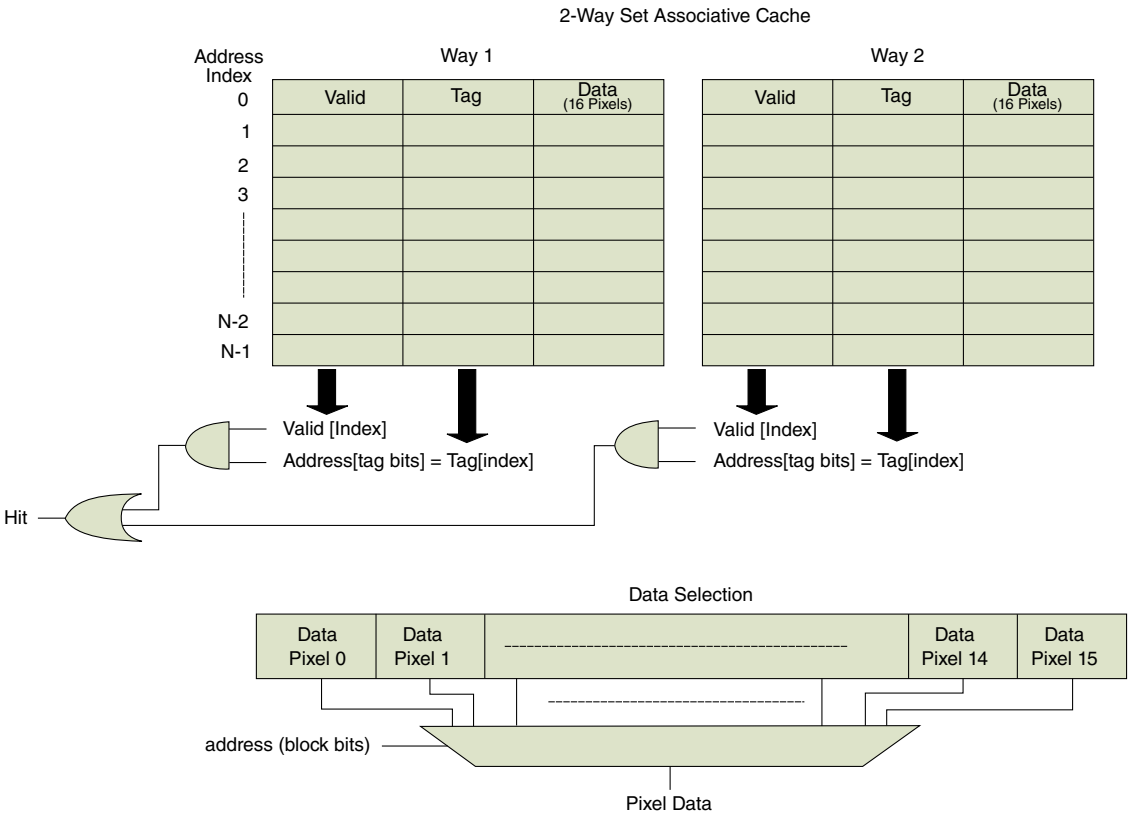

Figure 13-79. 2-Way Set Associative Cache and Data Selection

13.6.3.21 Output Modes

The LUT has three output modes for color space conversion.

1. Y8
2. RGBW4444CFA
3. RGB888

13.6.3.22 Y8

With out_mode set to Y8, in conjunction with DIRECT_Y8 lookup mode, the intended operation is Gama Correction.

Only the third byte is processed by the lookup table. The third byte is represented by the Y value or the R value in the data path since pixel data is either YUV[23:0] or RGB[23:0] where the Y or R byte encompass bits [23:16] respectfully. So, bits 15:0 are

always bypassed and left unchanged. Currently, the LUT is intended to process Y data when any YUV, Y8, or Y4 output pixel formats are selected. However, this resource can be enabled and used for any conceivable purpose.

Note: When the DIRECT_RGB444, DIRECT_RGB454 or CACHE_RGB565 lookup mode is selected in conjunction with the Y8 output mode the low order byte of the two bytes read from the LUT memory will be used as the Gama Correction value.

13.6.3.23 RGBW4444CFA

With REG_LUT_CTRL[OUT_MODE] set to RGBW4444CFA, the REG_CFA[DATA] is used to select one nibble from the LUT 16 bit output value.

The LUT memory lookup will contain a RGBW4444 value. The REG_CFA[DATA] will select the R,G,B or W nibble as the pixel value to present to the PXP data path based on the matrix defined by the REG_CFA[DATA] register. The 4 bit value is presented in the Y, or third byte lane, of the PXP data path. The final pixel transferred to the next PXP stage is {CFA[3:0],CFA[3:0],LUT[15:0]}

13.6.3.23.1 CFA Correction

The 32-bit REG__CFA[DATA] register is used to encode 16 CFA correction values.

The CFA correction values are encoded as follows:

- 00 selects R
- 01 selects G
- 10 selects B
- 11 selects W

The CFA correction uses 4x4 block processing. Figure 5; CFA mapping translation shows how CFA 4x4 blocks will iterate over the PXP's 8x8 or 16x16 pixel block being processed:

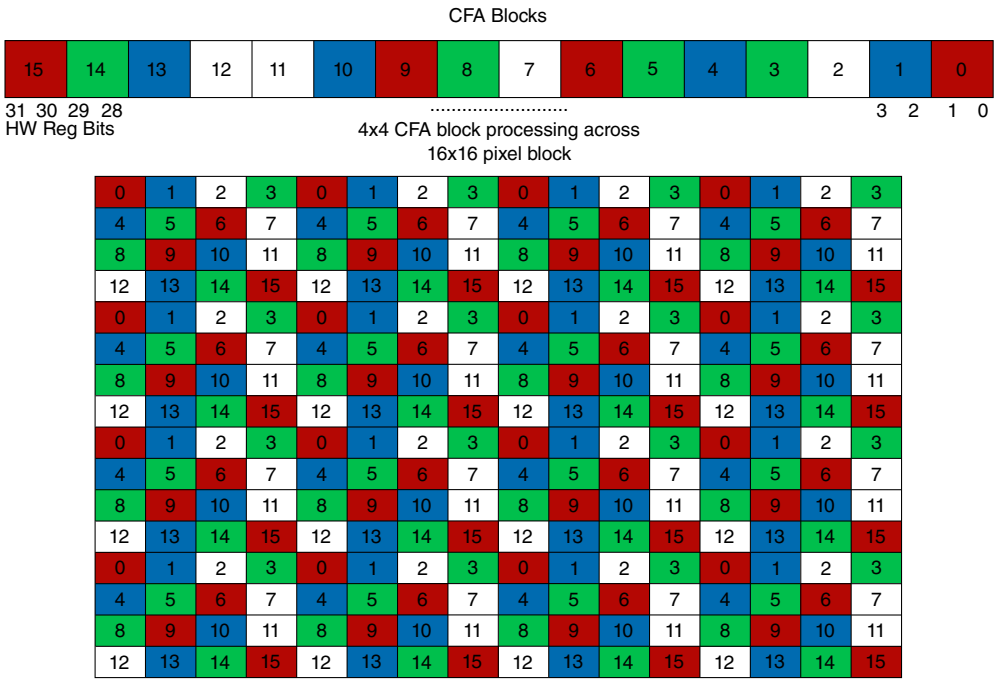

Figure 13-80. CFA mapping translation

13.6.3.24 RGB888

With out_mode set to RGB888, the memory output data is interpolated from RGB565 to RGB888.

The RGB[23:0] data is formatted as follows: R[7:3]R[7:5],G[7:2]G[7:6],B[7:3]B[7:5].

13.6.3.25 Rotation

There are two rotation engines integrated into the PXP. Rotation can occur after compositing the AS and PS buffers in the output stage.

The PS buffer can be rotated and later composited with the AS surface that is not rotated. The rotation1 engine can also be used with the Input Fetch engine.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in a alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

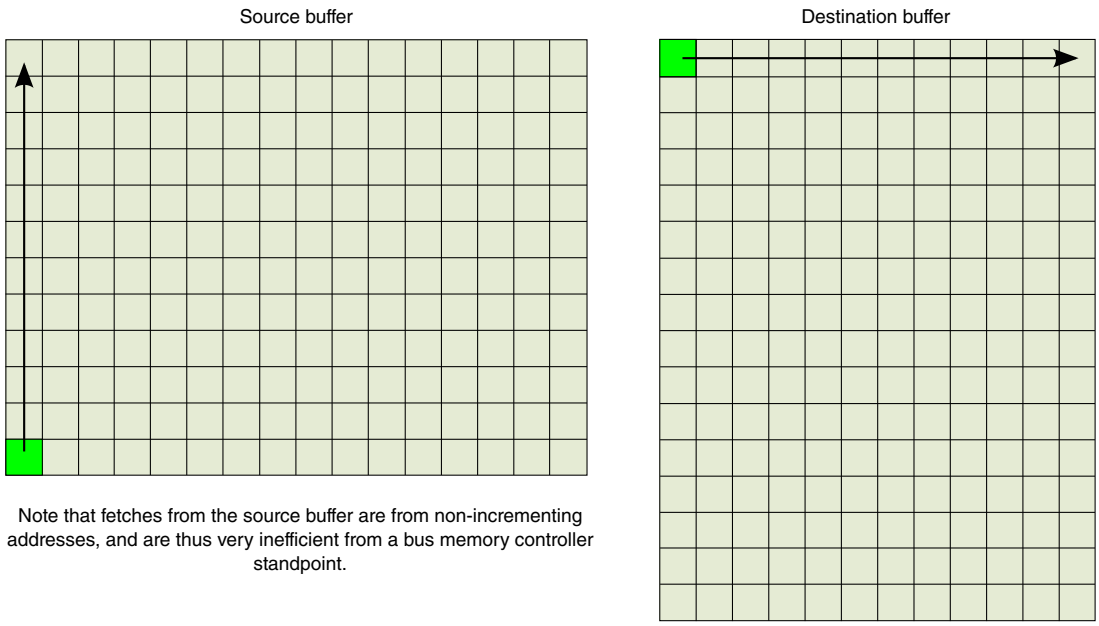

Figure 13-81. Rotation Read and Write

In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

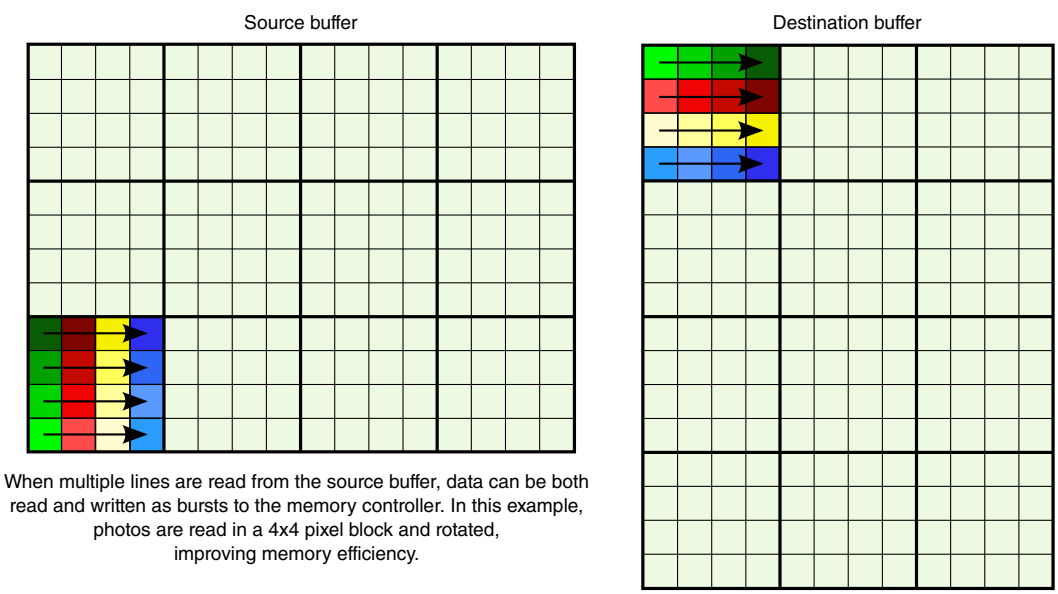

Figure 13-82. Rotated Sub-blocks

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.

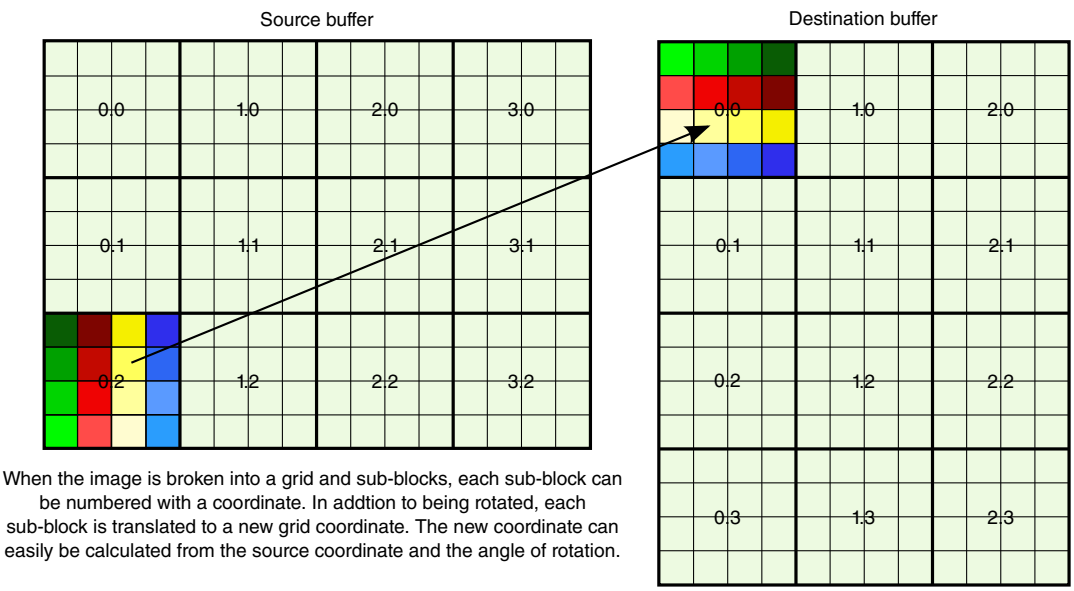

Figure 13-83. Grid of Sub-Blocks with Coordinates

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks. When using the Rotate engine with the input fetch engine, you need to program the input fetch engine to work in 8x8 block mode.

NOTE

An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation

is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address -(4*pitch).

NOTE

First position Rotation occurs after compositing the AS and PS buffers in the output stage. When processing PS and AS buffers that are unaligned (buffers are not aligned to block boundaries), a rotation operation that is combined with a flip, decimation, or scaling operation will not execute correctly. Rotation operation must be done in separate passes. Combination operations execute correctly for aligned buffers.

NOTE

Second position Rotation only supports simple aligned rotation. Unaligned buffer rotation will not execute correctly. Rotation operations combined with flip, scaling, or decimation will not execute correctly.

13.6.3.26 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks. It can also connect to the dither engine using the handshake mode. This works for the output engine programmed in the scan line mode as well as block mode. For more details, please refer to the Dither fetch engine.

13.6.3.27 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

13.6.3.28 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG_CTRL[BLOCK_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

13.6.3.29 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.

Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

13.6.3.30 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

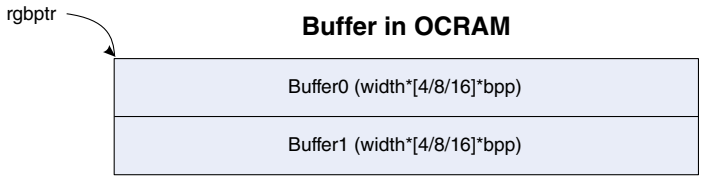

Figure 13-84. Buffer in OCRAM

The storage required can be calculated for an 8x8 block size as

- storage = 16 (lines) * rotated_row_length * pixel_size

and for 16x16 block size as

- storage = 32 (lines) * rotated_row_length * pixel_size

where pixel_size = 4 for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

Image Size	Storage (16bpp)	Storage (24bpp)	Storage (32bpp)
320x240 (QVGA) - 0/180 rotation	10KB	15KB	20KB
320x240 (QVGA) - 90/270 rotation	7.5KB	11.5KB	15KB
640x480 (VGA) - 0/180 rotation	20KB	30KB	40KB
640x480 (VGA) - 90/270 rotation	15KB	22.5KB	30KB

The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

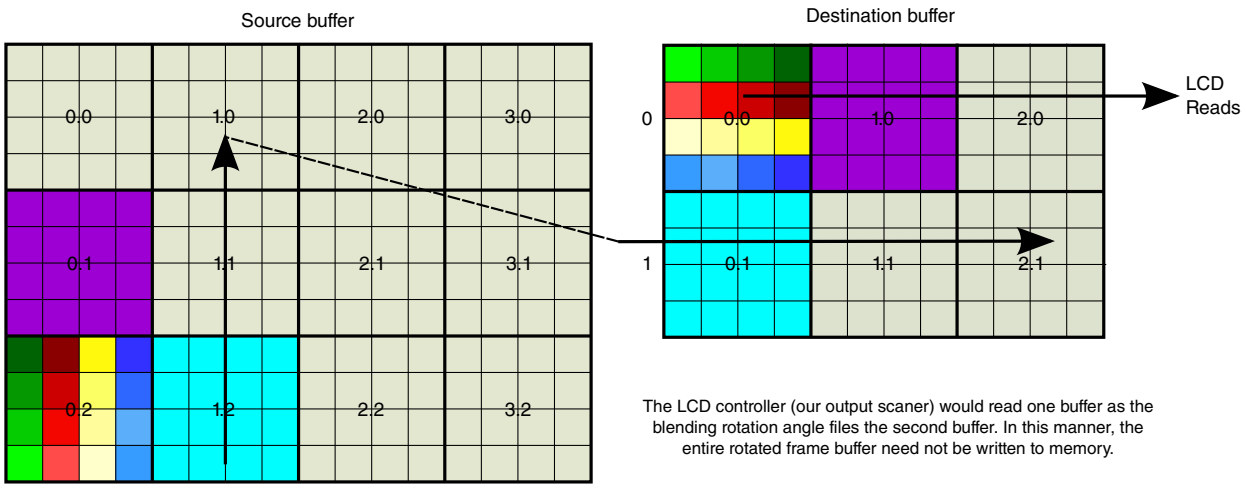

Figure 13-85. Minimal Rotation Buffer Organization

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. Once the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.

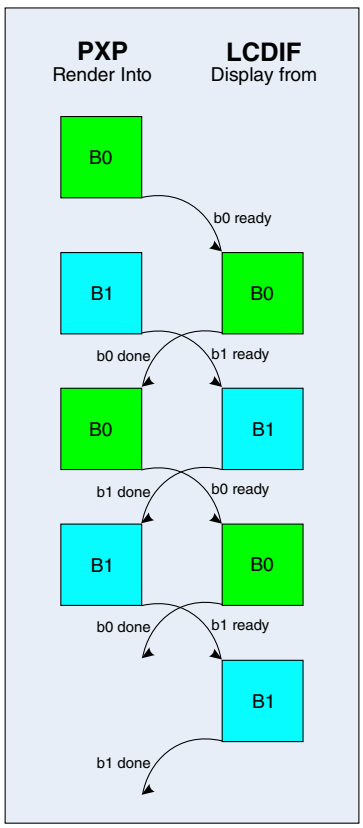

Figure 13-86. PXP and LCDIF Buffer Sharing

To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the pxp_lcdif_bx_ready (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the lcdif_pxp_bx_done signal.

The basic protocol is shown in the diagram below:

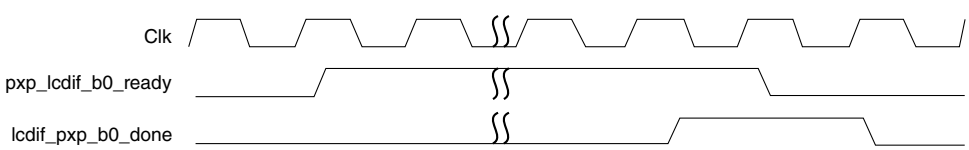

Figure 13-87. Buffer Sharing Protocol

The PXP will continue to assert the bx_ready signal until the corresponding bx_done signal is sampled high for one clock cycle. It will then deassert the bn_ready until the next time the buffer has been filled. After the PXP samples the bx_done signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

13.6.3.31 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the buffer_ready signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

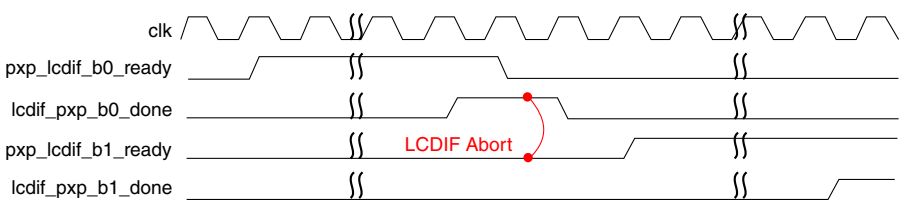

Figure 13-88. LCDIF Abort

13.6.3.32 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations

are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color keyed, process by CSC and LUT resources as individual pixel components. This allows efficient block processing with supporting arbitrary alignment for both the AS and PS surfaces. The resulting pixel block is then written to the corresponding block in the output buffer.

13.6.3.33 Pixel Handling

All pixels are internally represented as 24-bit values regardless of input or output pixel formats.

The pixels get converted in the AS and PS buffer engines to 24-bit pixel values.. There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for blending within the RGB color space. Compositing of AS and PS images can only occur in the RGB color space. If composting is not required, then YUV pixels can be transferred and processed at all PXP pixel resource components.. The color orientation of pixels within the PXP can be controlled by the CSC1, CSC2, and LUT resources.

For RGB, input pixels are converted into 24-bit pixel values using the following rules:

1. 32-bit ARGB8888 pixels are read directly with no conversion for both the AS and PS.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555 triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB888 and ARGB555 pixel modes. Also, output pixels can be assigned an alpha value using the REG_OUT_CTRL[ALPHA] register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as either RGB or YUV pixels values. The CSC2 or LUT can convert internal RGB/YUV pixels into the correct output format. In this way, any PS color space can be blended with AS RGB pixels and output in any color space.

13.6.3.34 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or REG_PS_BACKGROUND register based on PS programmed coordinates).

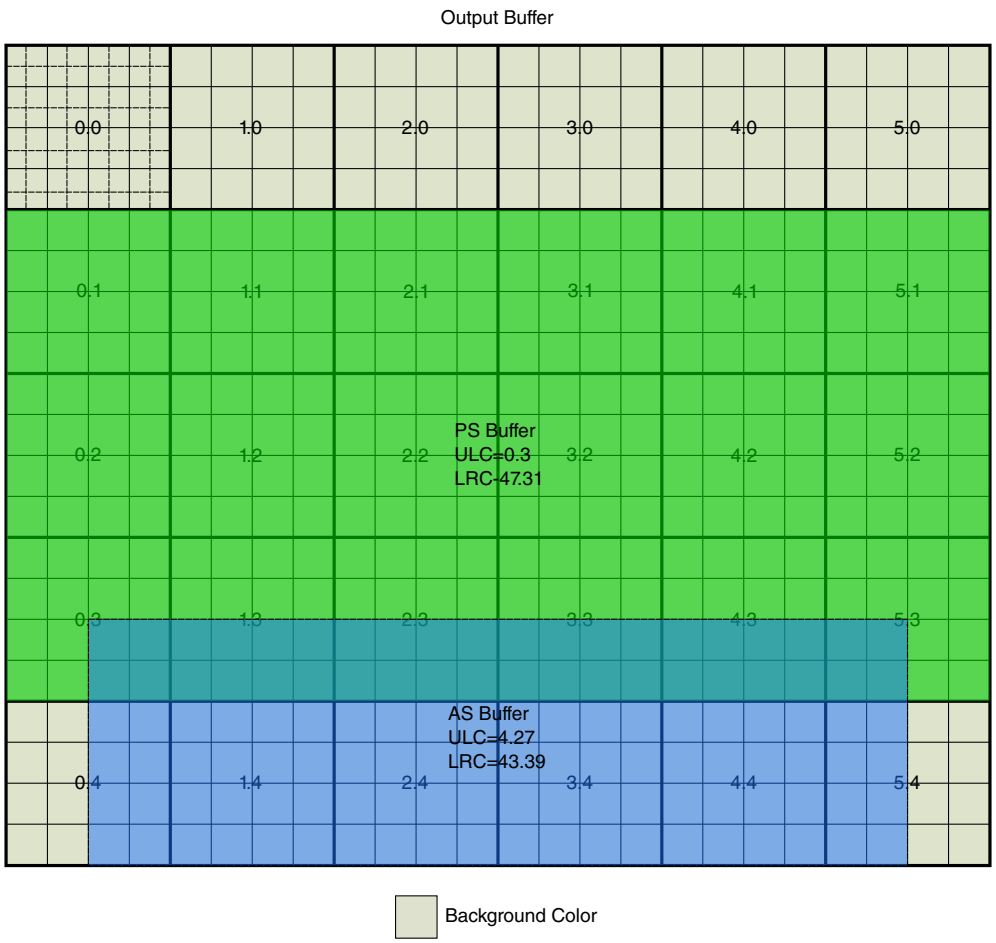

Figure 13-89. Output Buffer Composition

13.6.3.35 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.

13.6.3.36 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG_OUT_PS_ULC and REG_OUT_PS_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG_PS_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

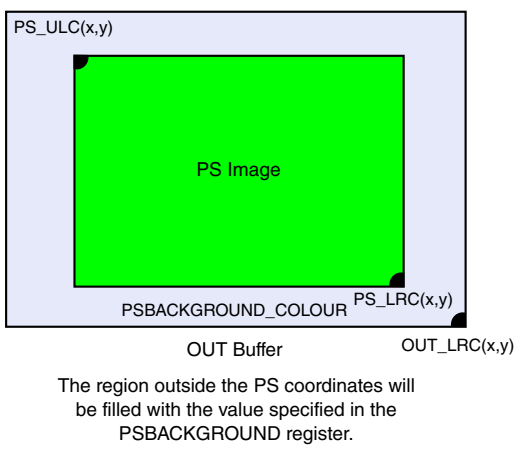

Figure 13-90. OUT Buffer

13.6.3.37 Clipping source images

A subset of the PS buffer can be used in rendering the output buffer. The PXP_PS_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP_PS_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP_OUT_PS_ULC within the output buffer. Essentially, the PXP_PS_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP_PS_PITCH will always indicate the number of bytes that are vertically adjacent in

the PS buffer. The settings in the PXP_PS_BUF, PXP_OUT_PS_ULC, and PXP_OUT_PS_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

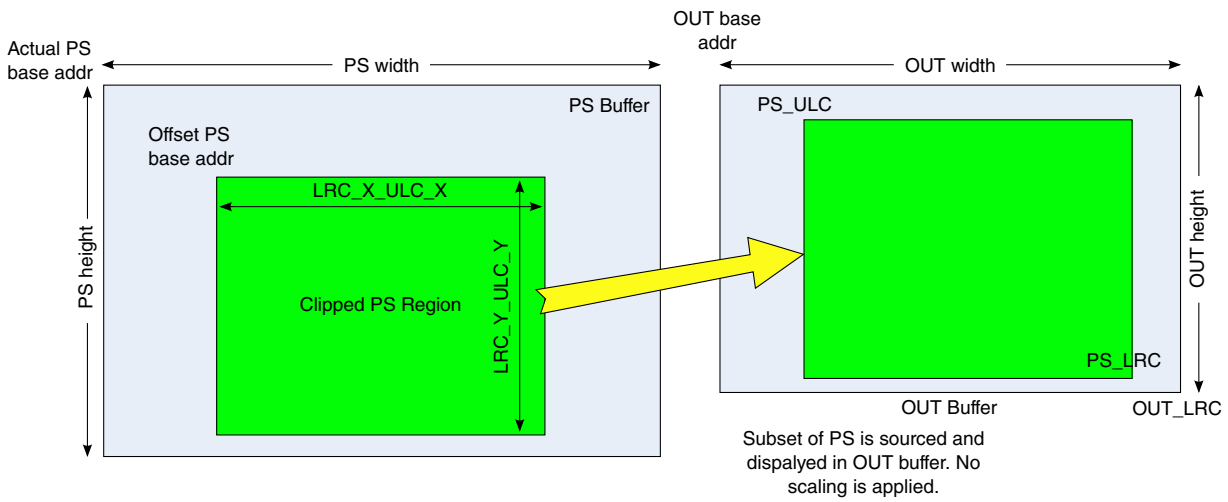

Figure 13-91. PS Buffer Scaling

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

x_base_addr_offset + x_scale * (LRC_X-ULC_X) <= PS_pitch

y_base_addr_offset + y_scale * (LRC_Y-ULC_Y) <= PS_size

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:

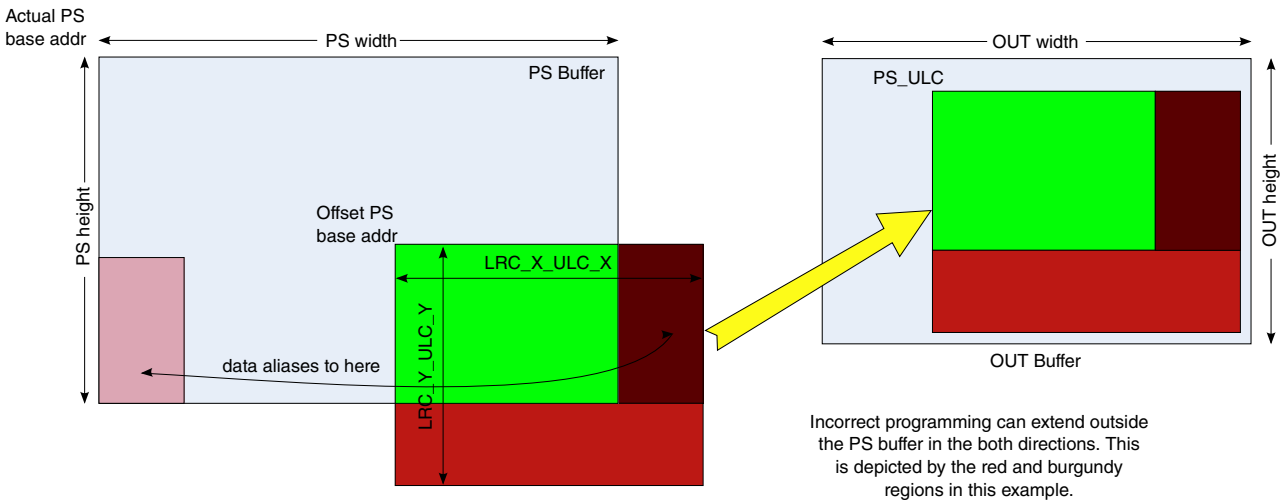

Figure 13-92. Example with Invalid Parameters

13.6.3.38 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG_PS_COLORKEYLOW and REG_PS_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color .

Figure 13-93. The PS image (player) and AS image (stadium)

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey: 00<R<80 70<G<ff 00<B<80

The resulting image becomes:

Figure 13-94. Resulting Image

13.6.3.39 In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

13.6.3.40 Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

13.6.3.41 Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA_MULTIPLY or ALPHA_OVERRIDE bit in the associated AS_CTRL register. If ALPHA_MULTIPLY is enabled, the 8-bit ALPHA value from the AS_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

13.6.3.42 Color Key Processing (AS_CTRL)

The AS_CTRL register also contains an ENABLE_COLORKEY bit that can be used to enable or disable color key substitution for the AS.

When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

13.6.4 Output Image Processing

Several PXP options affect the resulting output image.

13.6.4.1 Output Image Size

The PXP generates an output image in the resolution programmed by the REG_OUT_LRC. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

13.6.4.2 Output Format

The result of PXP operations are written to the buffer pointed to by the REG_OUT_BUF/ REG_OUT_BUF2 registers. The pixel format is controlled by the REG_OUT_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the REG_OUT_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.

13.6.4.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

13.6.5 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the REG_NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and LCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the REG_NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect

After writing the REG_NEXT register, the PXP will set the REG_NEXT[ENABLED] bit of the REG_NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the REG_NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the REG_PXP[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the REG_PXP[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.

13.6.6 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

13.6.6.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes
3. Rotation 1 engine doesn't support rotation of data in YUV420 format.
4. CSC2 cannot perform RGB to YCbCr and RGB to YUV conversion correctly.

13.6.7 Dither Engine Block

The dither engine takes in a buffer of Y8 grayscale pixels (8 bpp) one at a time in raster order from the Fetch engine that is connected to its input. It is designed to process ~1 pixel/clk. It can process the pixels in a number of ways. It can write out the pixels unmodified (pass through), it can quantize the pixels from 8 bits to any smaller number of bits down to 1 bpp. In addition to quantization, it can perform 1 of three different dithering algorithms on the pixel stream. The dithering algorithms supported are Floyd-Steinberg, Atkinson and Ordered dithering. The block contains internal storage for intermediate error data and LUT data which is completely managed within the block.

The pixels passed through the output interface to the connected Store Engine on the output side. The Store Engine is responsible for storing the dithered pixels out to memory or passes them to the WFE-A Fetch engine through bypass mode. The Fetch, Dither and Store engines work together as a unit and they must all three be programmed appropriately and started for the pixels to be read, processed and written correctly. The Store Engine interrupt signal is the indication to software that the operation has completed.

A LUT (Look Up Table) transform can be configured to be done on the pixel either before or after dither dithering but not both. In addition there is a “final” independent register based LUT that can be applied at the end of the dither process just before the pixel is written out to the Store Engine. The LUT values for this final LUT are programmed by software into register.

There are 3 instances of the dither processing block (Dither0, Dither1 and Dither2) instantiated in the system and each has separate controls.

There are 3 instances of the dither processing block (Dither0, Dither1 and Dither2) instantiated in the system and each has separate controls.

13.6.7.1 Top Level Connections

The dithering engine is connected to the Fetch Engine on the input side and the Store Engine on the output side. See the figure below:

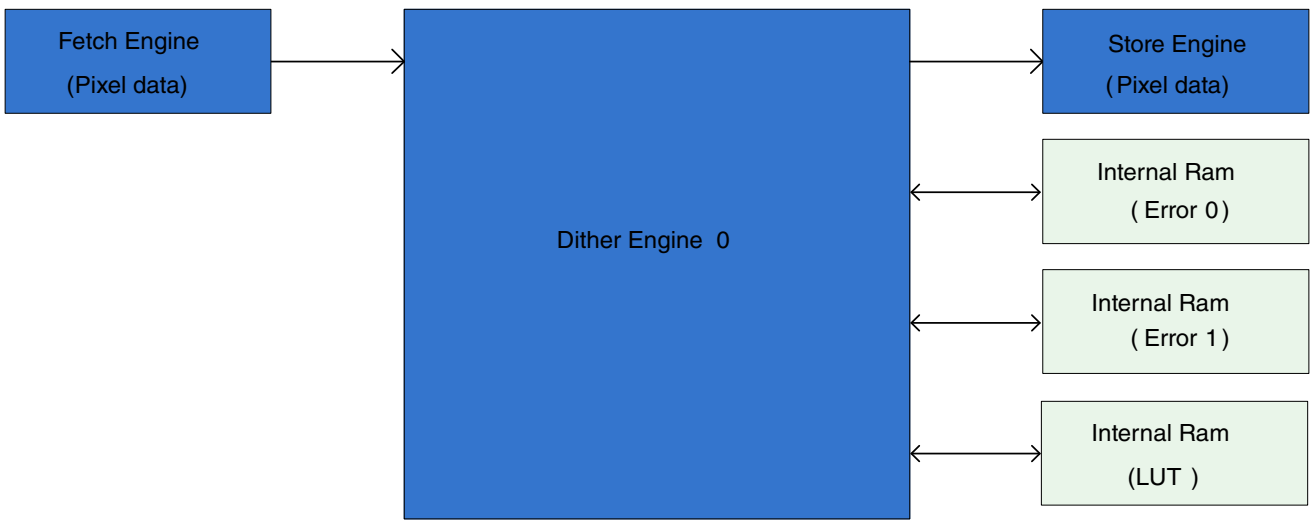

Figure 13-95. Dither Engine External Connections

The Dither Engine must be configured and enabled through the HW_DITHER_CTRL control register. The data flow is controlled through the valid, ready and pixel handshake signals with the Fetch and Store blocks. The Dither Engine must be enabled and given all required information such as which dithering algorithm to use, LUT configuration, etc. After starting, the Fetch Engine will signal to the dither engine when it has data for processing. When error information is needed, the block will only take in the pixel and error information when all handshakes are ready. In this case the pixel and error data must be kept synchronized at the processing step. After that however, they can be written out independently to the store engine (They don't have to be written out on the same cycle).

The dimension information of the operation is not programmed in the Dither engine. It comes from the higher level pxp control register fields.

13.6.7.2 Dither Engine Design

The following diagram shows the detailed internal structure of the Dither Engine.

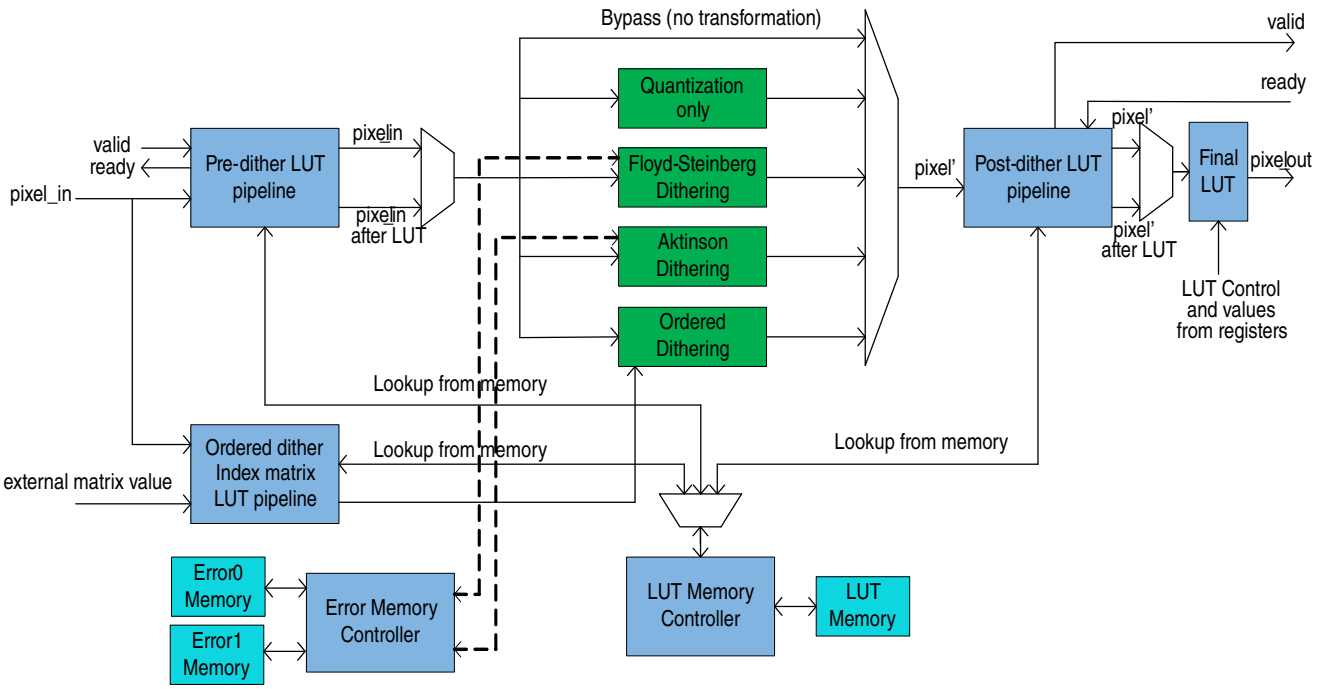

Figure 13-96. Detailed Block Diagram

Before a detailed discussion of block functionality, it is important to note that there are 3 instances of the dither block within the PXP. All three, Dither0, Dither1 and Dither2 are connected to the same Fetch and Store engines. The system works in two configurations

1. Y8 configuration:- In this configuration only Dither0 is enabled. The Fetch Engine will fetch Y8 data and feet it to Dither0. Dither0 then writes resultant data, Y4 for instance, to the Store engine.
2. RGB configuration:- In this mode all three dither engine instances are enabled. The Fetch Engine reads in RGB data from memory and gives 8 bits of the triplet to each dither engine. The resulting quantized or dithered data from each dither engine is passed to the same Store engine as in Y8 configuration and the Store Engine synchronizes, packs the data back together and writes it memory.

The Dither0 instance can operate in any of the 5 dither modes mentioned below. The Dither1 and Dither2 instances can only operate in Pass Through, Ordered Dither and Quantization Only modes. It also has the functionality to do a regsiter based final LUT at the end of dither processing. This LUT is controlled by the FINAL_LUT_ENABLE bit. Notice that in the HW_PXP_DITHER_CTRL register there are separate ENABLEx,

DITHER_MODEx and IDX_MATRIXx_SIZE controls for each engine. The NUM_QUANT_BIT and LUT_MODE control fields are common and apply to all dither engine instances.

The Dither0 instance is connected to three dedicated instances of internal memory. The error memories are only used when Floyd-Steinberg or Atkinson dithering is selected and are only connected and used by the Dither0 instance. Initialization of these memories is not required.

The Dither1 and Dither2 instances only have dedicated LUT memories connected, one RAM for each of the two instances. There are no error RAM's associated with Dither1 or Dither2.

To be included in a pxp processing flow operation, the HW_PXP_CTRL_ENABLE_DITHER or HW_PXP_CTRL2_ENABLE_DITHER bit must be set when the operation is executed. This is in addition to the HW_PXP_DITHER_CTRL.ENABLEx bits.

The process flow through the Dither Engine is detailed in the following sections.

Step1: Pre-Dither

The pixels are read into the pre-dither pipeline sub-block through the handshake with the Fetch Engine/ If there is error data or Ordered dither LUT matrix data that corresponds with the current pixel (this is mode dependent) then all these elements are fetched, synchronized and presented to the dither stage (green blocks in the above figure) simultaneously. The pre-dither, post_dither and Ordered dither matrix LUT pipeline module instances keep the data synchronized and flowing through the block. The pixel can go through a lookup table before the dither stage in the Pre-dither LUT pipeline or after in the Post-dither LU T pipeline. These blocks and the Ordered dither index pipeline block share the LUT memory through the LUT Memory Controller block. There is only one memory that is shared between these three functions and only one use can be selected for a given operation. In other words, the block can be configured to use pre-dither lookup, post-dither lookup or ordered dither mode but only one at a time. The pre or post lookup function is enabled through the HW_PXP_DITHER_CTRL.LUT_MODE field. Ordered dithering is enabled through the HW_PXP_DITHER_CTRL.DITHER_MODEx field (Again, the memory can be used for only one purpose during any given operation). The LUT function uses an 8 bit address (the input data) to lookup 8 bits of data. The LUT memory must be pre-configured with the desired lookup table data.

Step2: Dither

After the pre-dither stage, the pixel and colateral data passes through the dither stage. There are 5 programmable modes in this stage that are specified with the HW_PXP_DITHER_CTRL.DITHER_MODEx field.

1. Pass Through:- In this mode the pixel data passes through unmodified
2. Floyd-Steinberg Dithering:- This mode quantizes and dithers the pixels according to the standard Floyd-Steinberg algorithm that can be found in the literature. This algorithm employs an error dispersion technique that saves a fraction of the quantization error from each pixel and adds those partial errors to neighboring pixels. Therefore, the error memory buffers shown in the diagram are used in this mode to save the partial errors and retreives them as they are needed when processing corresponding pixels in the next row below the current row.
3. Atkinson Dithering:- This mode employs the standard Atkinson dithering algorithm to quantize and dither the pixels. The standard algorithm in the literature is implemented. Atkinson is an error dispersion algorithm similar to Floyd-Steinberg except that the partial error coeficients are different and the error is dispersed two lines below the current row instead of one line below.
4. Ordered Dithering:- This is a standard algorithm that applies an index, or bayer matrix to the pixels. Applying this matrix has the effect of changing the likelihood of a pixel being rounded up or down when being quatized. If this mode is specified, it requires use of the LUT memory so the HW_PXP_DITHER_CTRL.LUT_MODE field must be set to 0, or off. The IDX_MATRIXx_SIZE field specifies the dimensions of the index, or bayer matrix. This is used to properly index into the LUT memory to retreive the correct corresponding value to apply to the current pixel.
5. Quantization only:- This mode simply quantizes the pixel from 8 down to whatever bits per pixel are specifed in the NUM_QUANT_BIT field. No dithering algorithm is used.

The output of this step is the quantized/dithered pixel packed into the most significant bits of an 8 bit byte. The unused bits in the lower part of the byte will be set to zero. Also, any partial error information that was generated is sent to the Error Memory Controller to be stored for future processing.

Step3: Post-Dither

The post-dither block is similar to its pre-dither counterpart. The processed pixel is queued up in preparation for write to the Store Engine. Also any relevant error information is stored out to memory for the next lines of the image. If DITHER_MODEx is not equal to Ordered mode, and a lookup operation is not selected in the pre-dither step, the LUT_MODE can be set to select a lookup operation in this step using the LUT memory.

Step4: Final Lookup

This combinatorial LUT step takes bits [7:4] of the output pixel and looks up an 8 bit value from the 16 value LUT to generate the final output pixel to the Store Engine. The LUT values are programmed into the LUT through the

HW_PXP_DITHER_FINAL_LUT_DATA0 - 3 registers. This operation is enabled through the HW_PXP_DITHER_CTRL.FINAL_LUT_ENABLE register field. This LUT is only available on the Dither0 instance.

1. Y8 configuration:- In this configuration only Dither0 is enabled. The Fetch Engine will fetch Y8 data and feet it to Dither0. Dither0 then writes resultant data, Y4 for instance, to the Store engine.
2. RGB configuration:- In this mode all three dither engine instances are enabled. The Fetch Engine reads in RGB data from memory and gives 8 bits of the triplet to each dither engine. The resulting quantized or dithered data from each dither engine is packed to 24 bit RGB and be written to memory by Store Engine.

1. Pass Through:- In this mode the pixel data passes through unmodified
2. Ordered Dithering:- This is a standard algorithm that applies an index, or bayer matrix to the pixels. Applying this matrix has the effect of changing the likelihood of a pixel being rounded up or down when being quatized. If this mode is specified, it requires use of the LUT memory so the HW_PXP_DITHER_CTRL.LUT_MODE field must be set to 0, or off. The IDX_MATRIXx_SIZE field specifies the dimensions of the index, or bayer matrix. This is used to properly index into the LUT memory to retreive the correct corresponding value to apply to the current pixel.
3. Quantization only:- This mode simply quantizes the pixel from 8 down to whatever bits per pixel are specifed in the NUM_QUANT_BIT field. No dithering algorithm is used.

13.6.7.3 Pipelined Data Flow

It is possible that the fetch engine could stall when there are valid pixels in various stages of the dither block. In this case the dither pipelines will not stall but will continue to drain and move data out to the store engine. Also, if Floyd-Steinberg or Atkinson dithering is selected, at the end of each row after the last pixel has been written out to the store engine there will be one extra error that will be written out to the error memories because the pixels and the corresponding errors are offset by one. This is a natural result of the error dispersion algorithms. The dither block handles flushing out this last error automatically before processing the next row. Also, if the Store Engine stalls for a period of time and can not take any more data, flow control is implemented within the Dither block back to the Fetch Engine so that no pixel or error data is lost or becomes unsynchonized.

There are three BUSY bits in the HW_PXP_DITHER_CTRL register, one for each Dither Engine instance that software can poll to discover if the engine is busy or idle.

13.6.7.4 Initialization of Dedicated Memories

The internal memories for the Dither Engine instances, including 2 error memories and 3 LUT memories can all be initialized through the register interface. This is done by configuring the HW_PXP_MEM_CTRL register and then writing the initialization data into the HW_PXP_INIT_MEM_DATA register. This simple interface is used as follows. Write the HW_PXP_MEM_CTRL.SELECT field with a value between 0-4 corresponding to the memory to be initialized. Write the HW_PXP_MEM_CTRL.ADDR field with the starting memory address to be written. Set the HW_PXP_MEM_CTRL.START field to begin the initialization operation. Note at all these fields can be set with a single write to the register. Then write the HW_PXP_MEM_DATA register with the data to be written to the location at HW_PXP_MEM_CTRL.ADDR. Each write to the data register increments and value of address so repeated writes to this register will put the data into sequential memory locations beginning with the offset in the ADDR field. The LUT memories are 8 bits wide. When 32 bit DATA writes occur with one of those memories selected, the lower 8 bits are written. To fill these memories 256 writes to the HW_PXP_MEM_DATA register are required. The error memories are 32 bits wide so all 32 bits are data are used to fill each location and they are 2048 locations deep. Note that initialization for these memories are not necessary.

13.6.7.5 Register Configuration Interface

The HW_PXP_DITHER_CTRL register control fields to be set for each operation are included in the following table.

Signal or Group	Description
ENABLE	The hardware signal enables the dither block to function.
DITHER_MODE	Dither mode 0: passthrough, 1: Floyd-Steinberg, 2: Atkinson, 3: Ordered, 4: no dithering quantization only, 5,6,7: Reserved. There is on field for each Dither Engine instance.
NUM_QUANT_BIT	How many bits to quantize to. Valid values are 7 down to 1.
LUT_MODE	Configures a LUT operation from local memory. The options are either pre-dither, post-dither or off. This setting affects all three Dither Engine instances.
IDX_MATRIXx_SIZE	These fields, one per instance, specifies the dimension (the matrix is square) of the Index Matrix used in Ordered dither mode.
FINAL_LUT_ENABLE	This field is only applicble to instance 0 of the three Dither Engines and enables/disables the final register based LUT of the output pixel just before outputing it to the Store Engine.

13.6.8 Waveform Engines

13.6.8.1 Overview

The WFE (Wavefrom Engine) is a very flexible, programable engine that can be used to implement various algorithms to transform the incoming data to the output. It is always used in connection with the Fetch Engine on the input side and a Store Engine on the output. These three sub-blocks work as a unit. There is an optional ALU block between the WFE and Store engines that can be used to make further modifications to the WFE output before storing the output. See the figure below.

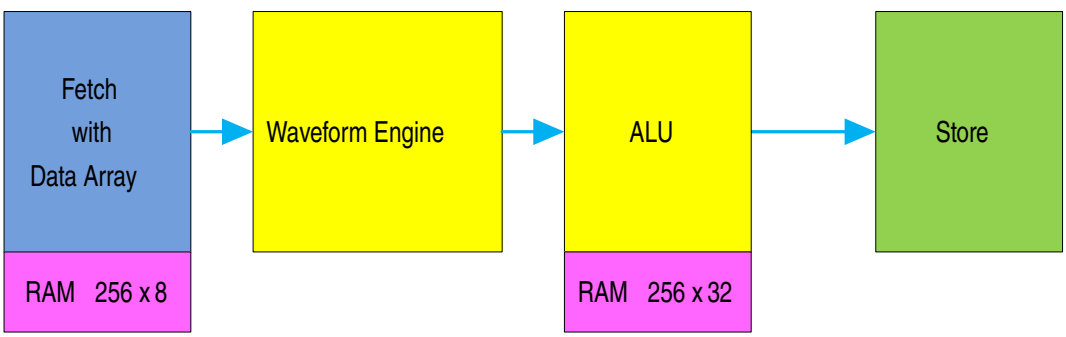

Figure 13-97. Block Diagram

The WFE can process one pixel and associated data per clock.

The Fetch Engine fetches and formats the input pixel data streams according to the requirements and programming of the WFE. The WFE takes in the data from the Fetch Engine through a standard valid/ready signalling interface.

Inside the WFE the data passes through a 3 stage pipeline. Each stage consists of various programmable logic elements including muxes, lookup tables, comparitors, ALU's and registers. The output information calculated in the WFE is output to the Store Engine also using a standard valid/ready signalling interface.

The Store Engine reads the data from the WFE in the programmed format reformats the data according to working buffer pixel formats and stores the frame and associated data to memory.

13.6.8.2 Functionality

There are two WFE instances arranged serially in the PXP standard flow, WFE-A and WFE-B.

In the standard usecase WFE-A is used for pixel collision detection and also to compute grayscale color transition information used later in the REGL/D algorithm.

In the standard usecase the WFE-B engine takes in pixel information and the results of WFE-A processing and implements the REAGL/D algorithm on the data. The output results in all the information necessary for the EPDC block to update the E-INK panel.

The definitions, functionality and programming of the logical elements within the WFE is Freescale, Inc. prorietary information. The register programming necessary for any given function required will be supplied by Freescale to the customer.

The WFE block can be independently held in reset by setting the HW_PXP_WFE_x_CTRL.SW_RESET bit to 1. This bit should only be set when the HW_PXP_WFE_x_CTRL.ENABLE bit is 0.

13.6.9 PXP Store Engine Block Description

13.6.9.1 Overview

The essential function of the Store Engine is to store input data from the input sub-block to memory or directly output to next sub-block. The input source is 32 bits per channel per valid clock. There are 4 instances of the Store Engine in the PXP. Please refer to the PXP block diagram for details. The main supported features are:

- Two DMA controllers thus it can work on two channel data storage at the output at the same time. If there is only one stream data input, store engine should use channel 0 but not channel1.
- Accepts as input up to 8 bytes data (two channels, 32 bits each) and 8 bits flag input. After shift operation it can store up to 64bpp per valid clock to memory.
- Data fill function for initialization. It can fill a fixed 32 bit data value to a specified memory buffer.
- Handshake mode with a downstream connected data Fetch Engine. It supports 1 scanline handshake with and 1 line, 3 lines and 5 lines array handshake modes. In handshake mode, the Store Engine signals to the Fetch Engine when data is avalible for processing thus eliminating the need for software intervention through interrupt service routines.

- Bypass mode which directly outputs the data to the downstream connected Fetch Engine after shift operation. This is done through a valid/ready data interface.
- Support for 8x8 and 16x16 block mode and scanline mode.
- Support for 8, 16 and 32 bpp input data format.

13.6.9.2 Top-level architecture

The PXP consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction , input and/or output rotation, dithering and waveform processing. It is also capable of fetching data from and storing data to memory.

The legacy blocks operate within the requirements of the legacy PXP architecture, and perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The legacy pipeline operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order. The dither blocks and the waveform processing engines (WFE) will operate in a scan line format based on the active size. The input fetch and store engines can work on either on a block by block basis or in the scan line format.

Figure 13-71 shows the high-level architecture of the scaling, color space conversion, blending, pixel correction , rotation engines, dithering, waveform processing, histogram along with four sets of fetch and store engines. The Alpha Surface Engine fetches one RGB graphics plane alpha surface (AS). The scaling engine fetches a single processed surface (PS), which can be blended with the AS surface. The scaling engine also supports an alpha channel for the PS image. Although the legacy PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS are inclusive within the output buffer.

Figure 13-72 represents a sample output buffer configuration with both an AS and PS included. The alignment of each AS and PS within the output buffer can be at any arbitrary pixel locations. For example, the PS has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS is bounded by the LRC of the output buffer, 15,15 for this example.

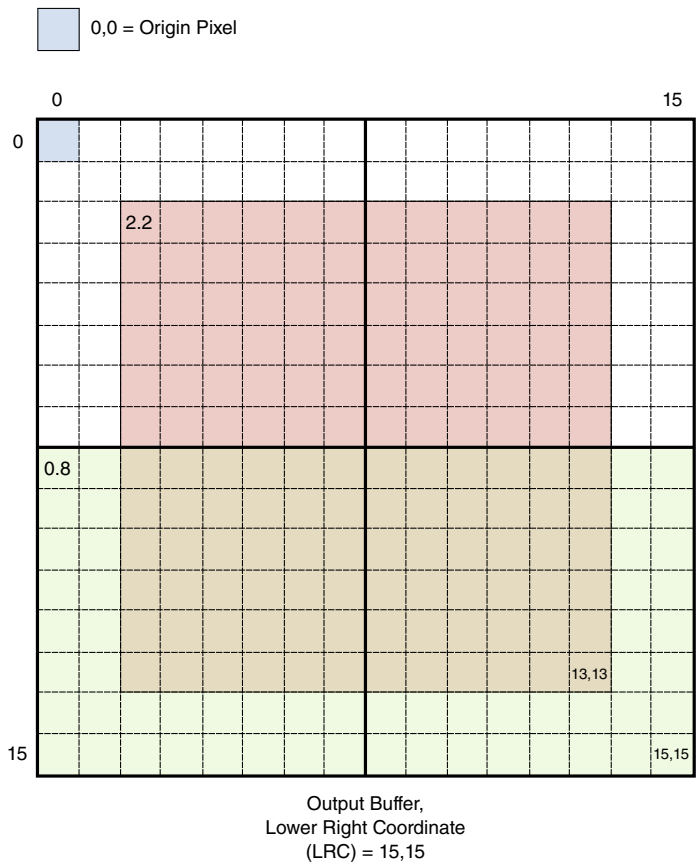

Figure 13-98. Sample output buffer configuration

The AS engine supports RGB pixel formats, and the PS engine supports ARGB, RGB, YUV, and YCbCr pixel formats. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There are two rotate engines in the PXP pipeline. Rotation can occur after image composition, at the output of the PS engine, or both. In the first scenario, all the data produced by the AS and PS engines is rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces. The Rotate engine at the input can also be used with the input fetch engine. For this, the fetch engine needs to be programmed in the blok mode to fetch a block of size 8x8. The CSC2 unit can convert to any RGB, YUV, or YCbCr color spaces for final output. Pixels can be corrected using a programmable LUT resource to achieve any desired pixels effects. For detailed information, please refer to Output Modes to RGBW4444CFA. The dither engine supports 3 dithering modes in addition to the standard quantization and pass-through modes. The dithering algorithms supported are: Ordered, Floyd-Steinberg and Atkinson. The WFE is a programmable engine that can be programed as required to process each pixel and pixel meta data. The Histogram sub-block collects statistics about the pixel data passing through it that is

useful to the EPDC in waveform selection and displaying the frame. The Histogram also contains mask and comparison functionality that can be used for collision detection and reporting of the collided area within an update area.

The PXP also supports two parallel image processing paths. The legacy flow can operate in parallel with the input fetch engine or the dithering or waveform processing engines. Please refer to HW_PXP_CTRL and HW_PXP_CTRL2 for details on how to enable each of the individual data flows. In addition to this, the CSC, Rotation 1 and LUT engines can be used as either part of the legacy flow or as a part of the second parallel data flow. These blocks can work in the scan line format or in block format. There are two separate blending engines for each flow.

13.6.9.3 Store Engine Design

13.6.9.3.1 Input Data Source

1. **Fixed Data Input**

   The Store Engine supports a fill function which writes a fixed value to a specific set of memory locations. The data received from the input is ignored. This function is usually used to initialize a memory buffer. The address of the buffer to fill is set in the HW_PXP_x_STORE_FILL_DATA_CH0 register. Also, this mode can only work through channel 0 and not channel 1.

   In this mode HW_PXP_INPUT_STORE_CTRL_CH0.FILL_DATA_EN=1.The fixed value is set in FILL_DATA_CH0 register. How many bits are valid from HW_PXP_INPUT_STORE_FILL_DATA_CH0 register is decided by HW_PXP_x_STORE_SHIFT_CTRL_CH0.OUTPUT_ACTIVE_BPP.

2. **Normal Data Input**

   Store Engine supports two 32 bits wide data channels and 8 bits flag input. If there is only one channel of data input, the channel 0 must be used not channel 1. In this case, HW_PXP_INPUT_STORE_CTRL_CH0.COMBINE_2CHANNEL=0.

   If both channels and 8 bits flag input contain valid data, then the COMBINE_2CHANNEL bit should be set to 1. The Store Engine will then combine the two channels of data into 64 bits of data send them with the 8 bits of flags to the shift module. After shift, the Store Engine will choose the active bits from the 64 bit

output according to HW_PXP_x_STORE_SHIFT_CTRL_CHx.OUTPUT_ACTIVE_BPP and then pack them in preparation for output.

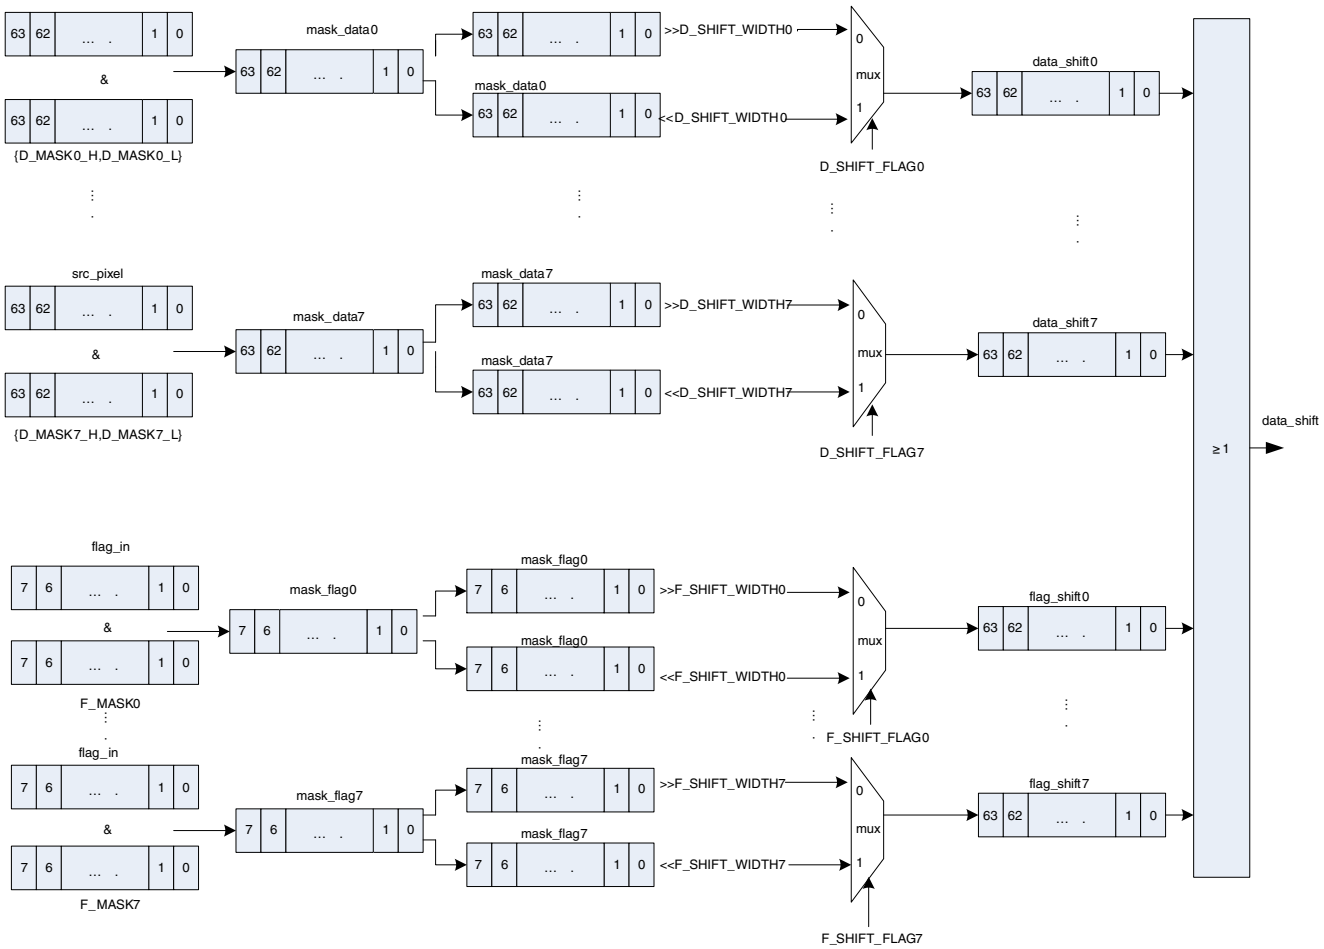
13.6.9.3.2 Store data shift operation

The data shift operation supports up to 8 data fields and 8 flag components to be shifted to any position within the 64 bit word. The data fields can be any width. This function is a way to reorder or reformat the component parts of the 64 bit word output. As data flows through the Store Engine each data word is processed the same way according to register configuration.

The following registers are used in shift operation. The pairs of {HW_PXP_x_STORE_D_MASKx_H_CHx, HW_PXP_x_STORE_D_MASKx_L_CHx} make up the 64 bits of mask for each MASKx component. There are a set of masks for each channel in each instance. The D_SHIFT_FLAG0 ~ D_SHIFT_FLAG7 fields in the HW_PXP_x_STORE_D/F_SHIFT_L/D_CHx registers specify which direction to shift (0: right shift 1: left shift) each data component0 ~ component7 after the mask is applied. The D_SHIFT_WIDTH0 through D_SHIFT_WIDTH7 fields specify how many bits to right or left shift each data component 0 through7 after the mask is applied.

The shift function works the same for the 8 bits of flag data. There are analogous “F_SHIFT” regsiters that contain the F_MASKx, F_SHIFT_FLAGx and F_SHIFT_WIDTHx register fields for swizzling the input flags.

The figure below shows how the shift function works.



13.6.9.3.3 Data Packing

After data shift, the 64 bits of data can be divided to two 32bit words depending on the value of the HW_PXP_x_STORE_CTRL_CHx.PACK_IN_SEL bits. If HW_PXP_x_STORE_CTRL_CH0.PACK_IN_SEL = 0, it will select active bits from all 64 bits of data. If equal to 1, it will select active bits from the lower 32 bits data.

For channel 1, if HW_PXP_x_STORE_CTRL_CH1.PACK_IN_SEL = 0, it will also select active bits from all 64 bits data and if equal to 1, it will select active bits from the higher 32 bits data.

Store Engine supports 8bpp, 16bpp, 32bpp and 64bpp active bits per pixel according to OUTPUT_ACTIVE_BPP register setting. When either channel's PACK_IN_SEL = 1 only 8bpp, 16bpp, 32bpp can be selected.

After shift and data output selection, the packing module will pack the data into a 64 bit string and store to a FIFO before writing out to memory.

Packing style according to active bpp is showed below.

OUTPUT_ACTIVE_BPP	Active bpp from 64 shift output data	Packed data
0	8 bits	{pix7, pix6, pix5, pix4, pix3, pix2, pix1, pix0}
1	16 bits	{pix3, pix2, pix1, pix0}
2	32 bits	{pix1, pix0}
3	64 bits	{pix0}

13.6.9.3.4 Data Store Format

- **Scanline mode**

  When HW_PXP_x_STORE_CTRL_CHx.BLOCK_EN=0, the Store Engine will store data the line by line in scanline mode. The AXI burst length is set by the HW_PXP_x_STORE_CTRL_CHx.WR_NUM_BYTES register field. In Scanline mode, it can support 8, 16, 32 and 64 bytes in a burst.

- **Block mode**

  When HW_PXP_x_STORE_CTRL_CHx.BLOCK_EN=1, the Store Engine support 8x8 and 16x16 block mode according to HW_PXP_x_STORE_CTRL_CHx.BLOCK_16 register bit. When BLOCK_16=1, the block size is 16*16 while if BLOCK_16=0 the size is 8*8 blocks. When BLOCK_EN=1, then HW_PXP_x_STORE_SHIFT_CTRL_CHx.OUTPUT_ACTIVE_BPP cannot be 3, that is, block mode can not work on a 64bpp data stream.

  When the Store Engine is configured block mode, the upstream Fetch Engine should be configured in block mode and with the same block size as well.

  When the total width or total height of image is no divisible by 8 or 16, the upstream Fetch Engine will fetch extra pixels or lines to fill out the final partial blocks. For example, if the size is 23*23, and block mode is 8*8, Fetch Engine will fetch 24*24 data pixels and output to store engine. The Store Engine has a crop function for this. That is, the extra pixels or lines will not be stored to memory by the Store Engine. This is accomplished by the hardware using the AXI bus byte enables.

  In block mode, the number of AXI bus write bytes is internally calculated from the OUTPUT_ACTIVE_BPP and BLOCK_16 (block size) register fields rather than the WR_NUM_BYTES field.

One limitation exists with block mode configuration. No YUV422 output format is not supported. So HW_PXP_x_STORE_SHIFT_CTRL_CHx.OUT_YUV422_1P_EN and OUT_YUV422_2P_EN must be disabled.

13.6.9.3.5 Output Format Modes

- **Normal mode**

  If HW_PXP_x_STORE_CTRL_CHx.STORE_BYPASS_EN = 0,

  HW_PXP_x_STORE_CTRL_CHx.STORE_MEMORY_EN=1 and

  HW_PXP_x_STORE_CTRL_CHx.HANDSHAKE_EN=0, the Store Engine is working in normal mode.

  In normal mode, the Store Engine will store the input data to memory frame by frame. The store frame start address is set in HW_PXP_x_STORE_ADDR_x_CHx. Two address registers exist for each channel. The second one is used for YUV422 2 plane mode.

  The Store Engine will stop storing data when the frame of data is finished. Another pxp_start signal will trigger the next frame operation. The frame size is specified by the HW_PXP_x_STORE_SIZE_CHx registers. The values should be set up for each channel in use. If both channels are being used, the height and width values in the HW_PXP_x_STORE_SIZE_CH0 and HW_PXP_x_STORE_SIZE_CH1 registers may be different but the total number of pixels in the frame must be the same. The only exception to this is when both channels are being used and the Store Engine is outputing data in handshake mode. In handshake mode the width and height must be set the same in both channel size registers.

  If the data shift mode is set to YUV422 single plane or 2 plane, two pixels, 64 bits, are read in and 32 bits are written. If the YUV data is coming from the upstream Fetch Engine it will be in YUV444 format as {8'h0, Y0, U0, V0, 8'h0, Y1, U1, V1}. Even though the YUV422 mode is set, the shift function must be set to shift the components into their proper position. For instance, for 1p mode, the shift MASK, FLAG and WIDTH parameters need to be set up on the 64 bits of pixel data to format each 32 bits (2 pixels) to be written out as {Y0, U0, Y1, V0}. Likewise in 2p mode, the ch0 data would be shifted to yield {Y0, Y1} with ch1 as {U0, Y0} for the first two pixels.

- **Bypass mode**

If STORE_BYPASS_EN=1, STORE_MEMORY_EN=0, The Store Engine will output the input data, after the shift function, directly to the downstream Fetch Engine instead of storing to memory. The AXI bus is inactive in this case. The data is output using the valid/ready external interface to the downstream connected Fetch Engine.

In bypass mode, if HW_PXP_x_STORE_CTRL_CH0.CH_EN=1, it will output the lower 32 bits of data. If HW_PXP_x_STORE_CTRL_CH1.CH_EN=1, it will output the high 32 bits of data.

- **Dual mode**

  If STORE_BYPASS_EN = 1 and HW_PXP_x_STORE_CTRL_CHx.STORE_MEMORY_EN = 1, the Store Engine is configured in Dual mode. That is, the Store Engine supports bypassing the data and also storing it to memory at the same time.

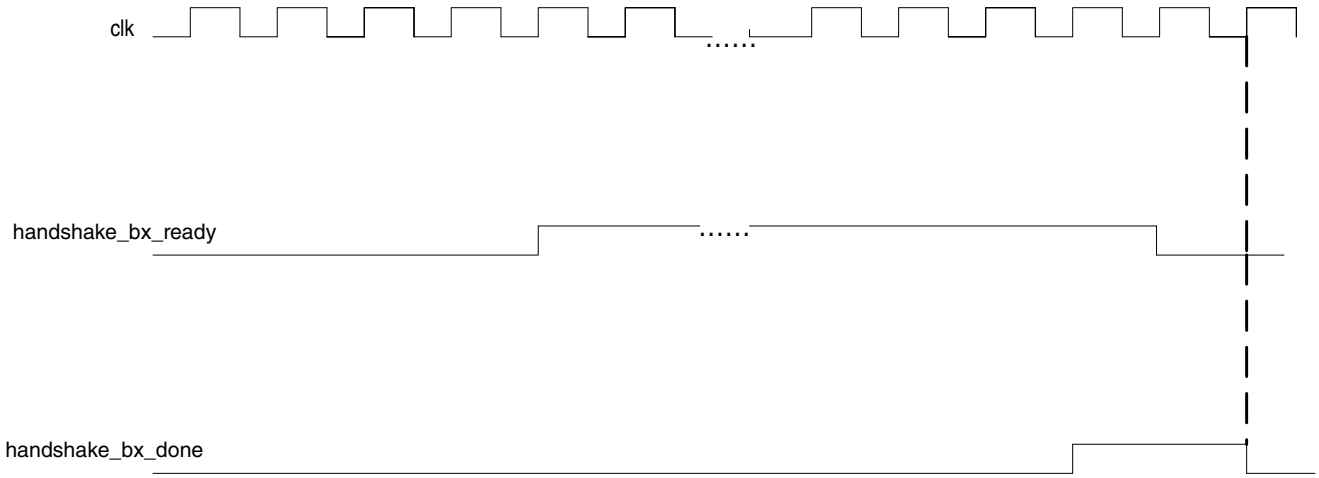
- **Handshake mode**

  The Store Engine supports a 1 scanline handshake configuration and 1 line, 3 lines and 5 lines array handshake configurations with next Fetch Engine. The 1 scanline mode is used for Store Engines connected to the Input_Fetch and Dither_Fetch instances. The array handshake modes are used in cases where the Store Engine is connected to the WFE_A_Fetch or WFE_B_Fetch instances. When HW_PXP_x_STORE_CTRL_CHx.HANDSHAKE_EN = 1, ARRAY_EN =1 and STORE_MEMORY_EN = 1, the Store Engine is in handshake mode(1 scanline handshake configuration is identical to 1 line array handshake configuration so the following sections will only discuss array handshake modes).

  The array handshake is used in cases where the Fetch Engine is in array mode. One line handshake config indicates that the Fetch Engine is working on 1x1 array mode. The 3 line handshake indicates the Fetch Engine work is in 3x3 array while 5 line handshake indicates 5x5 array mode.

  To accomplish the buffer sharing, Store Engine and the attached Fetch Engine will maintain buffer status using a pair of handshake signals. When a buffer is filled by the Store Engine, it will assert the handshake_bx_ready (where x is 0 or 1) signal to indicate to the fetch engine that the buffer has valid data. The prefetch engine will then release the buffer by asserting the handshake_bx_done signal.

  The basic protocol and timing is shown in the diagram below:



Unlike scanline handshake, there is only 1 buffer in memory. The buffer size is (array_line + 1).

- 1 line array handshake

  When HW_PXP_x_STORE_CTRL_CHx.ARRAY_LINE_NUM = 0, the configuration is 1 line handshake mode. The buffer size is 2 * OUT_PITCH (2 lines). The first ready occurs when the Store Engine finishes writing 1 line.

- 3 line array handshake

  When ARRAY_LINE_NUM = 1, the configuration is 3 line handshake mode. The buffer size is 4 * OUT_PITCH. The first ready occurs when the Store Engine finishes writing 2 lines.

- 5 line array handshake

  When ARRAY_LINE_NUM=2, the configuration is 5 line handshake mode. The buffer size is 6*OUT_PITCH. The first ready occurs when store engine finishes writing 3 lines.

13.6.9.3.6 Limitations

When both channels are active, they should be configured to work in the same mode. For example, if channel 0 is configured for bypass mode then channel 1 must also be configured the same way. In the case of the input Fetch and Store instances, see overall block diagram, if the path between them includes the LUT processing block then the Fetch and Store Engines must be in block mode. The LUT will not function correctly in scanline mode.

13.6.10 PXP Fetch Engine Block Description

13.6.10.1 Overview

The main function of Fetch Engine is to fetch data from memory or directly from the input bypass channel and output to another downstream module as 32 bits per pixel per valid clock.

The Fetch Engine has two channel DMA controllers and thus can fetch two memory data buffers at the same time. The Fetch Engine supports an expansion and shift function on the fetched data and then output as 32 bits per pixel according to different data format. It supports 8x8 or 16x16 block mode and scanline mode. The block also supports rotation function with rotation module when in block mode. It can support vertical flip, horizontal flip, 90/180/270 degree rotation angle.Using the expansion function, the user can read in rgb555, rgb565, rgb444, argb1555, argb4444, yuv422_2p or yuv422_1p input data format and convert to argb8888, rgb888 or yuv444 format at the output.The Fetch Engine can interface with a connected Store Engine block directly in one of two ways, handshake mode and bypass mode as described further below. In handshake mode 1 line, 8 line and 16 line configurations are possible. In bypass mode memory accesses are bypassed altogether and data passes directly from a Store Engine to its connected Fetch.Input formats of 8bpp, 16bpp, 32bpp, 64bpp are supported.

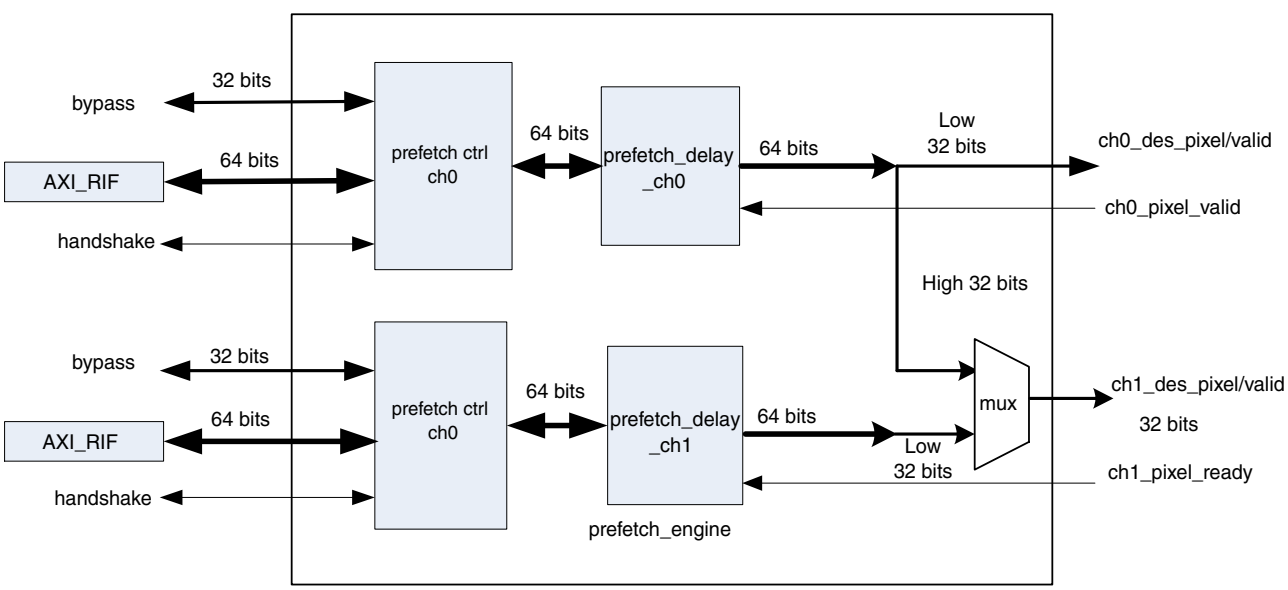


Figure 13-99. High level block diagram

The following diagram shows the internal structure of the Fetch_ctrl engine.

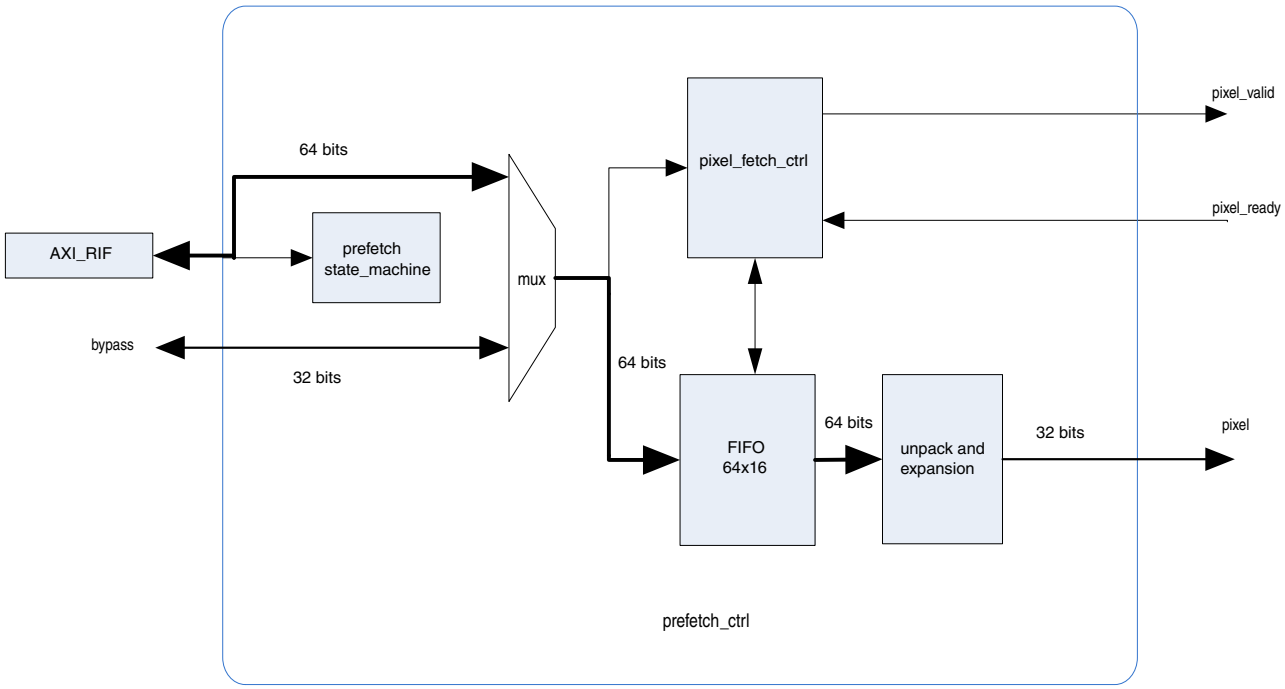

Figure 13-100. Fetch Control block diagram

13.6.10.2 Fetch Data formats

The Fetch Engine supports input 8bpp, 16bpp, 32bpp, 64bpp data format according to INPUT_ACTIVE_BPP register setting in the HW_PXP_x_FETCH_SHIFT_CTRL_CHx registers. (“x” is a wildcard that is replaced with the fetch module instance or the channel number. This notation is used because there are several instances with unique names and channels 0 and 1.)

When input data is 64bpp, since output data bus is 32 bits per channel, the Fetch Engine will need to be configured to use both output channels (32 bits each) to transmit the 64 bits of data at the output. Thus, when input data is 64bpp, the Fetch Engine supports only channel 0 data input but not channel 1 at the same time.

The Fetch Engine supports an expansion function. When you set EXPAND_EN=1, the engine will change the input format to a unified YUV444 or ARGB888/RGB888 format. Otherwise it will remain in the same format and output to an external module. Note the expand funtion is not available if the input data is YUV422 format, 1 plane or 2 plane data fetching is supported. When EXPAND_FORMAT=7, pefetch_engine will fetch YUV422 format data from two plane. One is for Y, the other is for UV. The start address of these two buffer planes are set by INPUT_BASE_ADDR_0_CHx (Y buffer) and

INPUT_BASE_ADDR_1_CHx (UV buffer) fields in the HW_PXP_x_FETCH_ADDR_x_CHx registers for that Fetch instance. Also, if input format is YUV422_2P, the EXPAND_EN must always be asserted. This combination is only used to transform YUV422_2P to YUV444 format.

The data format in memory and output is shown in table below. For input formats that read multiple pixels within the 64 bit input word, there will be multiple output cycles for each input read to expand and output all the pixels in the input word.

X means this parameter is a “don’t care”.

INPUT_ACTIVE_BPP	Input data valid bits(bpp)	Data store in memory	EXPAND_EN	EXPAND_FORMAT	After expanding(32 bit word)	Data output format in 32 bit bus
0	8 bits	{pix7, pix6, pix5, pix4, pix3, pix2, pix1, pix0}	0	Any value except 7	NA	{24’h0, pix0}
1	16bits	{pix3, pix2, pix1, pix0}	0	Any value except 7	NA	{16’h0,pix0}
2	32bits	{pix1, pix0}	0	Any value except 7	NA	{pix0}
3	64bits	{ pix0}	X	X	NA	Channel 0 bus output { pix0[31:0]} , Channel 1 bus output { pix0[63:32]}
1	16bits	{pix3, pix2, pix1, pix0}	1	0 (rgb565)	{8’h0,rgb888}	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	1 (rgb555)	{8’h0,rgb888}	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	2 (argb1555)	{8{a}},rgb888 }	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	3 (rgb444)	{8’h0,rgb888}	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	4 (argb4444)	{ {2{a}}, rgb888 }	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	5 (yuyv/yvyu)	{8’h0,yuv444} /{8’h0,yvu444}	{pix0}
1	16bits	{pix3, pix2, pix1, pix0}	1	6 (uyvy/vyuy)	{8’h0,yuv444} /{8’h0,yvu444}	{pix0}
x	x	Address0 {Y7,Y6,Y5,Y4,Y3,Y2,Y1,Y0} Address1 {U6V6U4V4U2V2U0V0}	1	7 (yuv422_2p)	{8’h0,yuv444}	{pix0}

Note that in 64 bpp mode, the expand and shift functions are not supported.

13.6.10.3 Data Fetching Format

- **Scanline mode**

  When HW_PXP_x_FETCH_CTRL_CHx.BLOCK_EN=0, the Fetch Engine will fetch data line by line using scanline mode. The burst length can be set by RD_NUM_BYTES register bits. In Scanline mode, it can support 8, 16, 32 and 64 bytes for a burst. The values RD_NUM_BYTES = 0,1,2,3 indicates 8,16,32,64 bytes per burst.

- **Block mode**

  When BLOCK_EN=1, Fetch Engine support 8*8 and 16*16 block mode according to BLOCK_16 register bit. When BLOCK_16=1 the block size is 16*16. When BLOCK_16=0, it is 8*8 block mode. When BLOCK_EN=1, INPUT_ACTIVE_BPP cannot be 3, that is, block mode cannot work on a 64bpp data stream.

  When the total width or total height of image is not divisible by 8 or 16 (according to block size) it will fetch extra pixels or lines to compensate to a complete block. For example, if the size is 23*23, and block mode is 8*8, Fetch Engine will fetch 24*24 data pixels and output to store engine. Store engine has a crop function for this.

  In block mode, AXI bus read number bytes is decided by input format and block size and overrides the RD_NUM_BYTES register field.

13.6.10.4 Fetch Data Shift Function

Fetch Engine supports a shift operation that will swizzle register defined data fields in the incoming data words. The post-shifted data is then output to the proper channel. Up to 4 component shift operations are supported.

The shift function can be disabled by asserting the HW_PXP_x_FETCH_SHIFT_CTRL_CHx.SHIFT_BYPASS bit. This function is bypassed by default.

The shift is configured with the HW_PXP_x_FETCH_SHIFT_OFFSET_CHx.OFFSETx and HW_PXP_x_FETCH_SHIFT_WIDTH_CHx.WIDTHx register fields. Each channel is controlled separately. The OFFSETx fields specify the starting position of the component fields in the incoming data word. The WIDTHx register fields specify the width of that component. There is register support for 4 component fields for each

channel. The specified fields are shifted in order and packed to the least significant part of the data word. The unspecified bits in the input word are discarded. If there are any unspecified bits in the most significant part of the output word they are zeroed out.

Not all fields must be specified. For example if field number three is not used then the WIDTH3 field should be left with a value of 0.

A few examples are shown in the figure below. In the example in figure, left, we are swizzling the data format of YVU444 to YUV444. The register fields should be set as follows:

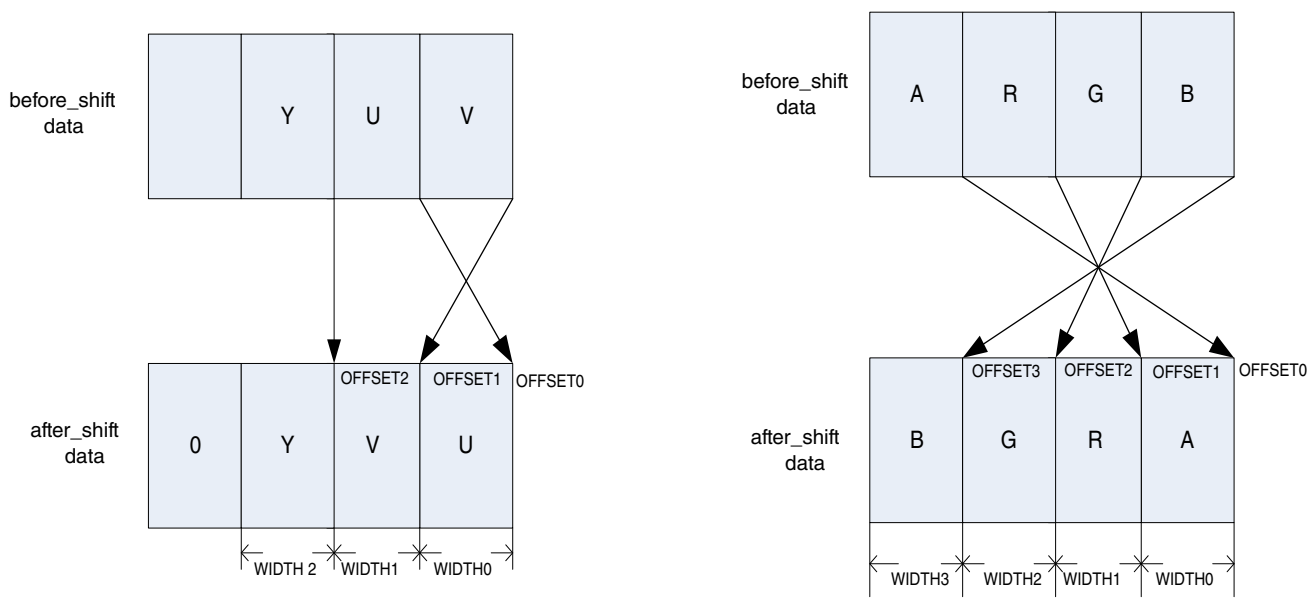
OFFSET0=8, WIDTH0=8, OFFSET1=0, WIDTH1=8, OFFSET2=16, WIDTH2=8, OFFSET3=0, WIDTH3=0

The result switches the position of the 8 but U and V components. The Y component remains in the same place and the high byte remains unchanged.

In the example in figure, right, we are swizzling the data format of ARGB888 to BGRA888. The register settings are:

OFFSET0=24, WIDTH0=8, OFFSET1=16, WIDTH1=8, OFFSET2=8, WIDTH2=8, OFFSET3=0, WIDTH3=8

All the components are swizzled and packed to the right in order from component 0 to 3.



13.6.10.5 Fetch Interface Modes

- **Normal mode**

If HW_PXP_x_FETCH_CTRL_CHx.BYPASS_PIXEL_EN=0 and HW_PXP_x_FETCH_CTRL_CHx.HANDSHAKE_EN=0, the Fetch Engine is working in the “normal” or default mode.

In normal mode, the Fetch engine will fetch data from output memory usually DDR frame by frame. The fetch frame start address is set in registers HW_PXP_DITHER_FETCH_ADDR_x_CH0.INPUT_BASE_ADDRx depending on which channel and plane format is used.

The Fetch Engine will stop to fetch data when one frame data is finished. Another pxp_start signal will trigger another frame fetching work.

- **Bypass mode**

  In the Fetch Engine, if HW_PXP_x_FETCH_CTRL_CHx.BYPASS_PIXEL_EN=1 it will fetch data directly from the input pixel of the upstream Store Engine and not from memory. In this case the AXI bus is inactive.

  In bypass mode, the pixel input will be 32 bits per pixel per valid cycle. The bypassed data will be stored to an internal FIFO first and then output to the next downstream block after the shift operation takes place.

  When BYPASS_EN=1, HANDSHAKE_EN should be equal to 0. Bypass mode and Handshake mode can not be set at the same time.

- **Handshake mode**

  If HW_PXP_x_FETCH_CTRL_CHx.HANDSHAKE_EN=1, the Fetch Engine is set to function in handshake mode.

  The Fetch Engine supports 1 line/ 8line/16lines handshake with the Store Engine module according to HW_PXP_x_FETCH_CTRL_CHx.HANDSHAKE_SCAN_LINE_NUM register bits.

  HANDSHAKE_SCAN_LINE_NUM=0, 1, 2 indicates 1 line, 8 lines, 16 lines handshake mode separately.

  One line handshake can only work in scanline mode, that is, under the condition of BLOCK_EN = 0. Eight lines handshake can only work on block 8x8 mode -- BLOCK_EN=1, BLOCK_16=0.

  Sixteen lines handshake configuration only works in block16x16 mode -- BLOCK_EN=1, BLOCK_16=1.

This is accomplished by creating two buffers in memory, where each correspond to 1/8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

The storage required can be calculated for 1 line handshake as:

Storage = 1(line) * 2(buffer) * width * bytes/pixel;

For 8 lines handshake config the requirements are:

Storage = 8(line) * 2(buffer) * width * bytes/pixel;

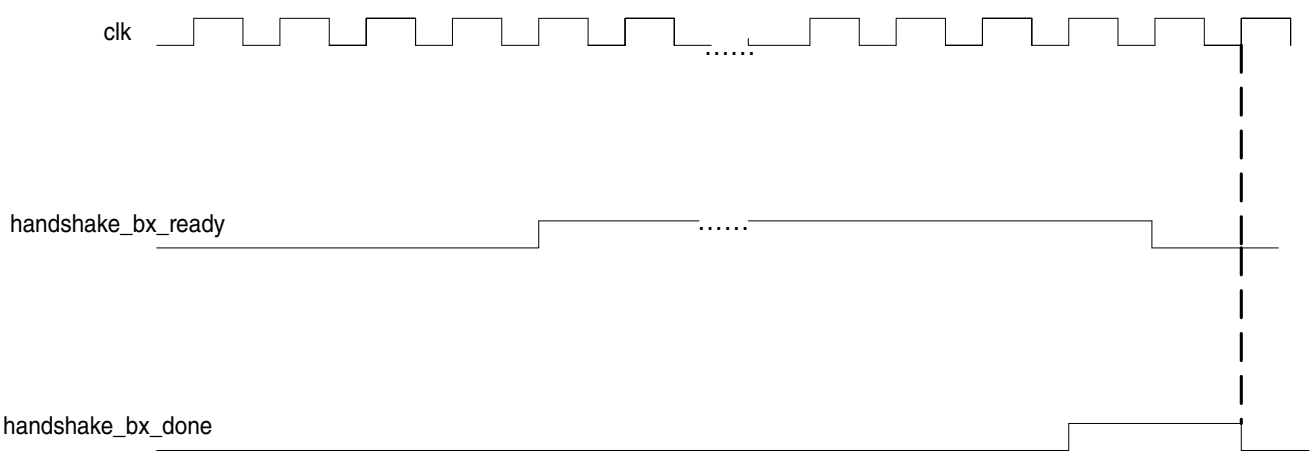
For 16 lines handshake config:

Storage =16(line) * 2(buffer) * width * bytes/pixel;

To accomplish the buffer sharing, the Fetch Engine and store engine will maintain buffer status using a pair of handshake signals. When a buffer is filled by store engine, it will assert the handshake_bx_ready (where x is 0 or 1) signal to indicate to the Fetch Engine that the buffer has valid data. After reading it the Fetch Engine will then release the buffer by asserting the handshake_bx_done signal. The Store Engine is then free to refill it and assert the handshake_bx_ready again.

The 1 scanline mode is used when a Fetch Engine is connected to a Store Engine. An example would be the Input_Store communicating with the Dither_Fetch. The 8 and 16 scanline modes are used when the Output Buffer is communicating with the Dither_Fetch.

The basic protocol is shown in the diagram below:



13.6.11 Histogram

The histogram block collects statistics about the pixel -5data passing through it. Its primary function is to compare the value against programmed values representing the allowed values in different bpp (bits per pixel) modes or bins. A flag value of 1 is recorded if all the pixel values were a match for one of the values programmed for that bit per pixel mode or bin. If there is a mismatch for at least one pixel then the update is not completely contained within that bin and the output flag is 0. There are 5 bits reported. One for each of 1-5 bpp. The results for each bpp bin are always reported. These results are a necessary input to the EPDC for selecting the proper waveform for update to the panel. The pixel value and the compare values are always 6 bits wide although the max effective bpp is 5.

There is also a mask function that can be used to filter out update pixels and exclude them from histogram calculations. It's primary use-case is to collect and report collisions of the current update being processed through the WFE-A and report to software how many pixels collided with current live updates, if any, and the coordinates of the minimum rectangle within the update that contains all collided pixels.

There are two identical instances of the histogram block in the system. The first one can be programmed through a system mux to take data from the outbuf sub-block from the legacy flow, WFE-A or WFE-B. The second instance can take data only from WFE-A or WFE-B.

13.6.11.1 Basic Operation

The basic controls for each histogram engine are contained within their HW_PXP_HIST_x_CTRL and HW_PXP_HIST_x_MASK registers. We will use histogram A registers for explanation purposes in the description below.

The HW_PXP_HIST_A_CTRL.ENABLE bit turns on the histogram block to process pixels. It must be turned on and off manually. The HW_PXP_HIST_A_CTRL.CLEAR bit must be set to clear the histogram results. The bit is self-clearing. The input data (pixel) to the block is 72 bits wide. The comparison is done on 6 bits of pixel data. Any contiguous 6 bits in the 72 bit string can be chosen for comparison using the HW_PXP_HIST_A_CTRL. PIXEL_OFFSET and HW_PXP_HIST_A_CTRL.PIXEL_WIDTH fields. The offset specifies the starting bit position in the string and the width field specifies the width which should not be wider than 6 bits in the current implementation. The mode values for comparison are contained

in the HW_PXP_HISTx_PARAMx register fields. Even though these fields are 6 bits wide, 5 bits is the effective width as the histogram can check for 32 unique pixel values in the largest mode, HIST32.

The result of which bpp modes were a match for all pixels since the output was cleared are continuously updated in the HW_PXP_HIST_A_CTRL.STATUS field. There is one bit for each bpp mode. All histogram bpp modes are checked simultaneously. The HW_PXP_HIST_A_BUF_SIZE fields specify the height and width of the update area. This allows the histogram engine to keep track of the relative coordinates of each new pixel it receives. It assumes the pixels are fed to it in raster order, left to right and top to bottom.

13.6.11.2 Mask Functionality

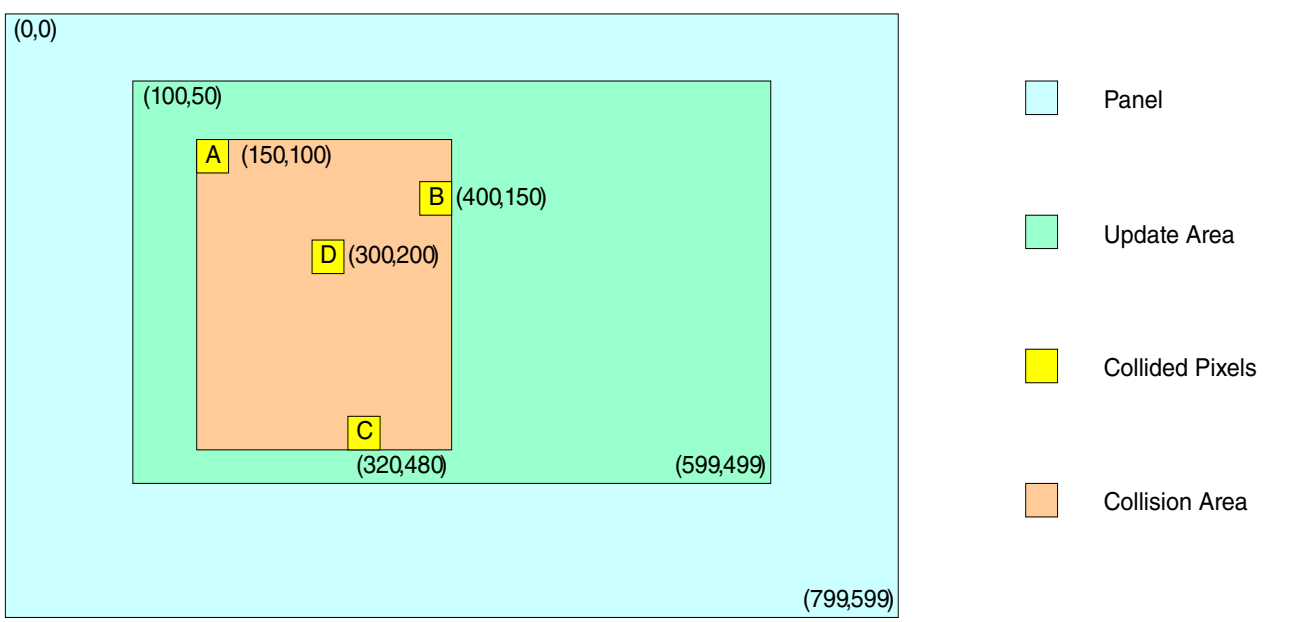
There is also a mask function within the histogram engine that tests a specified string of bits from the input against values programmed into the mask register. The use-case for this is to report collision detection back to controlling software. If the mask test passes then the pixel is active and is processed in the engine and statistics collected. If the pixel is not active then it is discarded and not processed – does not contribute to the output results. Based on the outcome of this mask test, there are some additional results that are output to register fields. They are the number of active pixels, the coordinates of the smallest bounding box including all active pixels and an array of 64 bits where the offset of each bit corresponds to the pixel value of processed pixel. The bit is set for each valid pixel value processed.

The configuration of the mask function is contained in the HW_PXP_HIST_x_MASK register. The HW_PXP_HIST_A_MASK.MASK_EN bit turns on the function. . The HW_PXP_HIST_A_CTRL.CLEAR bit clears the results. The HW_PXP_HIST_A_MASK.MASK_MODE field specifies the logical operation for the test. The options are “equal”, “not equal”, “inside” or “outside.” The HW_PXP_HIST_A_MASK.MASK_VALUE0 and HW_PXP_HIST_A_MASK.MASK_VALUE1 are used for comparison with the incoming value depending on the mode chosen. The starting bit of mask field in the 72 bit input data is specified by the HW_PXP_HIST_A_MASK.MASK_OFFSET register field and the width is given by HW_PXP_HIST_A_MASK.MASK_WIDTH. The width of the mask is a maximum of 8 bits. If the mask mode test passes for a given input then the HW_PXP_HIST_A_TOTAL_PIXEL read only value is incremented. The x and y coordinates of the pixel are used to calculate the minimum rectangle the will enclose all valid pixels. This information can be read from the HW_PXP_HIST_A_ACTIVE_AREA_X and HW_PXP_HIST_A_ACTIVE_AREA_Y registers. Also, the values of the valid pixels are recorded in the HW_PXP_HIST_A_RAW_STAT0 and HW_PXP_HIST_A_RAW_STAT0 registers.

These registers make up 64 one bit fields where the offsets of the bit that are set are the pixel values of the active pixels. (The values as specifed by the HW_PXP_HIST_A_CTRL. PIXEL_OFFSET and HW_PXP_HIST_A_CTRL.PIXEL_WIDTH fields.)

13.6.11.3 Collision use-case Example

In this example, the histogram engine is used to test for and report collision information within the update. Refer to the figure below. With normal WFE-A processing, within the 72 bit output there will be a one bit collision flag that is assert to 1 if there was a collision on that update pixel. There will also be a 6 bit field that specifies the EPDC LUT number for that pixel in the working buffer. If there was a collsion this LUT number identifies the unique colliding live update. To covey all this information to software using the histogram engine, the HW_PXP_HIST_A_CTRL. PIXEL_OFFSET and HW_PXP_HIST_A_CTRL.PIXEL_WIDTH should be set to point to the current LUT in the input bus. The HW_PXP_HIST_A_MASK.MASK_OFFSET and HW_PXP_HIST_A_MASK.MASK_WIDTH fields should be set to point to the collsion bit. The HW_PXP_HIST_A_MASK.MASK_MODE should be 0 or “equal” and the HW_PXP_HIST_A_MASK.MASK_VALUE0 should be set to 1.



The figure above shows the processed results of our example. There is an update region, 499x449, offset within the800x600 panel display. After enabling the histogram and processing the update, there is a collided region within the update region and 4 collided pixels were detected. The results are as follows.

The HW_PXP_HIST_A_TOTAL_PIXEL register would equal to 4 showing that 4 pixels were found by the mask function to have their collision bits set.

The relative collision area are would be given in the HW_PXP_HIST_A_ACTIVE_AREA_X and Y register as MIN_X_OFFSET = 50, MAX_X_OFFSET = 300, MIN_Y_OFFSET = 50, MAX_Y_OFFSET = 380.

If pixel A is being updated by LUT 1, pixel B and C are being updated LUT 5, and pixel D is being updated by LUT 12, then the LUT Collision Status = 0x00001022 (bit 1, 2, 12 are set). That is HW_PXP_HIST_A_RAW_STAT0 would be equal to 0x00001022 and HW_PXP_HIST_A_RAW_STAT1 would be 0x00000000.

13.6.12 PXP Memory Map/Register Definition

PXP Hardware Register Format Summary

PXP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3070_0000	Control Register 0 (PXP_HW_PXP_CTRL)	32	R/W	C700_8000h	13.6.12.1/ 3875
3070_0010	Status Register (PXP_HW_PXP_STAT)	32	R/W	0000_0000h	13.6.12.2/ 3878
3070_0020	Output Buffer Control Register (PXP_HW_PXP_OUT_CTRL)	32	R/W	0000_0000h	13.6.12.3/ 3880
3070_0030	Output Frame Buffer Pointer (PXP_HW_PXP_OUT_BUF)	32	R/W	0000_0000h	13.6.12.4/ 3882
3070_0040	Output Frame Buffer Pointer #2 (PXP_HW_PXP_OUT_BUF2)	32	R/W	0000_0000h	13.6.12.5/ 3883
3070_0050	Output Buffer Pitch (PXP_HW_PXP_OUT_PITCH)	32	R/W	0000_0000h	13.6.12.6/ 3883
3070_0060	Output Surface Lower Right Coordinate (PXP_HW_PXP_OUT_LRC)	32	R/W	0000_0000h	13.6.12.7/ 3884
3070_0070	Processed Surface Upper Left Coordinate (PXP_HW_PXP_OUT_PS_ULC)	32	R/W	0000_0000h	13.6.12.8/ 3885
3070_0080	Processed Surface Lower Right Coordinate (PXP_HW_PXP_OUT_PS_LRC)	32	R/W	0000_0000h	13.6.12.9/ 3886
3070_0090	Alpha Surface Upper Left Coordinate (PXP_HW_PXP_OUT_AS_ULC)	32	R/W	0000_0000h	13.6.12.10/ 3887
3070_00A0	Alpha Surface Lower Right Coordinate (PXP_HW_PXP_OUT_AS_LRC)	32	R/W	0000_0000h	13.6.12.11/ 3888
3070_00B0	Processed Surface (PS) Control Register (PXP_HW_PXP_PS_CTRL)	32	R/W	0000_0000h	13.6.12.12/ 3889

13.6.12.1 Control Register 0 (PXP_HW_PXP_CTRL)

The CTRL register contains controls for the PXP module.

HW_PXP_CTRL: 0x000

HW_PXP_CTRL_SET: 0x004

HW_PXP_CTRL_CLR: 0x008

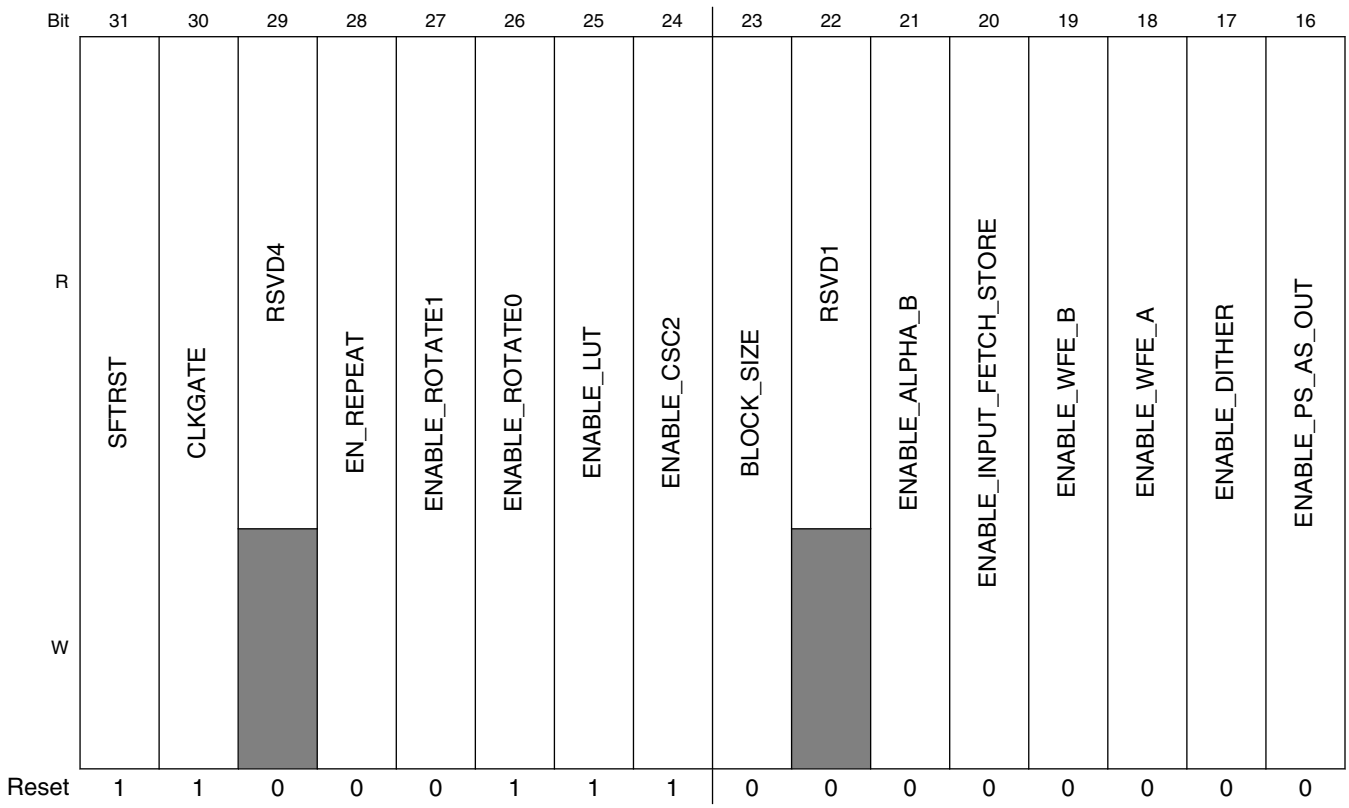
HW_PXP_CTRL_TOG: 0x00C

The Control register contains the primary controls for the PXP block.

EXAMPLE

```
REG_CTRL_SET(BM_PXP_CTRL_SFTRST);
REG_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 3070_0000h base + 0h offset = 3070_0000h



PXP_HW_PXP_CTRL field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal PXP operation. Set this bit to one (default) to disable clocking with the PXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the PXP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.

Table continues on the next page...

PXP_HW_PXP_CTRL field descriptions (continued)

Field	Description
29 RSVD4	Reserved, always set to zero.
28 EN_REPEAT	Enable the PXP to run continuously. When this bit is set, the PXP will repeat based on the current configuration register settings. If this bit is not set, the PXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue.
27 ENABLE_ ROTATE1	Enable the ROTATE1 engine in the PXP primary processing flow.
26 ENABLE_ ROTATE0	Enable the ROTATE0 engine in the PXP primary processing flow.
25 ENABLE_LUT	Enable the LUT engine in the PXP primary processing flow.
24 ENABLE_CSC2	Enable the CSC2 engine in the PXP primary processing flow.
23 BLOCK_SIZE	Select the block size to process through the Rotate block. 0x0 **8X8** — Process 8x8 pixel blocks. 0x1 **16X16** — Process 16x16 pixel blocks.
22 RSVD1	Reserved, always set to zero.
21 ENABLE_ ALPHA_B	Enable the Alpha-B engine in the PXP primary processing flow.
20 ENABLE_ INPUT_FETCH_ STORE	Enable the Input Fetch and Store engine in the PXP primary processing flow.
19 ENABLE_WFE_B	Enable the WFE-B engine in the PXP primary processing flow.
18 ENABLE_WFE_A	Enable the WFE-A engine in the PXP primary processing flow.
17 ENABLE_ DITHER	Enable the Dithering engine in the PXP primary processing flow.
16 ENABLE_PS_ AS_OUT	Enable the PS engine, AS engine, OUTBUF in the PXP primary processing flow.
15 VFLIP1	Indicates that the input should be flipped vertically (effect applied before rotation).
14 HFLIP1	Indicates that the input should be flipped horizontally (effect applied before rotation).
13–12 ROTATE1	Indicates the clockwise rotation to be applied at the input buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation.

Table continues on the next page...

PXP_HW_PXP_CTRL field descriptions (continued)

Field	Description
	0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
11 VFLIP0	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP0	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).
9–8 ROTATE0	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
7–6 RSVD0	Reserved, always set to zero.
5 HANDSHAKE_ ABORT_SKIP	When skip is enable, even the abort asserted, pxp will not assert the ready directly but wait for whole block line complete.
4 ENABLE_LCD0_ HANDSHAKE	Enable handshake with LCD0 controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
3 LUT_DMA_IRQ_ ENABLE	LUT DMA interrupt enable. When set, the PXP will issue an interrupt when the LUT DMA has finished transferring data.
2 NEXT_IRQ_ ENABLE	Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued.
1 IRQ_ENABLE	Interrupt enable. NOTE: When using the HW_PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.
0 ENABLE	Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the HW_PXP_STAT when polling for PXP completion.

13.6.12.2 Status Register (PXP_HW_PXP_STAT)

The PXP Interrupt Status register provides interrupt status information.

HW_PXP_STAT: 0x010

HW_PXP_STAT_SET: 0x014

HW_PXP_STAT_CLR: 0x018

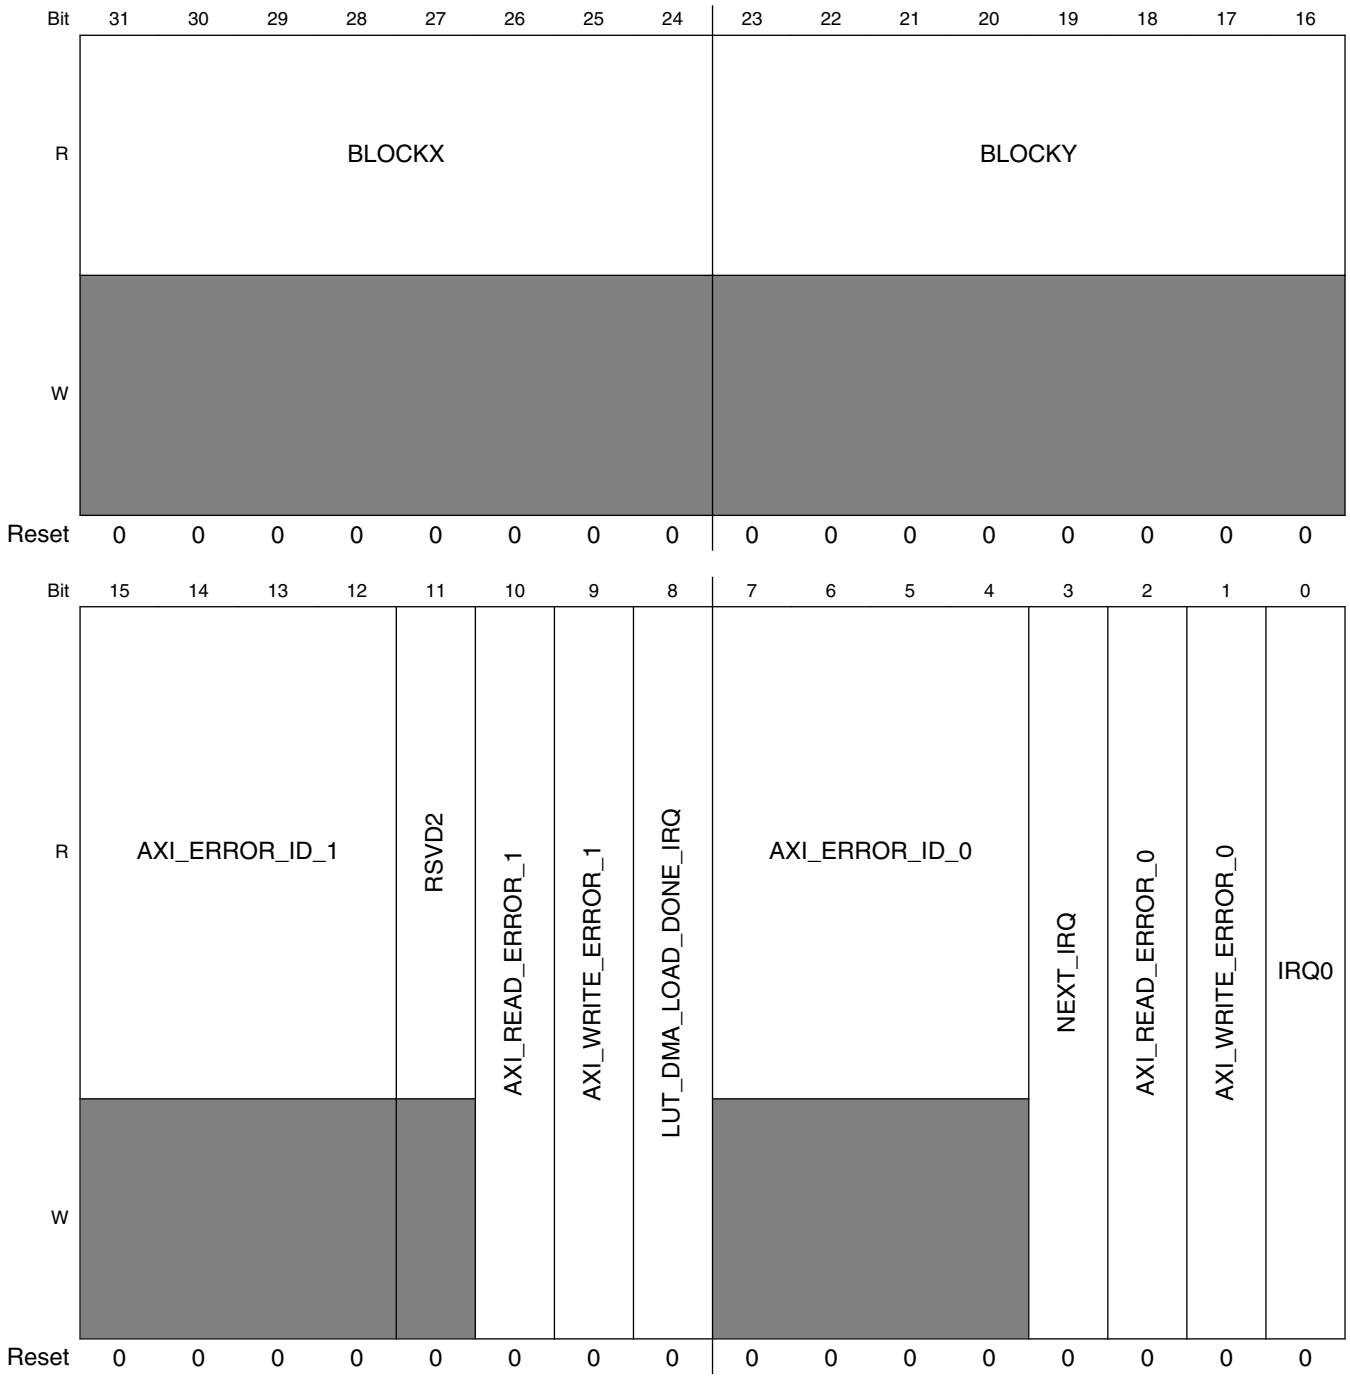
HW_PXP_STAT_TOG: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

EXAMPLE

```
REG_STAT_CLR(BM_PXP_STAT_IRQ);  // clear CSC interrupt
```

Address: 3070_0000h base + 10h offset = 3070_0010h



PXP_HW_PXP_STAT field descriptions

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the X coordinate of the block currently being rendered.
15–12 AXI_ERROR_ID_1	Indicates the AXI1 ID of the failing bus operation.
11 RSVD2	Reserved, always set to zero.
10 AXI_READ_ERROR_1	Indicates PXP encountered an AXI read error and processing has been terminated.
9 AXI_WRITE_ERROR_1	Indicates PXP encountered an AXI write error and processing has been terminated.
8 LUT_DMA_LOAD_DONE_IRQ	Indicates that the LUT DMA transfer has completed.
7–4 AXI_ERROR_ID_0	Indicates the AXI0 ID of the failing bus operation.
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ERROR_0	Indicates PXP encountered an AXI read error and processing has been terminated.
1 AXI_WRITE_ERROR_0	Indicates PXP encountered an AXI write error and processing has been terminated.
0 IRQ0	Indicates current PXP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set.

13.6.12.3 Output Buffer Control Register (PXP_HW_PXP_OUT_CTRL)

The OUT_CTRL register contains controls for the Output Buffer.

HW_PXP_OUT_CTRL: 0x020

HW_PXP_OUT_CTRL_SET: 0x024

HW_PXP_OUT_CTRL_CLR: 0x028

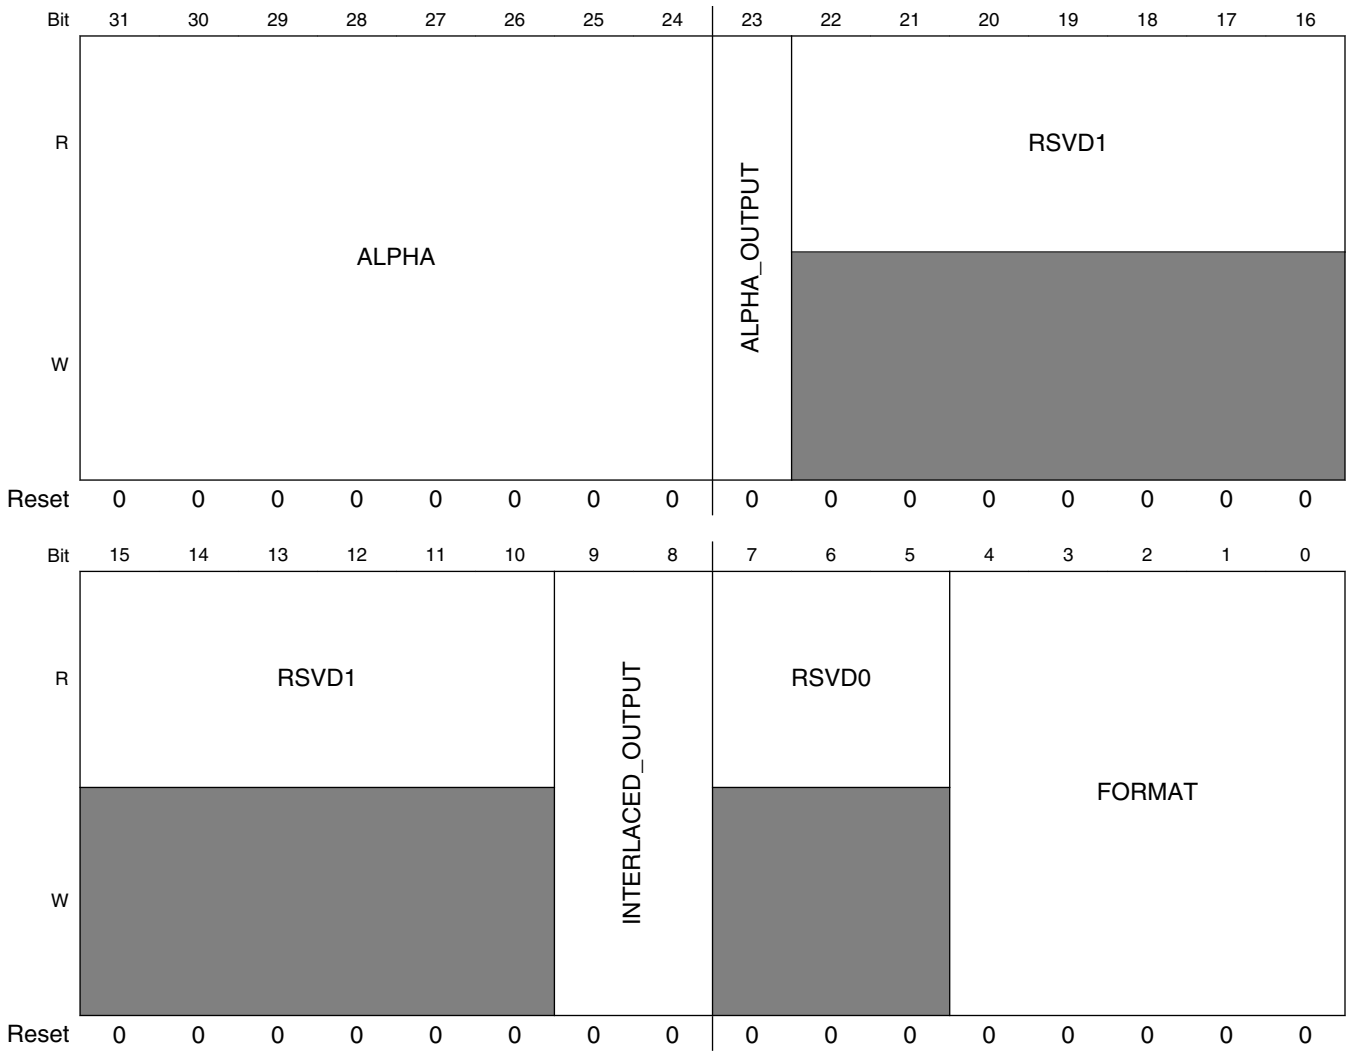
HW_PXP_OUT_CTRL_TOG: 0x02C

Control register to determine OUT buffer processing.

EXAMPLE

```
REG_CTRL_SET(BM_PXP_CTRL_SFTRST);
REG_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 3070_0000h base + 20h offset = 3070_0020h



PXP_HW_PXP_OUT_CTRL field descriptions

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.
23 ALPHA_ OUTPUT	Indicates that alpha component in output buffer pixels should be overwritten by REG_OUT_CTRL[ALPHA] register. If 0, retain their alpha value from the computed alpha for that pixel.
22–10 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_OUT_CTRL field descriptions (continued)

Field	Description
9–8 INTERLACED_ OUTPUT	Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported. 0x0 **PROGRESSIVE** — All data written in progressive format to the OUTBUF Pointer. 0x1 **FIELD0** — Interlaced output: only data for field 0 is written to the OUTBUF Pointer. 0x2 **FIELD1** — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer. 0x3 **INTERLACED** — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.
7–5 RSVD0	Reserved, always set to zero.
FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format. 0x0 **ARGB8888** — 32-bit pixels 0x4 **RGB888** — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.) 0x5 **RGB888P** — 24-bit pixels (packed 24-bit format) 0x8 **ARGB1555** — 16-bit pixels 0x9 **ARGB4444** — 16-bit pixels 0xC **RGB555** — 16-bit pixels 0xD **RGB444** — 16-bit pixels 0xE **RGB565** — 16-bit pixels 0x10 **YUV1P444** — 32-bit pixels (1-plane XYUV unpacked) 0x12 **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 **Y8** — 8-bit monochrome pixels (1-plane Y luma output) 0x15 **Y4** — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0x19 **YUV2P420** — 16-bit pixels (2-plane UV) 0x1A **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0x1B **YVU2P420** — 16-bit pixels (2-plane VU)

13.6.12.4 Output Frame Buffer Pointer (PXP_HW_PXP_OUT_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

This register is used by the logic to point to the current output location for the output frame buffer.

EXAMPLE

```
REG_OUT_BUF_WR( buffer );
```

Address: 3070_0000h base + 30h offset = 3070_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_OUT_BUF field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

13.6.12.5 Output Frame Buffer Pointer #2 (PXP_HW_PXP_OUT_BUF2)

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is NOT used as the pointer to the 2nd buffer when in LCDIF_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

EXAMPLE

```
REG_OUT_BUF_WR( field0 );  // buffer for interlaced field 0
REG_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 3070_0000h base + 40h offset = 3070_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_OUT_BUF2 field descriptions

Field	Description
ADDR	Current address pointer for the output frame buffer. The address can have any byte alignment. 64B alignment is recommended for optimal performance.

13.6.12.6 Output Buffer Pitch (PXP_HW_PXP_OUT_PITCH)

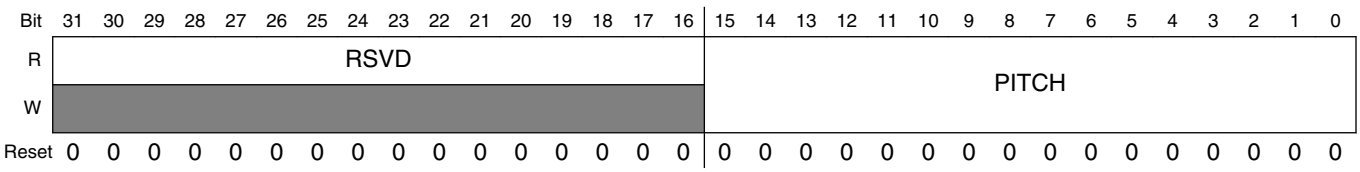
This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

EXAMPLE

```
REG_OUT_PITCH_WR( 68 * 4 );  // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 3070_0000h base + 50h offset = 3070_0050h



PXP_HW_PXP_OUT_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

13.6.12.7 Output Surface Lower Right Coordinate (PXP_HW_PXP_OUT_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accomodate the rotated size.

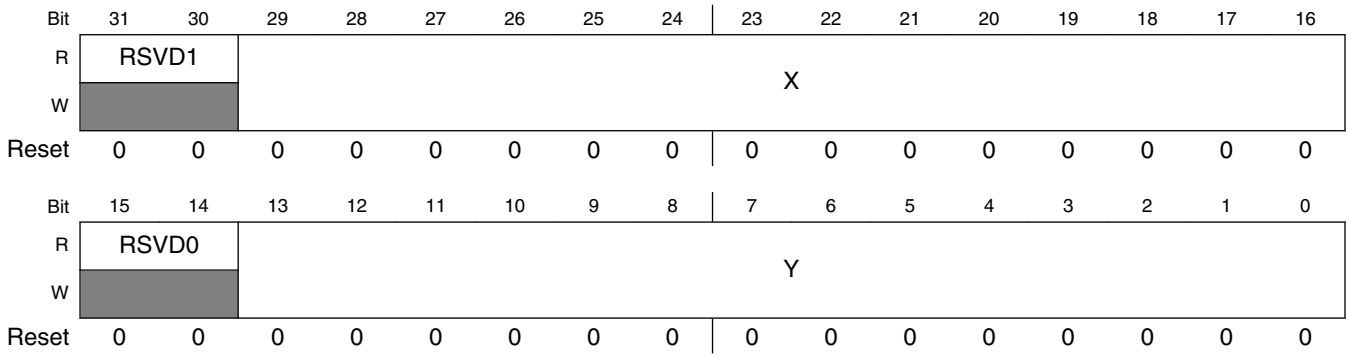
This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisable by N pixels in either dimension.

EXAMPLE

```
REG_OUT_LRC[X]=319;  // set width of output frame buffer to 320 pixels
REG_OUT_LRC[Y]=243;  // set height of output frame buffer to 244 pixels which is not
divisable by block size N

REG_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319)  |  BF_PXP_OUT_LRC_Y(243) );
```

Address: 3070_0000h base + 60h offset = 3070_0060h



PXP_HW_PXP_OUT_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	Indicates number of horizontal PIXELS in the output surface (non-rotated). The output buffer pixel width minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.
15–14 RSVD0	Reserved, always set to zero.
Y	Indicates the number of vertical PIXELS in the output surface (non-rotated). The output buffer pixel height minus 1 should be programmed. The image size is not required to be a multiple of 8 pixels. The PXP will clip the pixel output at this boundary.

13.6.12.8 Processed Surface Upper Left Coordinate (PXP_HW_PXP_OUT_PS_ULC)

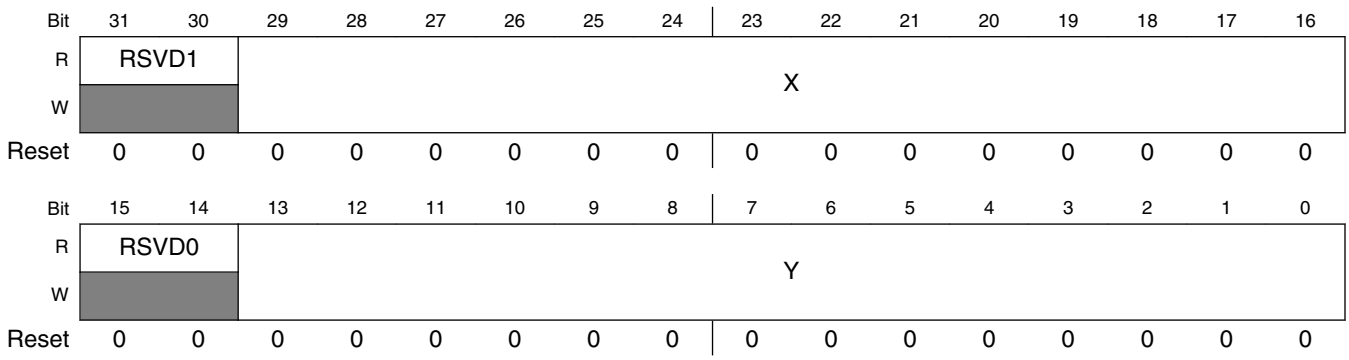
This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the REG_OUT_LRC[X,Y] extents are valid. The lowest valid value for these fields is 0,0. If the value of the REG_OUT_PS_ULC is greater than the REG_OUT_LRC, then no PS pixels will be fetched from memory, but only REG_PS_BACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the REG_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
REG_OUT_PS_ULC_WR(0,0x0002_0002); // Processed Surface upper left coordinate at (X,Y) =
2,2.  The PS surface will not effect pixels in the first and second row and column of the
output buffer.
```

Address: 3070_0000h base + 70h offset = 3070_0070h



PXP_HW_PXP_OUT_PS_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the processed surface (PS) in the output buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the processed surface in the output buffer.

13.6.12.9 Processed Surface Lower Right Coordinate (PXP_HW_PXP_OUT_PS_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the REG_OUT_LRC[X,Y] extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the REG_OUT_LRC extents will use the PS to render pixels into the output buffer.

EXAMPLE

```
REG_OUT_PS_ULC_WR(0,0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one
pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
REG_OUT_PS_LRC_WR(0,0x03FF_03FF);
```

Address: 3070_0000h base + 80h offset = 3070_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PXP_HW_PXP_OUT_PS_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the processed surface (PS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the processed surface in the output frame buffer.

13.6.12.10 Alpha Surface Upper Left Coordinate (PXP_HW_PXP_OUT_AS_ULC)

This register contains the upper left location for the Alpha Surface in the output buffer.

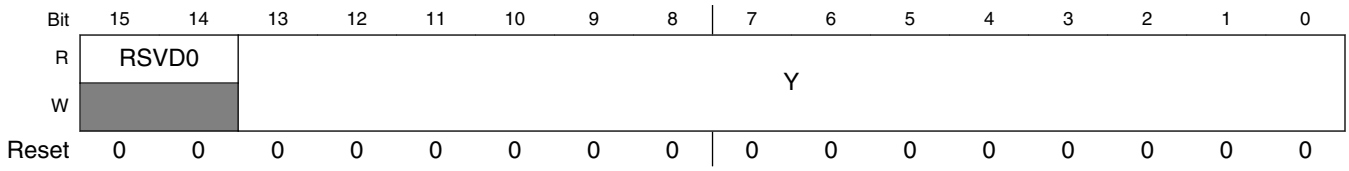
This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the REG_OUT_LRC[X,Y] extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
REG_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1.
The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 3070_0000h base + 90h offset = 3070_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD1								X							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



PXP_HW_PXP_OUT_AS_ULC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the upper left X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the upper left Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

13.6.12.11 Alpha Surface Lower Right Coordinate (PXP_HW_PXP_OUT_AS_LRC)

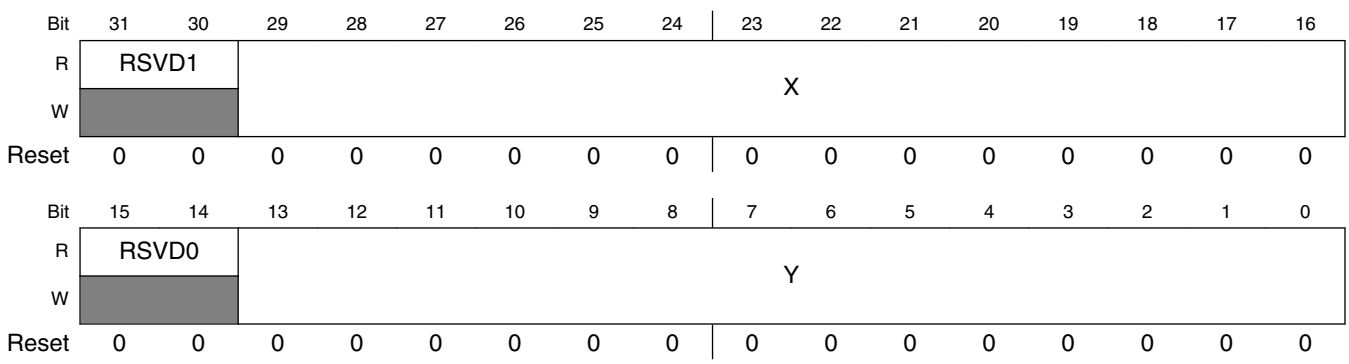
This register contains the lower right extent for Alpha Surface in the output buffer.

This register contains the lower right coordinate of AS in the output frame buffer (in pixels). Values that are within the REG_OUT_LRC[X,Y] extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are less than or equal to the lower right coordinates will use the AS to render pixels in the output buffer.

EXAMPLE

```
REG_AS_LRC_WR(0,0x03FF_03FF); // Alpha Surface lower right coordinate at (X,Y) = 1023,1023.
```

Address: 3070_0000h base + A0h offset = 3070_00A0h



PXP_HW_PXP_OUT_AS_LRC field descriptions

Field	Description
31–30 RSVD1	Reserved, always set to zero.
29–16 X	This field indicates the lower right X-coordinate (in pixels) of the alpha surface (AS) in the output frame buffer.
15–14 RSVD0	Reserved, always set to zero.
Y	This field indicates the lower right Y-coordinate (in pixels) of the alpha surface in the output frame buffer.

13.6.12.12 Processed Surface (PS) Control Register (PXP_HW_PXP_PS_CTRL)

The PS_CTRL register contains controls for the Processed Surface Buffer.

HW_PXP_PS_CTRL: 0x0B0

HW_PXP_PS_CTRL_SET: 0x0b4

HW_PXP_PS_CTRL_CLR: 0x0B8

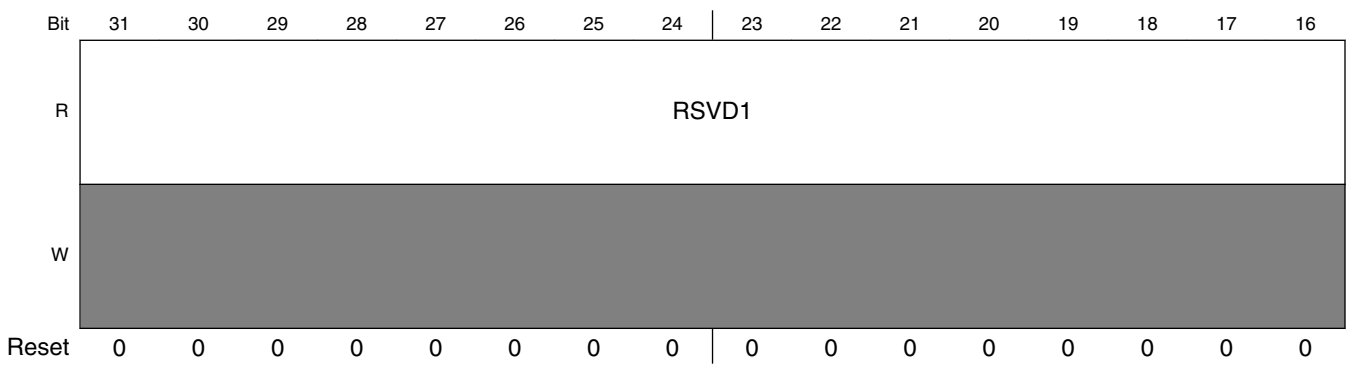
HW_PXP_PS_CTRL_TOG: 0x0BC

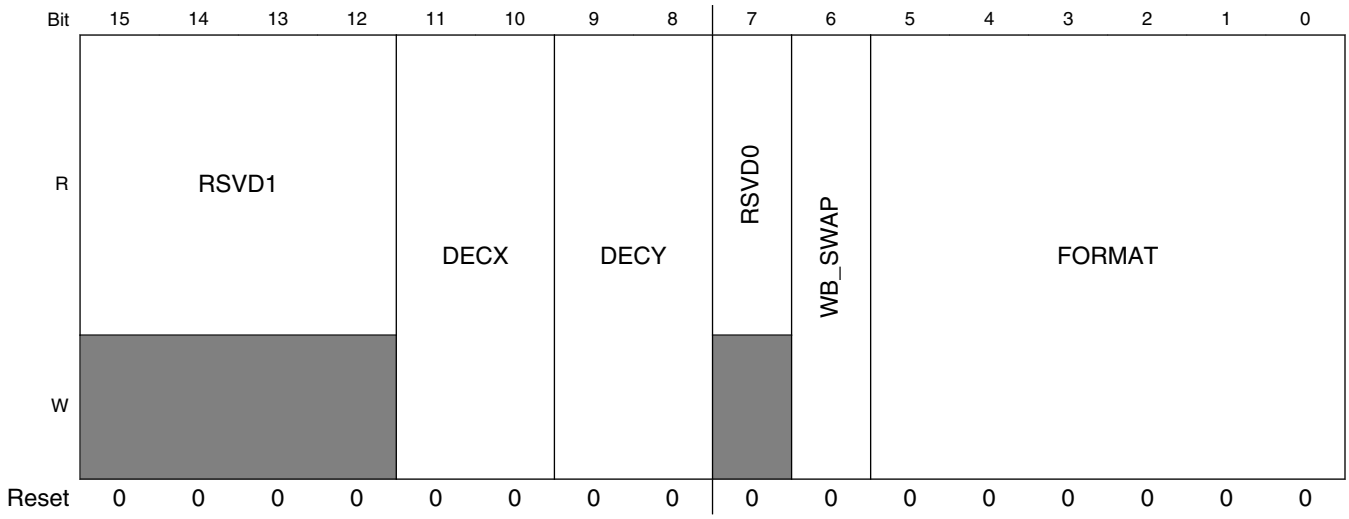
Control register to determine PS buffer processing.

EXAMPLE

```
REG_CTRL_SET(BM_PXP_CTRL_SFTRST);
REG_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 3070_0000h base + B0h offset = 3070_00B0h





PXP_HW_PXP_PS_CTRL field descriptions

Field	Description
31–12 RSVD1	Reserved, always set to zero.
11–10 DECX	Horizontal pre decimation filter control. 0x0 **DISABLE** — Disable pre-decimation filter. 0x1 **DECX2** — Decimate PS by 2. 0x2 **DECX4** — Decimate PS by 4. 0x3 **DECX8** — Decimate PS by 8.
9–8 DECY	Verticle pre decimation filter control. 0x0 **DISABLE** — Disable pre-decimation filter. 0x1 **DECY2** — Decimate PS by 2. 0x2 **DECY4** — Decimate PS by 4. 0x3 **DECY8** — Decimate PS by 8.
7 RSVD0	Reserved, always set to zero.
6 WB_SWAP	Swap bytes in words. For each 16 bit word, the two bytes will be swapped.
FORMAT	PS buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSC1_COEF0 register. 0x4 **RGB888** — 32-bit pixels (unpacked 24-bit format) 0xC **RGB555** — 16-bit pixels 0xD **RGB444** — 16-bit pixels 0xE **RGB565** — 16-bit pixels 0x10 **YUV1P444** — 32-bit pixels (1-plane XYUV unpacked) 0x12 **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0x13 **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0x14 **Y8** — 8-bit monochrome pixels (1-plane Y luma output) 0x15 **Y4** — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0x18 **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0x19 **YUV2P420** — 16-bit pixels (2-plane UV)

Table continues on the next page...

PXP_HW_PXP_PS_CTRL field descriptions (continued)

Field	Description
	0x1A **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0x1B **YVU2P420** — 16-bit pixels (2-plane VU) 0x1E **YUV422** — 16-bit pixels (3-plane format) 0x1F **YUV420** — 16-bit pixels (3-plane format)

13.6.12.13 PS Input Buffer Address (PXP_HW_PXP_PS_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
REG_PS_BUF_WR(image_rgb); // RGB image
REG_PS_BUF_WR(image_y);   // Y (luma) image data
REG_PS_UBUF_WR(image_u);  // U (Cb) image data
REG_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 3070_0000h base + C0h offset = 3070_00C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_PS_BUF field descriptions

Field	Description
ADDR	Address pointer for the PS RGB or Y (luma) input buffer.

13.6.12.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP_HW_PXP_PS_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
REG_PS_BUF_WR(image_y);   // Y (luma) image data
REG_PS_UBUF_WR(image_u);  // U (Cb) image data
REG_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 3070_0000h base + D0h offset = 3070_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_PS_UBUF field descriptions

Field	Description
ADDR	Address pointer for the PS U/Cb or 2 plane UV Chroma input buffer.

13.6.12.15 PS V/Cr Input Buffer Address (PXP_HW_PXP_PS_VBUF)

PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits]7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

```
REG_PS_BUF_WR(image_y);   // Y (luma) image data
REG_PS_UBUF_WR(image_u);  // U (Cb) image data
REG_PS_VBUF_WR(image_v);  // V (Cr) image data
```

Address: 3070_0000h base + E0h offset = 3070_00E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_PS_VBUF field descriptions

Field	Description
ADDR	Address pointer for the PS V/Cr Chroma input buffer.

13.6.12.16 Processed Surface Pitch (PXP_HW_PXP_PS_PITCH)

This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

EXAMPLE

```
REG_PS_PITCH_WR( 64 * 4 );  // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 3070_0000h base + F0h offset = 3070_00F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																PITCH															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_PS_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

13.6.12.17 PS Background Color (PXP_HW_PXP_PS_BACKGROUND_0)

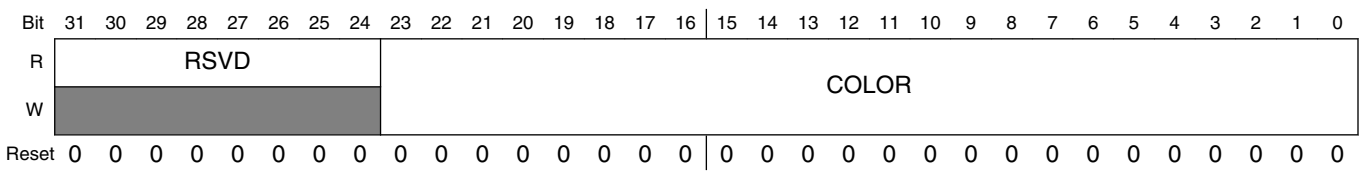
PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image. This value is used by the Alpha A block.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

EXAMPLE

```
REG_PS_BACKGROUND_WR(0x00000000);  // letterbox is black
REG_PS_BACKGROUND_WR(0x00800000);  // letterbox is dark red
REG_PS_BACKGROUND_WR(0x00008000);  // letterbox is dark green
REG_PS_BACKGROUND_WR(0x00000080);  // letterbox is dark blue
```

Address: 3070_0000h base + 100h offset = 3070_0100h



PXP_HW_PXP_PS_BACKGROUND_0 field descriptions

Field	Description
31–24 RSVD	Reserved, always set to zero.
COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/ LRC.

13.6.12.18 PS Scale Factor Register (PXP_HW_PXP_PS_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

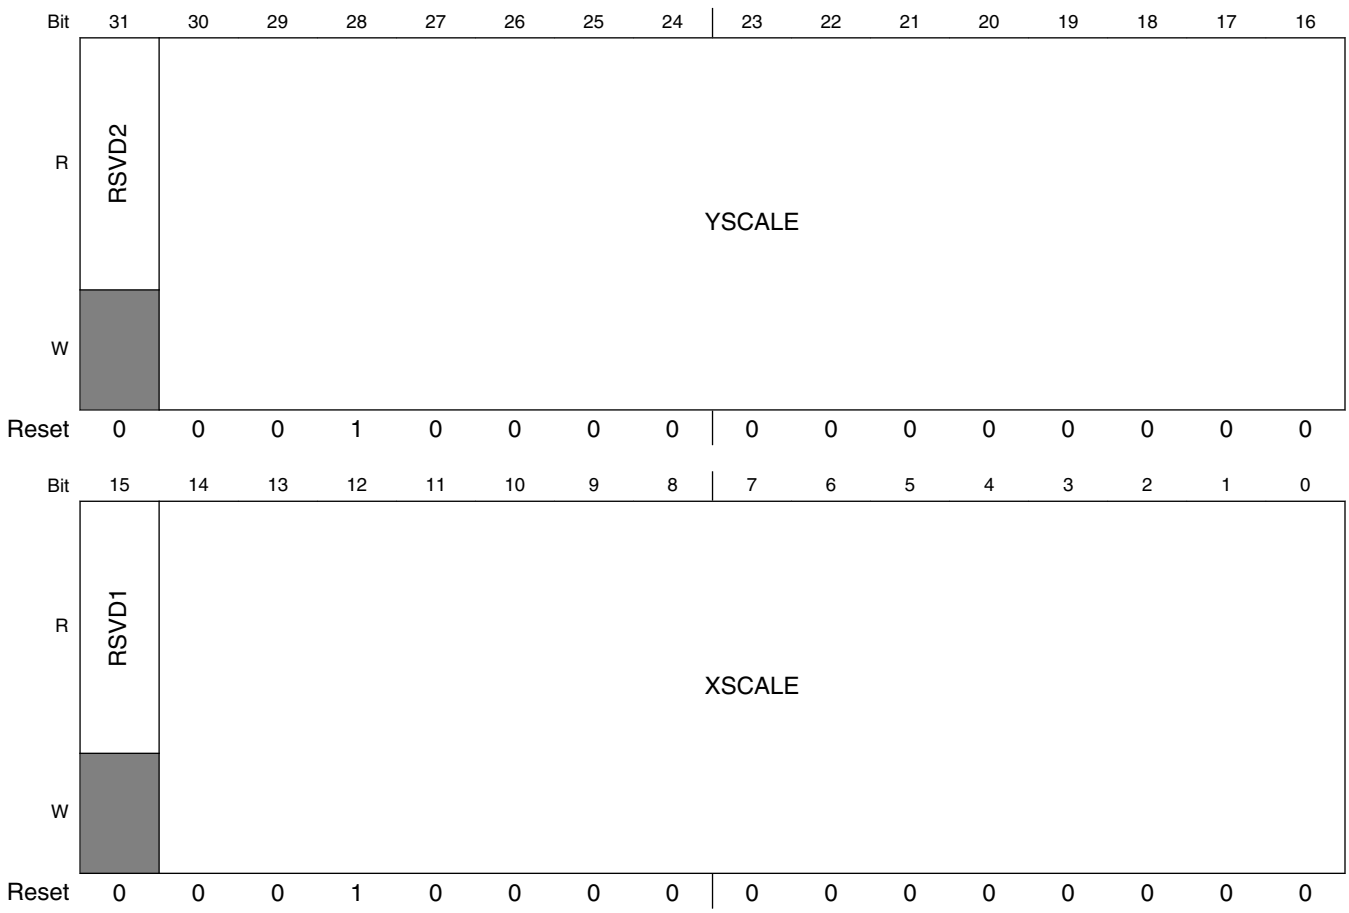
The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is 2^12 for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 10.0000_0000_0000 should be

loaded into this register. To scale up by a factor of 4, the value of 1/4, or 00.0100_0000_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010_0000_0000 should be loaded.

EXAMPLE

```
REG_PS_SCALE_WR(0x10001000);  // 1:1  scaling (0x1.000)
REG_PS_SCALE_WR(0x08000800);  // 2x   scaling (0x0.800)
REG_PS_SCALE_WR(0x20002000);  // 1/2x scaling (0x2.000)
```

Address: 3070_0000h base + 110h offset = 3070_0110h



PXP_HW_PXP_PS_SCALE field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 YSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the Y scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.
15 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_PS_SCALE field descriptions (continued)

Field	Description
XSCALE	This is a two bit integer and 12 bit fractional representation (##.####_####_####) of the X scaling factor for the PS source buffer. The maximum value programmed should be 2 since scaling down by a factor greater than 2 is not supported with the bilinear filter. Decimation and the bilinear filter should be used together to achieve scaling by more than a factor of 2.

13.6.12.19 PS Scale Offset Register (PXP_HW_PXP_PS_OFFSET)

PS Scale Offset. This register provides the initial scale offset for the PS buffer.

The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of (1/2*P0) + (1/2*P1). This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

EXAMPLE

```
REG_PS_SCALE_WR(0x2000_2000);   // 1/2x scaling (0x2.000)
REG_PS_OFFSET_WR(0x0800_0800);  // half-pixel offset in both X and Y to ensure averaging
versus pixel decimation
```

Address: 3070_0000h base + 120h offset = 3070_0120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD2				YOFFSET												RSVD1				XOFFSET											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_PS_OFFSET field descriptions

Field	Description
31–28 RSVD2	Reserved, always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.
15–12 RSVD1	Reserved, always set to zero.
XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed pixel offset which gets added to the scaled address to determine source data for the scaling engine.

13.6.12.20 PS Color Key Low (PXP_HW_PXP_PS_CLRKEYLOW_0)

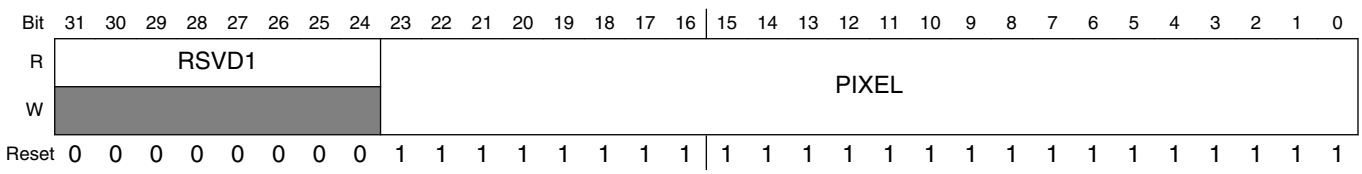
This register contains the color key low value for the PS buffer. This value is used by the Alpha A block.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between REG_PS_CLRKEYLOW and REG_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the REG_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                    // colorkey values between
REG_PS_CLRKEYLOW_WR (0x008000); // medium green and
REG_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 3070_0000h base + 130h offset = 3070_0130h



PXP_HW_PXP_PS_CLRKEYLOW_0 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

13.6.12.21 PS Color Key High (PXP_HW_PXP_PS_CLRKEYHIGH_0)

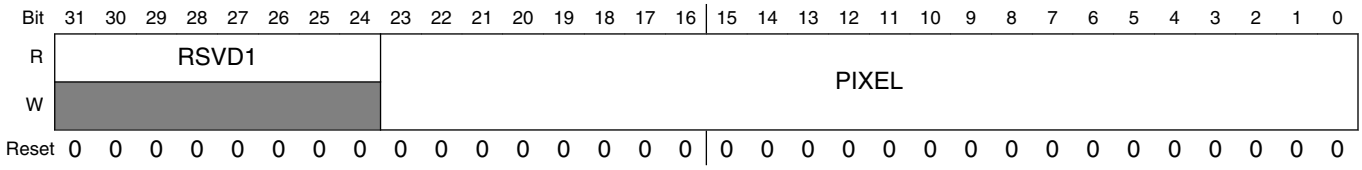
This register contains the color key high value for the PS buffer. This value is used by the Alpha A block.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between REG_PS_CLRKEYLOW and REG_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the REG_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                        // colorkey values between
REG_PS_CLRKEYLOW_WR (0x008000); // medium green and
REG_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 3070_0000h base + 140h offset = 3070_0140h



PXP_HW_PXP_PS_CLRKEYHIGH_0 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

13.6.12.22 Alpha Surface Control (PXP_HW_PXP_AS_CTRL)

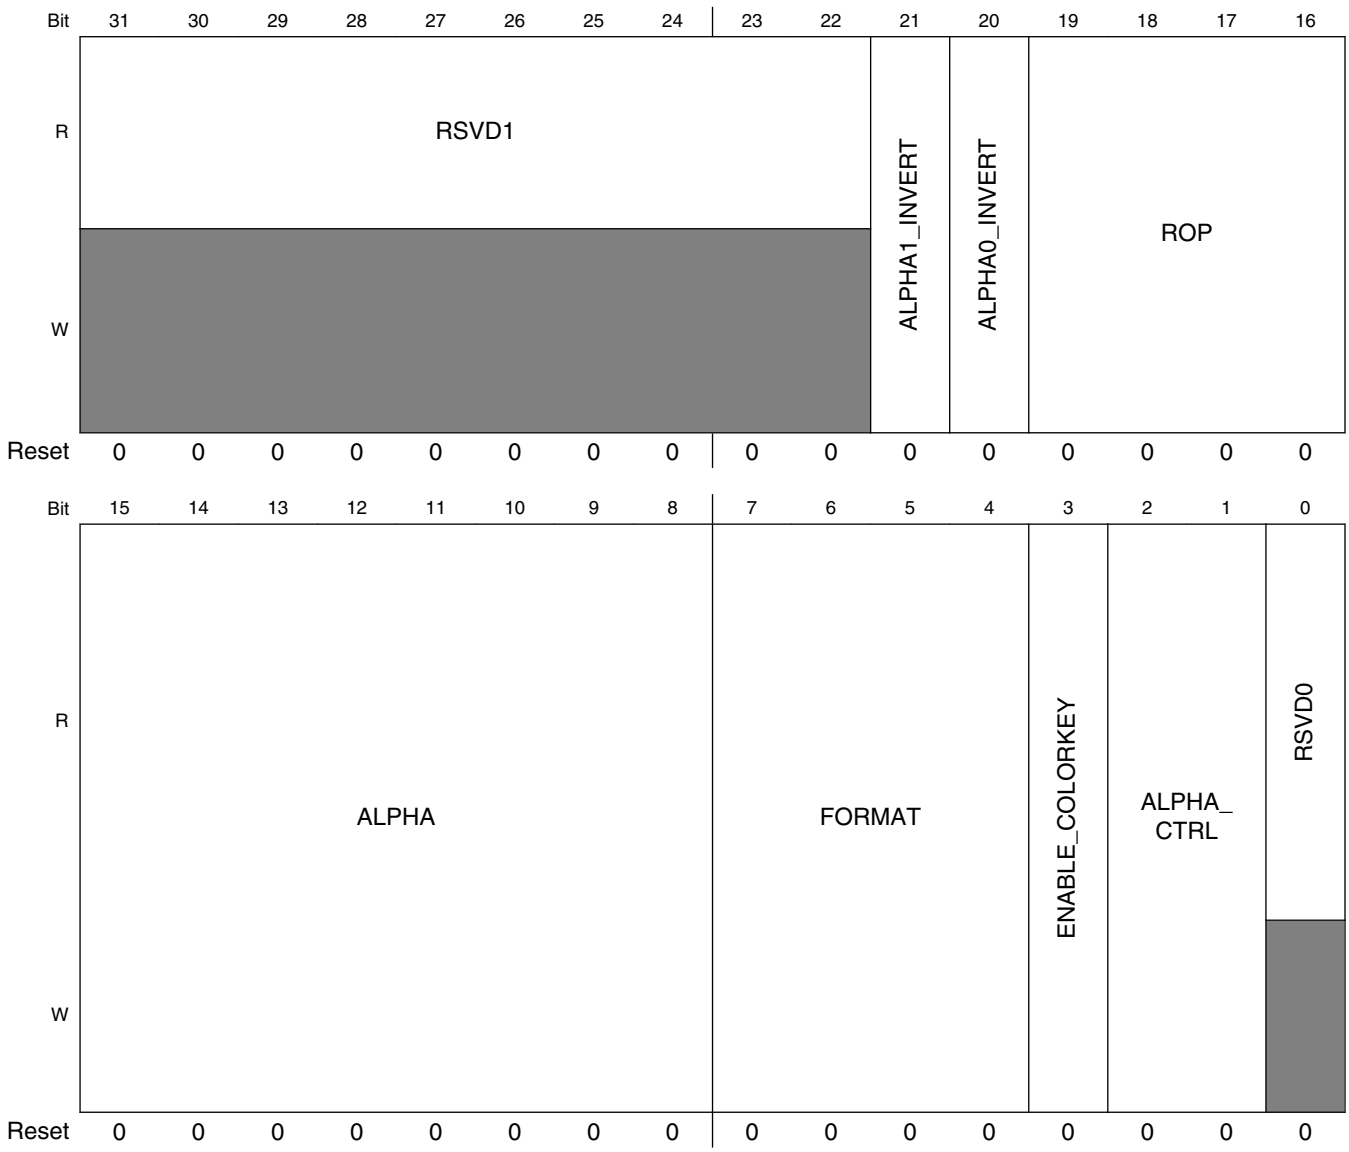
This register contains buffer control for the Alpha Surface 0 input buffer.

Control register to determine AS buffer processing.

EXAMPLE

```
u32 asparam;
      asparam  = BF_PXP_ASPARAM_ENABLE    (1);
      asparam |= BF_PXP_ASPARAM_ALPHA_CTRL(BV_PXP_ASPARAM_ALPHA_CTRL__ROPs);
      asparam |= BF_PXP_ASPARAM_FORMAT    (BV_PXP_ASPARAM_FORMAT__ARGB8888);
      asparam |= BF_PXP_ASPARAM_ROP       (BV_PXP_ASPARAM_ROP__XORAS);
REG_ASPARAM_WR(0,asparam);  // enable alpha surface to perform XOR ROP using RGB8888 AS
pixel format
```

Address: 3070_0000h base + 150h offset = 3070_0150h



PXP_HW_PXP_AS_CTRL field descriptions

Field	Description
31–22 RSVD1	Reserved, always set to zero.
21 ALPHA1_ INVERT	Setting this bit to logic 0 will not alter the alpha1 value. A logic 1 will invert the alpha1 value and apply (1-alpha) for image composition.
20 ALPHA0_ INVERT	Setting this bit to logic 0 will not alter the alpha0 value. A logic 1 will invert the alpha0 value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. 0x0 **MASKAS** — AS AND PS

Table continues on the next page...

PXP_HW_PXP_AS_CTRL field descriptions (continued)

Field	Description
	0x1 **MASKNOTAS** — nAS AND PS 0x2 **MASKASNOT** — AS AND nPS 0x3 **MERGEAS** — AS OR PS 0x4 **MERGENOTAS** — nAS OR PS 0x5 **MERGEASNOT** — AS OR nPS 0x6 **NOTCOPYAS** — nAS 0x7 **NOT** — nPS 0x8 **NOTMASKAS** — AS NAND PS 0x9 **NOTMERGEAS** — AS NOR PS 0xA **XORAS** — AS XOR PS 0xB **NOTXORAS** — AS XNOR PS
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in REG_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. 0x0 **ARGB8888** — 32-bit pixels with alpha 0x1 **RGBA8888** — 32-bit pixels with alpha 0x4 **RGB888** — 32-bit pixels without alpha (unpacked 24-bit format) 0x8 **ARGB1555** — 16-bit pixels with alpha 0x9 **ARGB4444** — 16-bit pixels with alpha 0xC **RGB555** — 16-bit pixels without alpha 0xD **RGB444** — 16-bit pixels without alpha 0xE **RGB565** — 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x0 **Embedded** — Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. 0x1 **Override** — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 **Multiply** — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 **ROPs** — Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 RSVD0	Reserved, always set to zero.

13.6.12.23 Alpha Surface Buffer Pointer (PXP_HW_PXP_AS_BUF)

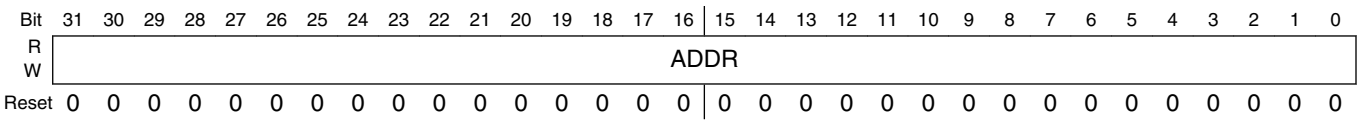
Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

EXAMPLE

```
u32* alpha_ptr;
REG_ASn_WR(0,alpha_ptr);
```

Address: 3070_0000h base + 160h offset = 3070_0160h



PXP_HW_PXP_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

13.6.12.24 Alpha Surface Pitch (PXP_HW_PXP_AS_PITCH)

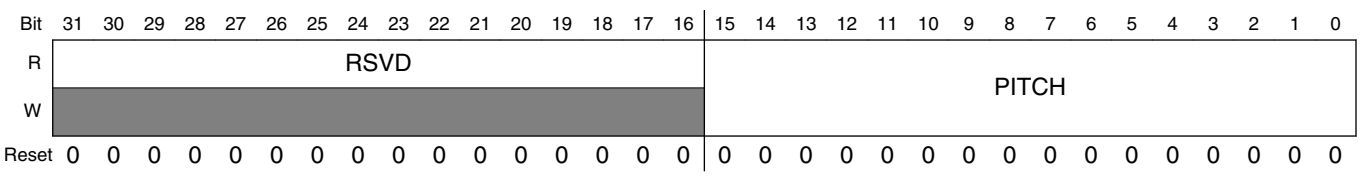
This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

EXAMPLE

```
REG_AS_PITCH_WR( 1920 * 4 );  // The output buffer pitch is HD resolution at 32 bits per
pixel
```

Address: 3070_0000h base + 170h offset = 3070_0170h



PXP_HW_PXP_AS_PITCH field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
PITCH	Indicates the number of bytes in memory between two vertically adjacent pixels.

13.6.12.25 Overlay Color Key Low (PXP_HW_PXP_AS_CLRKEYLOW_0)

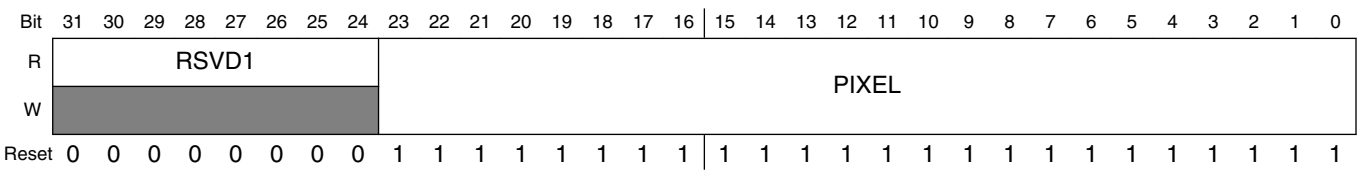
This register contains the color key low value for the AS buffer. This value is used by the Alpha A block.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
REG_AS_CLRKEYLOW_WR (0x000000); // black and
REG_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 3070_0000h base + 180h offset = 3070_0180h



PXP_HW_PXP_AS_CLRKEYLOW_0 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

13.6.12.26 Overlay Color Key High (PXP_HW_PXP_AS_CLRKEYHIGH_0)

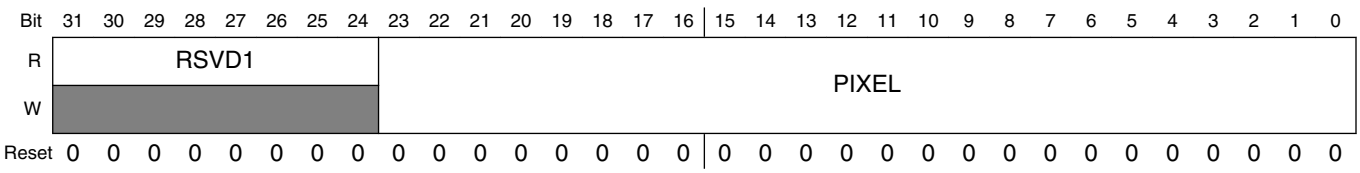
This register contains the color key high value for the AS buffer. This value is used by the Alpha A block.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
REG_AS_CLRKEYLOW_WR (0x000000); // black and
REG_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 3070_0000h base + 190h offset = 3070_0190h



PXP_HW_PXP_AS_CLRKEYHIGH_0 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

13.6.12.27 Color Space Conversion Coefficient Register 0 (PXP_HW_PXP_CSC1_COEF0)

This register contains color space conversion coefficients in two's compliment notation.

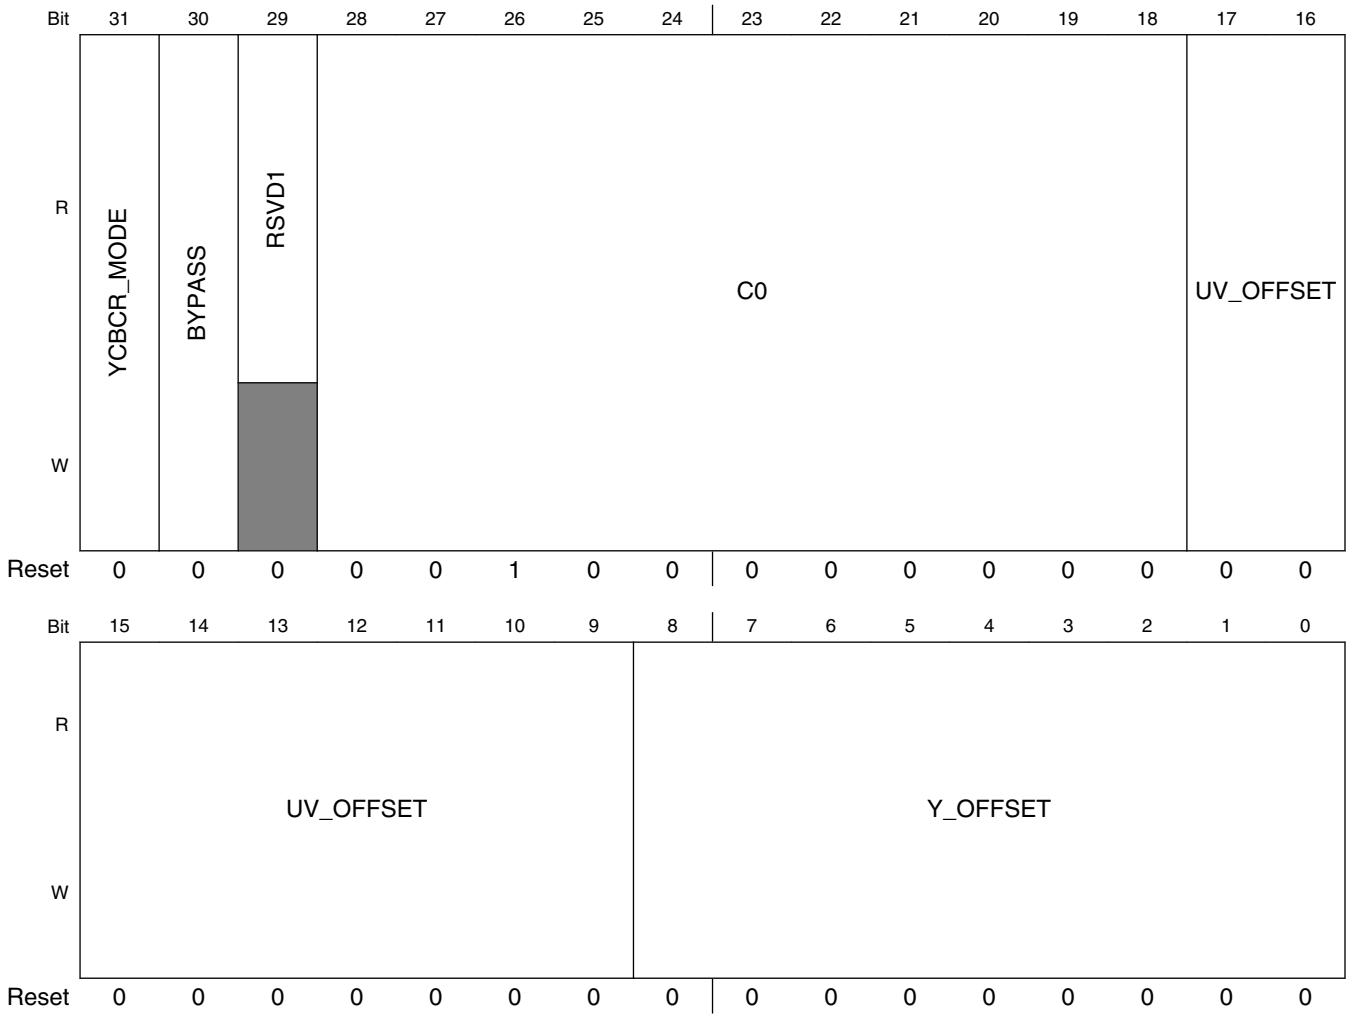
The Coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

EXAMPLE

```
//  The equations used for Colorspace conversion are:
//     R = C0*(Y+YOFFSET)                    + C1(V+UV_OFFSET)
//     G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//     R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

   REG_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
   REG_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
   REG_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 3070_0000h base + 1A0h offset = 3070_01A0h



PXP_HW_PXP_CSC1_COEF0 field descriptions

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. Set to 0 when converting YUV to RGB data. This bit changes the behavior of the scaler when performing U/V scaling.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 RSVD1	Reserved, always set to zero.
28–18 C0	Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17–9 UV_OFFSET	Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
Y_OFFSET	Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

13.6.12.28 Color Space Conversion Coefficient Register 1 (PXP_HW_PXP_CSC1_COEF1)

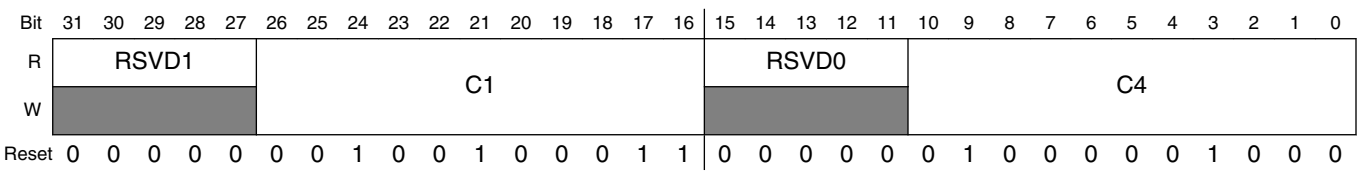
This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

EXAMPLE

```
REG_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
REG_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
REG_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 3070_0000h base + 1B0h offset = 3070_01B0h



PXP_HW_PXP_CSC1_COEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C1	Two's compliment Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15–11 RSVD0	Reserved, always set to zero.
C4	Two's compliment Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

13.6.12.29 Color Space Conversion Coefficient Register 2 (PXP_HW_PXP_CSC1_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

EXAMPLE

```
// NOTE: The default values for the CSCCOEF2 register are incorrect.  C2 should be 0x76B and
C3 should be 0x79C for proper operation.

   REG_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
   REG_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
   REG_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 3070_0000h base + 1C0h offset = 3070_01C0h

PXP_HW_PXP_CSC1_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's compliment Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 RSVD0	Reserved, always set to zero.
C3	Two's compliment Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

13.6.12.30 Color Space Conversion Control Register. (PXP_HW_PXP_CSC2_CTRL)

This register contains the control registers to configure the CSC module.

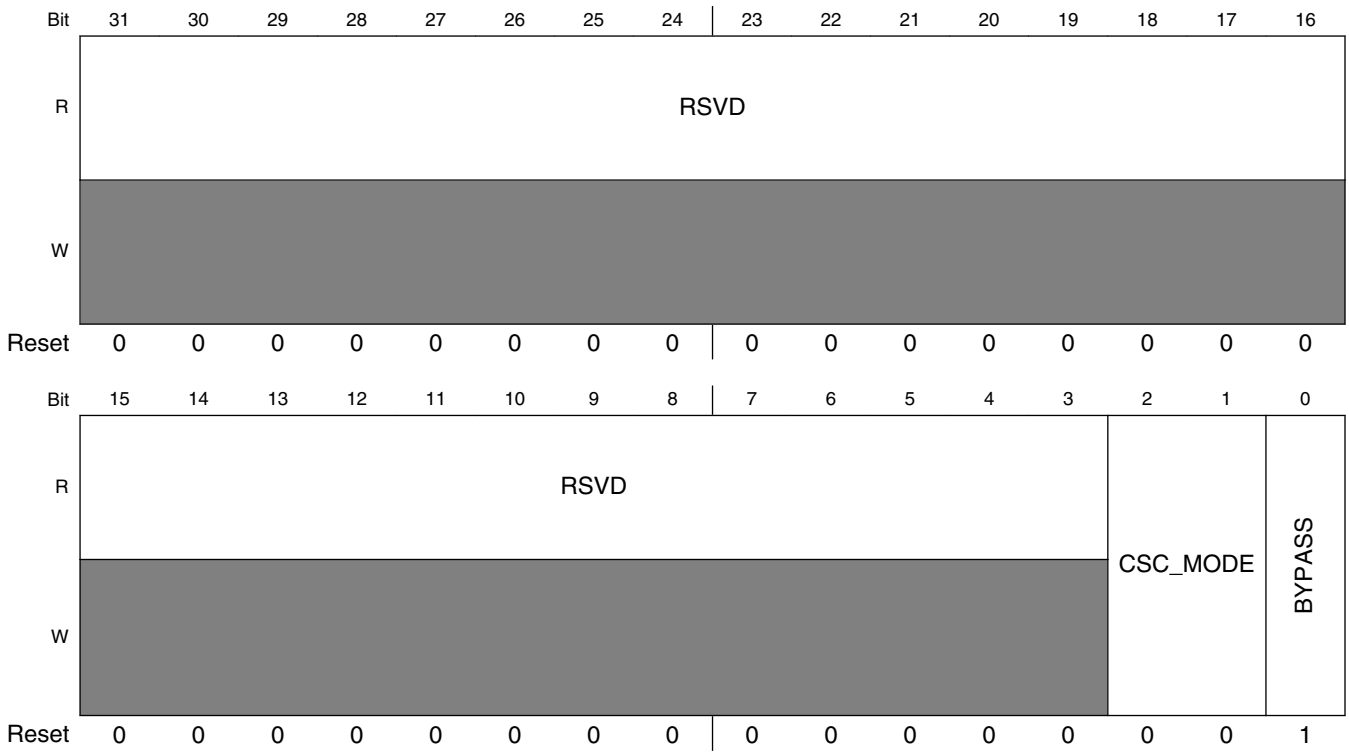
The CSC control register will configure the CSC module to perform color space conversion between the RGB/YUV/YCbCr color spaces.

EXAMPLE

```
//Converting from YUV/YCbCr color spaces to the RGB color space uses the
//following equation structure:
//
// R = A1(Y-D1) + A2(U-D2) + A3(V-D3)
// G = B1(Y-D1) + B2(U-D2) + B3(V-D3)
```

```
// B = C1(Y-D1) + C2(U-D2) + C3(V-D3)
//
//Converting from the RGB color space to YUV/YCbCr color spaces uses the
//following equation structure:
//
// Y = A1*R + A2*G + A3*B + D1
// U = B1*R + B2*G + B3*B + D2
// V = C1*R + C2*G + C3*B + D3
//
//All math is signed, so all coefficients come in as two's comp numbers
//
```

Address: 3070_0000h base + 1D0h offset = 3070_01D0h



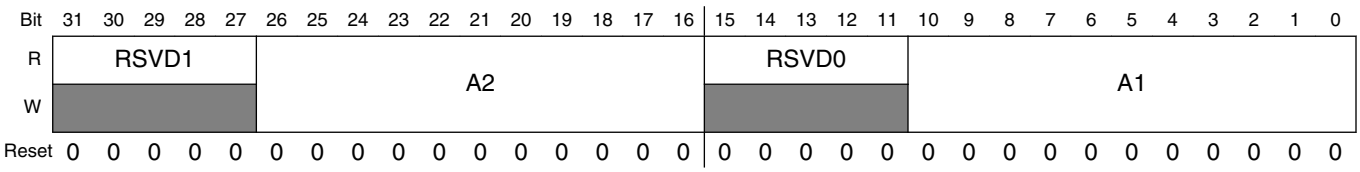
PXP_HW_PXP_CSC2_CTRL field descriptions

Field	Description
31–3 RSVD	Reserved, always set to zero.
2–1 CSC_MODE	This field controls how the CSC unit operates on pixels when the CSC is not bypassed. 0x0 **YUV2RGB** — Convert from YUV to RGB. 0x1 **YCbCr2RGB** — Convert from YCbCr to RGB. 0x2 **RGB2YUV** — Convert from RGB to YUV. 0x3 **RGB2YCbCr** — Convert from RGB to YCbCr.
0 BYPASS	This bit controls whether the pixels entering the CSC2 unit get converted or not. When BYPASS is set, no operations occur on the pixels. When BYPASS is cleared, the selected CSC operation takes place.

13.6.12.31 Color Space Conversion Coefficient Register 0 (PXP_HW_PXP_CSC2_COEF0)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 1E0h offset = 3070_01E0h



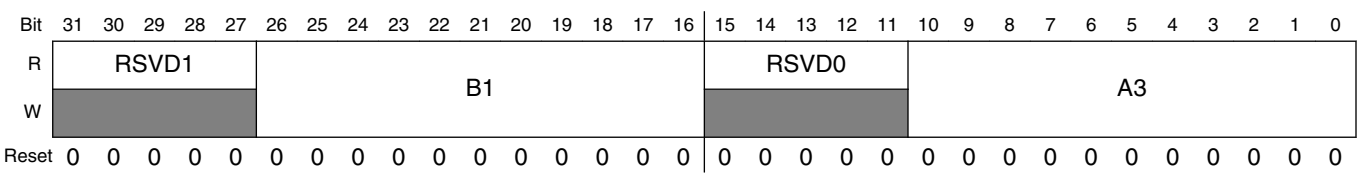
PXP_HW_PXP_CSC2_COEF0 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 A2	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
A1	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

13.6.12.32 Color Space Conversion Coefficient Register 1 (PXP_HW_PXP_CSC2_COEF1)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 1F0h offset = 3070_01F0h



PXP_HW_PXP_CSC2_COEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B1	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

Table continues on the next page...

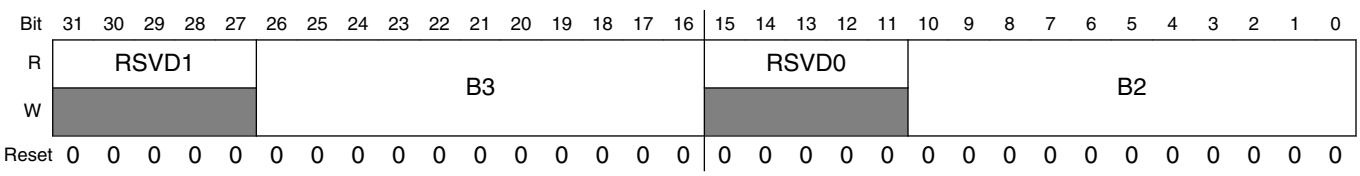
PXP_HW_PXP_CSC2_COEF1 field descriptions (continued)

Field	Description
15–11 RSVD0	Reserved, always set to zero.
A3	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

13.6.12.33 Color Space Conversion Coefficient Register 2 (PXP_HW_PXP_CSC2_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 200h offset = 3070_0200h



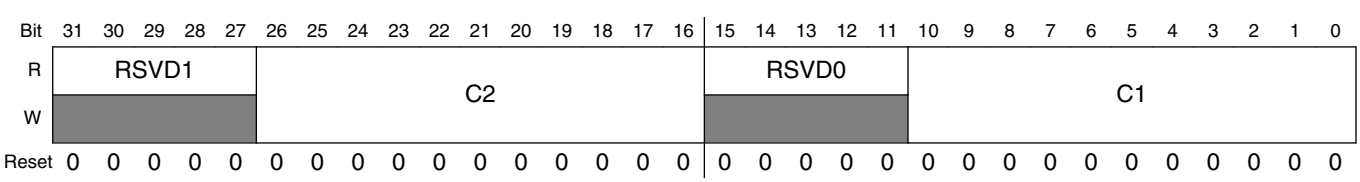
PXP_HW_PXP_CSC2_COEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B3	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
B2	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

13.6.12.34 Color Space Conversion Coefficient Register 3 (PXP_HW_PXP_CSC2_COEF3)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 210h offset = 3070_0210h



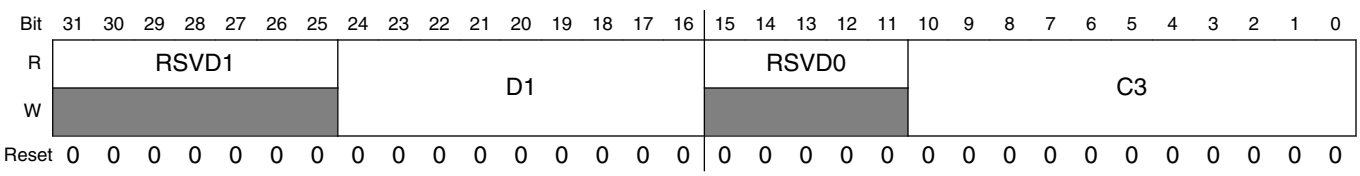
PXP_HW_PXP_CSC2_COEF3 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
C1	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

13.6.12.35 Color Space Conversion Coefficient Register 4 (PXP_HW_PXP_CSC2_COEF4)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 220h offset = 3070_0220h



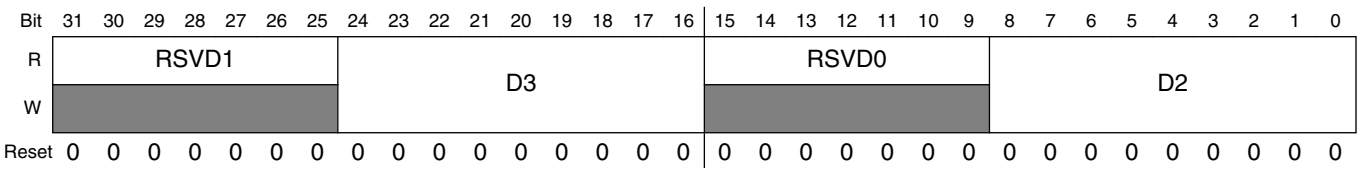
PXP_HW_PXP_CSC2_COEF4 field descriptions

Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D1	Two's compliment coefficient integer offset to be added.
15–11 RSVD0	Reserved, always set to zero.
C3	Two's compliment coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

13.6.12.36 Color Space Conversion Coefficient Register 5 (PXP_HW_PXP_CSC2_COEF5)

This register contains color space conversion coefficients in two's compliment notation.

Address: 3070_0000h base + 230h offset = 3070_0230h



PXP_HW_PXP_CSC2_COEF5 field descriptions

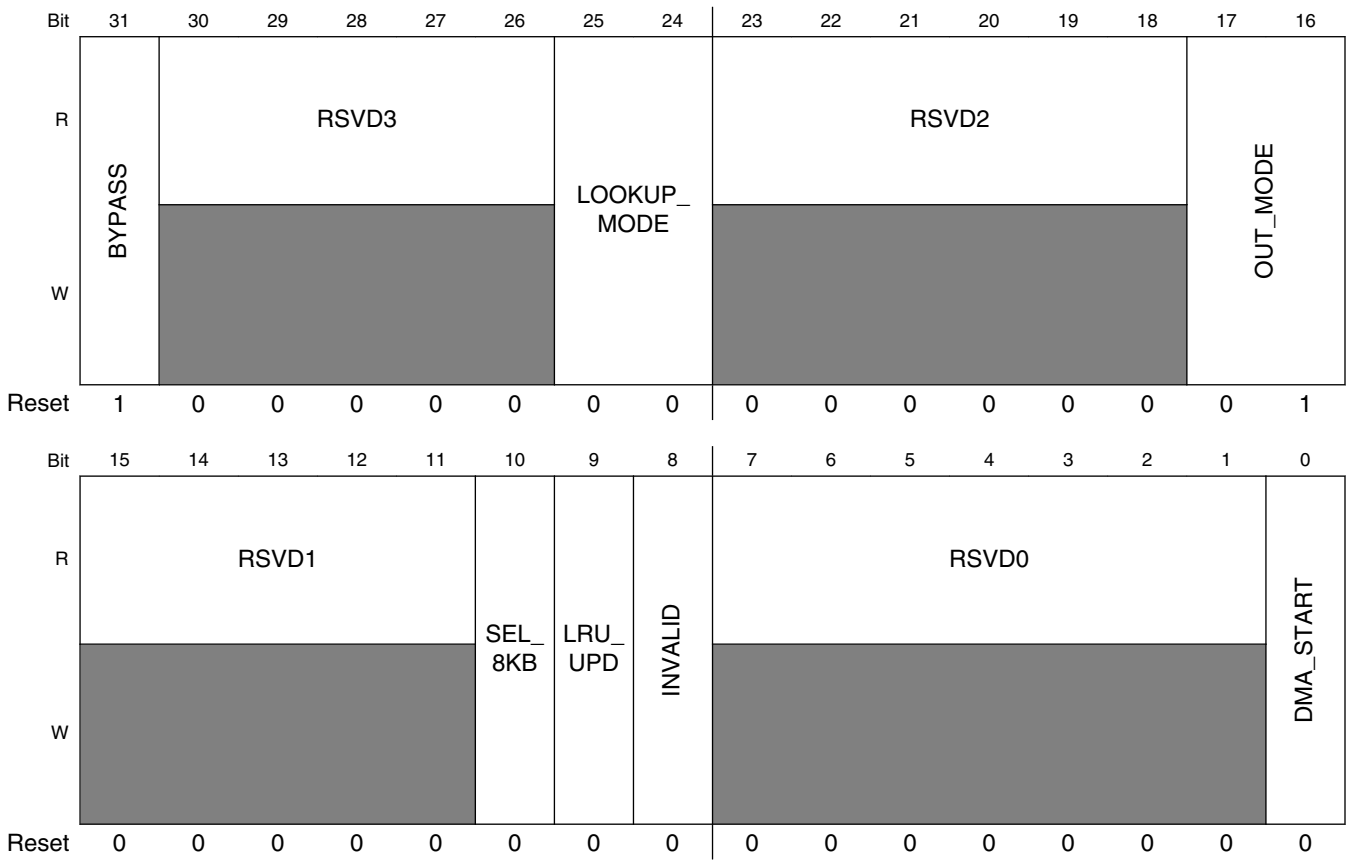
Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D3	Two's compliment coefficient integer offset to be added.
15–9 RSVD0	Reserved, always set to zero.
D2	Two's compliment D1 coefficient integer offset to be added.

13.6.12.37 Lookup Table Control Register. (PXP_HW_PXP_LUT_CTRL)

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e. R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

Address: 3070_0000h base + 240h offset = 3070_0240h



PXP_HW_PXP_LUT_CTRL field descriptions

Field	Description
31 BYPASS	Setting this bit will bypass the LUT memory resource completely. No pixel transfermations will occur at this stage of the PXP pixel rpocessing pipeline.
30–26 RSVD3	Reserved, always set to zero.
25–24 LOOKUP_MODE	Configure the input address for the 16KB LUT memory. The address into the LUT uses different parts of the pixel data path bytes. The data path is defined as three bytes, conceptually as RGB/YUV/YCbCr[23:0]. Also referred to as R/Y[7:0],G/U[7:0],B/V[7:0] 0x0 **CACHE_RGB565** — LUT ADDR = R[7:3],G[7:2],B[7:3]. Use all 16KB of LUT for indirect cached 128KB lookup. 0x1 **DIRECT_Y8** — LUT ADDR = 16'b0,Y[7:0]. Use only the first 256 bytes of LUT. Only the Y, or third data path byte, is tranformed. 0x2 **DIRECT_RGB444** — LUT ADDR = R[7:4],G[7:4],B[7:4]. Use one 8KB bank of LUT selected by SEL_8KB. 0x3 **DIRECT_RGB454** — LUT ADDR = R[7:4],G[7:3],B[7:4]. Use all 16KB of LUT.
23–18 RSVD2	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_LUT_CTRL field descriptions (continued)

Field	Description
17–16 OUT_MODE	Select the output mode of operation for the LUT resource. There are four bytes [3-0] in the data path at the output of the LUT resource. Byte lane 3 is always bypassed and usually contains an alpha value. The LUT can be programmed to transform bytes 2,1,0 according to the options available in this field. 0x0 **RESERVED** — Reserved, not valid when using the LUT to transform pixels. 0x1 **Y8** — R/Y byte lane 2 lookup, bytes 1,0 bypassed. 0x2 **RGBW4444CFA** — Byte lane 2 = CFA_Y8, byte lane 1,0 = RGBW4444. 0x3 **RGB888** — RGB565->RGB888 conversion for Gamma correction.
15–11 RSVD1	Reserved, always set to zero.
10 SEL_8KB	Selects which 8KB bank of memory to use for direct 12bpp lookup modes. Logic 0 indicates first 8KB, logic 1 indicates second 8KB. Two direct LUT arrays can be stored and one can be selected for a given PXP operation.
9 LRU_UPD	Least Recently Used Policy Update Control: 1=> block LRU update for hit after miss. 0=> update LRU for all hits including hit after miss.
8 INVALID	Invalidate the cache LRU and valid bits. This bit will automatically reset when set to a logic 1.
7–1 RSVD0	Reserved, always set to zero.
0 DMA_START	Setting this bit will result in the DMA operation to load the PXP LUT memory based on REG_LUT_ADDR_NUM_BYTES, REG_LUT_ADDR_ADDR, and REG_LUT_MEM_ADDR. This bit will automatically reset when set to a logic 1. Note: The LOOKUP_MODE must not be set to CACHE_RGB565 when starting and performing DMA transfers.

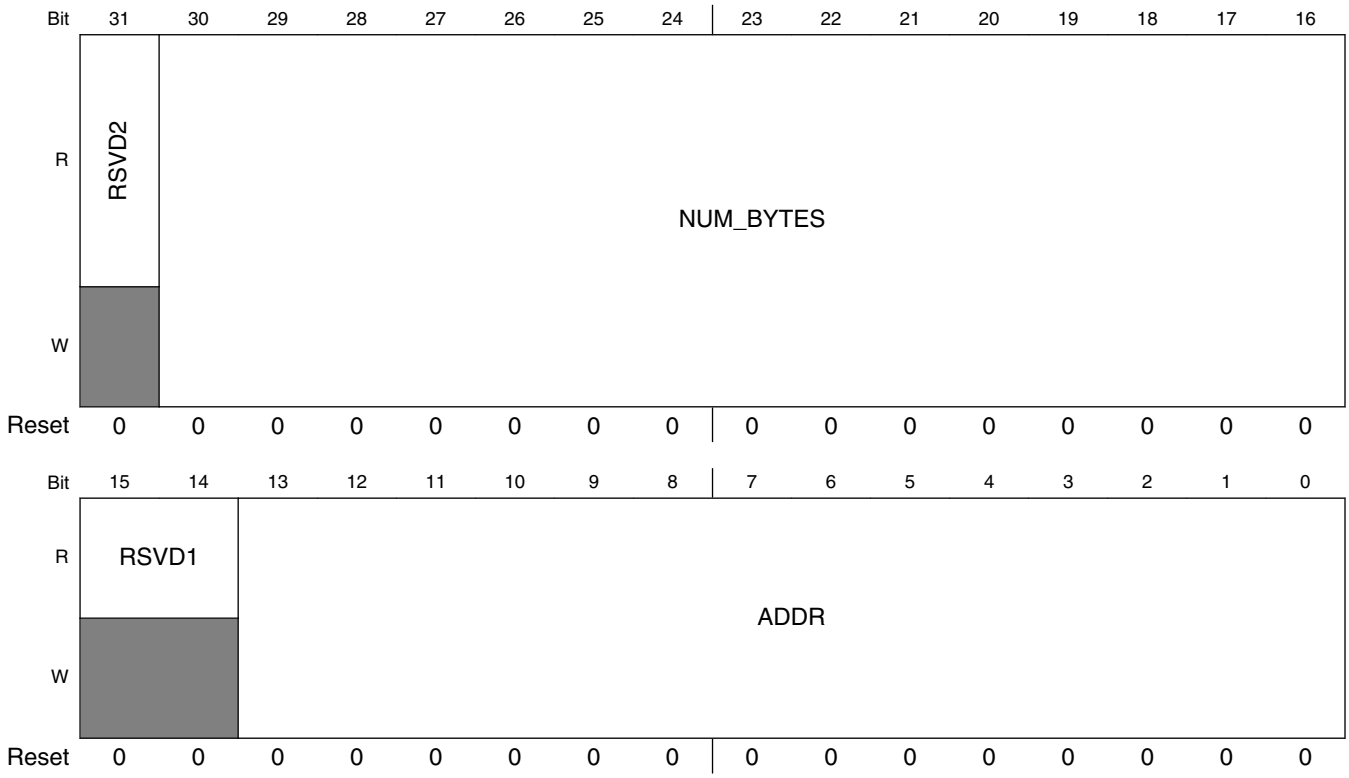
13.6.12.38 Lookup Table Control Register. (PXP_HW_PXP_LUT_ADDR)

This register is used to access/control the Monochrome Lookup table.

The Y8 LUT input mode will take the high order data path byte and transform it using the LUT memory. This is an 8-bit to 8-bit transformation. The two low order bytes bypass the LUT and are not transformed, but bypassed without modification. This option can be used for monochrome gamma correction. The Direct Lookup mode will use the high nibble of each data byte and truncate the low nibble to generate the lookup address, i.e. R[7:0]G[7:0]B[7:0] -> R[7:4]G[7:4]B[7:4]. 4K pixels (12-bit address) with 2 bytes per pixel is supported in this mode. Cached Lookup mode will use the high order bits, R[7:3],G[7:2],B[7:3] or RGB565, to address the cached LUT memory. 64KB LUT tables, using 16KB of internal LUT memory, can be indirectly transformed to 16-bit output

pixels (as in RGBW4444/RGB565). This is used for 16bpp gamma correction or EPD color panel support. Cache misses are internally managed by the PXP LUT Cache controller.

Address: 3070_0000h base + 250h offset = 3070_0250h



PXP_HW_PXP_LUT_ADDR field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 NUM_BYTES	Indicates the number of bytes to load via a DMA operation. This field must be divisable by 8 and the least significant 3 bits must be 0. The value 8 indicates load 8 bytes from the external address indicated by REG_LUT_MEM_ADDR to the LUT memory location indicated by REG_LUT_CTRL_ADDR.
15–14 RSVD1	Reserved, always set to zero.
ADDR	LUT indexed address pointer. This address into the LUT memory is always four byte aligned for PIO access, and eight byte aligned for DMA access. The least two significant bits are not used to drive the LUT memory array. For PIO LUT access, when the LUT data register is written, the contents of the LUT at the address specified by this address field will be loaded with a 32-bit DWORD. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data register to initialize the entire LUT array with recursive writes to the LUT data register. For DMA access, this register indicates the LUT memory address of the 8 byte QWORD to be loaded. When using the NUM_BYTES field to load more than 8 bytes, the register should be programmed with the first LUT memory location to be filled and each load of the LUT memory will increment this address field until NUM_BYTES has been loaded.

13.6.12.39 Lookup Table Data Register. (PXP_HW_PXP_LUT_DATA)

This register is used to load data into the lookup table.

Address: 3070_0000h base + 260h offset = 3070_0260h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_LUT_DATA field descriptions

Field	Description
DATA	Writing this field will load 4 bytes, aligned to four byte boundaries, of data indexed by the ADDR field of the REG_LUT_CTRL register.

13.6.12.40 Lookup Table External Memory Address Register. (PXP_HW_PXP_LUT_EXTMEM)

This register is used as the external memory base address for LUT data transfers.

For DMA LUT memory loads, this is the base address from which data will be sourced to store into the LUT memory array. For Cached LUT memory pixel transformations, this register will store the base address of the full 64K pixel LUT translation table.

Address: 3070_0000h base + 270h offset = 3070_0270h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_LUT_EXTMEM field descriptions

Field	Description
ADDR	This register contains the external memory address used for LUT memory operation.

13.6.12.41 Color Filter Array Register. (PXP_HW_PXP_CFA)

This register contains the pattern of the CFA mapping within PXP macro blocks.

There are sixteen 2 bit values in this register each mapping a selected component to the output pixel. The two bit values are defined as 0=>R, 1=>G, 2=>B, and 3=>W. The first byte represents the repetitive pattern of RGBW pixels in the CFA for the first line

segment of each processed PXP block. The second byte represents the pattern in the second line segment of the block, and so on. The first byte repeats two times for 8x8 macro block mode, and repeats four times for 16x16 block mode.

Address: 3070_0000h base + 280h offset = 3070_0280h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_ALPHA_B_CTRL_1 field descriptions (continued)

Field	Description
	0x3 **MERGEAS** — AS OR PS 0x4 **MERGENOTAS** — nAS OR PS 0x5 **MERGEASNOT** — AS OR nPS 0x6 **NOTCOPYAS** — nAS 0x7 **NOT** — nPS 0x8 **NOTMASKAS** — AS NAND PS 0x9 **NOTMERGEAS** — AS NOR PS 0xA **XORAS** — AS XOR PS 0xB **NOTXORAS** — AS XNOR PS
3–2 RSVD1	Reserved, always set to zero.
1 OL_CLRKEY_ENABLE	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
0 ROP_ENABLE	ROP ENABLE

13.6.12.45 PS Background Color 1 (PXP_HW_PXP_PS_BACKGROUND_1)

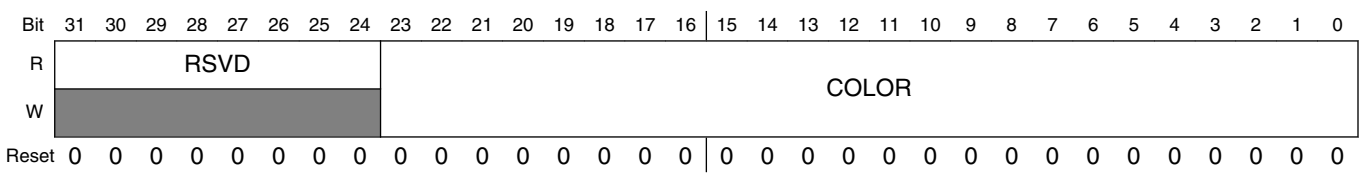
PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image. This value is used by the Alpha B block.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

EXAMPLE

```
REG_PS_BACKGROUND_WR(0x00000000);  // letterbox is black
REG_PS_BACKGROUND_WR(0x00800000);  // letterbox is dark red
REG_PS_BACKGROUND_WR(0x00008000);  // letterbox is dark green
REG_PS_BACKGROUND_WR(0x00000080);  // letterbox is dark blue
```

Address: 3070_0000h base + 2C0h offset = 3070_02C0h



PXP_HW_PXP_PS_BACKGROUND_1 field descriptions

Field	Description
31–24 RSVD	Reserved, always set to zero.
COLOR	Background color (in 24bpp format) for any pixels not within the buffer range specified by the PS ULC/ LRC.

13.6.12.46 PS Color Key Low 1 (PXP_HW_PXP_PS_CLRKEYLOW_1)

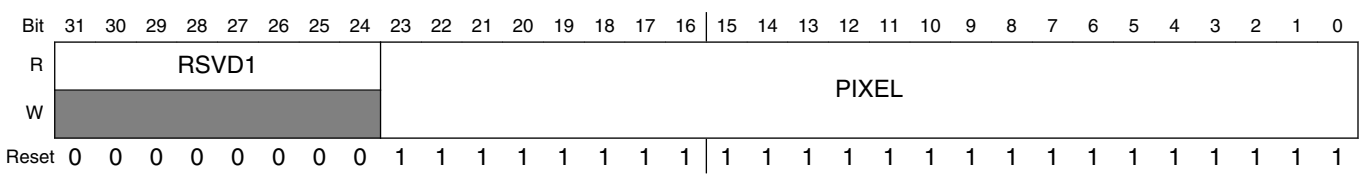
This register contains the color key low value for the PS buffer 1. This value is used by the Alpha B block.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between REG_PS_CLRKEYLOW and REG_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the REG_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                    // colorkey values between
REG_PS_CLRKEYLOW_WR (0x008000); // medium green and
REG_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 3070_0000h base + 2D0h offset = 3070_02D0h



PXP_HW_PXP_PS_CLRKEYLOW_1 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

13.6.12.47 PS Color Key High 1 (PXP_HW_PXP_PS_CLRKEYHIGH_1)

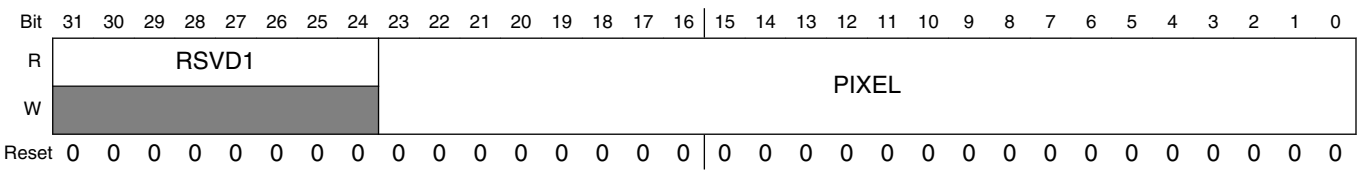
This register contains the color key high value for the PS buffer. This value is used by the Alpha B block.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between REG_PS_CLRKEYLOW and REG_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the REG_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
                                    // colorkey values between
REG_PS_CLRKEYLOW_WR (0x008000); // medium green and
REG_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 3070_0000h base + 2E0h offset = 3070_02E0h



PXP_HW_PXP_PS_CLRKEYHIGH_1 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of color key applied to PS buffer. To disable PS colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

13.6.12.48 Overlay Color Key Low (PXP_HW_PXP_AS_CLRKEYLOW_1)

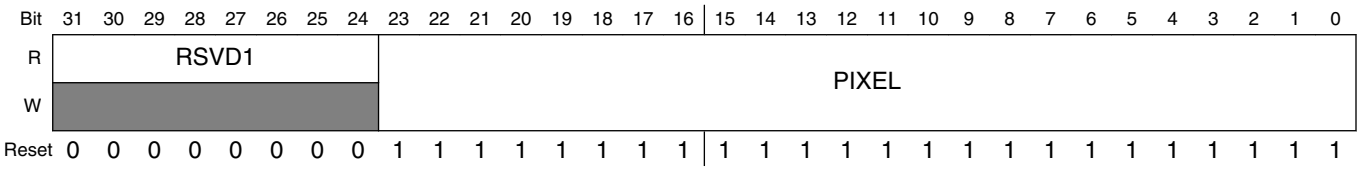
This register contains the color key low value for the AS buffer. This value is used by the Alpha B block.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
REG_AS_CLRKEYLOW_WR (0x000000); // black and
REG_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 3070_0000h base + 2F0h offset = 3070_02F0h



PXP_HW_PXP_AS_CLRKEYLOW_1 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	Low range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

13.6.12.49 Overlay Color Key High (PXP_HW_PXP_AS_CLRKEYHIGH_1)

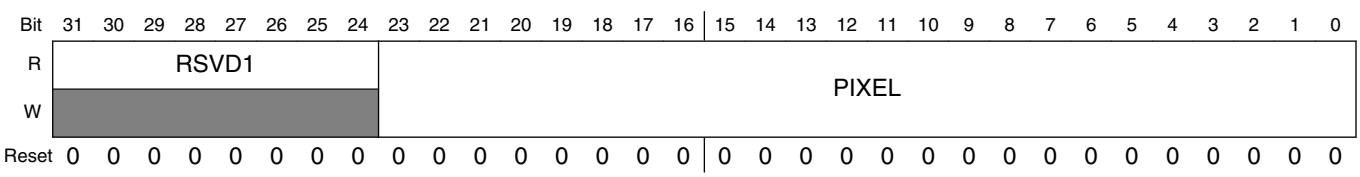
This register contains the color key high value for the AS buffer. This value is used by the Alpha B block.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
                                    // colorkey values between
REG_AS_CLRKEYLOW_WR (0x000000); // black and
REG_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 3070_0000h base + 300h offset = 3070_0300h



PXP_HW_PXP_AS_CLRKEYHIGH_1 field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
PIXEL	High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.

13.6.12.50 Control Register 2 (PXP_HW_PXP_CTRL2)

The CTRL register contains controls for the secondary processing flow in PXP module.

HW_PXP_CTRL2: 0x310

HW_PXP_CTRL2_SET: 0x314

HW_PXP_CTRL2_CLR: 0x318

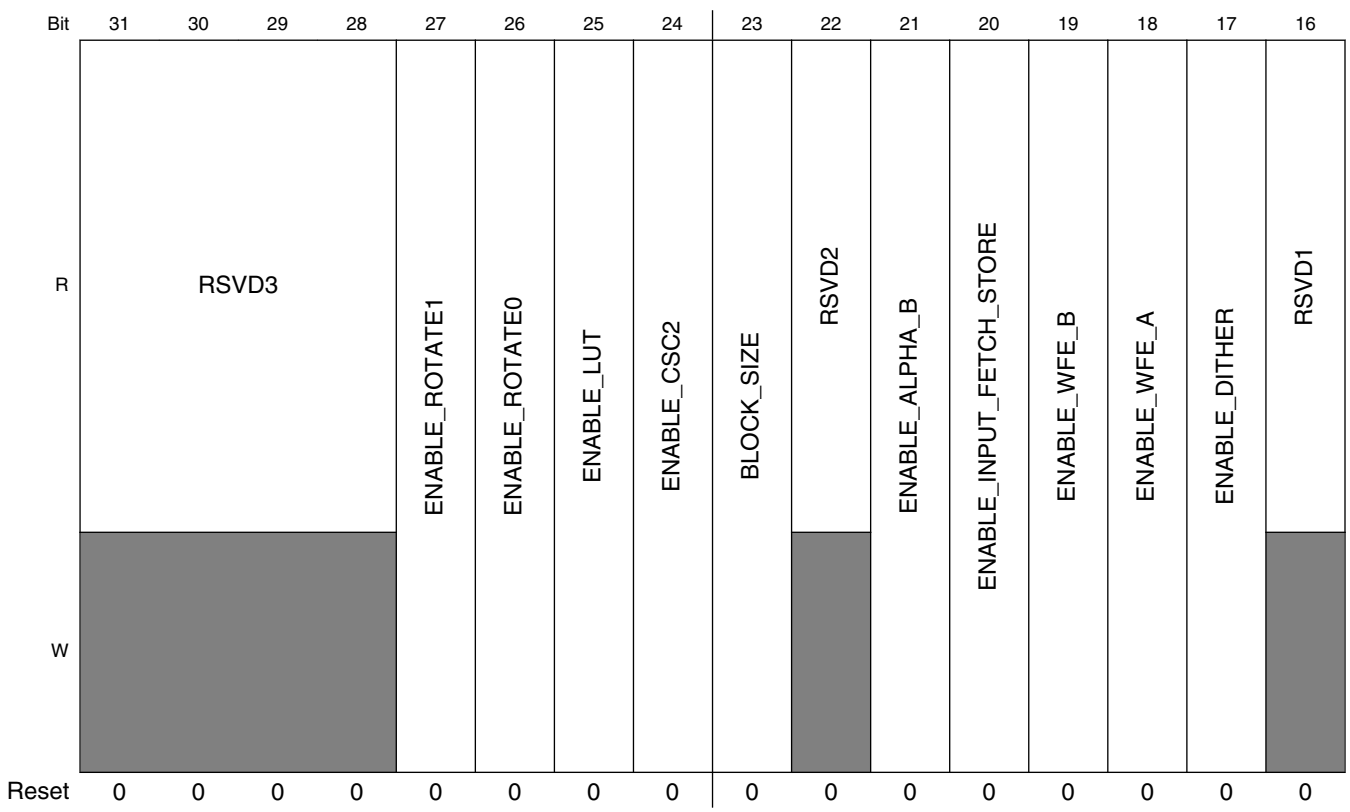
HW_PXP_CTRL2_TOG: 0x31C

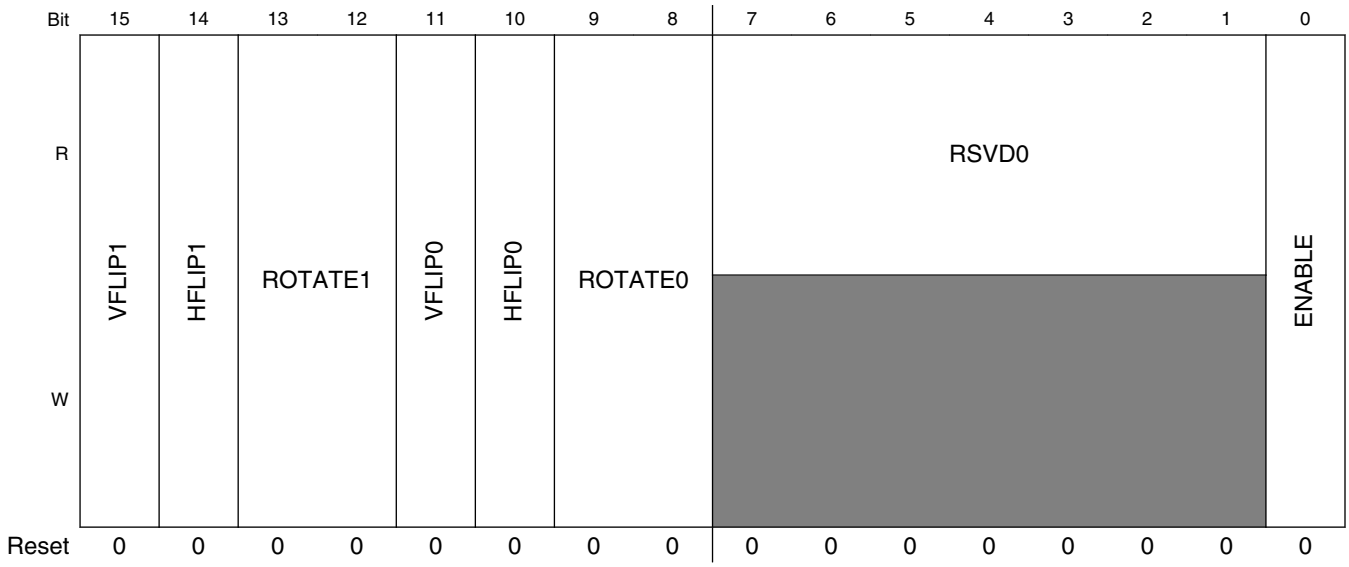
The Control register contains the controls for the secondary data flow in PXP block.

EXAMPLE

```
REG_CTRL_SET(BM_PXP_CTRL_SFTRST);
REG_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 3070_0000h base + 310h offset = 3070_0310h





PXP_HW_PXP_CTRL2 field descriptions

Field	Description
31–28 RSVD3	Reserved, always set to zero.
27 ENABLE_ ROTATE1	Enable the ROTATE1 engine in the PXP secondary processing flow.
26 ENABLE_ ROTATE0	Enable the ROTATE0 engine in the PXP secondary processing flow.
25 ENABLE_LUT	Enable the LUT engine in the PXP secondary processing flow.
24 ENABLE_CSC2	Enable the CSC2 engine in the PXP secondary processing flow.
23 BLOCK_SIZE	Select the block size to process through the Rotate block. 0x0 **8X8** — Process 8x8 pixel blocks. 0x1 **16X16** — Process 16x16 pixel blocks.
22 RSVD2	Reserved, always set to zero.
21 ENABLE_ ALPHA_B	Enable the Alpha-B engine in the PXP secondary processing flow.
20 ENABLE_ INPUT_FETCH_ STORE	Enable the Input Fetch and Store engine in the PXP secondary processing flow.
19 ENABLE_WFE_B	Enable the WFE-B engine in the PXP secondary processing flow.
18 ENABLE_WFE_A	Enable the WFE-A engine in the PXP secondary processing flow.

Table continues on the next page...

PXP_HW_PXP_CTRL2 field descriptions (continued)

Field	Description
17 ENABLE_ DITHER	Enable the Dithering engine in the PXP secondary processing flow.
16 RSVD1	Reserved, always set to zero.
15 VFLIP1	Indicates that the input should be flipped vertically (effect applied before rotation).
14 HFLIP1	Indicates that the input should be flipped horizontally (effect applied before rotation).
13–12 ROTATE1	Indicates the clockwise rotation to be applied at the input buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
11 VFLIP0	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP0	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).
9–8 ROTATE0	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
7–1 RSVD0	Reserved, always set to zero.
0 ENABLE	Enables PXP secondary data processing flow with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the HW_PXP_STAT when polling for PXP completion.

13.6.12.51 PXP Power Control Register. (PXP_HW_PXP_POWER_REG0)

This register controls power states for PXP memories.

Address: 3070_0000h base + 320h offset = 3070_0320h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CTRL																				ROT0_ MEM_ LP_ STATE			LUT_LP_ STATE_ WAY1_ BANKN			LUT_LP_ STATE_ WAY0_ BANKN			LUT_LP_ STATE_ WAY0_ BANK0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_POWER_REG0 field descriptions

Field	Description
31–12 CTRL	This register contains power control for the PXP.
11–9 ROT0_MEM_LP_ STATE	Select the low power state of the ROT 0 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
8–6 LUT_LP_ STATE_WAY1_ BANKN	Select the low power state of the LUT's WAY0-BANK0,1,2,3 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
5–3 LUT_LP_ STATE_WAY0_ BANKN	Select the low power state of the LUT's WAY0-BANK1,2,3 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
LUT_LP_ STATE_WAY0_ BANK0	Select the low power state of the LUT's WAY0-BANK0 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.

13.6.12.52 PXP Power Control Register 1. (PXP_HW_PXP_POWER_REG1)

This register controls power states for PXP memories.

Address: 3070_0000h base + 330h offset = 3070_0330h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RSVD0								ALU_B_MEM_LP_STATE			ALU_A_MEM_LP_STATE			DITH2_LUT_MEM_LP_STATE	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DITH2_LUT_MEM_LP_STATE	DITH1_LUT_MEM_LP_STATE			DITH0_ERR1_MEM_LP_STATE			DITH0_ERR0_MEM_LP_STATE			DITH0_LUT_MEM_LP_STATE			ROT1_MEM_LP_STATE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_POWER_REG1 field descriptions

Field	Description
31–24 RSVD0	This register contains power control for the PXP.
23–21 ALU_B_MEM_LP_STATE	Select the low power state of the ALU B memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
20–18 ALU_A_MEM_LP_STATE	Select the low power state of the ALU A memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
17–15 DITH2_LUT_MEM_LP_STATE	Select the low power state of the dither2 LUT memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
14–12 DITH1_LUT_MEM_LP_STATE	Select the low power state of the dither1 LUT memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
11–9 DITH0_ERR1_MEM_LP_STATE	Select the low power state of the dither0 ERR1 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
8–6 DITH0_ERR0_MEM_LP_STATE	Select the low power state of the dither0 ERR0 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.

Table continues on the next page...

PXP_HW_PXP_POWER_REG1 field descriptions (continued)

Field	Description
5–3 DITH0_LUT_ MEM_LP_STATE	Select the low power state of the dither0 LUT memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.
ROT1_MEM_LP_ STATE	Select the low power state of the ROT 1 memory. 0x0 **NONE** — Memory is not in low power state. 0x1 **LS** — Light Sleep Mode. Low leakage mode, maintain memory contents. 0x2 **DS** — Deep Sleep Mode. Low leakage mode, maintain memory contents. 0x4 **SD** — Shut Down Mode. Shut Down periphery and core, no memory retention.

13.6.12.53 PXP_HW_PXP_DATA_PATH_CTRL1

This register helps decide the data path gthrough the PXP.

HW_PXP_DATA_PATH_CTRL1: 0x350

HW_PXP_DATA_PATH_CTRL1_SET: 0x354

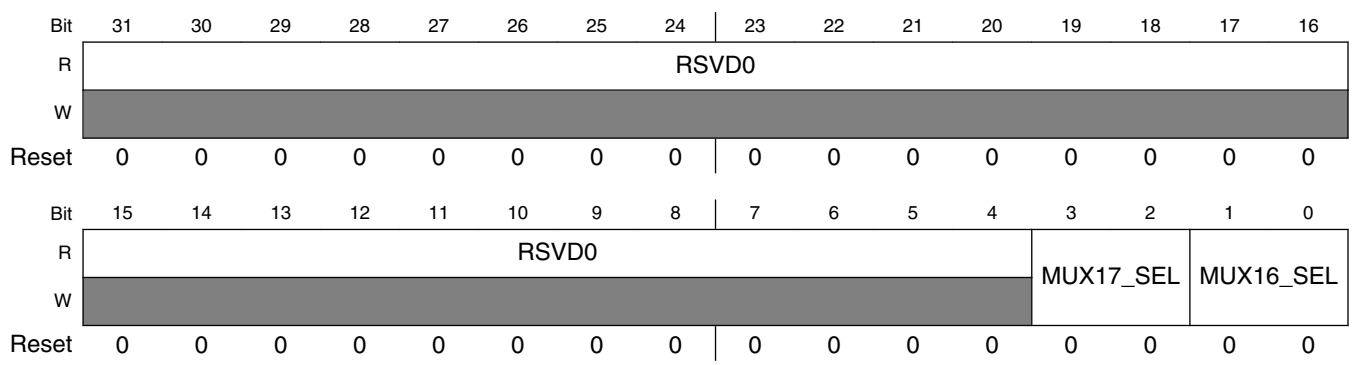
HW_PXP_DATA_PATH_CTRL1_CLR: 0x358

HW_PXP_DATA_PATH_CTRL1_TOG: 0x35C

The Control register contains the control bits for the data path through the PXP.

EXAMPLE

Address: 3070_0000h base + 350h offset = 3070_0350h



PXP_HW_PXP_DATA_PATH_CTRL1 field descriptions

Field	Description
31–4 RSVD0	Reserved. This field always reads 0.
3–2 MUX17_SEL	This field chooses the data path through MUX 17. 0x0 **0** — Output of ALU A 0x1 **1** — Output of ALU B 0x2 **2** — No output 0x3 **3** — No Output
MUX16_SEL	This mux chooses the data path through MUX 16. 0x0 **0** — Output of ALU A Engine 0x1 **1** — histogram_pixel output from output 0x2 **2** — Output of ALU B Engine 0x3 **3** — No output

13.6.12.54 Initialize memory buffer control Register (PXP_HW_PXP_INIT_MEM_CTRL)

Controls initializing/writing to dither and ALU memory buffers.

HW_PXP_INIT_MEM_CTRL: 0x360

HW_PXP_INIT_MEM_CTRL_SET: 0x364

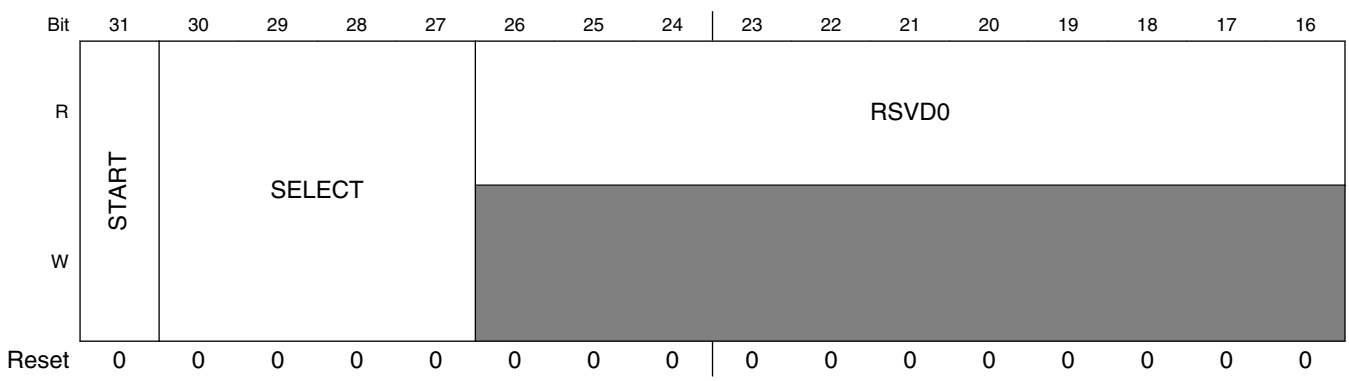
HW_PXP_INIT_MEM_CTRL_CLR: 0x368

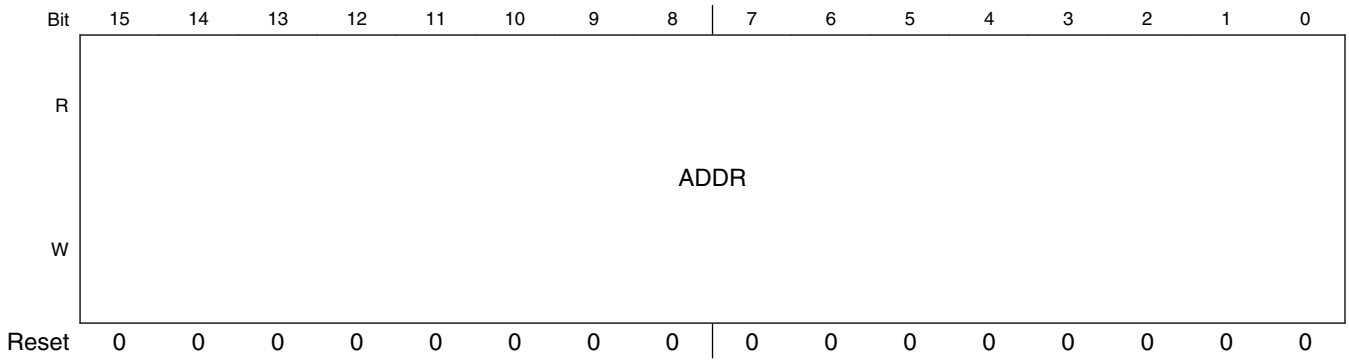
HW_PXP_INIT_MEM_CTRL_TOG: 0x36C

This register controls IRQ the intializing of internal pxp rams.

EXAMPLE

Address: 3070_0000h base + 360h offset = 3070_0360h





PXP_HW_PXP_INIT_MEM_CTRL field descriptions

Field	Description
31 START	Enable writing to the memory.
30–27 SELECT	Select which memory to write. 0x0 **DITHER0_LUT** — Select the LUT memory for access 0x1 **DITHER0_ERR0** — Select the ERR0 memory for access 0x2 **DITHER0_ERR1** — Select the ERR1 memory for access 0x3 **DITHER1_LUT** — Select the LUT memory for access 0x4 **DITHER2_LUT** — Select the LUT memory for access 0x5 **ALU_A** — Select the ALU instr memory for access 0x6 **ALU_B** — Select the ALU instr memory for access 0x7 **WFE_A_FETCH** — Select the WFE-A fetch memory for access 0x8 **WFE_B_FETCH** — Select the WFE-B fetch memory for access
26–16 RSVD0	Reserved.
ADDR	Base address to start writing. The control logic will increment the address value internally each time the data register is written.

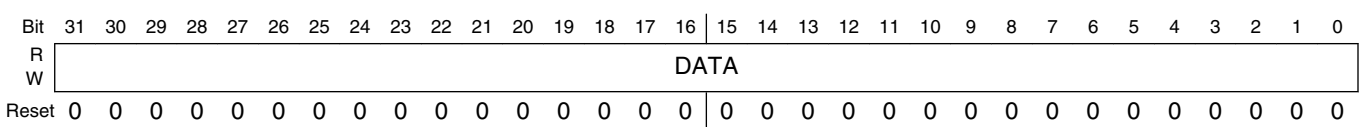
13.6.12.55 Write data Register (PXP_HW_PXP_INIT_MEM_DATA)

Write data for initializing/writing to dither, ALU and fetch memory buffers.

This register holds the data word to intialize internal pxp rams.

EXAMPLE

Address: 3070_0000h base + 370h offset = 3070_0370h



PXP_HW_PXP_INIT_MEM_DATA field descriptions

Field	Description
DATA	Data value to be written to the memory. A write to this register kicks off a write cycle to the memory selected.

13.6.12.56 Write data Register (PXP_HW_PXP_INIT_MEM_DATA_HIGH)

Write data for initializing/writing to the most significant 32 bits of the fetch memory buffers.

This register holds the upper data word to intialize internal pxp fetch rams.

EXAMPLE

Address: 3070_0000h base + 380h offset = 3070_0380h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INIT_MEM_DATA_HIGH field descriptions

Field	Description
DATA	Data value to be written to the most significant 32 bits of the fetch memories. this register must be written before the HW_PXP_INIT_MEM_DATA as that register triggers the write cycle to memory.

13.6.12.57 PXP IRQ Mask Register (PXP_HW_PXP_IRQ_MASK)

Controls masking for all PXP interrupts

HW_PXP_IRQ_MASK: 0x390

HW_PXP_IRQ_MASK_SET: 0x394

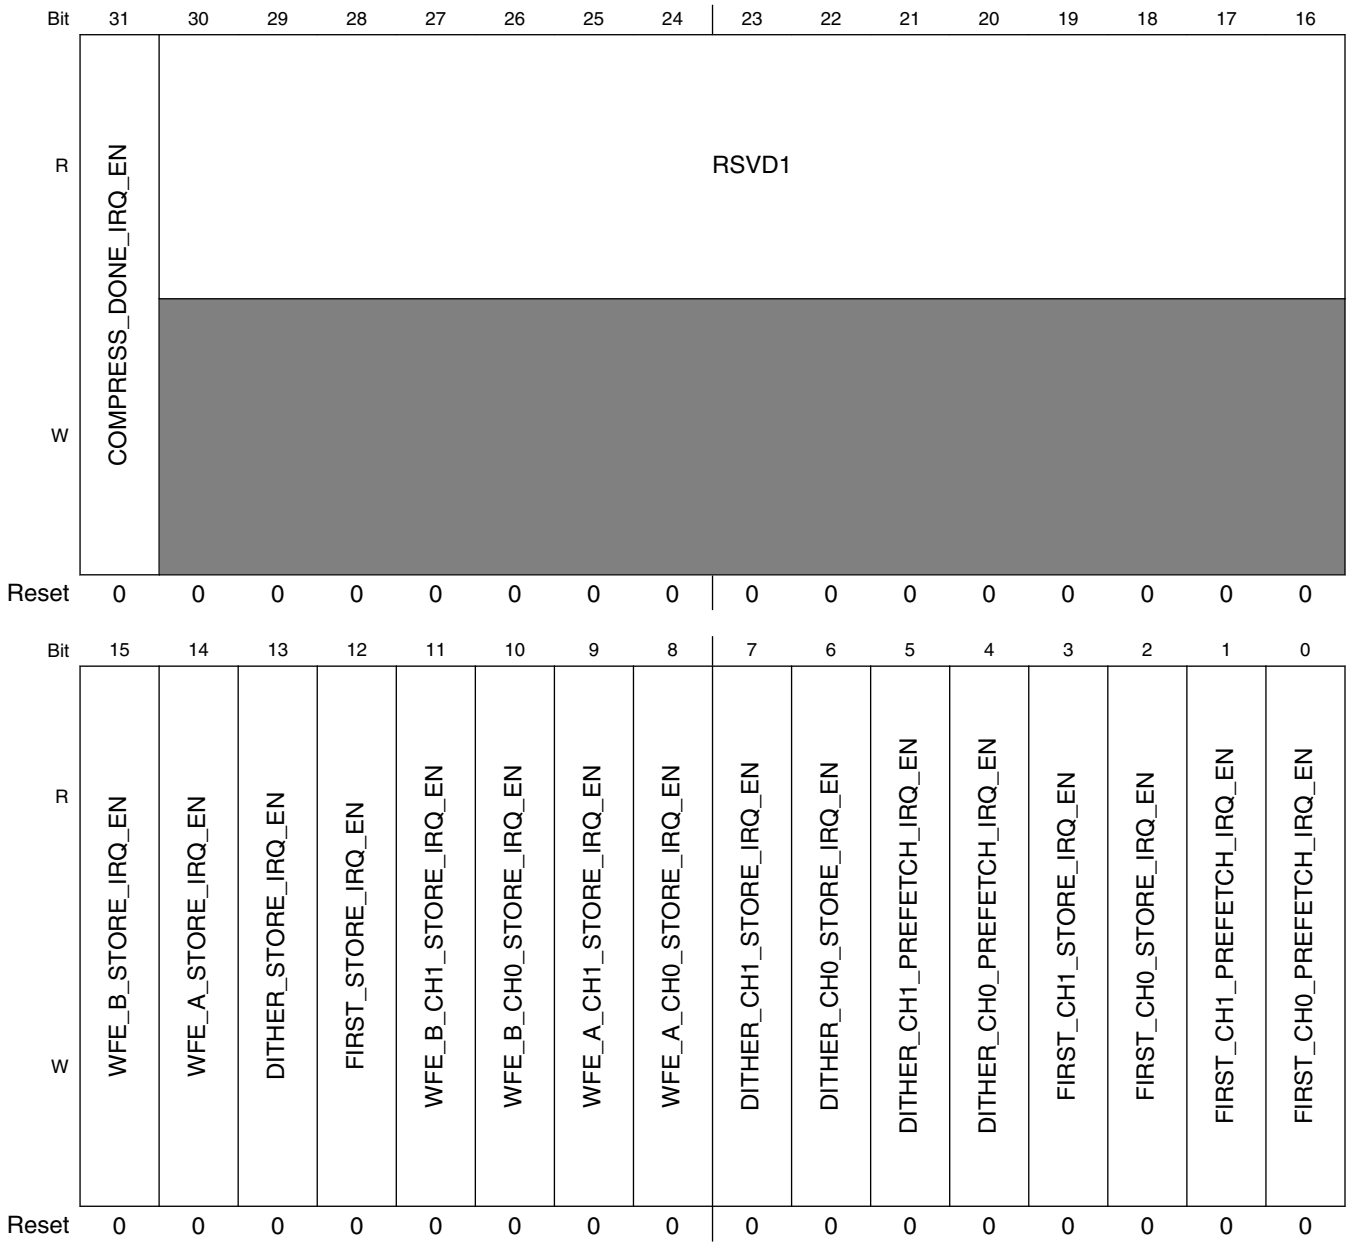
HW_PXP_IRQ_MASK_CLR: 0x398

HW_PXP_IRQ_MASK_TOG: 0x39C

This register controls IRQ masks for all PXP interrupts

EXAMPLE

Address: 3070_0000h base + 390h offset = 3070_0390h



PXP_HW_PXP_IRQ_MASK field descriptions

Field	Description
31 COMPRESS_ DONE_IRQ_EN	Enable compression done interrupt detection.
30–16 RSVD1	Reserved.
15 WFE_B_ STORE_IRQ_EN	Enable WFE B store engine interrupt detection.

Table continues on the next page...

PXP_HW_PXP_IRQ_MASK field descriptions (continued)

Field	Description
14 WFE_A_ STORE_IRQ_EN	Enable WFE A store engine interrupt detection.
13 DITHER_ STORE_IRQ_EN	Enable dither store engine interrupt detection.
12 FIRST_STORE_ IRQ_EN	Enable First store engine interrupt detection
11 WFE_B_CH1_ STORE_IRQ_EN	Enable WFE B ch1 store engine interrupt detection.
10 WFE_B_CH0_ STORE_IRQ_EN	Enable WFE B ch0 store engine interrupt detection.
9 WFE_A_CH1_ STORE_IRQ_EN	Enable WFE A ch1 store engine interrupt detection.
8 WFE_A_CH0_ STORE_IRQ_EN	Enable WFE A ch0 store engine interrupt detection.
7 DITHER_CH1_ STORE_IRQ_EN	Enable dither ch1 store engine interrupt detection.
6 DITHER_CH0_ STORE_IRQ_EN	Enable dither ch0 store engine interrupt detection.
5 DITHER_CH1_ PREFETCH_ IRQ_EN	Enable Dither ch1 prefetch engine interrupt detection
4 DITHER_CH0_ PREFETCH_ IRQ_EN	Enable Dither ch0 prefetch engine interrupt detection
3 FIRST_CH1_ STORE_IRQ_EN	Enable First ch1 store engine interrupt detection
2 FIRST_CH0_ STORE_IRQ_EN	Enable First ch0 store engine interrupt detection
1 FIRST_CH1_ PREFETCH_ IRQ_EN	Enable First ch1 prefetch engine interrupt detection
0 FIRST_CH0_ PREFETCH_ IRQ_EN	Enable First ch0 prefetch engine interrupt detection

13.6.12.58 PXP Interrupt Register (PXP_HW_PXP_IRQ)

PXP Fetch and Store engine IRQs. Each interrupt has a corresponding mask register in HW_EPDC_IRQ_MASK

HW_PXP_IRQ: 0x3A0

HW_PXP_IRQ_SET: 0x3A4

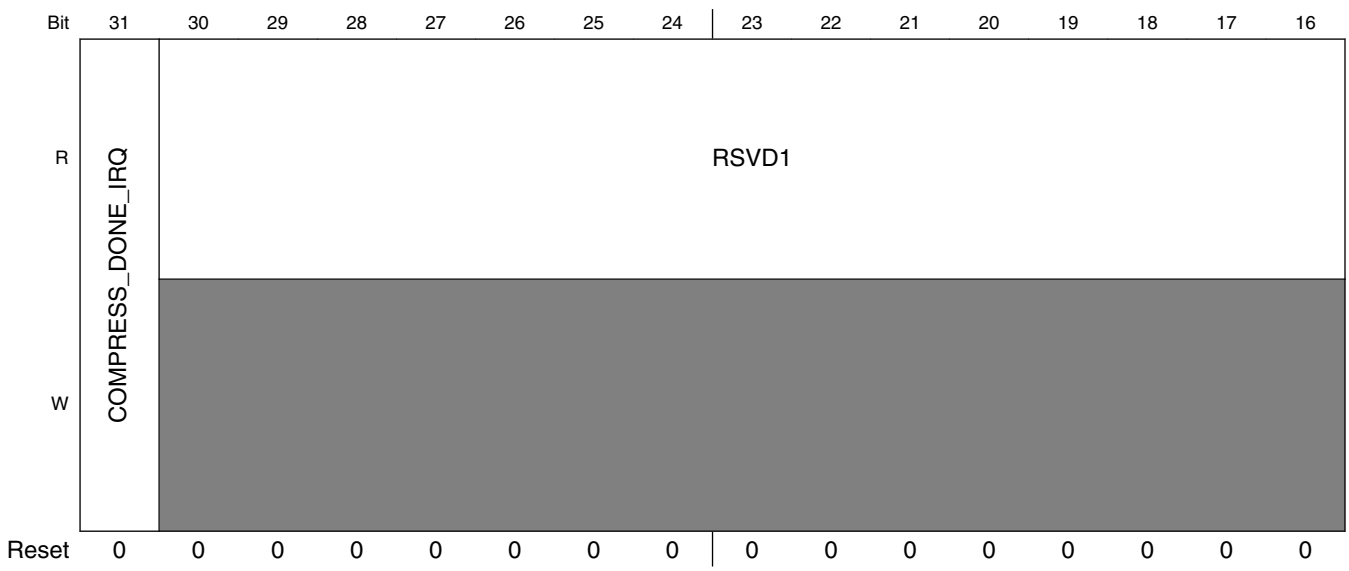
HW_PXP_IRQ_CLR: 0x3a8

HW_PXP_IRQ_TOG: 0x3AC

This register houses the interrupt bits for the Prefetch and Store Engines

EXAMPLE

Address: 3070_0000h base + 3A0h offset = 3070_03A0h



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WFE_B_STORE_IRQ	WFE_A_STORE_IRQ	DITHER_STORE_IRQ	FIRST_STORE_IRQ	WFE_B_CH1_STORE_IRQ	WFE_B_CH0_STORE_IRQ	WFE_A_CH1_STORE_IRQ	WFE_A_CH0_STORE_IRQ	DITHER_CH1_STORE_IRQ	DITHER_CH0_STORE_IRQ	DITHER_CH1_PREFETCH_IRQ	DITHER_CH0_PREFETCH_IRQ	FIRST_CH1_STORE_IRQ	FIRST_CH0_STORE_IRQ	FIRST_CH1_PREFETCH_IRQ	FIRST_CH0_PREFETCH_IRQ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_IRQ field descriptions

Field	Description
31 COMPRESS_ DONE_IRQ	compression done Interrupt
30–16 RSVD1	Reserved.
15 WFE_B_ STORE_IRQ	WFE B store engine Interrupt
14 WFE_A_ STORE_IRQ	WFE A store engine Interrupt.
13 DITHER_ STORE_IRQ	Dither store engine Interrupt
12 FIRST_STORE_ IRQ	Initial store engine interrupt
11 WFE_B_CH1_ STORE_IRQ	WFE B ch1 store engine Interrupt
10 WFE_B_CH0_ STORE_IRQ	WFE B ch0 store engine Interrupt
9 WFE_A_CH1_ STORE_IRQ	WFE A ch1 store engine Interrupt.
8 WFE_A_CH0_ STORE_IRQ	WFE A ch0 store engine Interrupt.

Table continues on the next page...

PXP_HW_PXP_IRQ field descriptions (continued)

Field	Description
7 DITHER_CH1_ STORE_IRQ	Dither ch1 store engine Interrupt
6 DITHER_CH0_ STORE_IRQ	Dither ch0 store engine Interrupt
5 DITHER_CH1_ PREFETCH_IRQ	Dither ch1 prefetch engine interrupt
4 DITHER_CH0_ PREFETCH_IRQ	Dither ch0 prefetch engine interrupt
3 FIRST_CH1_ STORE_IRQ	Initial ch1 store engine interrupt
2 FIRST_CH0_ STORE_IRQ	Initial ch0 store engine interrupt
1 FIRST_CH1_ PREFETCH_IRQ	Initial ch1 prefetch engine interrupt
0 FIRST_CH0_ PREFETCH_IRQ	Initial ch0 prefetch engine interrupt

13.6.12.59 Next Frame Pointer (PXP_HW_PXP_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register reload operation must be performed when the current frame processing is complete. At the end of a frame, the PXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT, VERSION. All other registers will be loaded in the order they appear in the register map. Once the pointer's contents have been loaded into the PXP's registers, the NEXT_IRQ interrupt will be issued (see the PXP_STATUS register).

EXAMPLE

```
// create register command structure in memory
  u32* pxp_commands0[48], pxp_commands1;
  u32  rc;

// initialize control structure for frame 0
  pxp_commands0[0] = ...; // CTRL
  pxp_commands0[1] = ...; // OUT Buffer
  ...
  pxp_commands0[47] = ..; // Overlay7 param2

// initialize control structure for frame 1
  pxp_commands1[0] = ...; // CTRL
  pxp_commands1[1] = ...; // OUT Buffer
  ...
  pxp_commands1[47] = ..; // Overlay7 param2

// poll until a command isn't queued
  while (rc=REG_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  REG_NEXT_WR(pxp_commands0);  // enable PXP operation 0 via command pointer

// poll until first command clears
  while (rc=REG_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  REG_NEXT_WR(pxp_commands1);  // enable PXP operation 1 via command pointer
```

Address: 3070_0000h base + 400h offset = 3070_0400h

PXP_HW_PXP_NEXT field descriptions

Field	Description
31–2 POINTER	A pointer to a data structure containing register values to be used when processing the next frame. The pointer must be 32-bit aligned and should reside in on-chip or off-chip memory.
1 RSVD	Reserved, always set to zero.
0 ENABLED	Indicates that the "next frame" functionality has been enabled. This bit reflects the status of the hardware semaphore indicating that a reload operation is pending at the end of the current frame.

13.6.12.60 Pre-fetch engine Control Channel 0 Register (PXP_HW_PXP_INPUT_FETCH_CTRL_CH0)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_FETCH_CTRL_CH0: 0x450

HW_PXP_INPUT_FETCH_CTRL_CH0_SET: 0x454

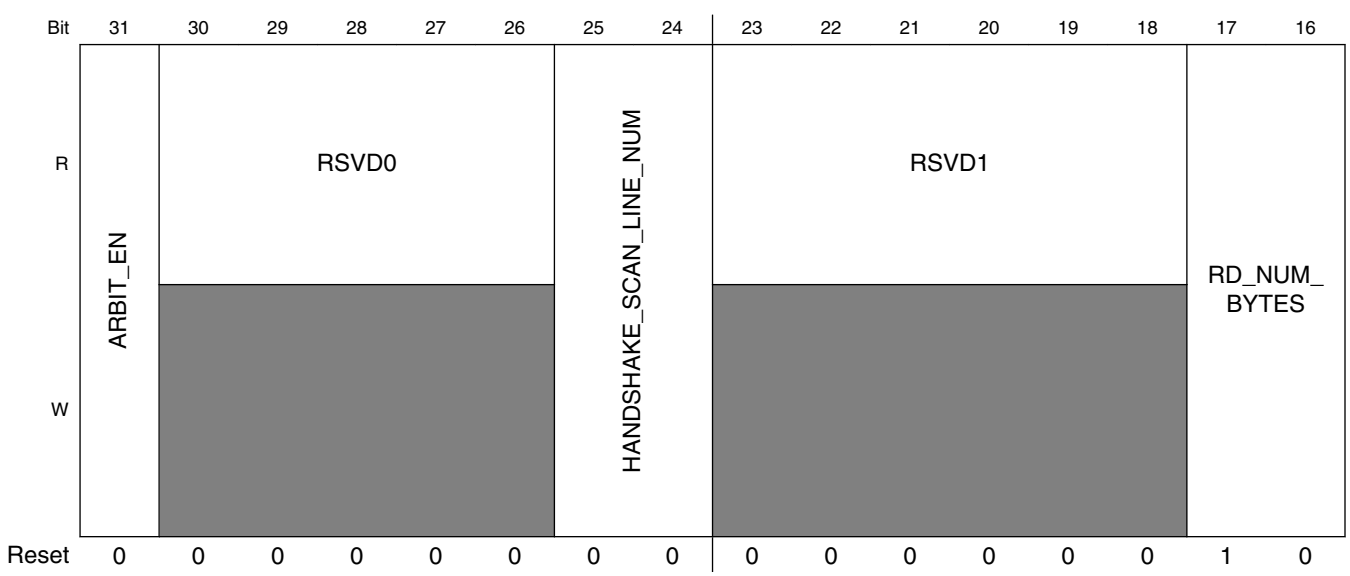
HW_PXP_INPUT_FETCH_CTRL_CH0_CLR: 0x458

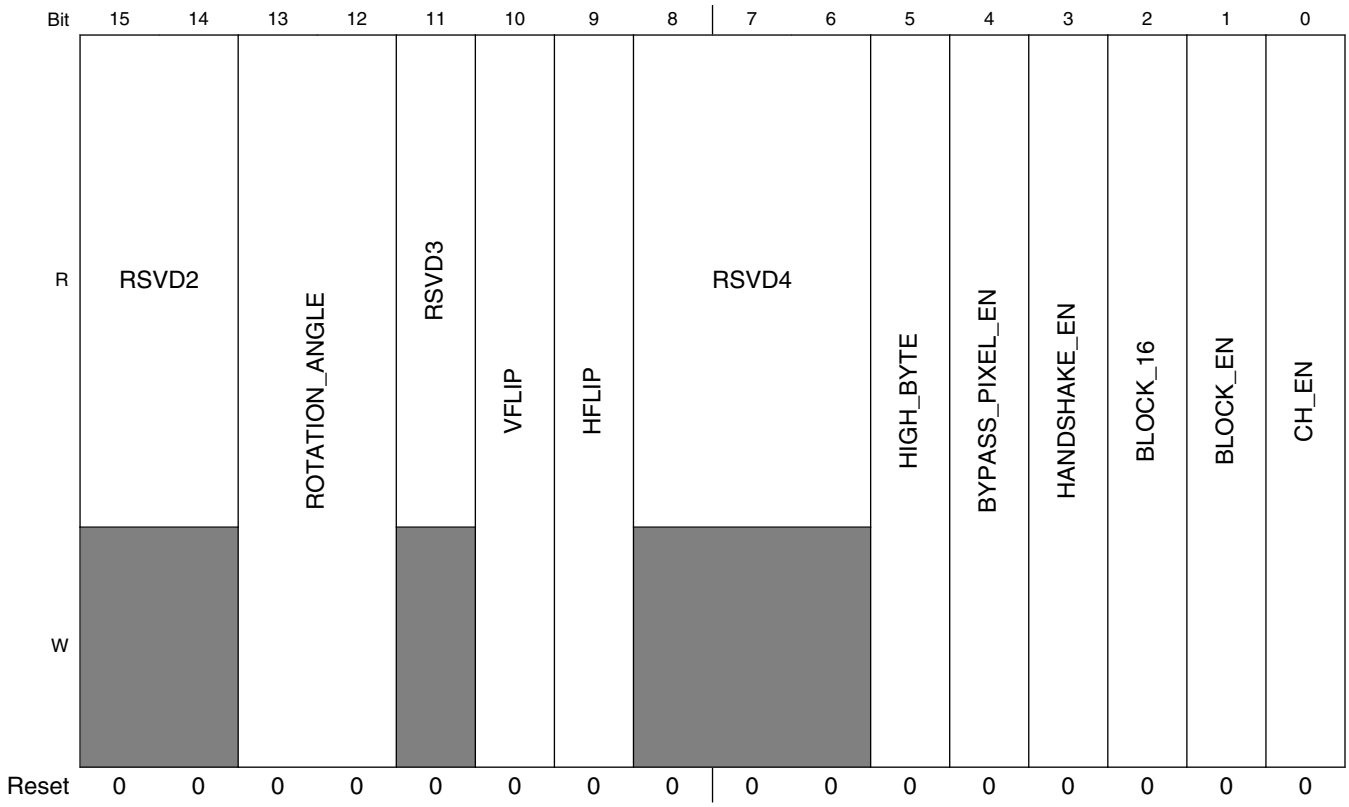
HW_PXP_INPUT_FETCH_CTRL_CH0_TOG: 0x45C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 450h offset = 3070_0450h





PXP_HW_PXP_INPUT_FETCH_CTRL_CH0 field descriptions

Field	Description
31 ARBIT_EN	Enables Arbitration 0x0 **0** — Arbitration disable. If using 2 channels, will output 2 axi bus sets. 0x1 **1** — Arbitration enable. If using 2 channel, will only output 1 axi bus sets
30–26 RSVD0	Reserved, always set to zero.
25–24 HANDSHAKE_ SCAN_LINE_ NUM	scan handshake line number 0x0 **0** — 1 line. 0x1 **1** — 8 lines 0x2 **2** — 16 lines 0x3 **3** — 16 lines
23–18 RSVD1	Reserved, always set to zero.
17–16 RD_NUM_ BYTES	Bytes in a read burst 0x0 **8_bytes** — 8 bytes. 0x1 **16_bytes** — 16 bytes. 0x2 **32_bytes** — 32 bytes. 0x3 **64_bytes** — 64 bytes.
15–14 RSVD2	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_INPUT_FETCH_CTRL_CH0 field descriptions (continued)

Field	Description
13–12 ROTATION_ ANGLE	0x0 **ROT_0** — Rotate image by 0 degrees. 0x1 **ROT_90** — Rotate image by 90 degrees. 0x2 **ROT_180** — Rotate image by 180 degrees. 0x3 **ROT_270** — Rotate image by 270 degrees.
11 RSVD3	Reserved, always set to zero.
10 VFLIP	Enables VFLIP 0x0 **0** — VFLIP disable 0x1 **1** — VFLIP enable
9 HFLIP	Enables HFLIP. 0x0 **0** — HFLIP disable 0x1 **1** — VFLIP enable
8–6 RSVD4	Reserved, always set to zero.
5 HIGH_BYTE	channel 0 high byte selection 0x0 **0** — In 64 bit mode, the output high byte will use channel1. 0x1 **1** — In 64 bit mode, the output high byte will use channel0
4 BYPASS_ PIXEL_EN	Selects Channel 0 pixel source 0x0 **0** — Channel 0 is from memory 0x1 **1** — Channel 0 is from previous process engine
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the store engine is disabled 0x1 **1** — Handshake with the store engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the prefetch mode. 0x0 **0** — Prefetch in scan mode 0x1 **1** — Prefetch in block mode
0 CH_EN	Channel enable. 0x0 **0** — Prefetch function is disable 0x1 **1** — Prefetch function is enable

13.6.12.61 Pre-fetch engine Control Channel 1 Register (PXP_HW_PXP_INPUT_FETCH_CTRL_CH1)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_FETCH_CTRL_CH1: 0x460

HW_PXP_INPUT_FETCH_CTRL_CH1_SET: 0x464

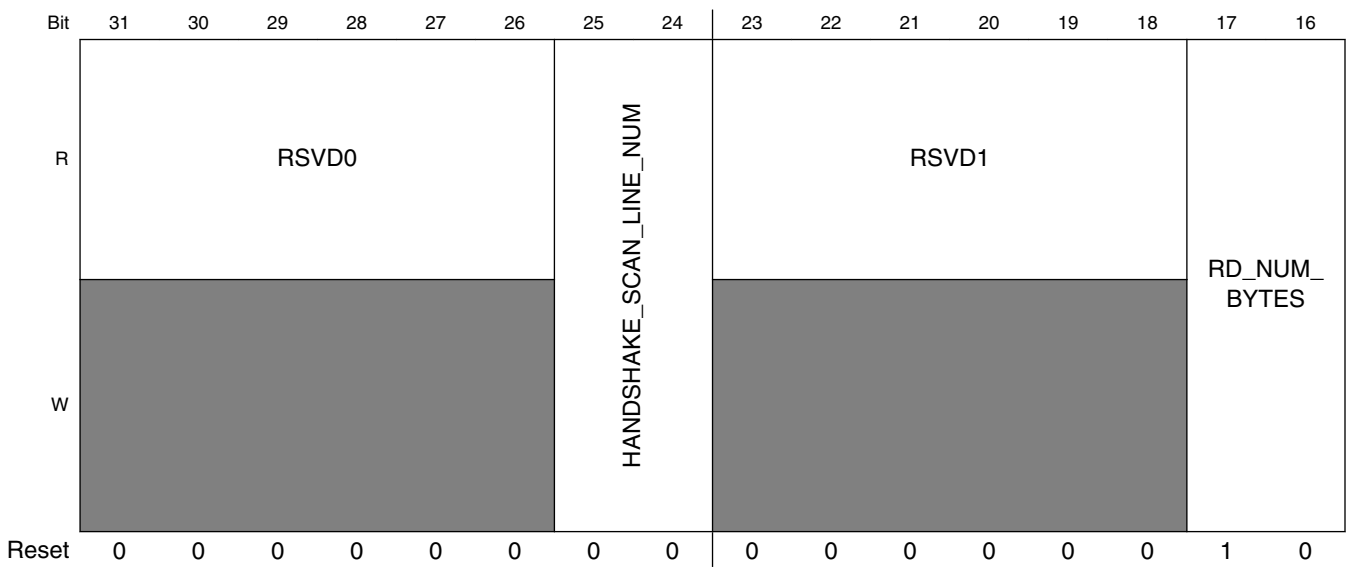
HW_PXP_INPUT_FETCH_CTRL_CH1_CLR: 0x468

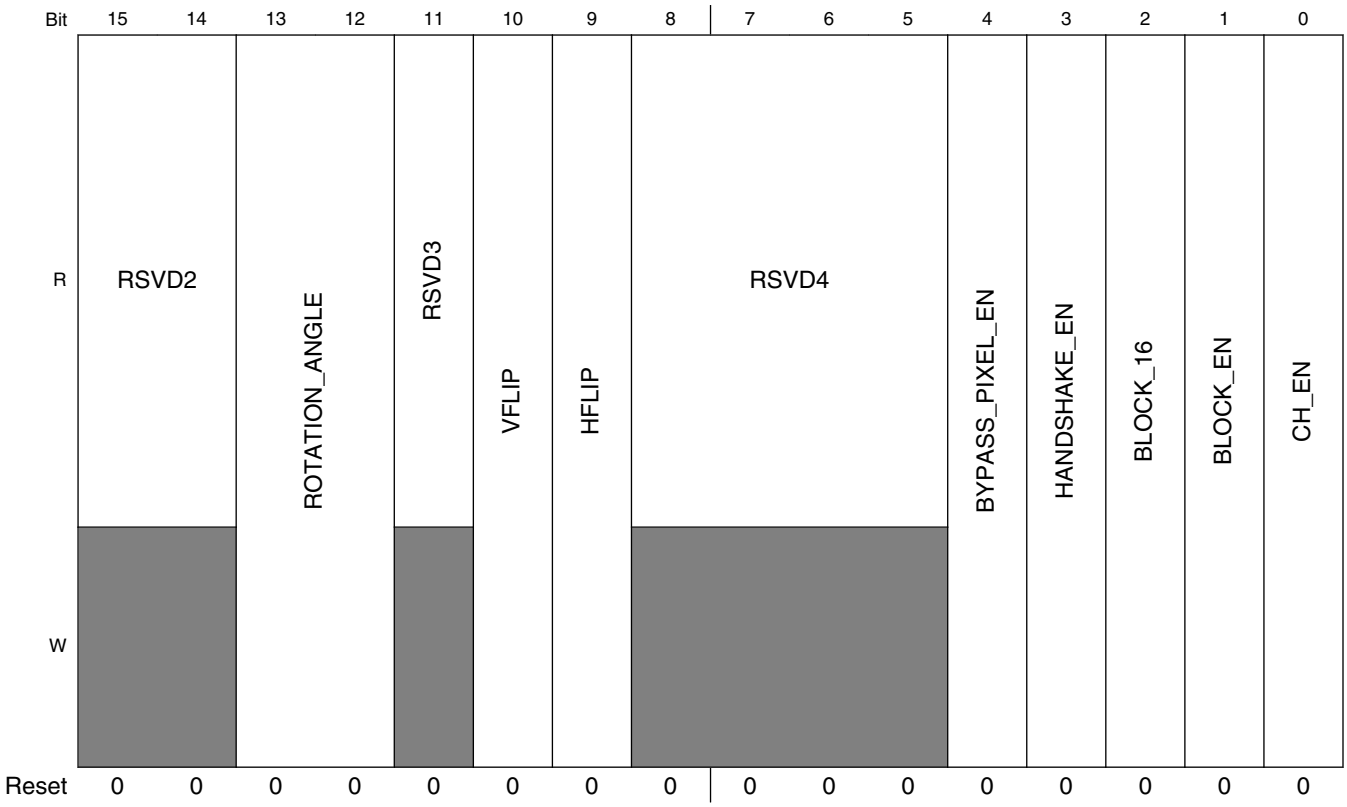
HW_PXP_INPUT_FETCH_CTRL_CH1_TOG: 0x46C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 460h offset = 3070_0460h





PXP_HW_PXP_INPUT_FETCH_CTRL_CH1 field descriptions

Field	Description
31–26 RSVD0	Reserved, always set to zero.
25–24 HANDSHAKE_ SCAN_LINE_ NUM	scan handshake line number 0x0 **0** — 1 line. 0x1 **1** — 8 lines 0x2 **2** — 16 lines 0x3 **3** — 16 lines
23–18 RSVD1	Reserved, always set to zero.
17–16 RD_NUM_ BYTES	Bytes in a read burst 0x0 **8_bytes** — 8 bytes. 0x1 **16_bytes** — 16 bytes. 0x2 **32_bytes** — 32 bytes. 0x3 **64_bytes** — 64 bytes.
15–14 RSVD2	Reserved, always set to zero.
13–12 ROTATION_ ANGLE	0x0 **ROT_0** — Rotate image by 0 degrees. 0x1 **ROT_90** — Rotate image by 90 degrees. 0x2 **ROT_180** — Rotate image by 180 degrees. 0x3 **ROT_270** — Rotate image by 270 degrees.

Table continues on the next page...

PXP_HW_PXP_INPUT_FETCH_CTRL_CH1 field descriptions (continued)

Field	Description
11 RSVD3	Reserved, always set to zero.
10 VFLIP	Enables VFLIP 0x0 **0** — VFLIP disable 0x1 **1** — VFLIP enable
9 HFLIP	Enables HFLIP. 0x0 **0** — HFLIP disable 0x1 **1** — VFLIP enable
8–5 RSVD4	Reserved, always set to zero.
4 BYPASS_ PIXEL_EN	Selects Channel 1 pixel source 0x0 **0** — Channel 1 is from memory 0x1 **1** — Channel 1 is from previous process engine
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the store engine is disabled 0x1 **1** — Handshake with the store engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the prefetch mode. 0x0 **0** — Prefetch in scan mode 0x1 **1** — Prefetch in block mode
0 CH_EN	Channel enable. 0x0 **0** — prefetch function is disable 0x1 **1** — prefetch function is enable

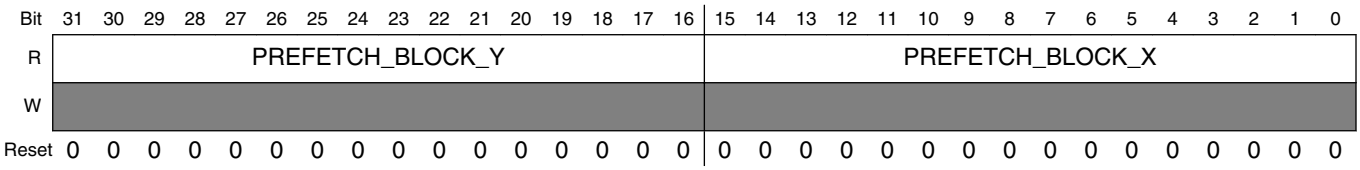
13.6.12.62 Pre-fetch engine status Channel 0 Register (PXP_HW_PXP_INPUT_FETCH_STATUS_CH0)

This register defines the status bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 470h offset = 3070_0470h



PXP_HW_PXP_INPUT_FETCH_STATUS_CH0 field descriptions

Field	Description
31–16 PREFETCH_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
PREFETCH_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

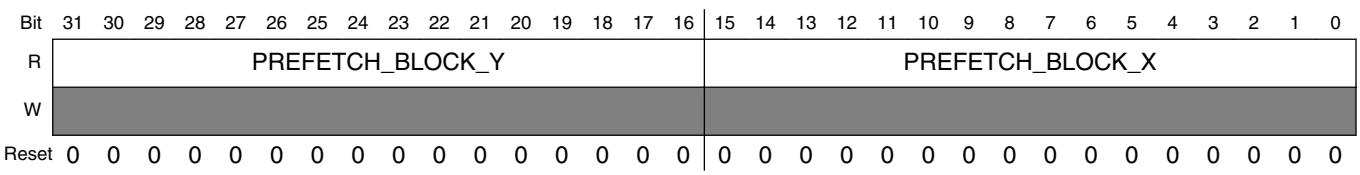
13.6.12.63 Store engine status Channel 1 Register (PXP_HW_PXP_INPUT_FETCH_STATUS_CH1)

This register defines the status bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 480h offset = 3070_0480h



PXP_HW_PXP_INPUT_FETCH_STATUS_CH1 field descriptions

Field	Description
31–16 PREFETCH_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
PREFETCH_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.64 PXP_HW_PXP_INPUT_FETCH_ACTIVE_SIZE_ULC_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 490h offset = 3070_0490h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_INPUT_FETCH_ACTIVE_SIZE_ULC_CH0 field descriptions

Field	Description
31–16 ACTIVE_SIZE_ ULC_Y	This field indicates the upper left Y-coordinate(in pixels) of the active surface of the total input memory
ACTIVE_SIZE_ ULC_X	This field indicates the upper left X-coordinate(in pixels) of the active surface of the total input memory

13.6.12.65 PXP_HW_PXP_INPUT_FETCH_ACTIVE_SIZE_LRC_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 4A0h offset = 3070_04A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH0 field descriptions (continued)

Field	Description
15–13 RSVD2	Reserved, always set to zero.
12–8 OFFSET1	Shift Offset for channel 0 componnent 1.
7–5 RSVD3	Reserved, always set to zero.
OFFSET0	Shift Offset for channel 0 componnent 0.

13.6.12.76 PXP_HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1: 0x550

HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1_SET: 0x554

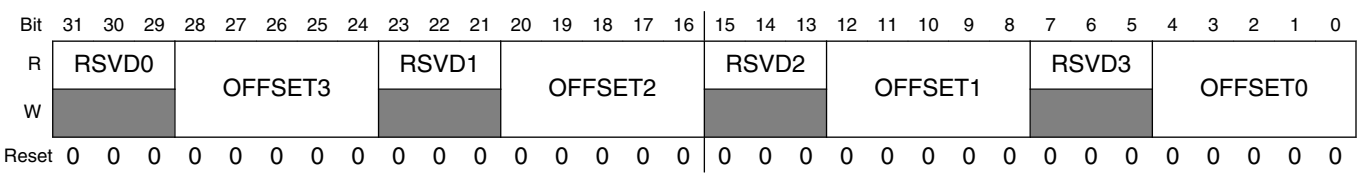
HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1_CLR: 0x558

HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1_TOG: 0x55C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 550h offset = 3070_0550h



PXP_HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1 field descriptions

Field	Description
31–29 RSVD0	Reserved, always set to zero.
28–24 OFFSET3	Shift Offset for channel 1 componnent 3.
23–21 RSVD1	Reserved, always set to zero.
20–16 OFFSET2	Shift Offset for channel 1 componnent 2.
15–13 RSVD2	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_INPUT_FETCH_SHIFT_OFFSET_CH1 field descriptions (continued)

Field	Description
12–8 OFFSET1	Shift Offset for channel 1 componnent 1.
7–5 RSVD3	Reserved, always set to zero.
OFFSET0	Shift Offset for channel 1 componnent 0.

13.6.12.77 PXP_HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0: 0x560

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0_SET: 0x564

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0_CLR: 0x568

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0_TOG: 0x56C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 560h offset = 3070_0560h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0																WIDTH3				WIDTH2				WIDTH1				WIDTH0			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0

PXP_HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH0 field descriptions

Field	Description
31–16 RSVD0	Reserved, always set to zero.
15–12 WIDTH3	Shift Width for channel 0 componnent 3.
11–8 WIDTH2	Shift Width for channel 0 componnent 2.
7–4 WIDTH1	Shift Width for channel 0 componnent 1.
WIDTH0	Shift Width for channel 0 componnent 0.

13.6.12.78 PXP_HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1: 0x570

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1_SET: 0x574

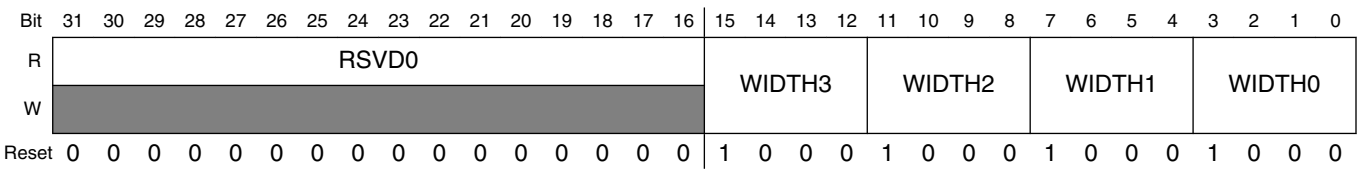
HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1_CLR: 0x578

HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1_TOG: 0x57C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 570h offset = 3070_0570h



PXP_HW_PXP_INPUT_FETCH_SHIFT_WIDTH_CH1 field descriptions

Field	Description
31–16 RSVD0	Reserved, always set to zero.
15–12 WIDTH3	Shift Width for channel 1 componnent 3.
11–8 WIDTH2	Shift Width for channel 1 componnent 2.
7–4 WIDTH1	Shift Width for channel 1 componnent 1.
WIDTH0	Shift Width for channel 1 componnent 0.

13.6.12.79 PXP_HW_PXP_INPUT_FETCH_ADDR_0_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 580h offset = 3070_0580h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_FETCH_ADDR_0_CH0 field descriptions

Field	Description
INPUT_BASE_ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

13.6.12.80 PXP_HW_PXP_INPUT_FETCH_ADDR_1_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 590h offset = 3070_0590h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_FETCH_ADDR_1_CH0 field descriptions

Field	Description
INPUT_BASE_ADDR1	input base address1. For 2 channel, indicated the channel1 base address. For 1 channel and YUV422 2 plane, indicate the UV base address

13.6.12.81 PXP_HW_PXP_INPUT_FETCH_ADDR_0_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5A0h offset = 3070_05A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_FETCH_ADDR_0_CH1 field descriptions

Field	Description
INPUT_BASE_ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

13.6.12.82 PXP_HW_PXP_INPUT_FETCH_ADDR_1_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5B0h offset = 3070_05B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_FETCH_ADDR_1_CH1 field descriptions

Field	Description
INPUT_BASE_ADDR1	input base address1. For 2 channel, indicated the channel1 base address. For 1 channel and YUV422 2 plane, indicate the UV base address

13.6.12.83 Store engine Control Channel 0 Register (PXP_HW_PXP_INPUT_STORE_CTRL_CH0)

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_INPUT_STORE_CTRL_CH0: 0x5C0

HW_PXP_INPUT_STORE_CTRL_CH0_SET: 0x5C4

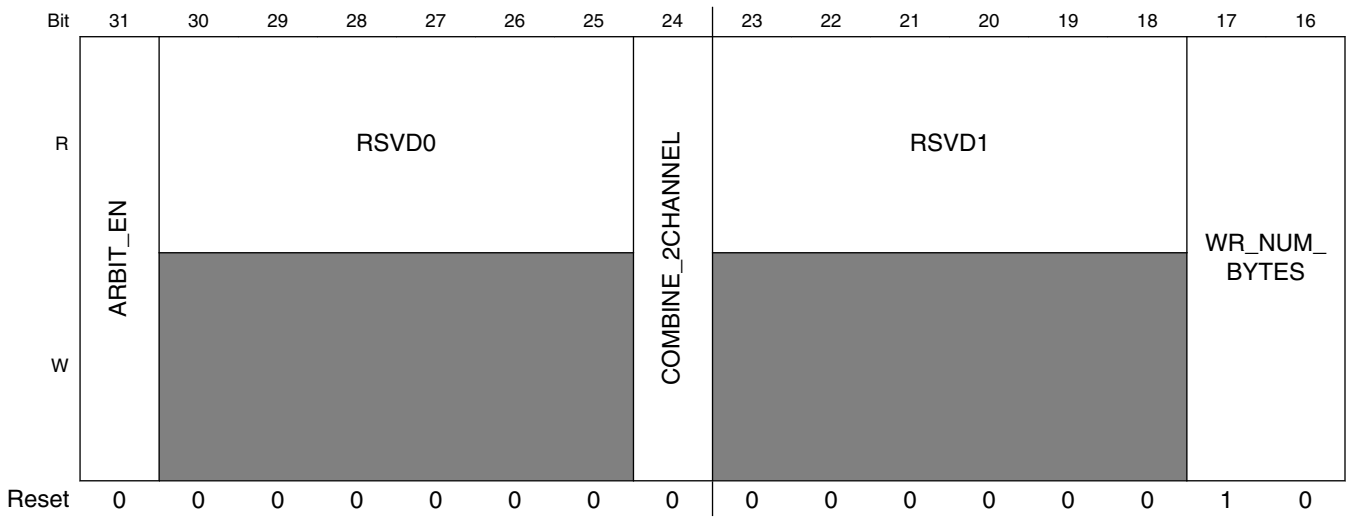
HW_PXP_INPUT_STORE_CTRL_CH0_CLR: 0x5C8

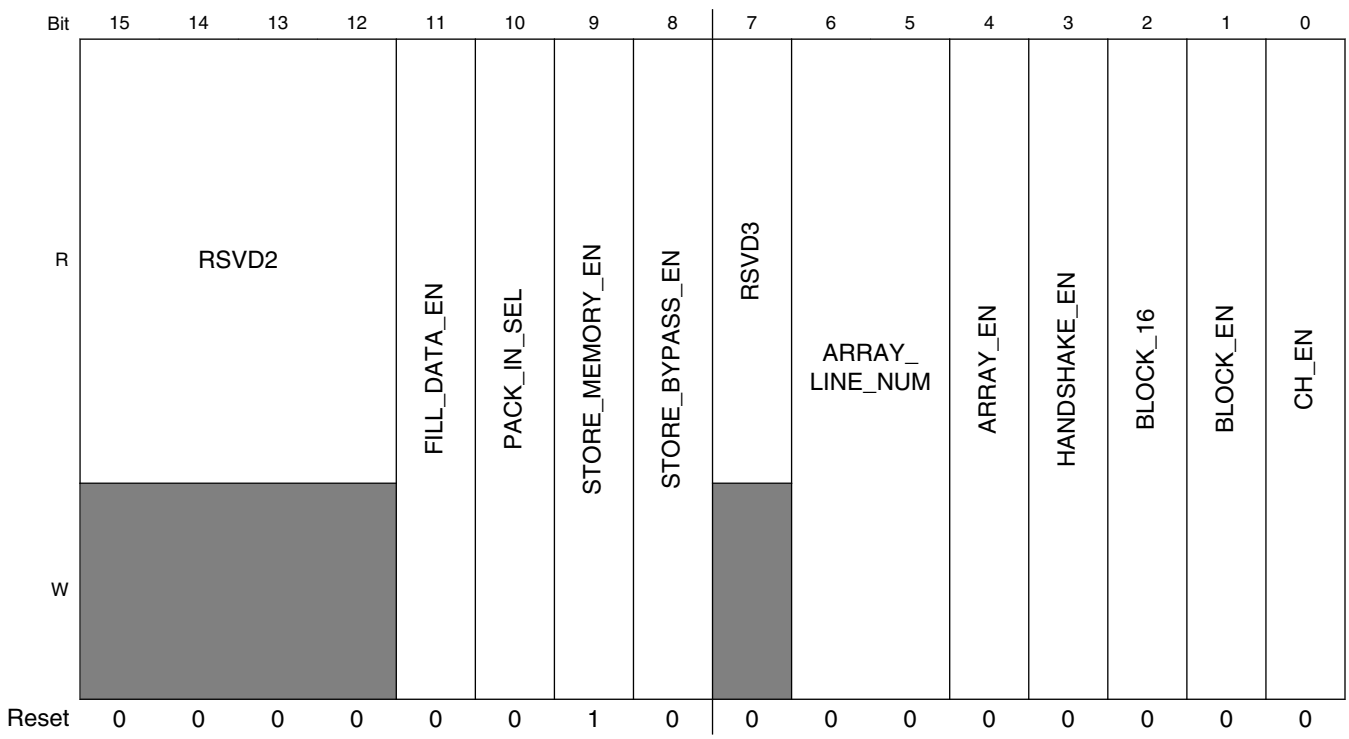
HW_PXP_INPUT_STORE_CTRL_CH0_TOG: 0x5CC

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5C0h offset = 3070_05C0h





PXP_HW_PXP_INPUT_STORE_CTRL_CH0 field descriptions

Field	Description
31 ARBIT_EN	Arbitration Enable 0x0 **0** — Arbitration disable. If using 2 channels, will output 2 axi bus sets 0x1 **1** — Arbitration enable. If using 2 channel, will only output 1 axi bus sets
30–25 RSVD0	Reserved, always set to zero.
24 COMBINE_2CHANNEL	Combine 2 channel Enable

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_CTRL_CH0 field descriptions (continued)

Field	Description
	0x0 **0** — combine 2 channel disable 0x1 **1** — combine 2 channel enable
23–18 RSVD1	Reserved, always set to zero.
17–16 WR_NUM_ BYTES	Bytes in a write burst 0x0 **8_bytes** — 8 bytes 0x1 **16_bytes** — 16 bytes 0x2 **32_bytes** — 32 bytes 0x3 **64_bytes** — 64 bytes
15–12 RSVD2	Reserved, always set to zero.
11 FILL_DATA_EN	fill data enable 0x0 **0** — Fill data mode disable. 0x1 **1** — Fill data mode enable. When using fill_data mode, store_engine will store fixed data defined in fill_data register
10 PACK_IN_SEL	pack_in_sel 0x0 **0** — select 64 shift out data to pack 0x1 **1** — select low 32 bit shift out data to pack
9 STORE_ MEMORY_EN	store memory enable 0x0 **0** — store memory mode disable. 0x1 **1** — store memory mode enable. Data will store to memory
8 STORE_ BYPASS_EN	store bypass enable 0x0 **0** — store bypass mode disable. 0x1 **1** — store bypass mode enable. Data will bypass to store output.
7 RSVD3	Reserved, always set to zero.
6–5 ARRAY_LINE_ NUM	Selects Array Size 0x0 **0** — Using 1x1 Array 0x1 **1** — Using 3x3 Array 0x2 **2** — Using 5x5 Array 0x3 **3** — Using 5x5 Array
4 ARRAY_EN	0x0 **0** — Array Handshake Disabled 0x1 **1** — Array Handshake Enabled
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the prefetch engine is disabled 0x1 **1** — Handshake with the prefetch engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_CTRL_CH0 field descriptions (continued)

Field	Description
1 BLOCK_EN	Choses the store mode. 0x0 **0** — Store in scan mode 0x1 **1** — Store in block mode
0 CH_EN	Channel enable. 0x0 **0** — Store function is disable 0x1 **1** — Store function is enable

13.6.12.84 Store engine Control Channel 1 Register (PXP_HW_PXP_INPUT_STORE_CTRL_CH1)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_INPUT_STORE_CTRL_CH1: 0x5D0

HW_PXP_INPUT_STORE_CTRL_CH1_SET: 0x5D4

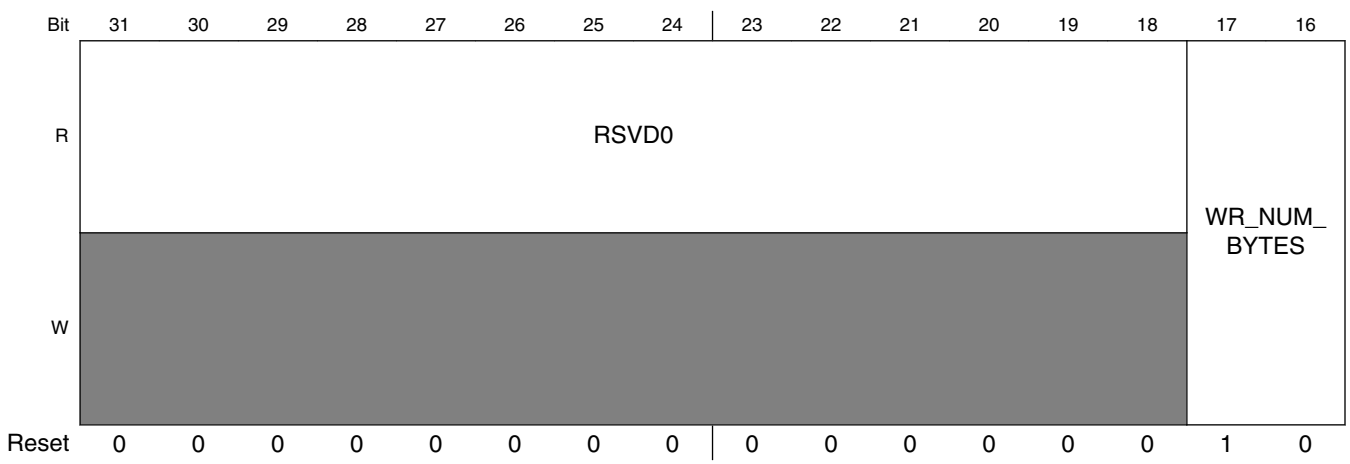
HW_PXP_INPUT_STORE_CTRL_CH1_CLR: 0x5D8

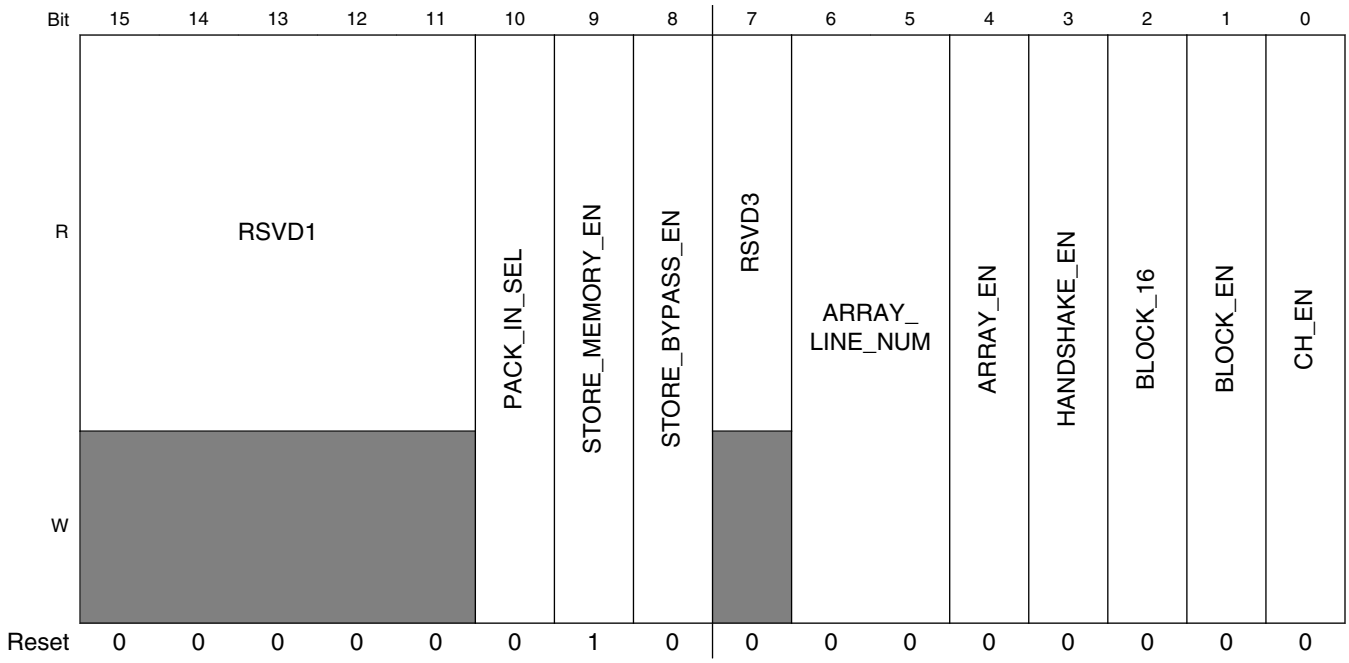
HW_PXP_INPUT_STORE_CTRL_CH1_TOG: 0x5DC

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5D0h offset = 3070_05D0h





PXP_HW_PXP_INPUT_STORE_CTRL_CH1 field descriptions

Field	Description
31–18 RSVD0	Reserved, always set to zero.
17–16 WR_NUM_ BYTES	Bytes in a write burst 0x0 **8_bytes** — 8 bytes 0x1 **16_bytes** — 16 bytes 0x2 **32_bytes** — 32 bytes 0x3 **64_bytes** — 64 bytes
15–11 RSVD1	Reserved, always set to zero.
10 PACK_IN_SEL	pack_in_sel 0x0 **0** — select 64 shift out data to pack 0x1 **1** — select channel 0 high 32 bit shift out data to pack
9 STORE_ MEMORY_EN	store memory enable 0x0 **0** — store memory mode disable. 0x1 **1** — store memory mode enable. Data will store to memory.
8 STORE_ BYPASS_EN	enable bit for store bypass 0x0 **0** — store bypass mode disable. 0x1 **1** — store bypass mode enable. Data will bypass to store output.
7 RSVD3	Reserved, always set to zero.
6–5 ARRAY_LINE_ NUM	Selects Array Size 0x0 **0** — Using 1x1 Array

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_CTRL_CH1 field descriptions (continued)

Field	Description
	0x1 **1** — Using 3x3 Array 0x2 **2** — Using 5x5 Array 0x3 **3** — Using 5x5 Array
4 ARRAY_EN	0x0 **0** — Array Handshake Disabled 0x1 **1** — Array Handshake Enabled
3 HANDSHAKE_ EN	Enable bit for handshake with the fetch engine. 0x0 **0** — Handshake with the fetch engine is disabled 0x1 **1** — Handshake with the fetch engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the store mode. 0x0 **0** — Store in scan mode 0x1 **1** — Store in block mode
0 CH_EN	Channel enable. 0x0 **0** — Store function is disable 0x1 **1** — Store function is enable

13.6.12.85 Store engine status Channel 0 Register (PXP_HW_PXP_INPUT_STORE_STATUS_CH0)

This register defines the status bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5E0h offset = 3070_05E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STORE_BLOCK_Y																STORE_BLOCK_X															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_STORE_STATUS_CH0 field descriptions

Field	Description
31–16 STORE_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_STATUS_CH0 field descriptions (continued)

Field	Description
STORE_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.86 Store engine status Channel 1 Register (PXP_HW_PXP_INPUT_STORE_STATUS_CH1)

This register defines the status bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 5F0h offset = 3070_05F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STORE_BLOCK_Y																STORE_BLOCK_X															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_STORE_STATUS_CH1 field descriptions

Field	Description
31–16 STORE_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
STORE_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.87 PXP_HW_PXP_INPUT_STORE_SIZE_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 600h offset = 3070_0600h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_HEIGHT																OUT_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_STORE_SIZE_CH0 field descriptions

Field	Description
31–16 OUT_HEIGHT	actual output height -1
OUT_WIDTH	actual output width -1

13.6.12.88 PXP_HW_PXP_INPUT_STORE_SIZE_CH1

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 610h offset = 3070_0610h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_HEIGHT																OUT_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_STORE_SIZE_CH1 field descriptions

Field	Description
31–16 OUT_HEIGHT	actual output height -1
OUT_WIDTH	actual output width -1

13.6.12.89 PXP_HW_PXP_INPUT_STORE_PITCH

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 620h offset = 3070_0620h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CH1_OUT_PITCH																CH0_OUT_PITCH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_INPUT_STORE_PITCH field descriptions

Field	Description
31–16 CH1_OUT_ PITCH	This field indicates the channel 1 input pitch
CH0_OUT_ PITCH	This field indicates the channel 0 input pitch

13.6.12.90 PXP_HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0: 0x630

HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0_SET: 0x634

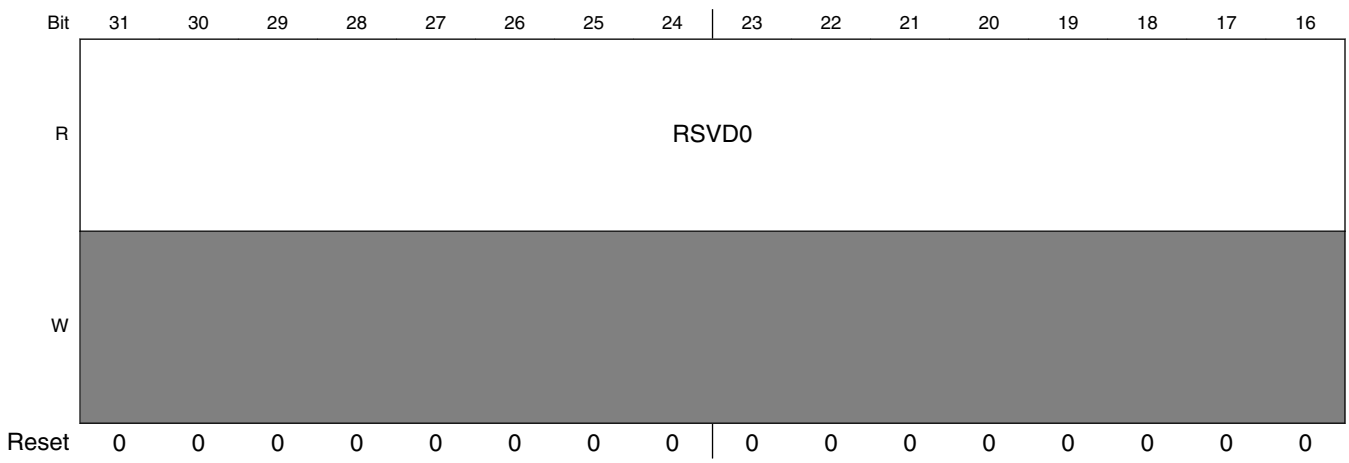
HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0_CLR: 0x638

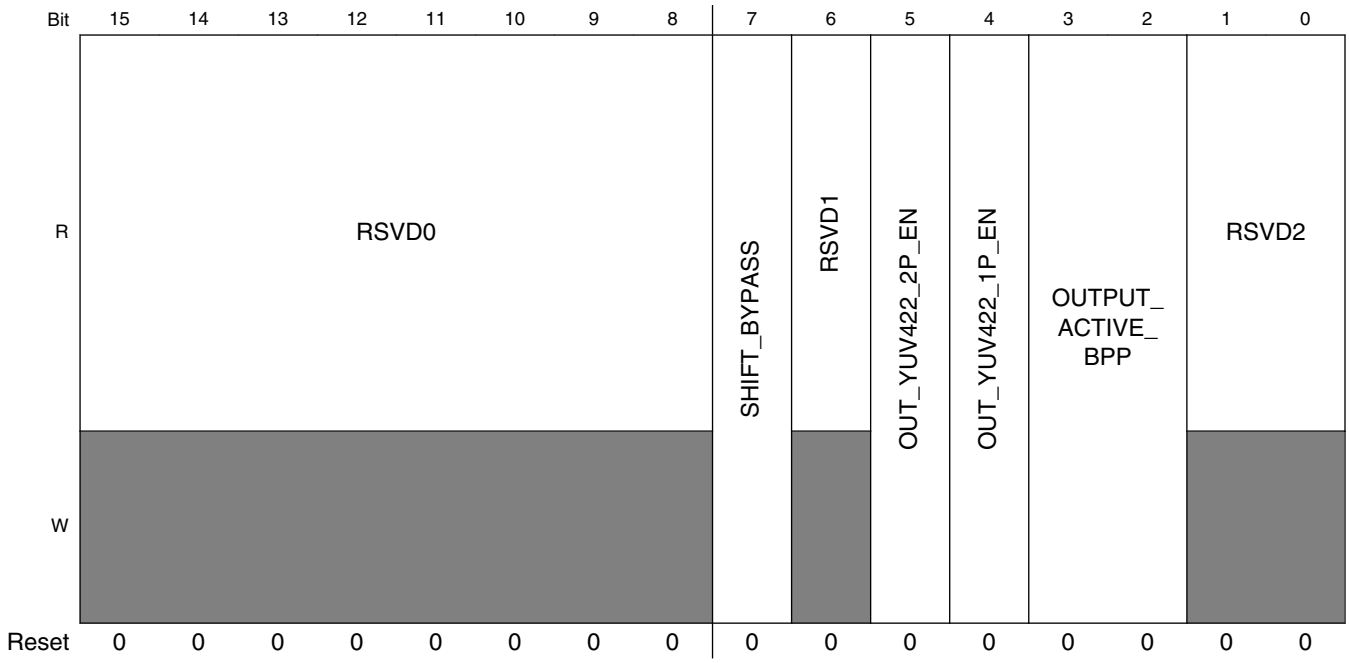
HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0_TOG: 0x63C

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 630h offset = 3070_0630h





PXP_HW_PXP_INPUT_STORE_SHIFT_CTRL_CH0 field descriptions

Field	Description
31–8 RSVD0	Reserved, always set to zero.
7 SHIFT_BYPASS	CH0 shift bypass 0x0 **0** — data will do shift processing. 0x1 **1** — data will bypass shift module.
6 RSVD1	Reserved, always set to zero.
5 OUT_YUV422_ 2P_EN	Enable for YUV422 2 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
4 OUT_YUV422_ 1P_EN	Enable for YUV422 1 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
3–2 OUTPUT_ ACTIVE_BPP	0x0 **0** — 8 bits 0x1 **1** — 16 bits 0x2 **2** — 32 bits 0x3 **3** — 32 bits
RSVD2	Reserved, always set to zero.

13.6.12.91 PXP_HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1: 0x640

HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1_SET: 0x644

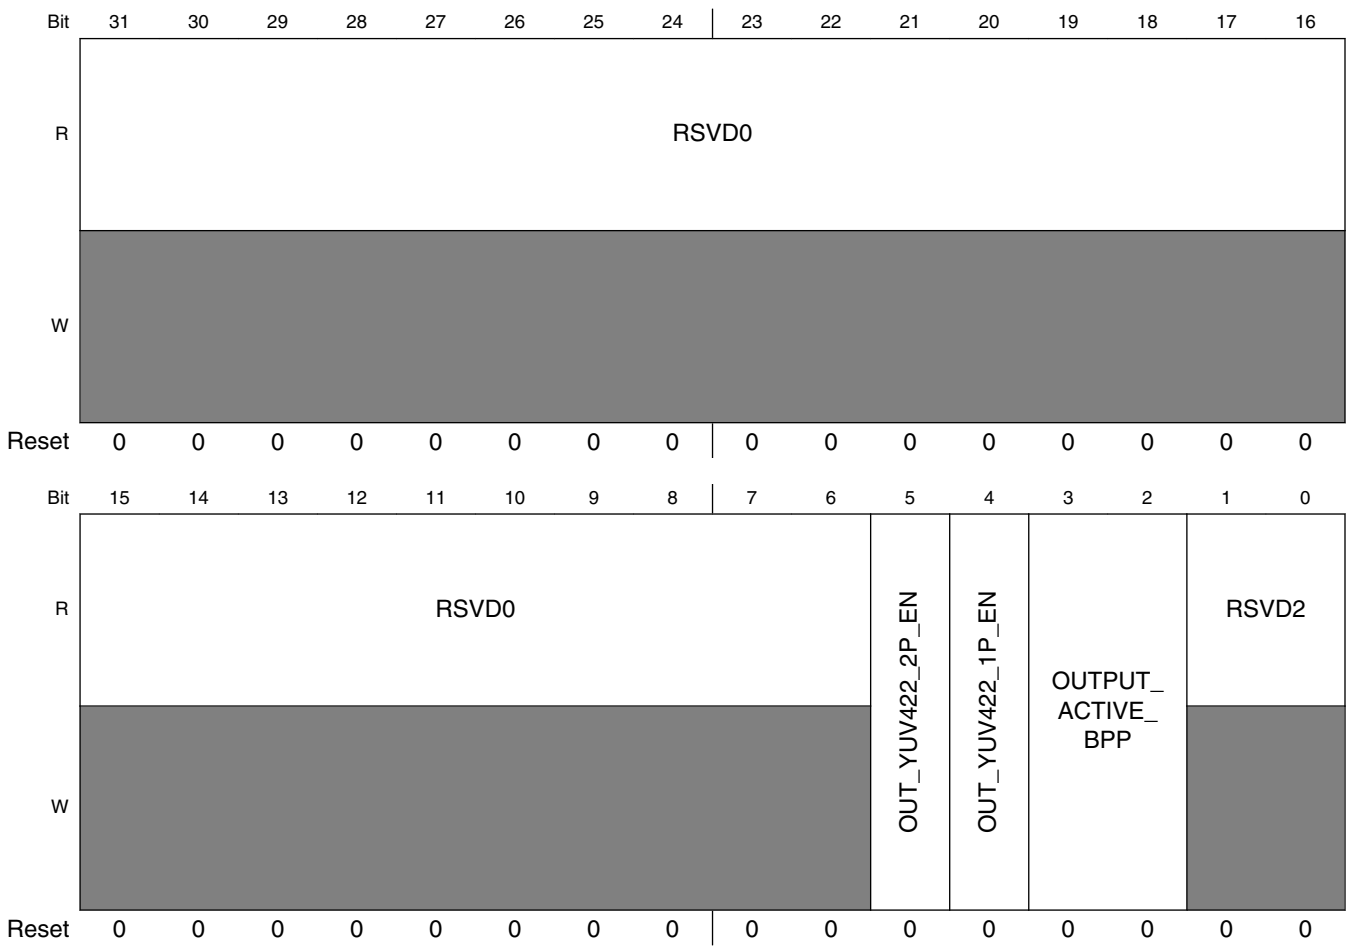
HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1_CLR: 0x648

HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1_TOG: 0x64C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 640h offset = 3070_0640h



PXP_HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1 field descriptions

Field	Description
31–6 RSVD0	Reserved, always set to zero.
5 OUT_YUV422_2P_EN	Enable for YUV422 2 plane

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_SHIFT_CTRL_CH1 field descriptions (continued)

Field	Description
	0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
4 OUT_YUV422_ 1P_EN	Enable for YUV422 1 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
3–2 OUTPUT_ ACTIVE_BPP	0x0 **0** — 8 bits 0x1 **1** — 16 bits 0x2 **2** — 32 bits 0x3 **3** — 32 bits
RSVD2	Reserved, always set to zero.

13.6.12.92 PXP_HW_PXP_INPUT_STORE_ADDR_0_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 690h offset = 3070_0690h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
D_MASK7_L_CH0	data mask7 low byte

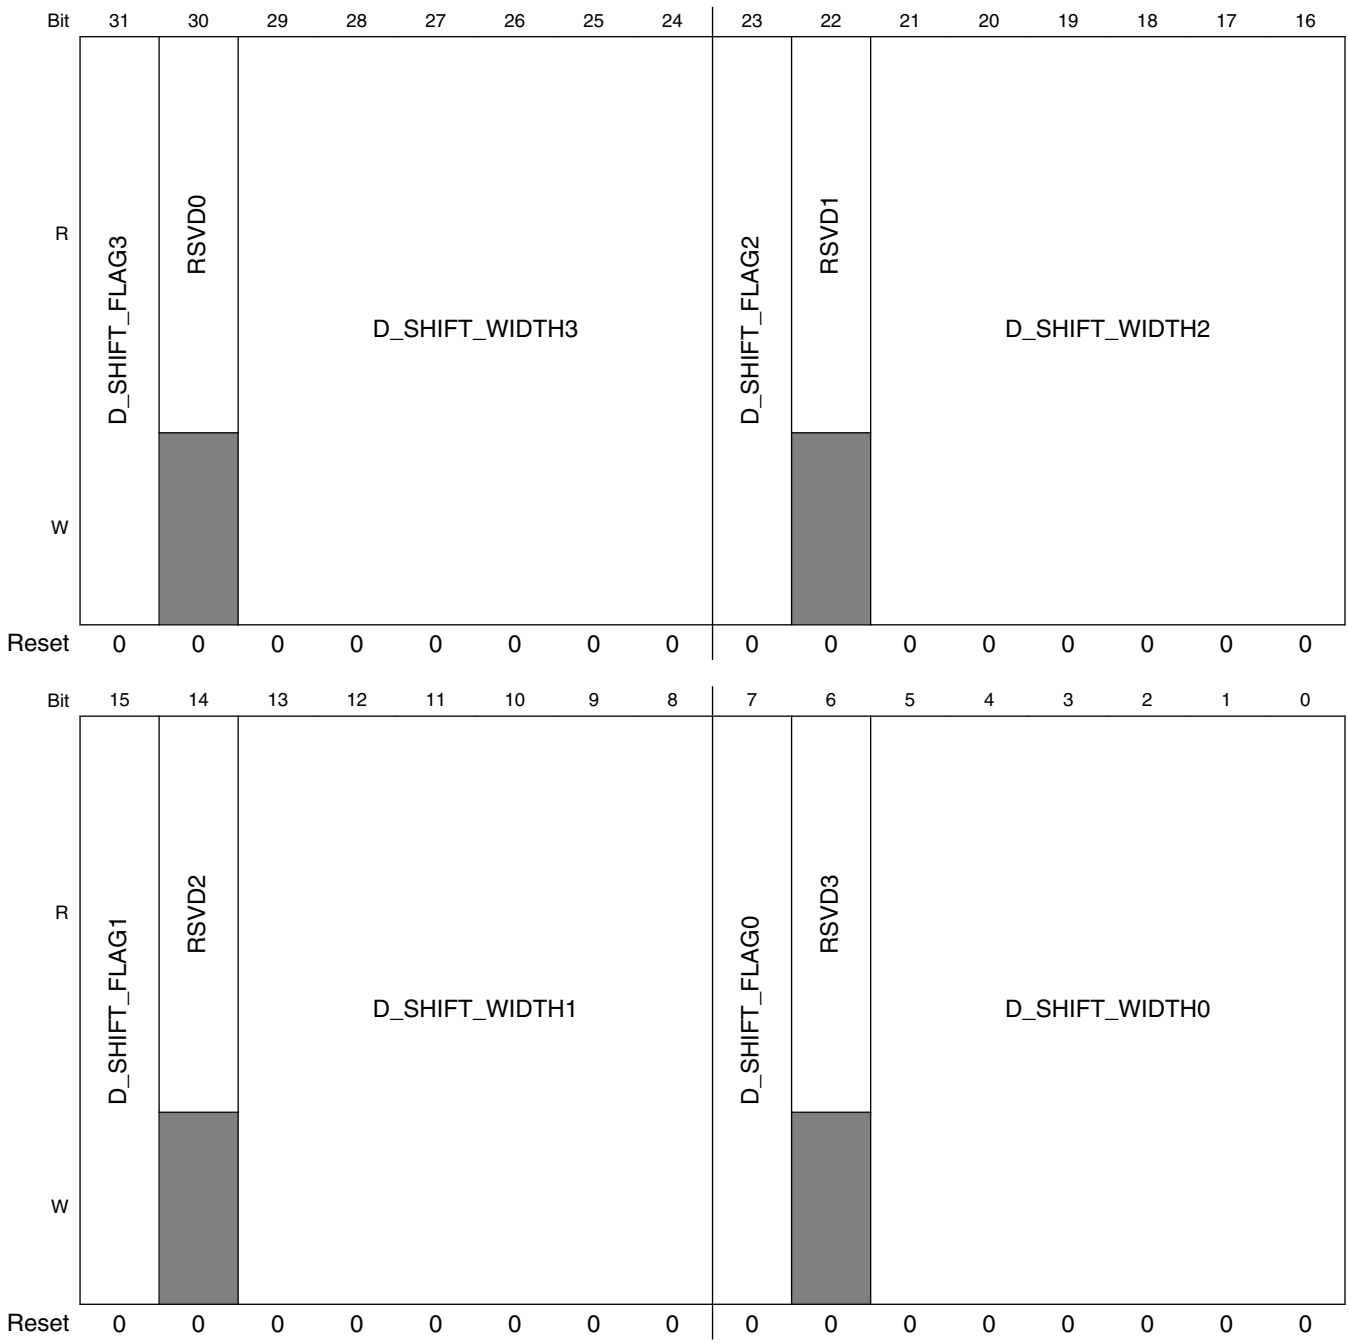
13.6.12.113 PXP_HW_PXP_INPUT_STORE_D_SHIFT_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 7F0h offset = 3070_07F0h



PXP_HW_PXP_INPUT_STORE_D_SHIFT_L_CH0 field descriptions

Field	Description
31 D_SHIFT_FLAG3	data shift flag 3
30 RSVD0	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_D_SHIFT_L_CH0 field descriptions (continued)

Field	Description
29–24 D_SHIFT_ WIDTH3	data shift width 3
23 D_SHIFT_FLAG2	data shift flag 2
22 RSVD1	Reserved, always set to zero.
21–16 D_SHIFT_ WIDTH2	data shift width 2
15 D_SHIFT_FLAG1	data shift flag 1
14 RSVD2	Reserved, always set to zero.
13–8 D_SHIFT_ WIDTH1	data shift width 1
7 D_SHIFT_FLAG0	data shift flag 0
6 RSVD3	Reserved, always set to zero.
D_SHIFT_ WIDTH0	data shift width 0

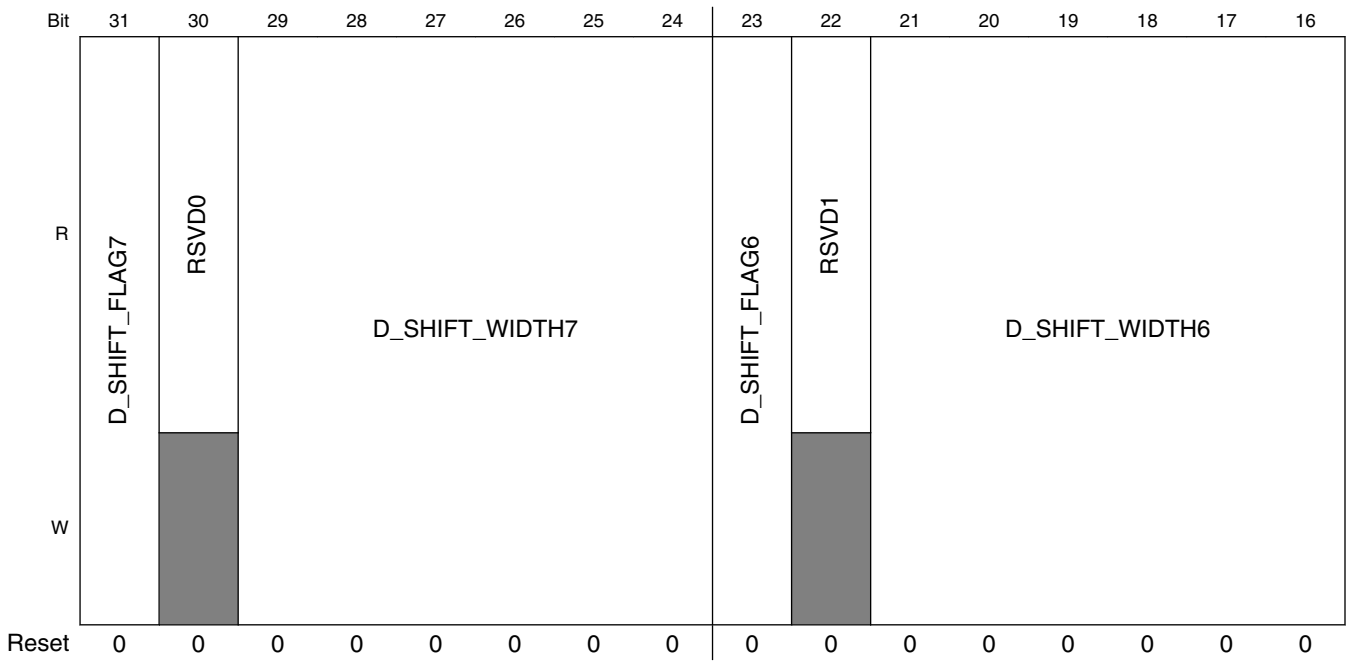
13.6.12.114 PXP_HW_PXP_INPUT_STORE_D_SHIFT_H_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 800h offset = 3070_0800h



PXP_HW_PXP_INPUT_STORE_D_SHIFT_H_CH0 field descriptions

Field	Description
31 D_SHIFT_FLAG7	data shift flag 7
30 RSVD0	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_D_SHIFT_H_CH0 field descriptions (continued)

Field	Description
29–24 D_SHIFT_ WIDTH7	data shift width 3
23 D_SHIFT_FLAG6	data shift flag 6
22 RSVD1	Reserved, always set to zero.
21–16 D_SHIFT_ WIDTH6	data shift width 6
15 D_SHIFT_FLAG5	data shift flag 5
14 RSVD2	Reserved, always set to zero.
13–8 D_SHIFT_ WIDTH5	data shift width 5
7 D_SHIFT_FLAG4	data shift flag 4
6 RSVD3	Reserved, always set to zero.
D_SHIFT_ WIDTH4	data shift width 4

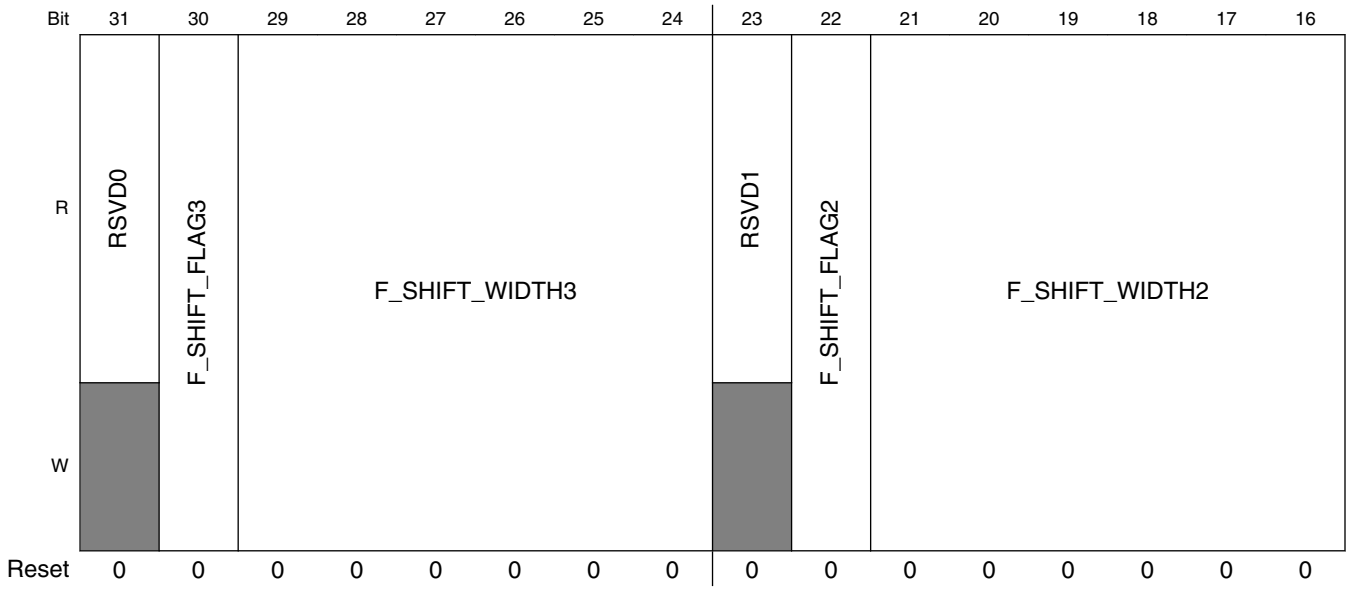
13.6.12.115 PXP_HW_PXP_INPUT_STORE_F_SHIFT_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 810h offset = 3070_0810h



PXP_HW_PXP_INPUT_STORE_F_SHIFT_L_CH0 field descriptions

Field	Description
31 RSVD0	Reserved, always set to zero.
30 F_SHIFT_FLAG3	flag shift flag3
29–24 F_SHIFT_ WIDTH3	flag shift width 3
23 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_F_SHIFT_L_CH0 field descriptions (continued)

Field	Description
22 F_SHIFT_FLAG2	flag shift flag2
21–16 F_SHIFT_ WIDTH2	flag shift width 2
15 RSVD2	Reserved, always set to zero.
14 F_SHIFT_FLAG1	flag shift flag1
13–8 F_SHIFT_ WIDTH1	flag shift width 1
7 RSVD3	Reserved, always set to zero.
6 F_SHIFT_FLAG0	flag shift flag0
F_SHIFT_ WIDTH0	flag shift width 0

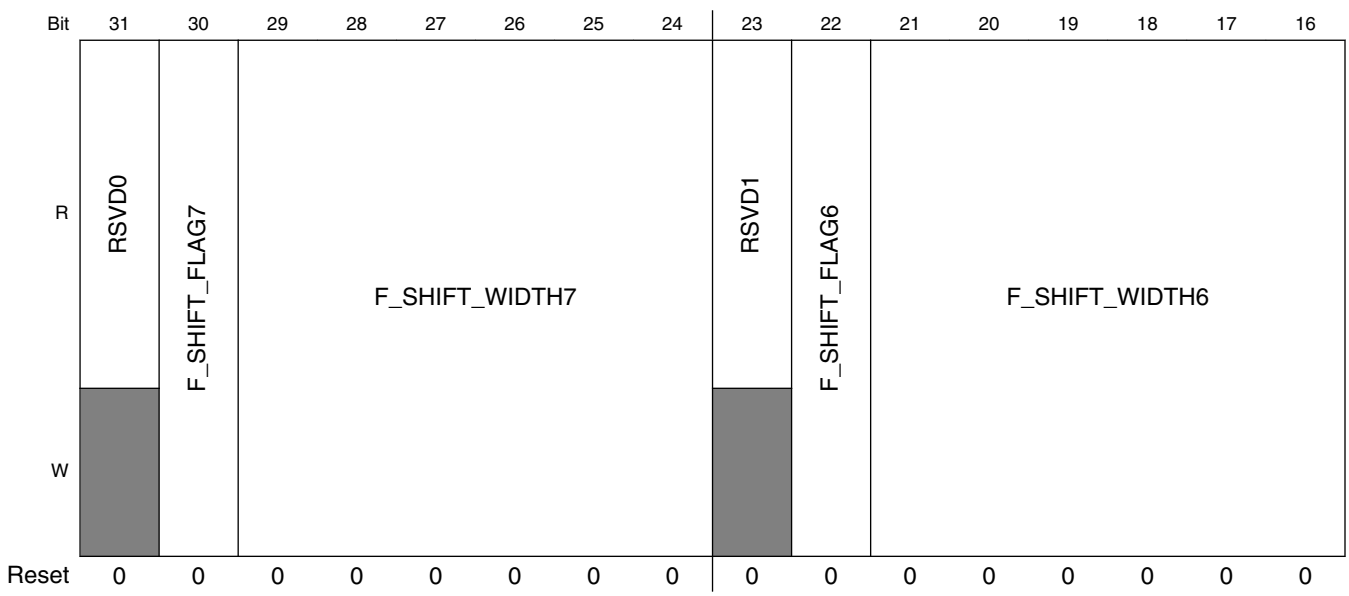
13.6.12.116 PXP_HW_PXP_INPUT_STORE_F_SHIFT_H_CH0

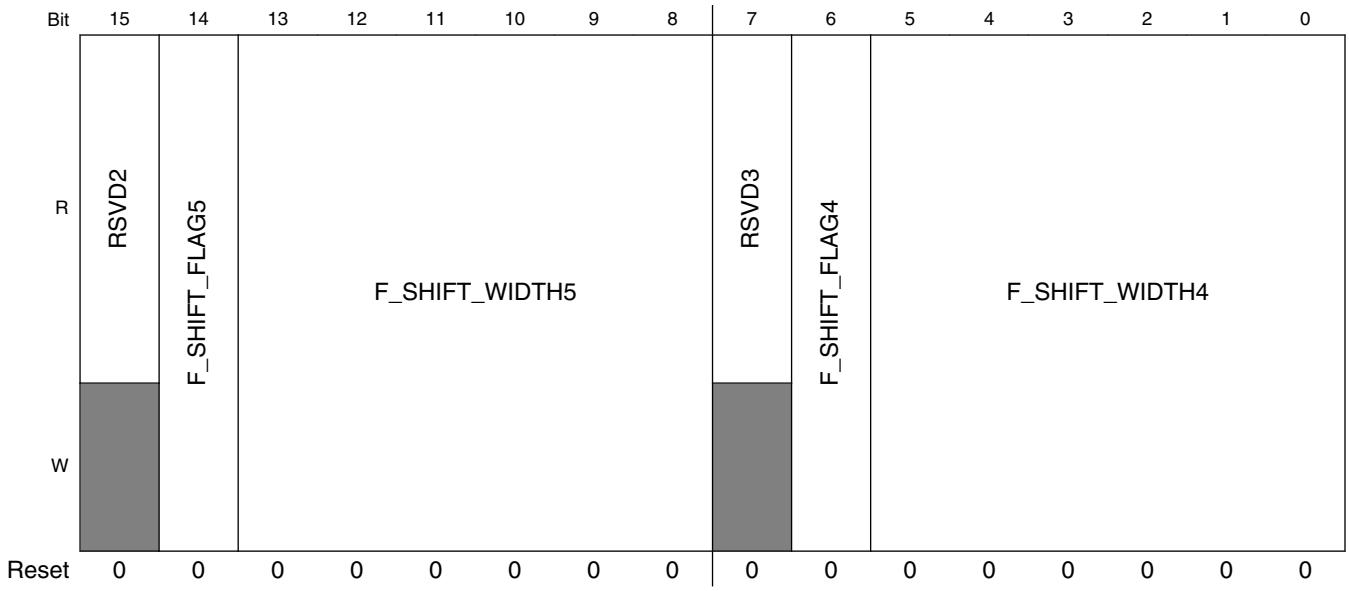
This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 820h offset = 3070_0820h





PXP_HW_PXP_INPUT_STORE_F_SHIFT_H_CH0 field descriptions

Field	Description
31 RSVD0	Reserved, always set to zero.
30 F_SHIFT_FLAG7	flag shift flag7
29–24 F_SHIFT_ WIDTH7	flag shift width 7
23 RSVD1	Reserved, always set to zero.
22 F_SHIFT_FLAG6	flag shift flag6
21–16 F_SHIFT_ WIDTH6	flag shift width 5
15 RSVD2	Reserved, always set to zero.
14 F_SHIFT_FLAG5	flag shift flag5
13–8 F_SHIFT_ WIDTH5	flag shift width 5
7 RSVD3	Reserved, always set to zero.
6 F_SHIFT_FLAG4	flag shift flag4
F_SHIFT_ WIDTH4	flag shift width 4

13.6.12.117 PXP_HW_PXP_INPUT_STORE_F_MASK_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

23–16 F_MASK2	flag mask2
15–8 F_MASK1	flag mask1
F_MASK0	flag mask0

13.6.12.118 PXP_HW_PXP_INPUT_STORE_F_MASK_H_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 840h offset = 3070_0840h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_INPUT_STORE_F_MASK_H_CH0 field descriptions

Field	Description
31–24 F_MASK7	flag mask7

Table continues on the next page...

PXP_HW_PXP_INPUT_STORE_F_MASK_H_CH0 field descriptions (continued)

Field	Description
23–16 F_MASK6	flag mask6
15–8 F_MASK5	flag mask5
F_MASK4	flag mask4

13.6.12.119 Pre-fetch engine Control Channel 0 Register (PXP_HW_PXP_DITHER_FETCH_CTRL_CH0)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_CTRL_CH0: 0x850

HW_PXP_DITHER_FETCH_CTRL_CH0_SET: 0x854

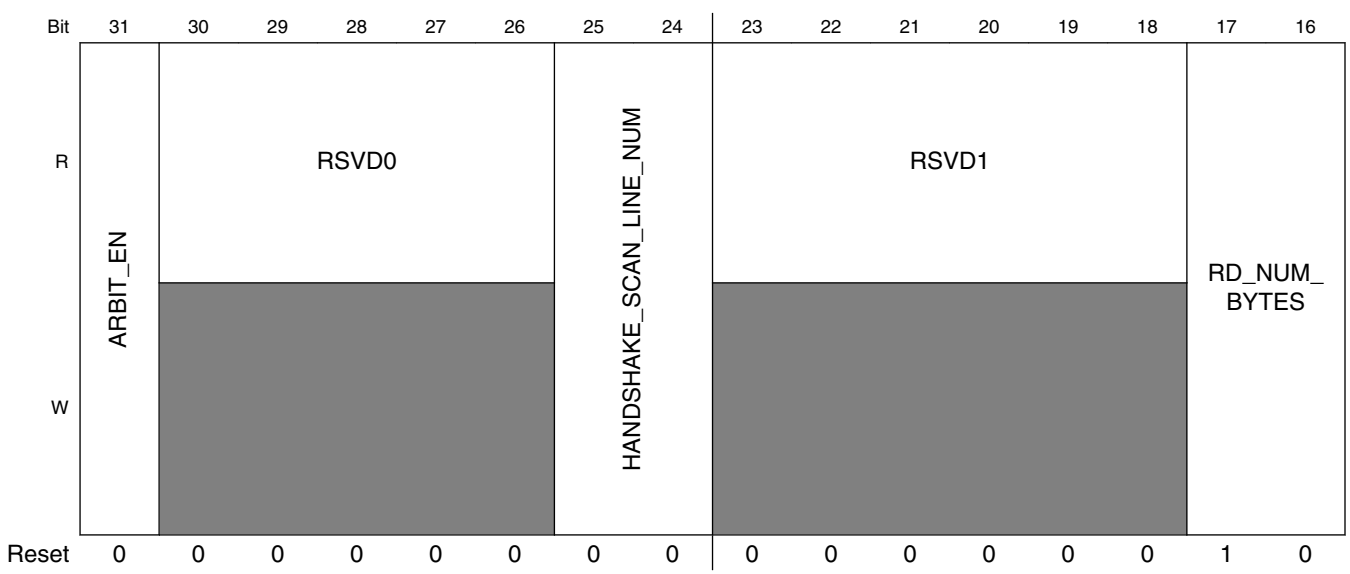
HW_PXP_DITHER_FETCH_CTRL_CH0_CLR: 0x858

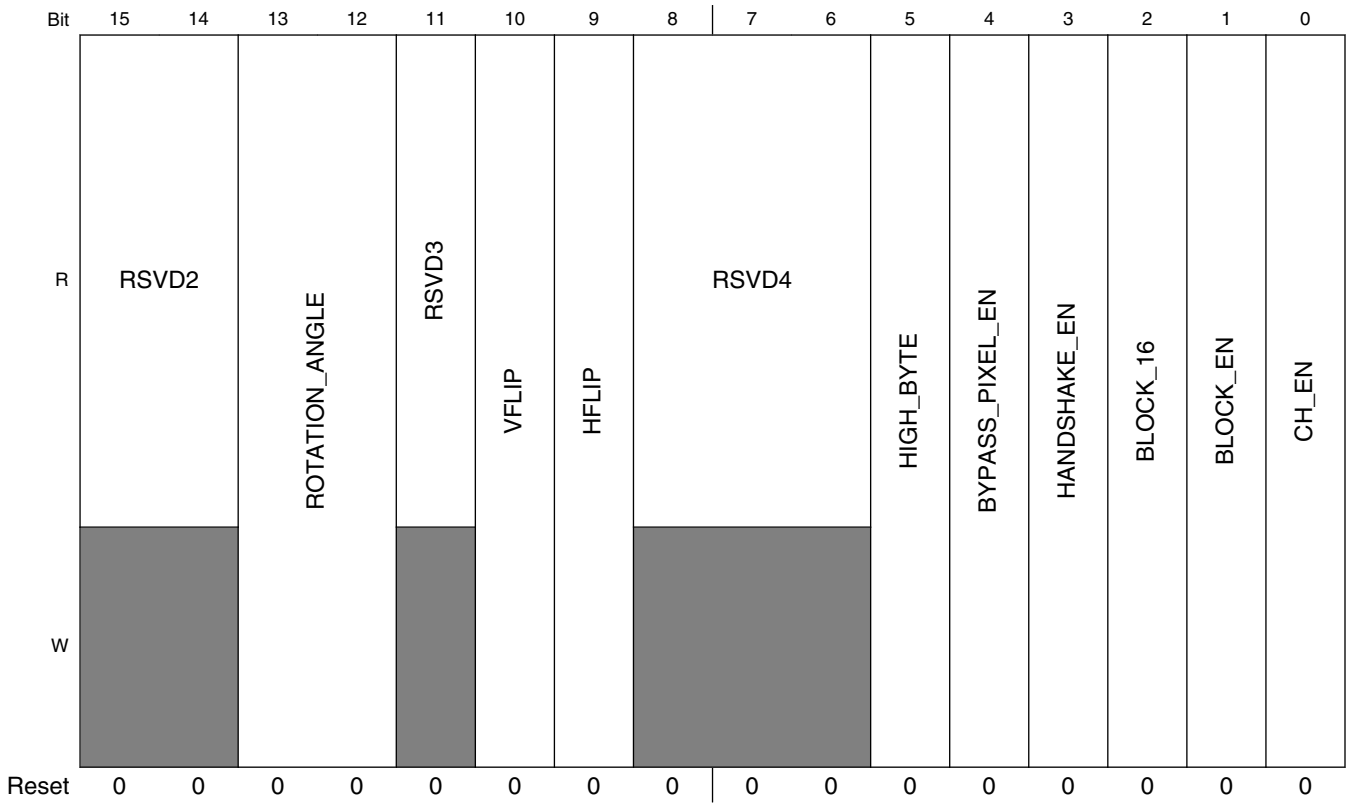
HW_PXP_DITHER_FETCH_CTRL_CH0_TOG: 0x85C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 850h offset = 3070_0850h





PXP_HW_PXP_DITHER_FETCH_CTRL_CH0 field descriptions

Field	Description
31 ARBIT_EN	Enables Arbitration 0x0 **0** — Arbitration disable. If using 2 channels, will output 2 axi bus sets. 0x1 **1** — Arbitration enable. If using 2 channel, will only output 1 axi bus sets
30–26 RSVD0	Reserved, always set to zero.
25–24 HANDSHAKE_ SCAN_LINE_ NUM	scan handshake line number 0x0 **0** — 1 line. 0x1 **1** — 8 lines 0x2 **2** — 16 lines 0x3 **3** — 16 lines
23–18 RSVD1	Reserved, always set to zero.
17–16 RD_NUM_ BYTES	Bytes in a read burst 0x0 **8_bytes** — 8 bytes. 0x1 **16_bytes** — 16 bytes. 0x2 **32_bytes** — 32 bytes. 0x3 **64_bytes** — 64 bytes.
15–14 RSVD2	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_DITHER_FETCH_CTRL_CH0 field descriptions (continued)

Field	Description
13–12 ROTATION_ ANGLE	0x0 **ROT_0** — Rotate image by 0 degrees. 0x1 **ROT_90** — Rotate image by 90 degrees. 0x2 **ROT_180** — Rotate image by 180 degrees. 0x3 **ROT_270** — Rotate image by 270 degrees.
11 RSVD3	Reserved, always set to zero.
10 VFLIP	Enables VFLIP 0x0 **0** — VFLIP disable 0x1 **1** — VFLIP enable
9 HFLIP	Enables HFLIP. 0x0 **0** — HFLIP disable 0x1 **1** — VFLIP enable
8–6 RSVD4	Reserved, always set to zero.
5 HIGH_BYTE	channel 0 high byte selection 0x0 **0** — In 64 bit mode, the output high byte will use channel1. 0x1 **1** — In 64 bit mode, the output high byte will use channel0
4 BYPASS_ PIXEL_EN	Selects Channel 0 pixel source 0x0 **0** — Channel 0 is from memory 0x1 **1** — Channel 0 is from previous process engine
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the store engine is disabled 0x1 **1** — Handshake with the store engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the prefetch mode. 0x0 **0** — Prefetch in scan mode 0x1 **1** — Prefetch in block mode
0 CH_EN	Channel enable. 0x0 **0** — Prefetch function is disable 0x1 **1** — Prefetch function is enable

13.6.12.120 Pre-fetch engine Control Channel 1 Register (PXP_HW_PXP_DITHER_FETCH_CTRL_CH1)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_CTRL_CH1: 0x860

HW_PXP_DITHER_FETCH_CTRL_CH1_SET: 0x864

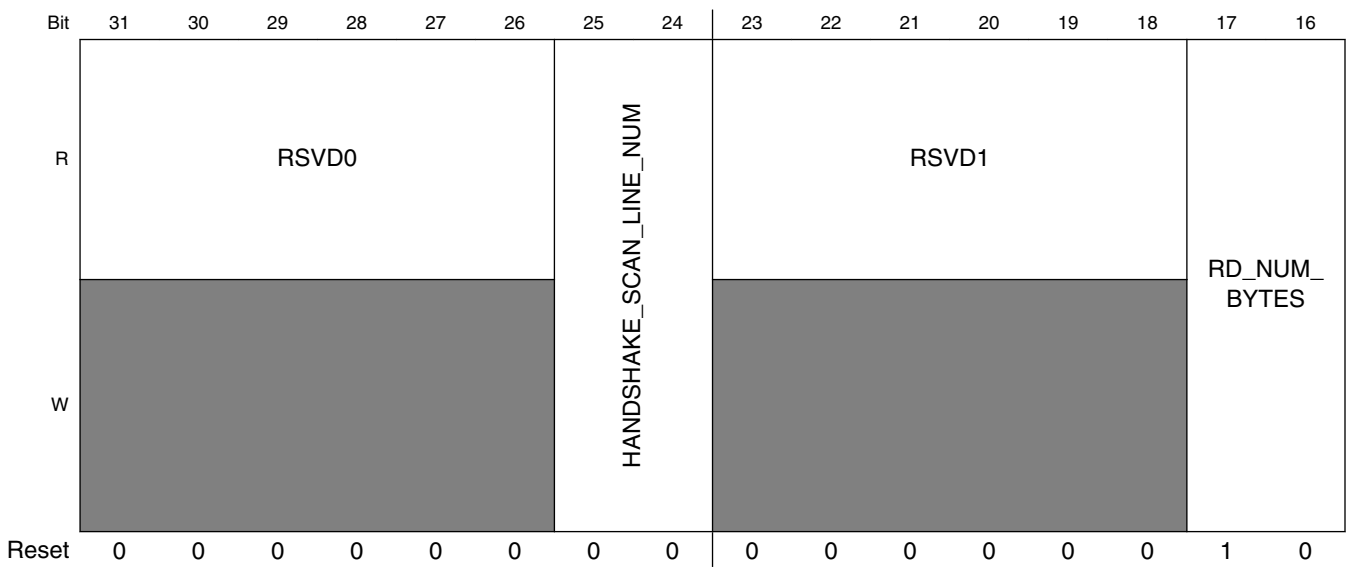
HW_PXP_DITHER_FETCH_CTRL_CH1_CLR: 0x868

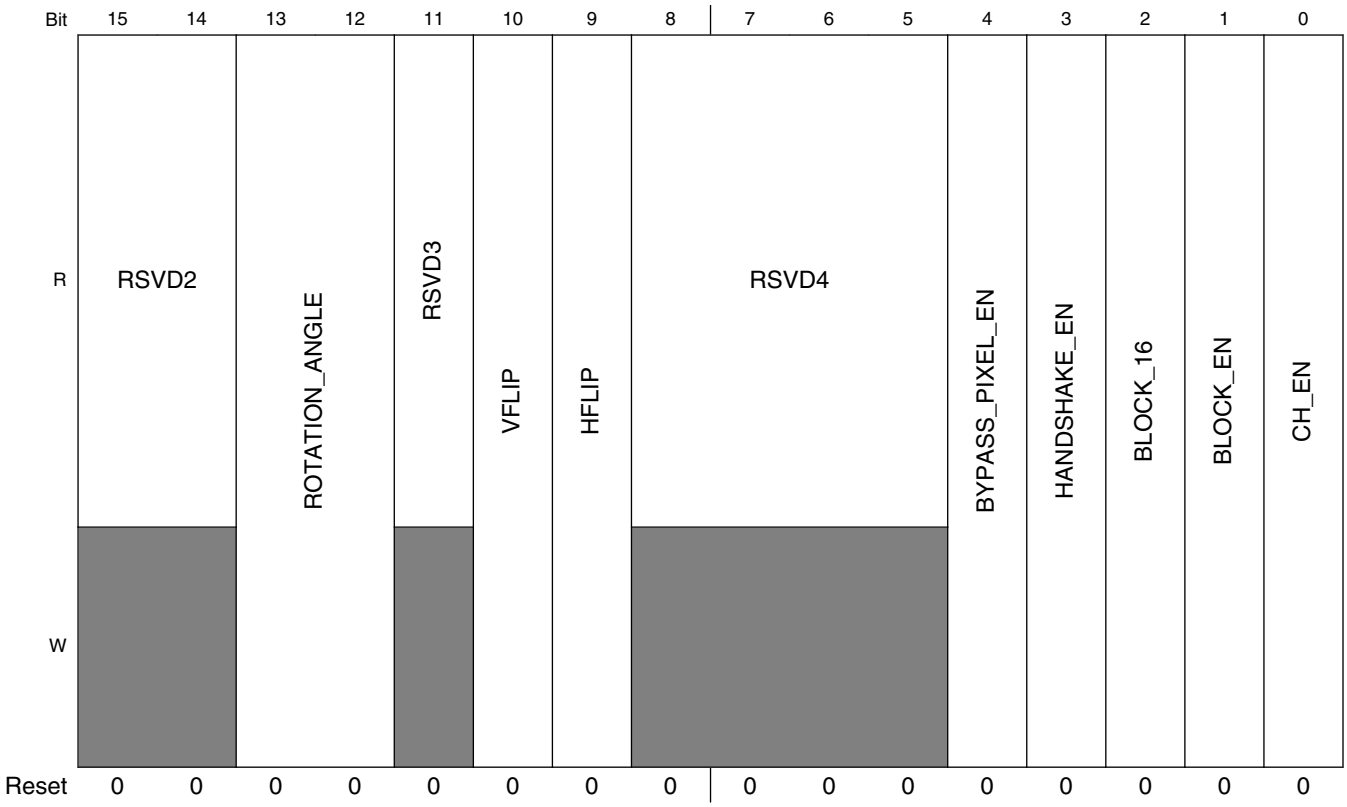
HW_PXP_DITHER_FETCH_CTRL_CH1_TOG: 0x86C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 860h offset = 3070_0860h





PXP_HW_PXP_DITHER_FETCH_CTRL_CH1 field descriptions

Field	Description
31–26 RSVD0	Reserved, always set to zero.
25–24 HANDSHAKE_ SCAN_LINE_ NUM	scan handshake line number 0x0 **0** — 1 line. 0x1 **1** — 8 lines 0x2 **2** — 16 lines 0x3 **3** — 16 lines
23–18 RSVD1	Reserved, always set to zero.
17–16 RD_NUM_ BYTES	Bytes in a read burst 0x0 **8_bytes** — 8 bytes. 0x1 **16_bytes** — 16 bytes. 0x2 **32_bytes** — 32 bytes. 0x3 **64_bytes** — 64 bytes.
15–14 RSVD2	Reserved, always set to zero.
13–12 ROTATION_ ANGLE	0x0 **ROT_0** — Rotate image by 0 degrees. 0x1 **ROT_90** — Rotate image by 90 degrees. 0x2 **ROT_180** — Rotate image by 180 degrees. 0x3 **ROT_270** — Rotate image by 270 degrees.

Table continues on the next page...

PXP_HW_PXP_DITHER_FETCH_CTRL_CH1 field descriptions (continued)

Field	Description
11 RSVD3	Reserved, always set to zero.
10 VFLIP	Enables VFLIP 0x0 **0** — VFLIP disable 0x1 **1** — VFLIP enable
9 HFLIP	Enables HFLIP. 0x0 **0** — HFLIP disable 0x1 **1** — VFLIP enable
8–5 RSVD4	Reserved, always set to zero.
4 BYPASS_ PIXEL_EN	Selects Channel 1 pixel source 0x0 **0** — Channel 1 is from memory 0x1 **1** — Channel 1 is from previous process engine
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the store engine is disabled 0x1 **1** — Handshake with the store engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the prefetch mode. 0x0 **0** — Prefetch in scan mode 0x1 **1** — Prefetch in block mode
0 CH_EN	Channel enable. 0x0 **0** — Prefetch function is disable 0x1 **1** — Prefetch function is enable

13.6.12.121 Pre-fetch engine status Channel 0 Register (PXP_HW_PXP_DITHER_FETCH_STATUS_CH0)

This register defines the status bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 870h offset = 3070_0870h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PREFETCH_BLOCK_Y																PREFETCH_BLOCK_X															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_STATUS_CH0 field descriptions

Field	Description
31–16 PREFETCH_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
PREFETCH_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.122 Store engine status Channel 1 Register (PXP_HW_PXP_DITHER_FETCH_STATUS_CH1)

This register defines the status bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 880h offset = 3070_0880h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PREFETCH_BLOCK_Y																PREFETCH_BLOCK_X

PXP_HW_PXP_DITHER_FETCH_STATUS_CH1 field descriptions

Field	Description
31–16 PREFETCH_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
PREFETCH_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.123 PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_ULC_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 890h offset = 3070_0890h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ACTIVE_SIZE_ULC_Y																ACTIVE_SIZE_ULC_X															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_ULC_CH0 field descriptions

Field	Description
31–16 ACTIVE_SIZE_ ULC_Y	This field indicates the upper left Y-coordinate(in pixels) of the active surface of the total input memory
ACTIVE_SIZE_ ULC_X	This field indicates the upper left X-coordinate(in pixels) of the active surface of the total input memory

13.6.12.124 PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_LRC_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 8A0h offset = 3070_08A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_LRC_CH0 field descriptions

Field	Description
31–16 ACTIVE_SIZE_ LRC_Y	This field indicates the upper left Y-coordinate(in pixels) of the active surface of the total input memory
ACTIVE_SIZE_ LRC_X	This field indicates the upper left X-coordinate(in pixels) of the active surface of the total input memory

13.6.12.125 PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_ULC_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 8B0h offset = 3070_08B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ACTIVE_SIZE_ULC_Y																ACTIVE_SIZE_ULC_X

PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_ULC_CH1 field descriptions

Field	Description
31–16 ACTIVE_SIZE_ ULC_Y	This field indicates the upper left Y-coordinate(in pixels) of the active surface of the total input memory
ACTIVE_SIZE_ ULC_X	This field indicates the upper left X-coordinate(in pixels) of the active surface of the total input memory

13.6.12.126 PXP_HW_PXP_DITHER_FETCH_ACTIVE_SIZE_LRC_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 8C0h offset = 3070_08C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PXP_HW_PXP_DITHER_FETCH_PITCH field descriptions

Field	Description
31–16 CH1_INPUT_ PITCH	This field indicates the channel 1 input pitch
CH0_INPUT_ PITCH	This field indicates the channel 0 input pitch

13.6.12.132 PXP_HW_PXP_DITHER_FETCH_SHIFT_CTRL_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_SHIFT_CTRL_CH0: 0x920

HW_PXP_DITHER_FETCH_SHIFT_CTRL_CH0_SET: 0x924

HW_PXP_DITHER_FETCH_SHIFT_CTRL_CH0_CLR: 0x928

HW_PXP_DITHER_FETCH_SHIFT_CTRL_CH0_TOG: 0x92C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 920h offset = 3070_0920h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.6.12.134 PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0: 0x940

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0_SET: 0x944

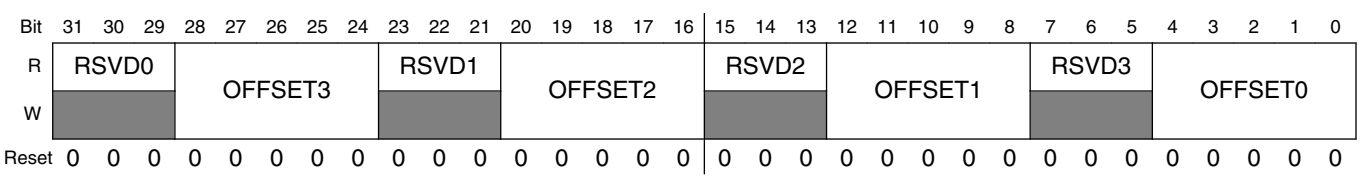
HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0_CLR: 0x948

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0_TOG: 0x94C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 940h offset = 3070_0940h



PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0 field descriptions

Field	Description
31–29 RSVD0	Reserved, always set to zero.
28–24 OFFSET3	Shift Offset for channel 0 componnent 3.
23–21 RSVD1	Reserved, always set to zero.
20–16 OFFSET2	Shift Offset for channel 0 componnent 2.

Table continues on the next page...

PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH0 field descriptions (continued)

Field	Description
15–13 RSVD2	Reserved, always set to zero.
12–8 OFFSET1	Shift Offset for channel 0 componnent 1.
7–5 RSVD3	Reserved, always set to zero.
OFFSET0	Shift Offset for channel 0 componnent 0.

13.6.12.135 PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1: 0x950

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1_SET: 0x954

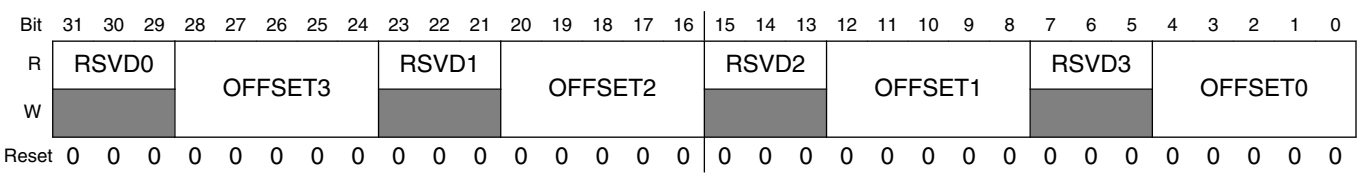
HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1_CLR: 0x958

HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1_TOG: 0x95C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 950h offset = 3070_0950h



PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1 field descriptions

Field	Description
31–29 RSVD0	Reserved, always set to zero.
28–24 OFFSET3	Shift Offset for channel 1 componnent 3.
23–21 RSVD1	Reserved, always set to zero.
20–16 OFFSET2	Shift Offset for channel 1 componnent 2.
15–13 RSVD2	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_DITHER_FETCH_SHIFT_OFFSET_CH1 field descriptions (continued)

Field	Description
12–8 OFFSET1	Shift Offset for channel 1 componnent 1.
7–5 RSVD3	Reserved, always set to zero.
OFFSET0	Shift Offset for channel 1 componnent 0.

13.6.12.136 PXP_HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0: 0x960

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0_SET: 0x964

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0_CLR: 0x968

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0_TOG: 0x96C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 960h offset = 3070_0960h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0																WIDTH3				WIDTH2				WIDTH1				WIDTH0			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0	0

PXP_HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH0 field descriptions

Field	Description
31–16 RSVD0	Reserved, always set to zero.
15–12 WIDTH3	Shift Width for channel 0 componnent 3.
11–8 WIDTH2	Shift Width for channel 0 componnent 2.
7–4 WIDTH1	Shift Width for channel 0 componnent 1.
WIDTH0	Shift Width for channel 0 componnent 0.

13.6.12.137 PXP_HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1: 0x970

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1_SET: 0x974

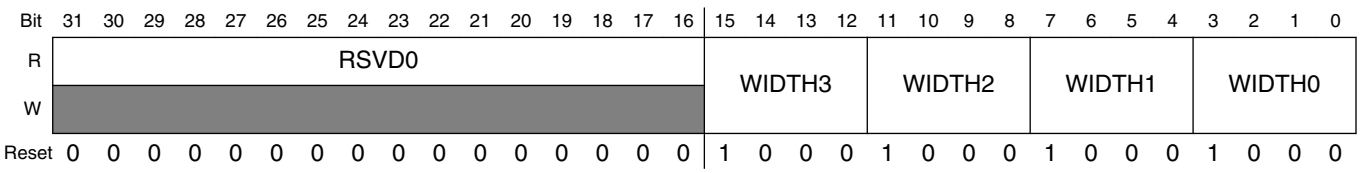
HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1_CLR: 0x978

HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1_TOG: 0x97C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 970h offset = 3070_0970h



PXP_HW_PXP_DITHER_FETCH_SHIFT_WIDTH_CH1 field descriptions

Field	Description
31–16 RSVD0	Reserved, always set to zero.
15–12 WIDTH3	Shift Width for channel 1 componnent 3.
11–8 WIDTH2	Shift Width for channel 1 componnent 2.
7–4 WIDTH1	Shift Width for channel 1 componnent 1.
WIDTH0	Shift Width for channel 1 componnent 0.

13.6.12.138 PXP_HW_PXP_DITHER_FETCH_ADDR_0_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 980h offset = 3070_0980h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_ADDR_0_CH0 field descriptions

Field	Description
INPUT_BASE_ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

13.6.12.139 PXP_HW_PXP_DITHER_FETCH_ADDR_1_CH0

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 990h offset = 3070_0990h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_ADDR_1_CH0 field descriptions

Field	Description
INPUT_BASE_ADDR1	input base address1. For 2 channel, indicated the channel1 base address. For 1 channel and YUV422 2 plane, indicate the UV base address

13.6.12.140 PXP_HW_PXP_DITHER_FETCH_ADDR_0_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9A0h offset = 3070_09A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_ADDR_0_CH1 field descriptions

Field	Description
INPUT_BASE_ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

13.6.12.141 PXP_HW_PXP_DITHER_FETCH_ADDR_1_CH1

This register defines the control bits for the pxp prefetch_engine sub-block.

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9B0h offset = 3070_09B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INPUT_BASE_ADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FETCH_ADDR_1_CH1 field descriptions

Field	Description
INPUT_BASE_ADDR1	input base address1. For 2 channel, indicated the channel1 base address. For 1 channel and YUV422 2 plane, indicate the UV base address

13.6.12.142 Store engine Control Channel 0 Register (PXP_HW_PXP_DITHER_STORE_CTRL_CH0)

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_DITHER_STORE_CTRL_CH0: 0x9C0

HW_PXP_DITHER_STORE_CTRL_CH0_SET: 0x9C4

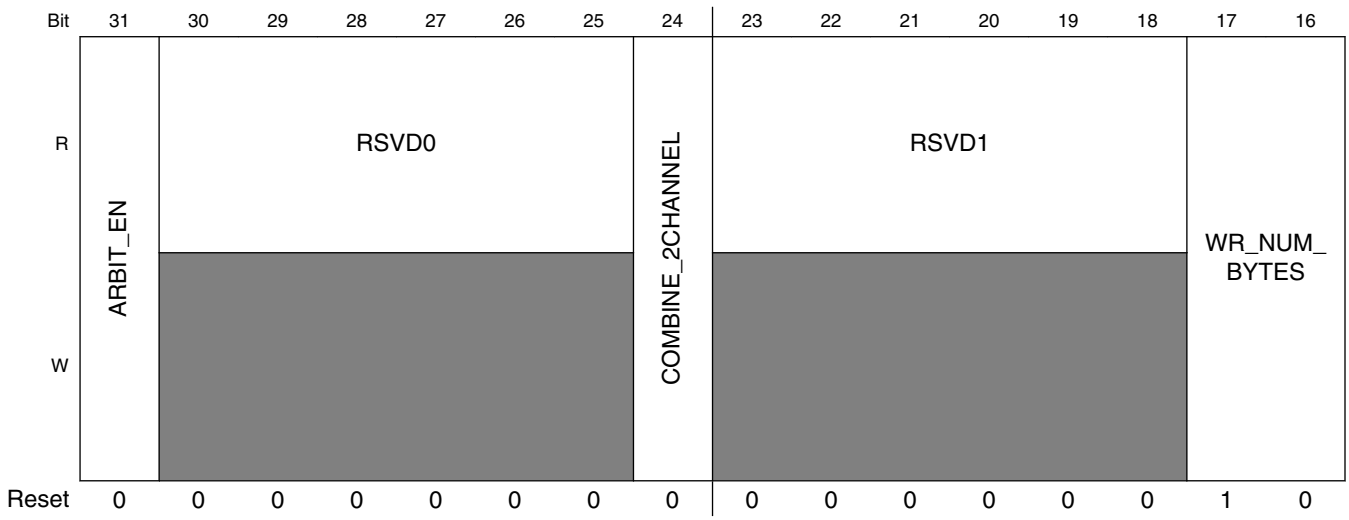
HW_PXP_DITHER_STORE_CTRL_CH0_CLR: 0x9C8

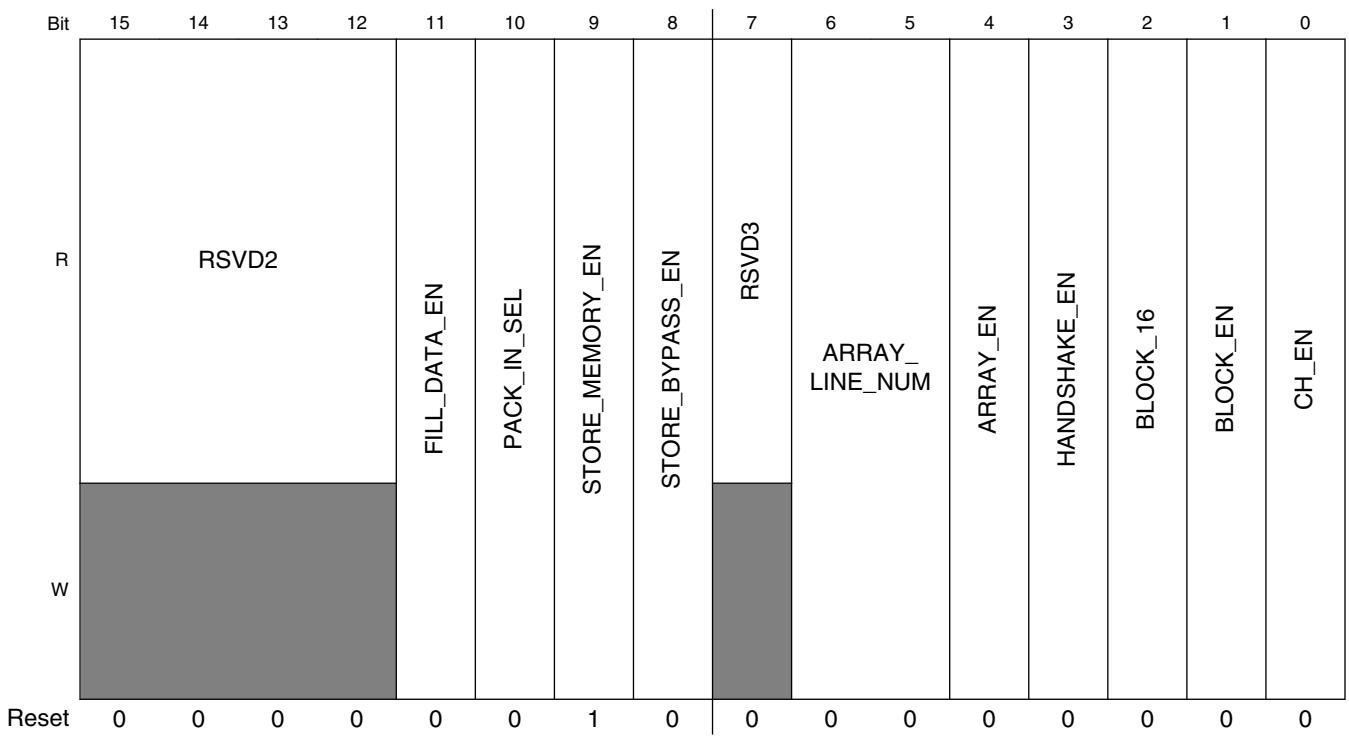
HW_PXP_DITHER_STORE_CTRL_CH0_TOG: 0x9CC

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9C0h offset = 3070_09C0h





PXP_HW_PXP_DITHER_STORE_CTRL_CH0 field descriptions

Field	Description
31 ARBIT_EN	Arbitration Enable 0x0 **0** — Arbitration disable. If using 2 channels, will output 2 axi bus sets 0x1 **1** — Arbitration enable. If using 2 channel, will only output 1 axi bus sets
30–25 RSVD0	Reserved, always set to zero.
24 COMBINE_2CHANNEL	Combine 2 channel Enable

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_CTRL_CH0 field descriptions (continued)

Field	Description
	0x0 **0** — combine 2 channel disable 0x1 **1** — combine 2 channel enable
23–18 RSVD1	Reserved, always set to zero.
17–16 WR_NUM_ BYTES	Bytes in a write burst 0x0 **8_bytes** — 8 bytes 0x1 **16_bytes** — 16 bytes 0x2 **32_bytes** — 32 bytes 0x3 **64_bytes** — 64 bytes
15–12 RSVD2	Reserved, always set to zero.
11 FILL_DATA_EN	enable bit for fill data 0x0 **0** — Fill data mode disable. 0x1 **1** — Fill data mode enable. When using fill_data mode, store_engine will store fixed data defined in fill_data register
10 PACK_IN_SEL	pack_in_sel 0x0 **0** — select 64 shift out data to pack 0x1 **1** — select low 32 bit shift out data to pack
9 STORE_ MEMORY_EN	store memory enable 0x0 **0** — store memory mode disable. 0x1 **1** — store memory mode enable. Data will store to memory
8 STORE_ BYPASS_EN	enable bit for store bypass 0x0 **0** — store bypass mode disable. 0x1 **1** — store bypass mode enable. Data will bypass to store output.
7 RSVD3	Reserved, always set to zero.
6–5 ARRAY_LINE_ NUM	Selects Array Size 0x0 **0** — Using 1x1 Array 0x1 **1** — Using 3x3 Array 0x2 **2** — Using 5x5 Array 0x3 **3** — Using 5x5 Array
4 ARRAY_EN	0x0 **0** — Array Handshake Disabled 0x1 **1** — Array Handshake Enabled
3 HANDSHAKE_ EN	Enable bit for handshake with the store engine. 0x0 **0** — Handshake with the prefetch engine is disabled 0x1 **1** — Handshake with the prefetch engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_CTRL_CH0 field descriptions (continued)

Field	Description
1 BLOCK_EN	Choses the store mode. 0x0 **0** — Store in scan mode 0x1 **1** — Store in block mode
0 CH_EN	Channel enable. 0x0 **0** — Store function is disable 0x1 **1** — Store function is enable

13.6.12.143 Store engine Control Channel 1 Register (PXP_HW_PXP_DITHER_STORE_CTRL_CH1)

This register defines the control bits for the pxp prefetch_engine sub-block.

HW_PXP_DITHER_STORE_CTRL_CH1: 0x9D0

HW_PXP_DITHER_STORE_CTRL_CH1_SET: 0x9D4

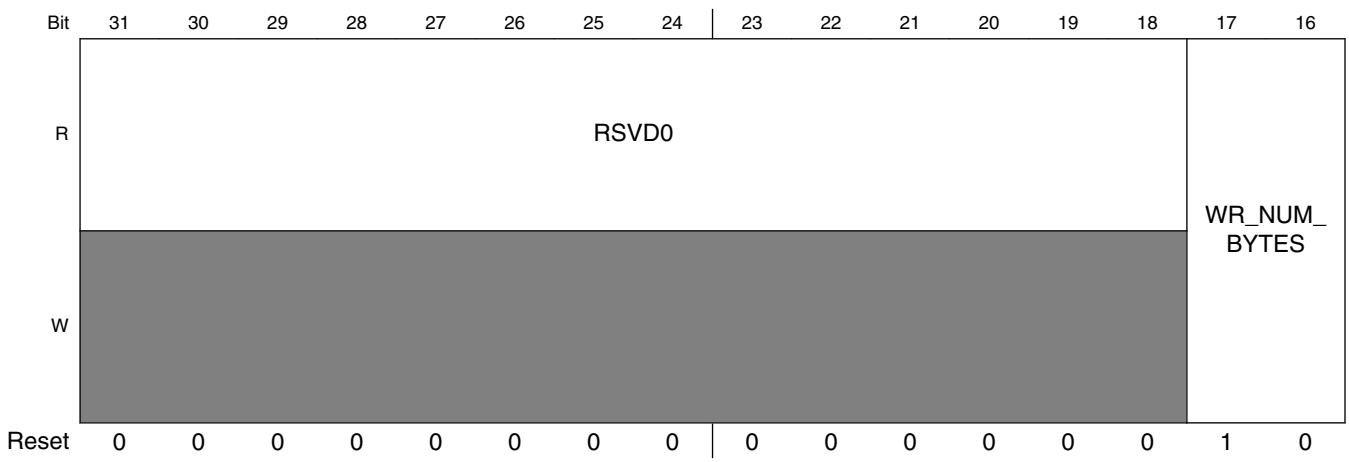
HW_PXP_DITHER_STORE_CTRL_CH1_CLR: 0x9D8

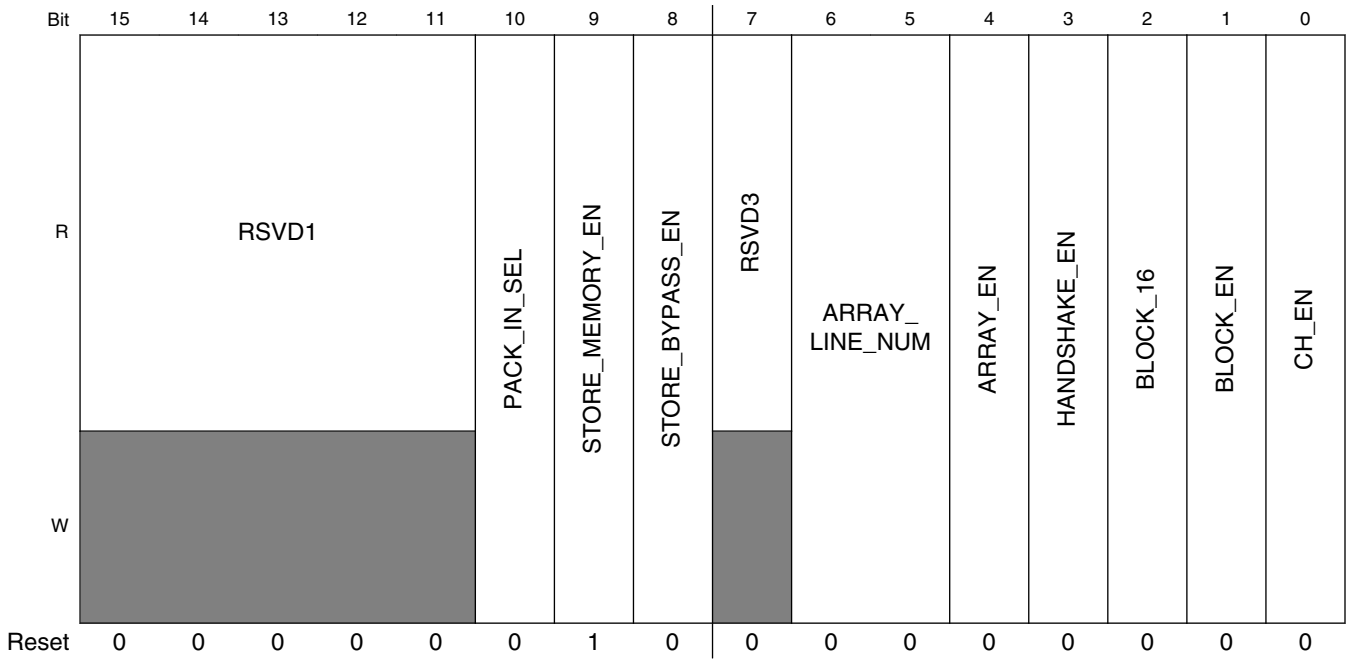
HW_PXP_DITHER_STORE_CTRL_CH1_TOG: 0x9DC

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9D0h offset = 3070_09D0h





PXP_HW_PXP_DITHER_STORE_CTRL_CH1 field descriptions

Field	Description
31–18 RSVD0	Reserved, always set to zero.
17–16 WR_NUM_ BYTES	Bytes in a write burst 0x0 **8_bytes** — 8 bytes 0x1 **16_bytes** — 16 bytes 0x2 **32_bytes** — 32 bytes 0x3 **64_bytes** — 64 bytes
15–11 RSVD1	Reserved, always set to zero.
10 PACK_IN_SEL	pack_in_sel 0x0 **0** — select 64 shift out data to pack 0x1 **1** — select channel 0 high 32 bit shift out data to pack
9 STORE_ MEMORY_EN	store memory enable 0x0 **0** — store memory mode disable. 0x1 **1** — store memory mode enable. Data will store to memory
8 STORE_ BYPASS_EN	enable bit for store bypass 0x0 **0** — store bypass mode disable. 0x1 **1** — store bypass mode enable. Data will bypass to store output.
7 RSVD3	Reserved, always set to zero.
6–5 ARRAY_LINE_ NUM	Selects Array Size 0x0 **0** — Using 1x1 Array

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_CTRL_CH1 field descriptions (continued)

Field	Description
	0x1 **1** — Using 3x3 Array 0x2 **2** — Using 5x5 Array 0x3 **3** — Using 5x5 Array
4 ARRAY_EN	0x0 **0** — Array Handshake Disabled 0x1 **1** — Array Handshake Enabled
3 HANDSHAKE_ EN	Enable bit for handshake with the fetch engine. 0x0 **0** — Handshake with the fetch engine is disabled 0x1 **1** — Handshake with the fetch engine is enabled
2 BLOCK_16	Determines the block sixe. 0x0 **8x8** — Block size is 8x8 0x1 **16x16** — Block size is 16x16
1 BLOCK_EN	Choses the store mode. 0x0 **0** — Store in scan mode 0x1 **1** — Store in block mode
0 CH_EN	Channel enable. 0x0 **0** — Store function is disable 0x1 **1** — Store function is enable

13.6.12.144 Store engine status Channel 0 Register (PXP_HW_PXP_DITHER_STORE_STATUS_CH0)

This register defines the status bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9E0h offset = 3070_09E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STORE_BLOCK_Y																STORE_BLOCK_X															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_STATUS_CH0 field descriptions

Field	Description
31–16 STORE_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_STATUS_CH0 field descriptions (continued)

Field	Description
STORE_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.145 Store engine status Channel 1 Register (PXP_HW_PXP_DITHER_STORE_STATUS_CH1)

This register defines the status bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + 9F0h offset = 3070_09F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STORE_BLOCK_Y																STORE_BLOCK_X															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_STATUS_CH1 field descriptions

Field	Description
31–16 STORE_ BLOCK_Y	When in scan mode, this field indicates the current Y coordinate of the frame. In block mode, it indicates the Y coordinate of the block currently being rendered.
STORE_ BLOCK_X	When in scan mode, this field is always 0. In block mode, it indicates the X coordinate of the block currently being rendered.

13.6.12.146 PXP_HW_PXP_DITHER_STORE_SIZE_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A00h offset = 3070_0A00h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_HEIGHT																OUT_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_SIZE_CH0 field descriptions

Field	Description
31–16 OUT_HEIGHT	actual output height -1
OUT_WIDTH	actual output width -1

13.6.12.147 PXP_HW_PXP_DITHER_STORE_SIZE_CH1

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A10h offset = 3070_0A10h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_HEIGHT																OUT_WIDTH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_SIZE_CH1 field descriptions

Field	Description
31–16 OUT_HEIGHT	actual output height -1
OUT_WIDTH	actual output width -1

13.6.12.148 PXP_HW_PXP_DITHER_STORE_PITCH

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A20h offset = 3070_0A20h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CH1_OUT_PITCH																CH0_OUT_PITCH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_PITCH field descriptions

Field	Description
31–16 CH1_OUT_ PITCH	This field indicates the channel 1 input pitch
CH0_OUT_ PITCH	This field indicates the channel 0 input pitch

13.6.12.149 PXP_HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0: 0xA30

HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0_SET: 0xA34

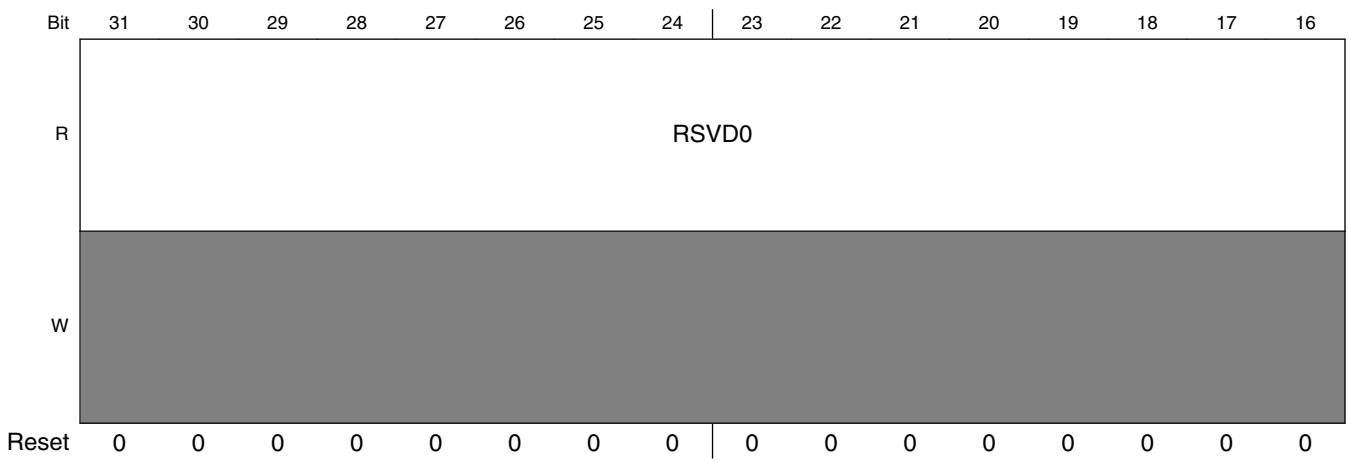
HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0_CLR: 0xA38

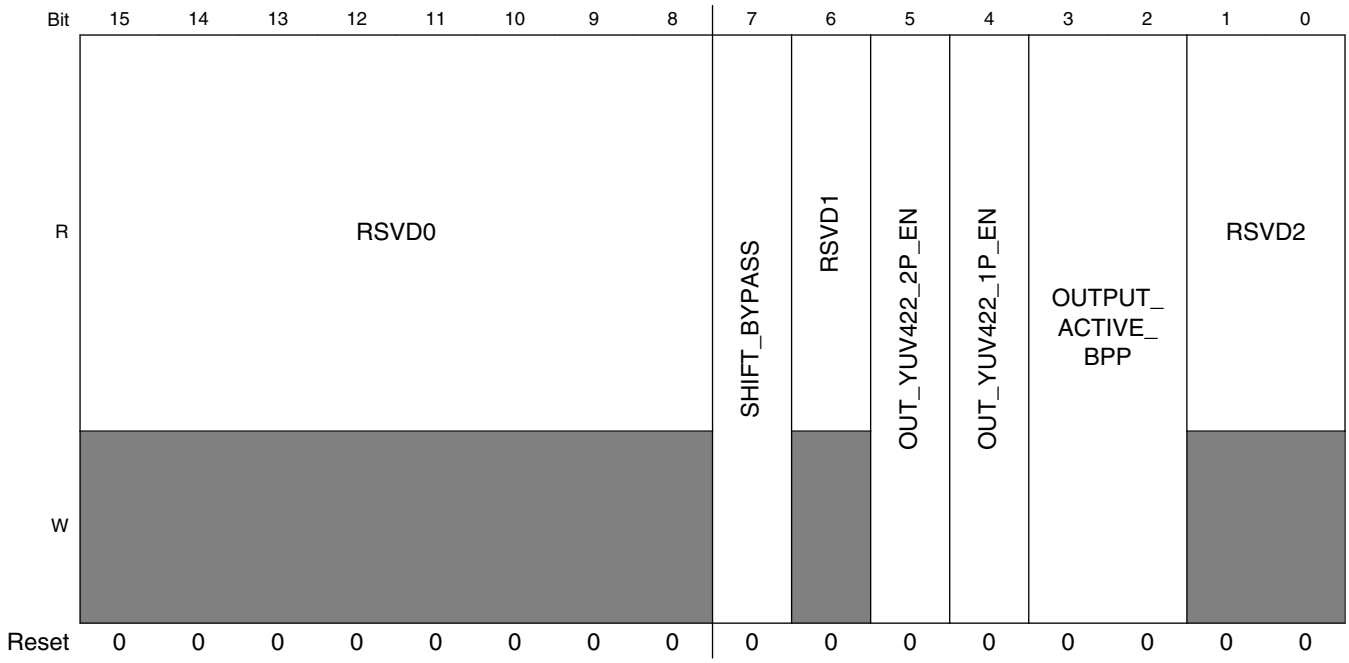
HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0_TOG: 0xA3C

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A30h offset = 3070_0A30h





PXP_HW_PXP_DITHER_STORE_SHIFT_CTRL_CH0 field descriptions

Field	Description
31–8 RSVD0	Reserved, always set to zero.
7 SHIFT_BYPASS	CH0 shift bypass 0x0 **0** — data will do shift processing. 0x1 **1** — data will bypass shift module.
6 RSVD1	Reserved, always set to zero.
5 OUT_YUV422_ 2P_EN	Enable for YUV422 2 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
4 OUT_YUV422_ 1P_EN	Enable for YUV422 1 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
3–2 OUTPUT_ ACTIVE_BPP	0x0 **0** — 8 bits 0x1 **1** — 16 bits 0x2 **2** — 32 bits 0x3 **3** — 32 bits
RSVD2	Reserved, always set to zero.

13.6.12.150 PXP_HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1

This register defines the control bits for the pxp store_engine sub-block.

HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1: 0xA40

HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1_SET: 0xA44

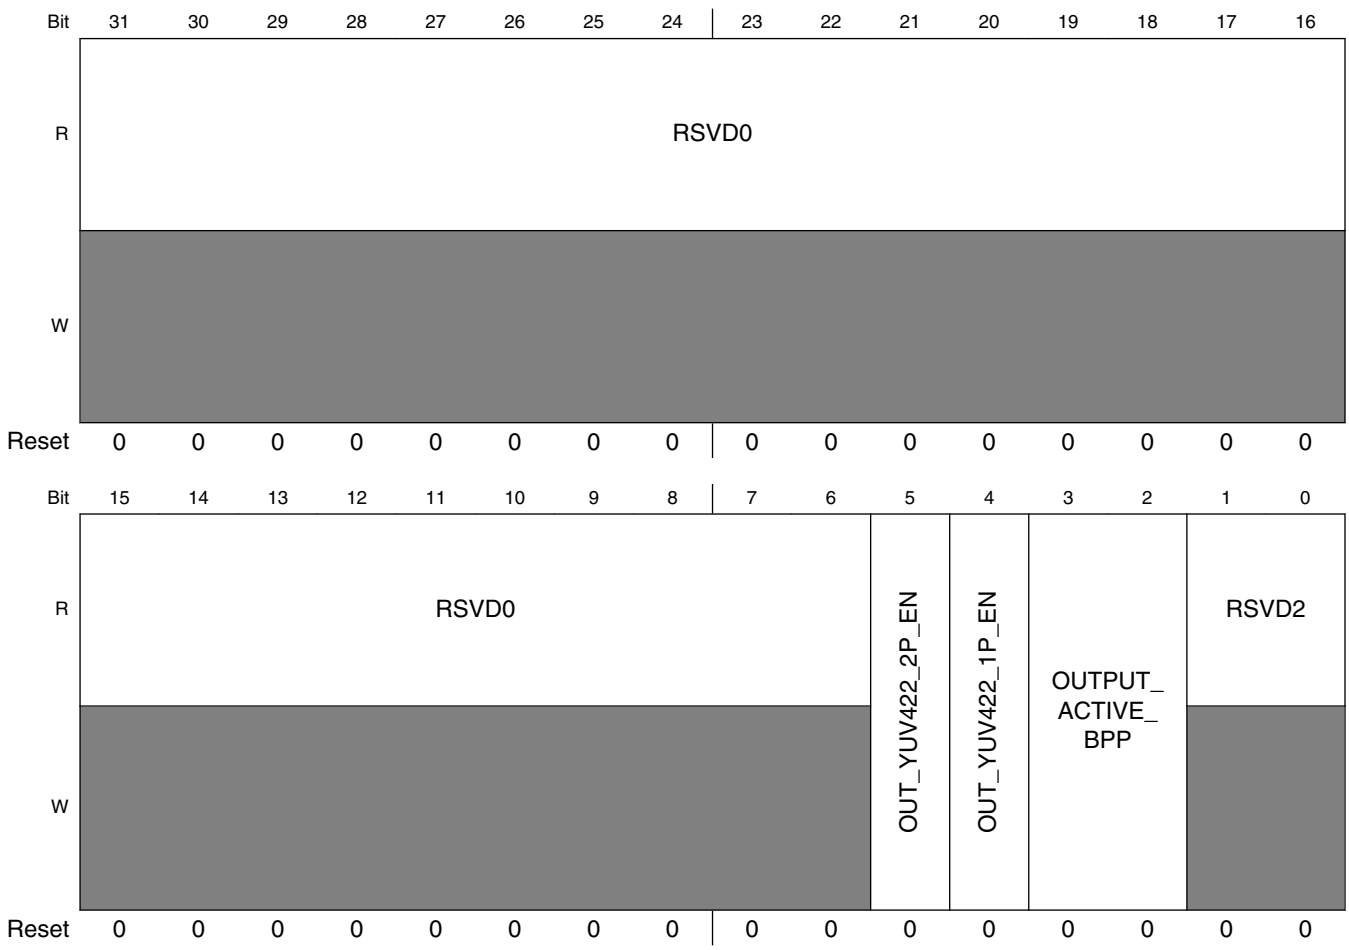
HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1_CLR: 0xA48

HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1_TOG: 0xA4C

The Control register contains the control bits for the pxp prefetch_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A40h offset = 3070_0A40h



PXP_HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1 field descriptions

Field	Description
31–6 RSVD0	Reserved, always set to zero.
5 OUT_YUV422_2P_EN	Enable for YUV422 2 plane

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_SHIFT_CTRL_CH1 field descriptions (continued)

Field	Description
	0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
4 OUT_YUV422_ 1P_EN	Enable for YUV422 1 plane 0x0 **0** — YUYV422 2 plane disabled. 0x1 **1** — YUYV422 2 plane enabled.
3–2 OUTPUT_ ACTIVE_BPP	0x0 **0** — 8 bits 0x1 **1** — 16 bits 0x2 **2** — 32 bits 0x3 **3** — 32 bits
RSVD2	Reserved, always set to zero.

13.6.12.151 PXP_HW_PXP_DITHER_STORE_ADDR_0_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + A90h offset = 3070_0A90h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_BASE_ADDR0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_ADDR_0_CH0 field descriptions

Field	Description
OUT_BASE_ ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

13.6.12.152 PXP_HW_PXP_DITHER_STORE_ADDR_1_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + AA0h offset = 3070_0AA0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	OUT_BASE_ADDR1

PXP_HW_PXP_DITHER_STORE_ADDR_0_CH1 field descriptions

Field	Description
OUT_BASE_ ADDR0	input base address0. For 2 channel, indicated the channel0 base address. For 1 channel and YUV422 2 plane, indicate the Y base address

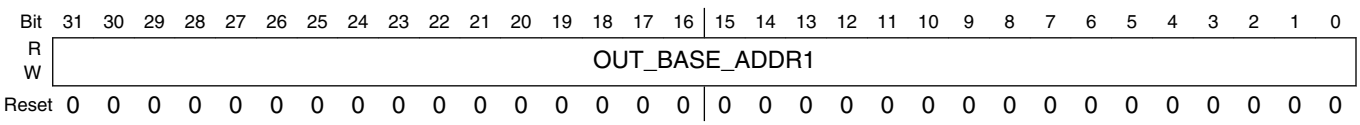
13.6.12.155 PXP_HW_PXP_DITHER_STORE_ADDR_1_CH1

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + AD0h offset = 3070_0AD0h



PXP_HW_PXP_DITHER_STORE_ADDR_1_CH1 field descriptions

Field	Description
OUT_BASE_ ADDR1	input base address1. For 2 channel, indicated the channel 1 base address. For 1 channel and YUV422 2 plane, indicate the UV base address

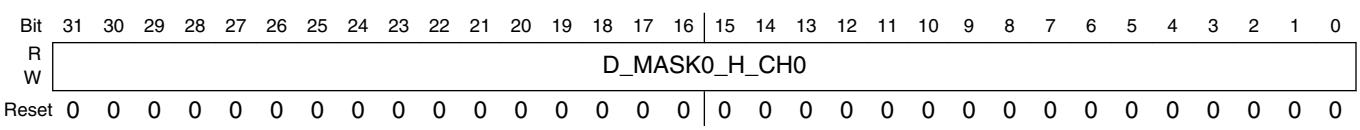
13.6.12.156 PXP_HW_PXP_DITHER_STORE_D_MASK0_H_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + AE0h offset = 3070_0AE0h



PXP_HW_PXP_DITHER_STORE_D_MASK0_H_CH0 field descriptions

Field	Description
D_MASK0_H_ CH0	data mask0 high byte

13.6.12.157 PXP_HW_PXP_DITHER_STORE_D_MASK0_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + AF0h offset = 3070_0AF0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

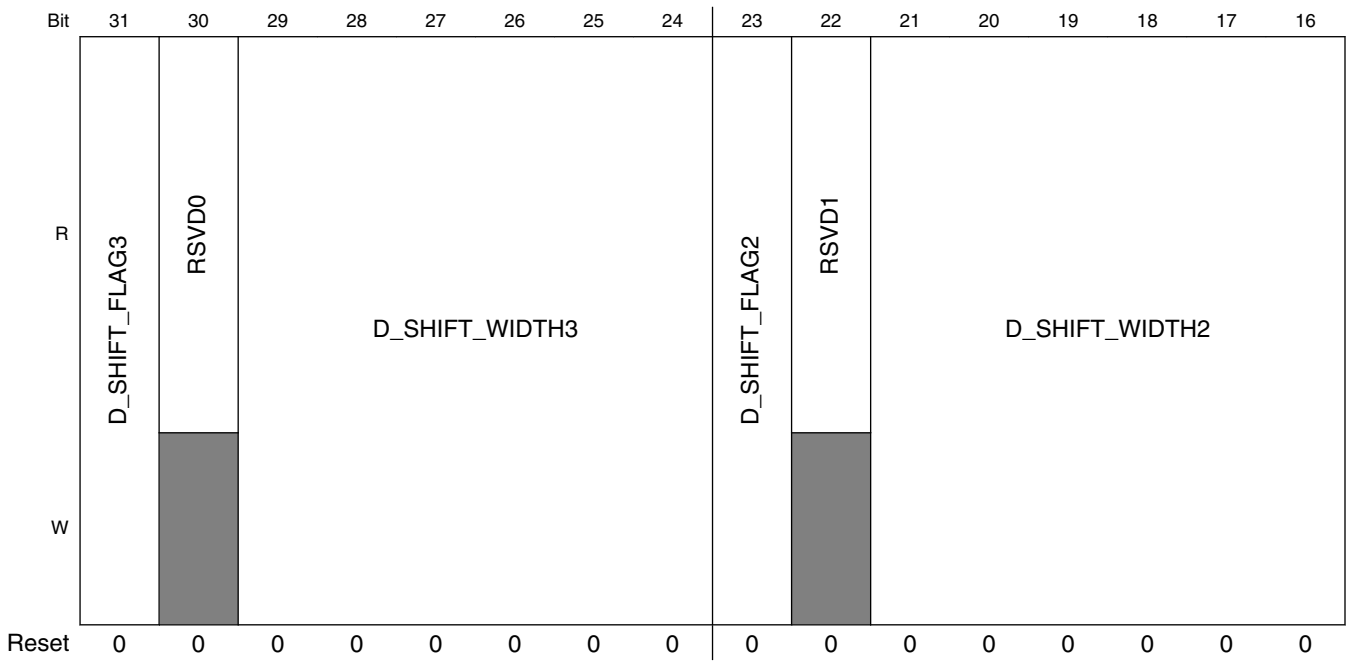
13.6.12.172 PXP_HW_PXP_DITHER_STORE_D_SHIFT_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + BE0h offset = 3070_0BE0h



PXP_HW_PXP_DITHER_STORE_D_SHIFT_L_CH0 field descriptions

Field	Description
31 D_SHIFT_FLAG3	data shift flag 3
30 RSVD0	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_D_SHIFT_L_CH0 field descriptions (continued)

Field	Description
29–24 D_SHIFT_ WIDTH3	data shift width 3
23 D_SHIFT_FLAG2	data shift flag 2
22 RSVD1	Reserved, always set to zero.
21–16 D_SHIFT_ WIDTH2	data shift width 2
15 D_SHIFT_FLAG1	data shift flag 1
14 RSVD2	Reserved, always set to zero.
13–8 D_SHIFT_ WIDTH1	data shift width 1
7 D_SHIFT_FLAG0	data shift flag 0
6 RSVD3	Reserved, always set to zero.
D_SHIFT_ WIDTH0	data shift width 0

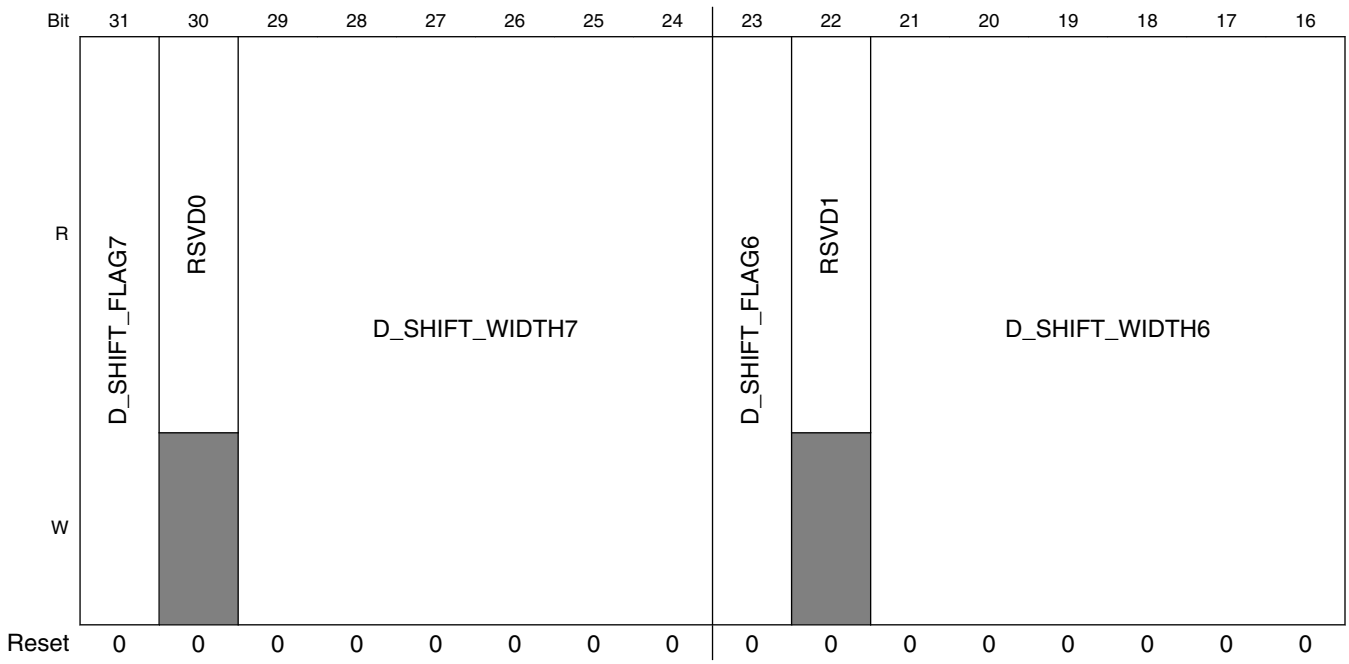
13.6.12.173 PXP_HW_PXP_DITHER_STORE_D_SHIFT_H_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + BF0h offset = 3070_0BF0h



PXP_HW_PXP_DITHER_STORE_D_SHIFT_H_CH0 field descriptions

Field	Description
31 D_SHIFT_FLAG7	data shift flag 7
30 RSVD0	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_D_SHIFT_H_CH0 field descriptions (continued)

Field	Description
29–24 D_SHIFT_ WIDTH7	data shift width 3
23 D_SHIFT_FLAG6	data shift flag 6
22 RSVD1	Reserved, always set to zero.
21–16 D_SHIFT_ WIDTH6	data shift width 6
15 D_SHIFT_FLAG5	data shift flag 5
14 RSVD2	Reserved, always set to zero.
13–8 D_SHIFT_ WIDTH5	data shift width 5
7 D_SHIFT_FLAG4	data shift flag 4
6 RSVD3	Reserved, always set to zero.
D_SHIFT_ WIDTH4	data shift width 4

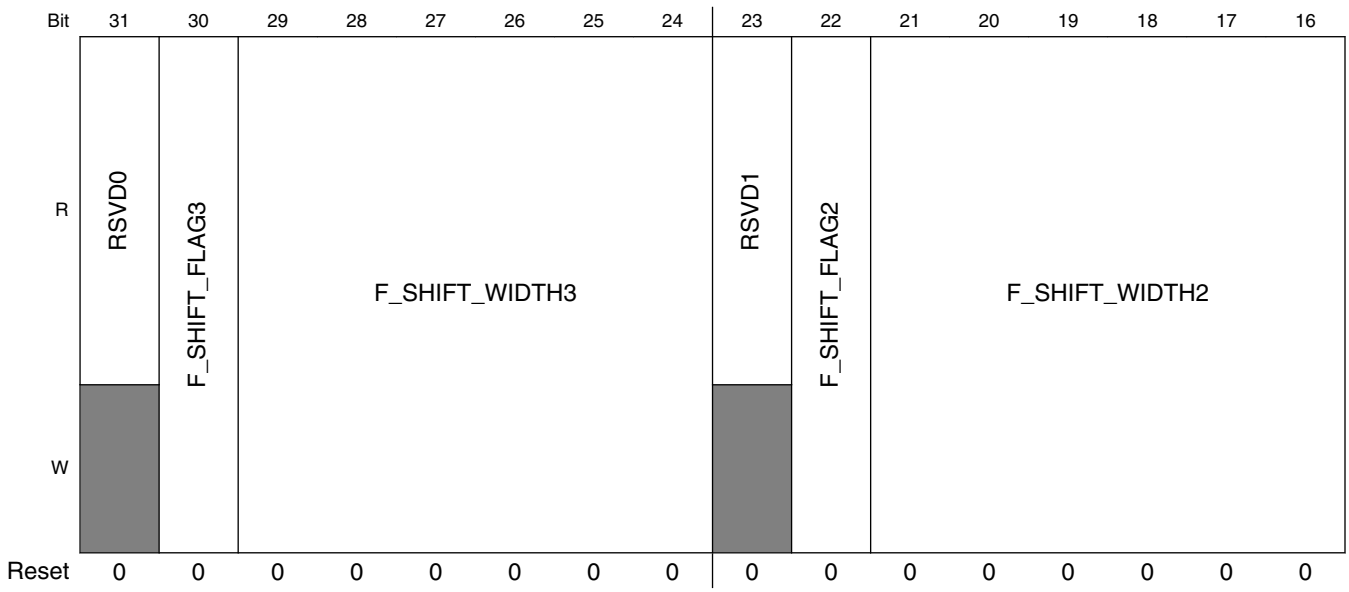
13.6.12.174 PXP_HW_PXP_DITHER_STORE_F_SHIFT_L_CH0

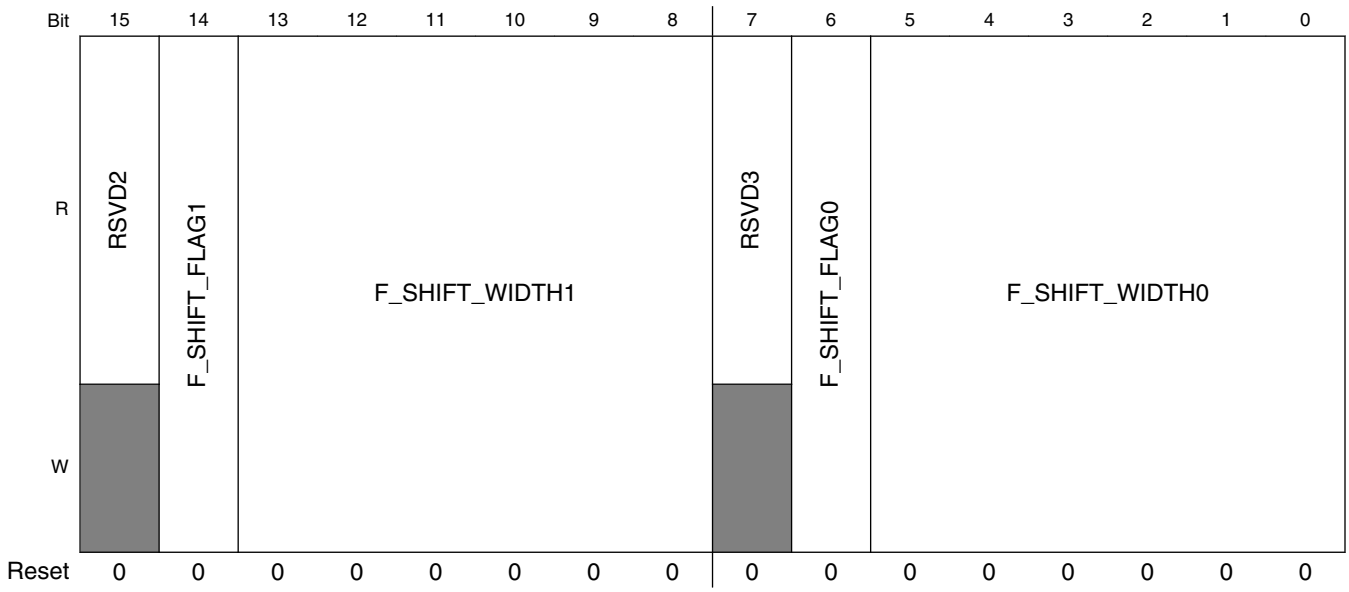
This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + C00h offset = 3070_0C00h





PXP_HW_PXP_DITHER_STORE_F_SHIFT_L_CH0 field descriptions

Field	Description
31 RSVD0	Reserved, always set to zero.
30 F_SHIFT_FLAG3	flag shift flag3
29–24 F_SHIFT_ WIDTH3	flag shift width 3
23 RSVD1	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_F_SHIFT_L_CH0 field descriptions (continued)

Field	Description
22 F_SHIFT_FLAG2	flag shift flag2
21–16 F_SHIFT_ WIDTH2	flag shift width 2
15 RSVD2	Reserved, always set to zero.
14 F_SHIFT_FLAG1	flag shift flag1
13–8 F_SHIFT_ WIDTH1	flag shift width 1
7 RSVD3	Reserved, always set to zero.
6 F_SHIFT_FLAG0	flag shift flag0
F_SHIFT_ WIDTH0	flag shift width 0

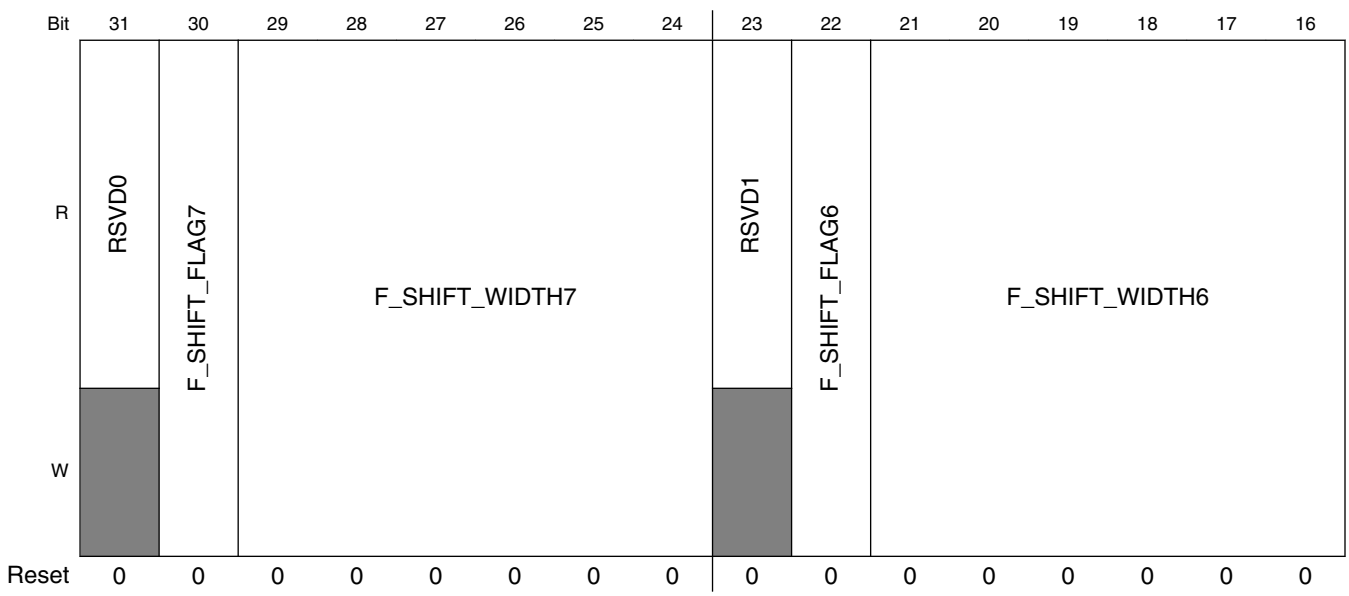
13.6.12.175 PXP_HW_PXP_DITHER_STORE_F_SHIFT_H_CH0

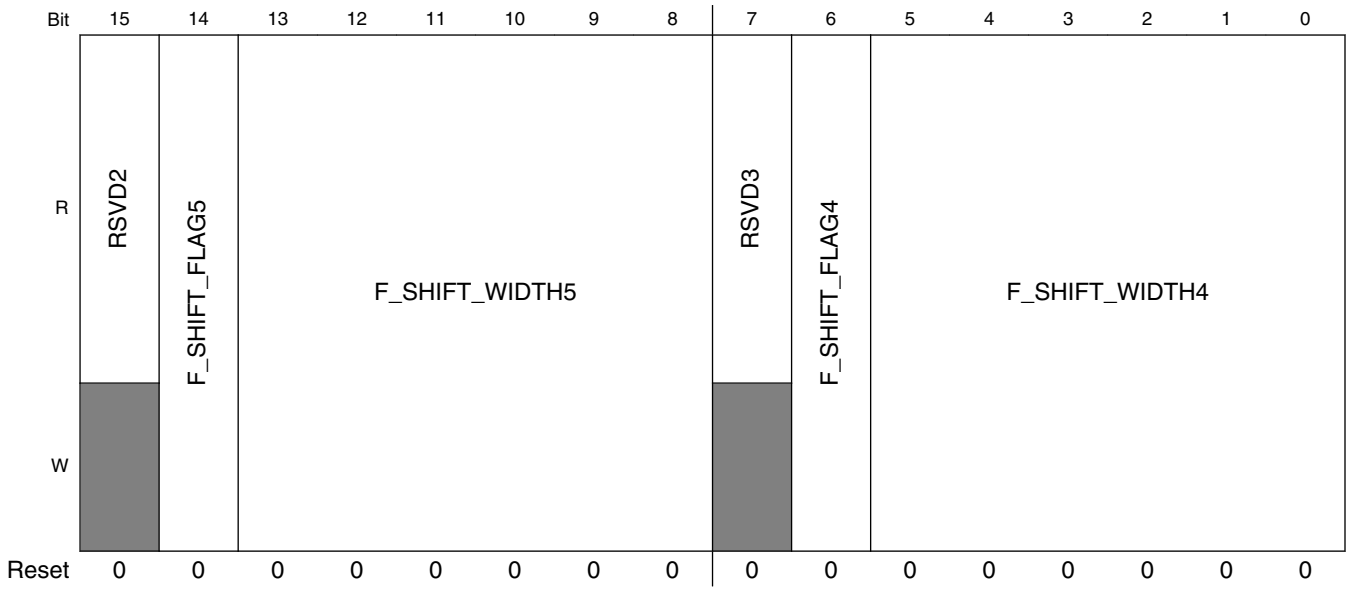
This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + C10h offset = 3070_0C10h





PXP_HW_PXP_DITHER_STORE_F_SHIFT_H_CH0 field descriptions

Field	Description
31 RSVD0	Reserved, always set to zero.
30 F_SHIFT_FLAG7	flag shift flag7
29–24 F_SHIFT_ WIDTH7	flag shift width 7
23 RSVD1	Reserved, always set to zero.
22 F_SHIFT_FLAG6	flag shift flag6
21–16 F_SHIFT_ WIDTH6	flag shift width 5
15 RSVD2	Reserved, always set to zero.
14 F_SHIFT_FLAG5	flag shift flag5
13–8 F_SHIFT_ WIDTH5	flag shift width 5
7 RSVD3	Reserved, always set to zero.
6 F_SHIFT_FLAG4	flag shift flag4
F_SHIFT_ WIDTH4	flag shift width 4

13.6.12.176 PXP_HW_PXP_DITHER_STORE_F_MASK_L_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + C20h offset = 3070_0C20h

PXP_HW_PXP_DITHER_STORE_F_MASK_L_CH0 field descriptions

Field	Description
31–24 F_MASK3	flag mask3
23–16 F_MASK2	flag mask2
15–8 F_MASK1	flag mask1
F_MASK0	flag mask0

13.6.12.177 PXP_HW_PXP_DITHER_STORE_F_MASK_H_CH0

This register defines the control bits for the pxp store_engine sub-block.

The Control register contains the control bits for the pxp store_engine sub-block.

EXAMPLE

Address: 3070_0000h base + C30h offset = 3070_0C30h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	F_MASK7								F_MASK6								F_MASK5								F_MASK4							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_STORE_F_MASK_H_CH0 field descriptions

Field	Description
31–24 F_MASK7	flag mask7

Table continues on the next page...

PXP_HW_PXP_DITHER_STORE_F_MASK_H_CH0 field descriptions (continued)

Field	Description
23–16 F_MASK6	flag mask6
15–8 F_MASK5	flag mask5
F_MASK4	flag mask4

13.6.12.178 Dither Control Register 0 (PXP_HW_PXP_DITHER_CTRL)

This register defines the control bits for the pxp dither sub-block.

HW_PXP_DITHER_CTRL: 0x1670

HW_PXP_DITHER_CTRL_SET: 0x1674

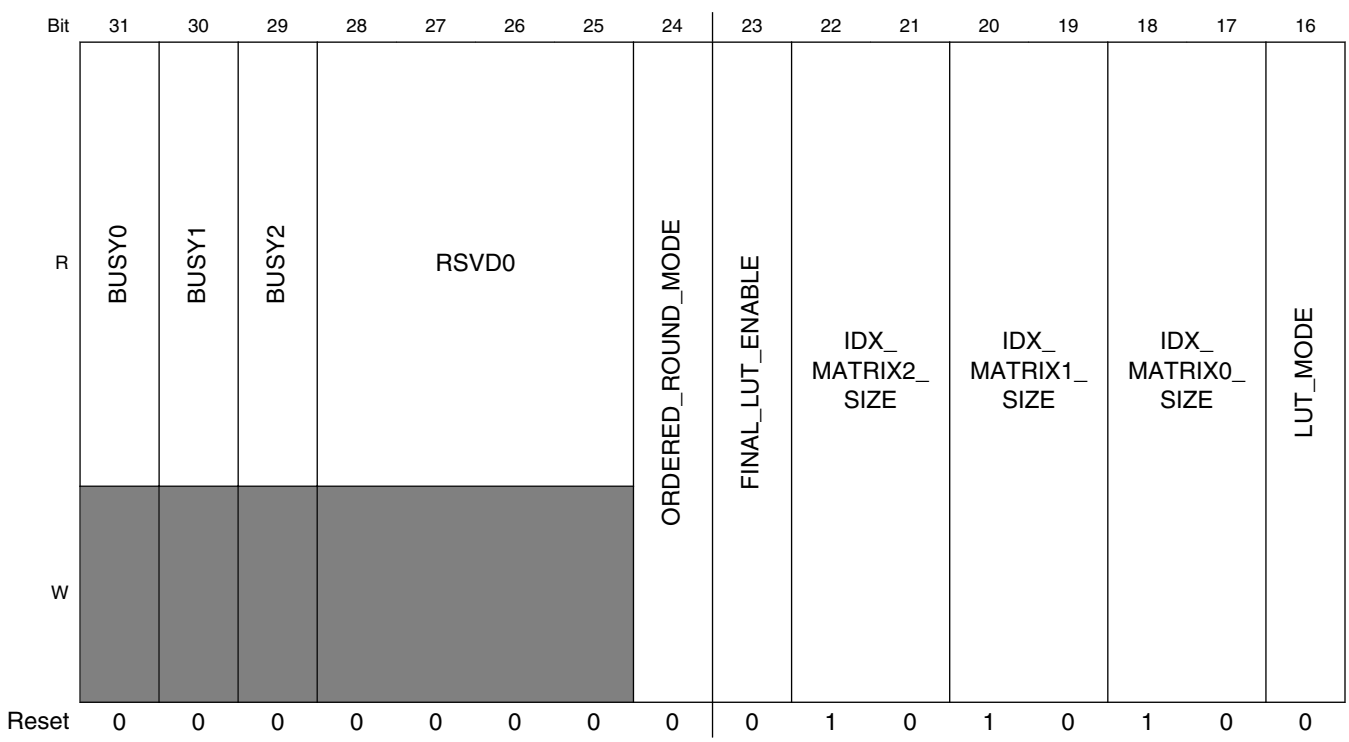
HW_PXP_DITHER_CTRL_CLR: 0x1678

HW_PXP_DITHER_CTRL_TOG: 0x167C

The Control register contains the primary controls for the PXP block.

EXAMPLE

Address: 3070_0000h base + 1670h offset = 3070_1670h



Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LUT_MODE	NUM_QUANT_BIT			DITHER_MODE2			DITHER_MODE1			DITHER_MODE0			ENABLE2	ENABLE1	ENABLE0
W																
Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_CTRL field descriptions

Field	Description
31 BUSY0	When set indicates if the dither engine 0 is busy -- started but not finished processing all of the pixels in the current frame.
30 BUSY1	When set indicates if the dither engine 1 is busy -- started but not finished processing all of the pixels in the current frame.
29 BUSY2	When set indicates if the dither engine 2 is busy -- started but not finished processing all of the pixels in the current frame.
28–25 RSVD0	Reserved, always set to zero.
24 ORDERED_ ROUND_MODE	For test purposes. In ordered mode only, this field specifies to use rounding or truncation when calculating the ouptput pixel. 0x0 **0** — Use truncation method. 0x1 **1** — Use rounding method.
23 FINAL_LUT_ ENABLE	Enables a final stage register based LUT at the last stage before output. the lookup transform values come from register bits, not internal memory. Therefore they must be setup by the user by writing to the registers before processing. 0x0 **Disabled** — The dither engine 2 will not process any frames. 0x1 **Enabled** — The dither engine 2 is on and ready for processing
22–21 IDX_MATRIX2_ SIZE	For Dither Engine 2. Specify dimension (assumed square) of the index matrix in the LUT memory so proper indexing can occur. 0x0 **0** — 4x4 0x1 **1** — 8x8 0x2 **2** — 16x16 0x3 **3** — Input value of index
20–19 IDX_MATRIX1_ SIZE	For Dither Engine 1. Specify dimension (assumed square) of the index matrix in the LUT memory so proper indexing can occur. 0x0 **0** — 4x4 0x1 **1** — 8x8

Table continues on the next page...

PXP_HW_PXP_DITHER_CTRL field descriptions (continued)

Field	Description
	0x2 **2** — 16x16 0x3 **3** — Input value of index
18–17 IDX_MATRIX0_SIZE	For Dither Engine 0. Specify dimension (assumed square) of the index matrix in the LUT memory so proper indexing can occur. 0x0 **0** — 4x4 0x1 **1** — 8x8 0x2 **2** — 16x16 0x3 **3** — Input value of index
16–15 LUT_MODE	Specify to use memory lut to transform pixel. Lookup pre or post dithering cannot be used with Ordered dithering. This field only has reference to the internal memory based LUT function. There is a final stage LUT that is enabled through the FINAL_LUT_ENABLE field in this register. This final stage LUT can be enabled in any dither mode or LUT mode. 0x0 **0** — LUT mode off. 0x1 **1** — Use LUT at pre-diter stage. 0x2 **2** — Use LUT at post-dither stage. 0x3 **3** — Reserved`
14–12 NUM_QUANT_BIT	Number of bits to quantize down to. From 8 to (0-7). 0x0 **0** — Reserved. 0x1 **1** — Quantize down to 1 bit. 0x2 **2** — Quantize down to 2 bits. 0x3 **3** — Quantize down to 3 bits. 0x4 **4** — Quantize down to 4 bits. 0x5 **5** — Quantize down to 5 bits. 0x6 **6** — Quantize down to 6 bits. 0x7 **7** — Quantize down to 7 bits.
11–9 DITHER_MODE2	Dither mode. 0x0 **0** — Pass through. 0x1 **1** — Reserved. 0x2 **2** — Reserved. 0x3 **3** — Ordered. 0x4 **4** — No Dithering, quantization only. 0x5 **5** — Reserved. 0x6 **6** — Reserved. 0x7 **7** — Reserved.
8–6 DITHER_MODE1	Dither mode. 0x0 **0** — Pass through. 0x1 **1** — Reserved. 0x2 **2** — Reserved 0x3 **3** — Ordered. 0x4 **4** — No Dithering, quantization only. 0x5 **5** — Reserved. 0x6 **6** — Reserved. 0x7 **7** — Reserved.

Table continues on the next page...

PXP_HW_PXP_DITHER_CTRL field descriptions (continued)

Field	Description
5–3 DITHER_MODE0	Dither mode. 0x0 **0** — Pass through. 0x1 **1** — Floyd-Steinberg. 0x2 **2** — Atkinson. 0x3 **3** — Ordered. 0x4 **4** — No Dithering, quantization only. 0x5 **5** — Reserved. 0x6 **6** — Reserved. 0x7 **7** — Reserved.
2 ENABLE2	Enables the dither engine 2 0x0 **Disabled** — The dither engine 2 will not process any frames. 0x1 **Enabled** — The dither engine 2 is on and ready for processing
1 ENABLE1	Enables the dither engine 1 0x0 **Disabled** — The dither engine 1 will not process any frames. 0x1 **Enabled** — The dither engine 1 is on and ready for processing
0 ENABLE0	Enables the dither engine 0 0x0 **Disabled** — The dither engine 0 will not process any frames. 0x1 **Enabled** — The dither engine 0 is on and ready for processing

13.6.12.179 Final stage lookup value Register (PXP_HW_PXP_DITHER_FINAL_LUT_DATA0)

8 bit data values for the final stage dither LUT.

HW_PXP_DITHER_FINAL_LUT_DATA0: 0x1680

HW_PXP_DITHER_FINAL_LUT_DATA0_SET: 0x1684

HW_PXP_DITHER_FINAL_LUT_DATA0_CLR: 0x1688

HW_PXP_DITHER_FINAL_LUT_DATA0_TOG: 0x168C

This register contains lookup data values for the final stage register based dither LUT.

EXAMPLE

Address: 3070_0000h base + 1680h offset = 3070_1680h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA3								DATA2								DATA1								DATA0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FINAL_LUT_DATA0 field descriptions

Field	Description
31–24 DATA3	Final stage LUT data value.
23–16 DATA2	Final stage LUT data value.
15–8 DATA1	Final stage LUT data value.
DATA0	Final stage LUT data value.

13.6.12.180 Final stage lookup value Register (PXP_HW_PXP_DITHER_FINAL_LUT_DATA1)

8 bit data values for the final stage dither LUT.

HW_PXP_DITHER_FINAL_LUT_DATA1: 0x1690

HW_PXP_DITHER_FINAL_LUT_DATA1_SET: 0x1694

HW_PXP_DITHER_FINAL_LUT_DATA1_CLR: 0x1698

HW_PXP_DITHER_FINAL_LUT_DATA1_TOG: 0x169C

This register contains lookup data values for the final stage register based dither LUT.

EXAMPLE

Address: 3070_0000h base + 1690h offset = 3070_1690h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA7								DATA6								DATA5								DATA4							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FINAL_LUT_DATA1 field descriptions

Field	Description
31–24 DATA7	Final stage LUT data value.
23–16 DATA6	Final stage LUT data value.
15–8 DATA5	Final stage LUT data value.
DATA4	Final stage LUT data value.

13.6.12.181 Final stage lookup value Register (PXP_HW_PXP_DITHER_FINAL_LUT_DATA2)

8 bit data values for the final stage dither LUT.

HW_PXP_DITHER_FINAL_LUT_DATA2: 0x16A0

HW_PXP_DITHER_FINAL_LUT_DATA2_SET: 0x16A4

HW_PXP_DITHER_FINAL_LUT_DATA2_CLR: 0x16A8

HW_PXP_DITHER_FINAL_LUT_DATA2_TOG: 0x16AC

This register contains lookup data values for the final stage register based dither LUT.

EXAMPLE

Address: 3070_0000h base + 16A0h offset = 3070_16A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA11								DATA10								DATA9								DATA8							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_DITHER_FINAL_LUT_DATA2 field descriptions

Field	Description
31–24 DATA11	Final stage LUT data value.
23–16 DATA10	Final stage LUT data value.
15–8 DATA9	Final stage LUT data value.
DATA8	Final stage LUT data value.

13.6.12.182 Final stage lookup value Register (PXP_HW_PXP_DITHER_FINAL_LUT_DATA3)

8 bit data values for the final stage dither LUT.

HW_PXP_DITHER_FINAL_LUT_DATA3: 0x16B0

HW_PXP_DITHER_FINAL_LUT_DATA3_SET: 0x16B4

HW_PXP_DITHER_FINAL_LUT_DATA3_CLR: 0x16B8

HW_PXP_DITHER_FINAL_LUT_DATA3_TOG: 0x16BC

This register contains lookup data values for the final stage register based dither LUT.

EXAMPLE

Address: 3070_0000h base + 16B0h offset = 3070_16B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA15								DATA14								DATA13								DATA12							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

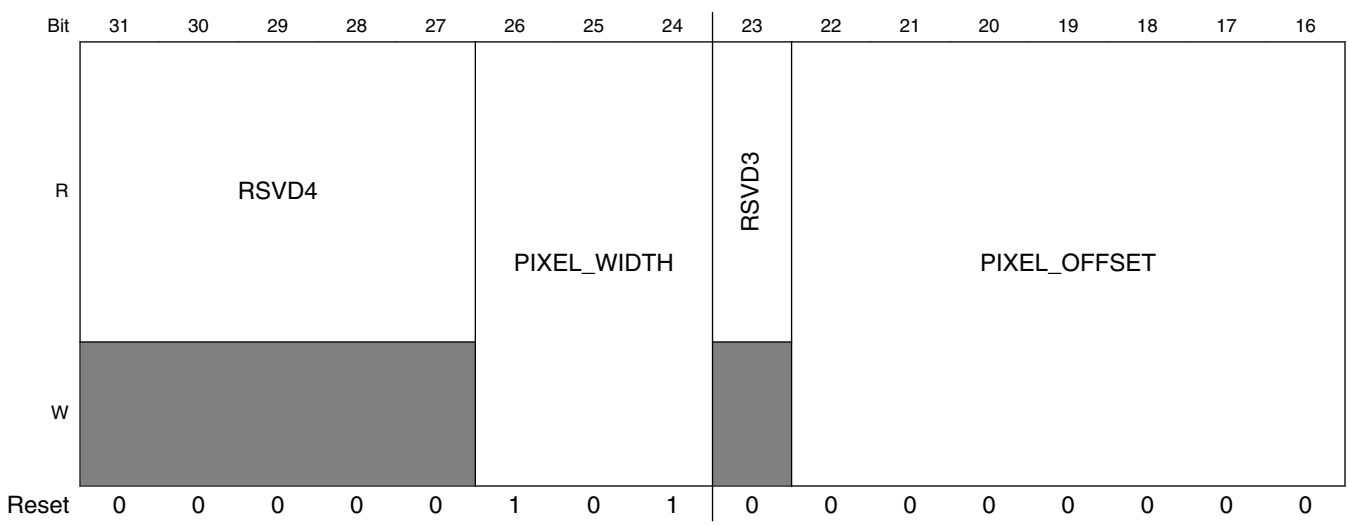
PXP_HW_PXP_DITHER_FINAL_LUT_DATA3 field descriptions

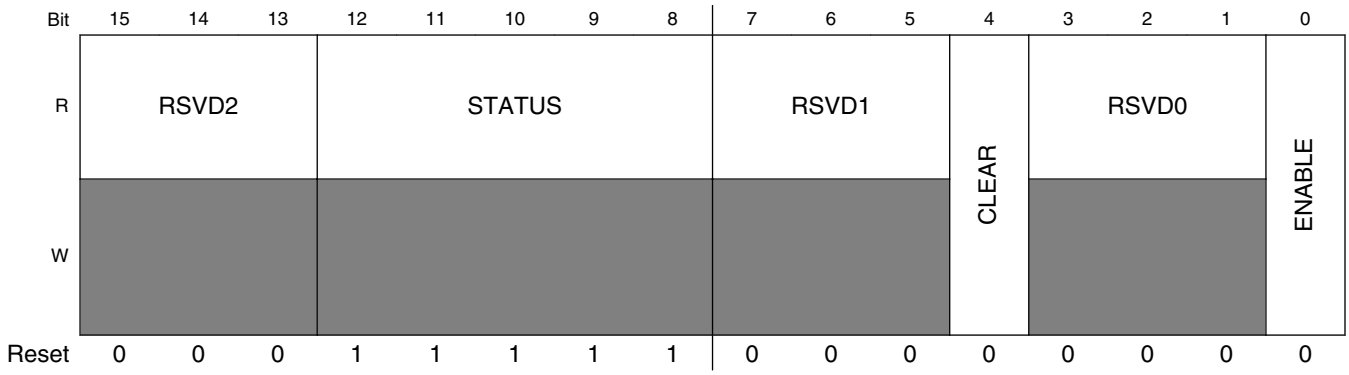
Field	Description
31–24 DATA15	Final stage LUT data value.
23–16 DATA14	Final stage LUT data value.
15–8 DATA13	Final stage LUT data value.
DATA12	Final stage LUT data value.

13.6.12.183 Histogram Control Register. (PXP_HW_PXP_HIST_A_CTRL)

Provides control and status registers for the PXP's histogram classification algorithm.

Address: 3070_0000h base + 2A00h offset = 3070_2A00h





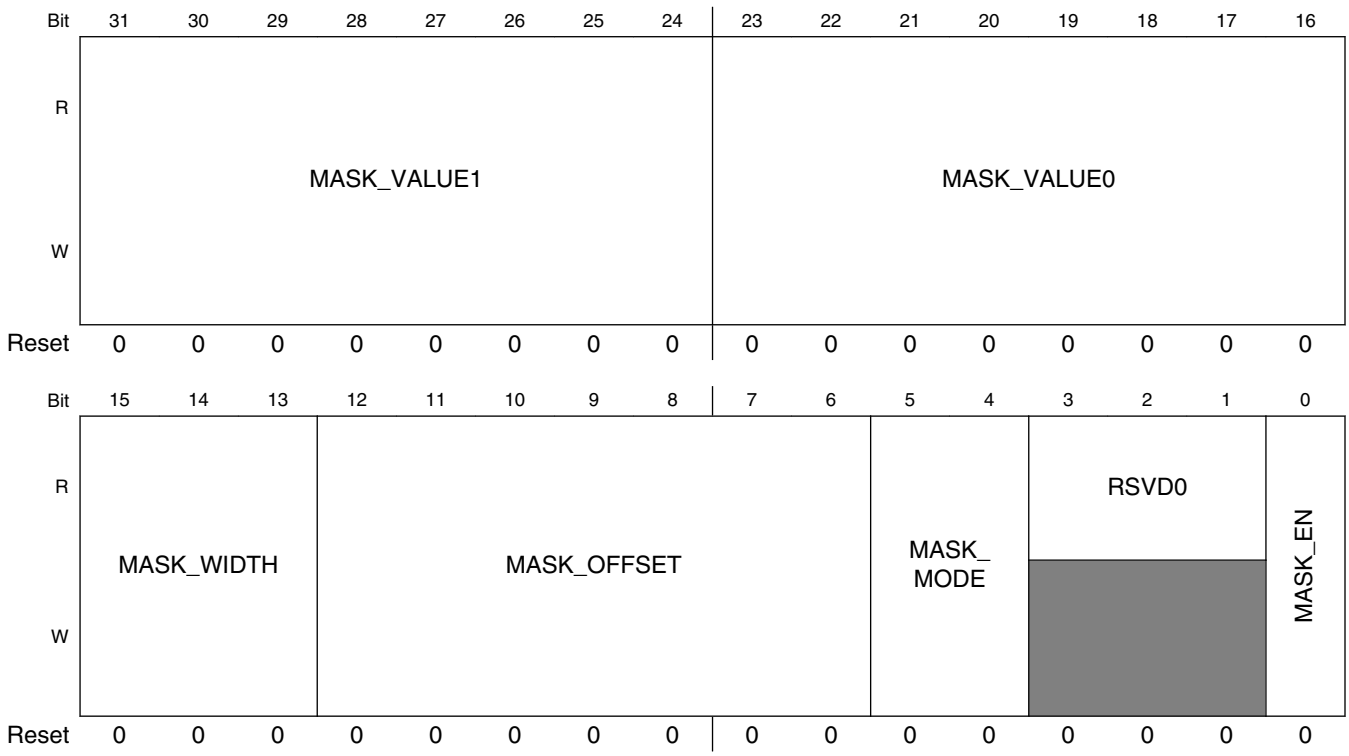
PXP_HW_PXP_HIST_A_CTRL field descriptions

Field	Description
31–27 RSVD4	Reserved, always set to zero.
26–24 PIXEL_WIDTH	The width of the pixel to be used for histogram calculation
23 RSVD3	Reserved, always set to zero.
22–16 PIXEL_OFFSET	The offset of the pixel to be used for histogram calculation
15–13 RSVD2	Reserved, always set to zero.
12–8 STATUS	Indicates which histogram matched the processed bitmap. Bit[0] indicates that the bitmap pixels were fully contained within the HIST2 (black / white) histogram. Bit[1] indicates that the bitmap pixels were fully contained within the HIST4 (2-bit grayscale) histogram. Bit[2] indicates that the bitmap pixels were fully contained within the HIST8 (3-bit grayscale) histogram. Bit[3] indicates that the bitmap pixels were fully contained within the HIST16 (4-bit grayscale) histogram. Bit[4] indicates that the bitmap pixels were fully contained within the HIST32 (5-bit grayscale) histogram.
7–5 RSVD1	Reserved, always set to zero.
4 CLEAR	Write 1 to clear the histogram result and will be self-clear after clear function finished
3–1 RSVD0	Reserved, always set to zero.
0 ENABLE	Enable the Histogram Engine

13.6.12.184 Histogram Pixel Mask Register. (PXP_HW_PXP_HIST_A_MASK)

Provides control registers for the pixel masking in PXP's histogram.

Address: 3070_0000h base + 2A10h offset = 3070_2A10h



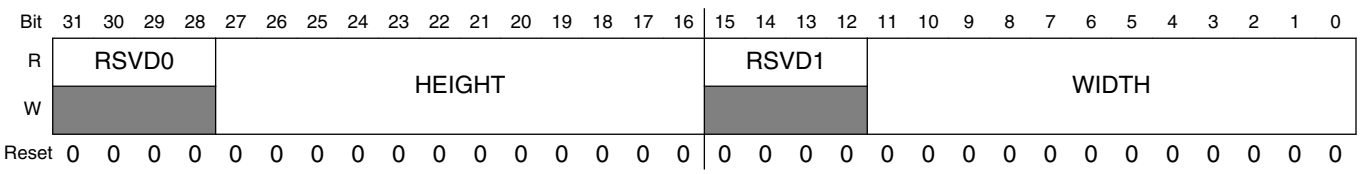
PXP_HW_PXP_HIST_A_MASK field descriptions

Field	Description
31–24 MASK_VALUE1	The value1 for mask condition checking
23–16 MASK_VALUE0	The value0 for mask condition checking
15–13 MASK_WIDTH	The width of the field to be checked against mask condition
12–6 MASK_OFFSET	The offset of the field to be checked against mask condition
5–4 MASK_MODE	Operation mode of pixel mask function 0x0 **EQUAL** — Run histogram for pixels equal to value0 0x1 **NOT_EQUAL** — Run histogram for pixels not equal to value0 0x2 **INSIDE** — Run histogram for pixels within the range of value0 to value1 0x3 **OUTSIDE** — Run histogram for pixels outside of the rang of value0 to value1
3–1 RSVD0	Reserved, always set to zero.
0 MASK_EN	Enable the Pixel Mask Function in Histogram

13.6.12.185 Histogram Pixel Buffer Size Register. (PXP_HW_PXP_HIST_A_BUF_SIZE)

This register defines the size of the buffer to be processed by the histogram engine.

Address: 3070_0000h base + 2A20h offset = 3070_2A20h



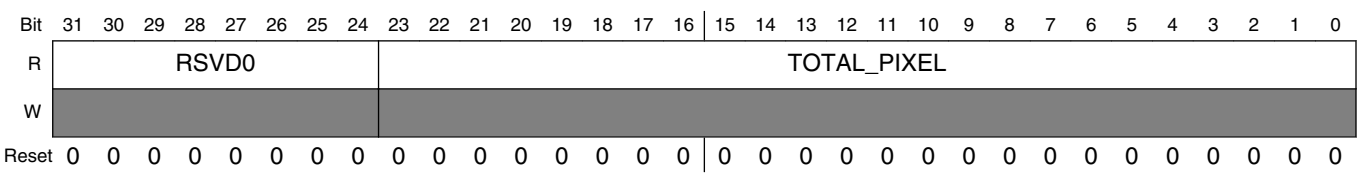
PXP_HW_PXP_HIST_A_BUF_SIZE field descriptions

Field	Description
31–28 RSVD0	Reserved. This field always reads 0.
27–16 HEIGHT	This indicate the buffer height in pixels
15–12 RSVD1	Reserved. This field always reads 0.
WIDTH	This indicate the buffer width in pixels

13.6.12.186 Total Number of Pixels Used by Histogram Engine. (PXP_HW_PXP_HIST_A_TOTAL_PIXEL)

This register shows the total number of pixels used by histogram engine

Address: 3070_0000h base + 2A30h offset = 3070_2A30h



PXP_HW_PXP_HIST_A_TOTAL_PIXEL field descriptions

Field	Description
31–24 RSVD0	Reserved. This field always reads 0.
TOTAL_PIXEL	Total number of pixels used by histogram engine, the pixels got masked will be skipped

13.6.12.187 The X Coordinate Offset for Active Area. (PXP_HW_PXP_HIST_A_ACTIVE_AREA_X)

This register shows the minimal and maximum X coordinate offset for the active area in histogram processing

Address: 3070_0000h base + 2A40h offset = 3070_2A40h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1				MAX_X_OFFSET												RSVD0				MIN_X_OFFSET												
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_HIST_A_ACTIVE_AREA_X field descriptions

Field	Description
31–28 RSVD1	Reserved. This field always reads 0.
27–16 MAX_X_OFFSET	Maximum X coordinate offset for the active area in histogram processing
15–12 RSVD0	Reserved. This field always reads 0.
MIN_X_OFFSET	Minimul X coordinate offset for the active area in histogram processing

13.6.12.188 The Y Coordinate Offset for Active Area. (PXP_HW_PXP_HIST_A_ACTIVE_AREA_Y)

This register shows the minimal and maximum Y coordinate offset for the active area in histogram processing

Address: 3070_0000h base + 2A50h offset = 3070_2A50h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD1				MAX_Y_OFFSET												RSVD0				MIN_Y_OFFSET												
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_HIST_A_ACTIVE_AREA_Y field descriptions

Field	Description
31–28 RSVD1	Reserved. This field always reads 0.

Table continues on the next page...

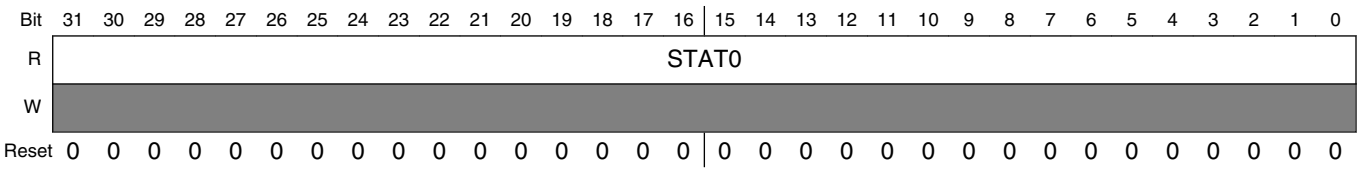
PXP_HW_PXP_HIST_A_ACTIVE_AREA_Y field descriptions (continued)

Field	Description
27–16 MAX_Y_OFFSET	Maximum Y coordinate offset for the active area in histogram processing
15–12 RSVD0	Reserved. This field always reads 0.
MIN_Y_OFFSET	Minimul Y coordinate offset for the active area in histogram processing

13.6.12.189 Histogram Result Based on RAW Pixel Value. (PXP_HW_PXP_HIST_A_RAW_STAT0)

This register shows the lower 32-bit of the histogram result based on raw pixel value

Address: 3070_0000h base + 2A60h offset = 3070_2A60h



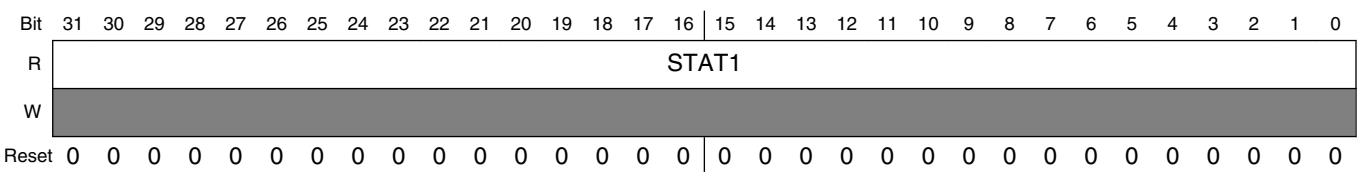
PXP_HW_PXP_HIST_A_RAW_STAT0 field descriptions

Field	Description
STAT0	Lower 32-bit result fo the histogram calculation

13.6.12.190 Histogram Result Based on RAW Pixel Value. (PXP_HW_PXP_HIST_A_RAW_STAT1)

This register shows the higher 32-bit of the histogram result based on raw pixel value

Address: 3070_0000h base + 2A70h offset = 3070_2A70h



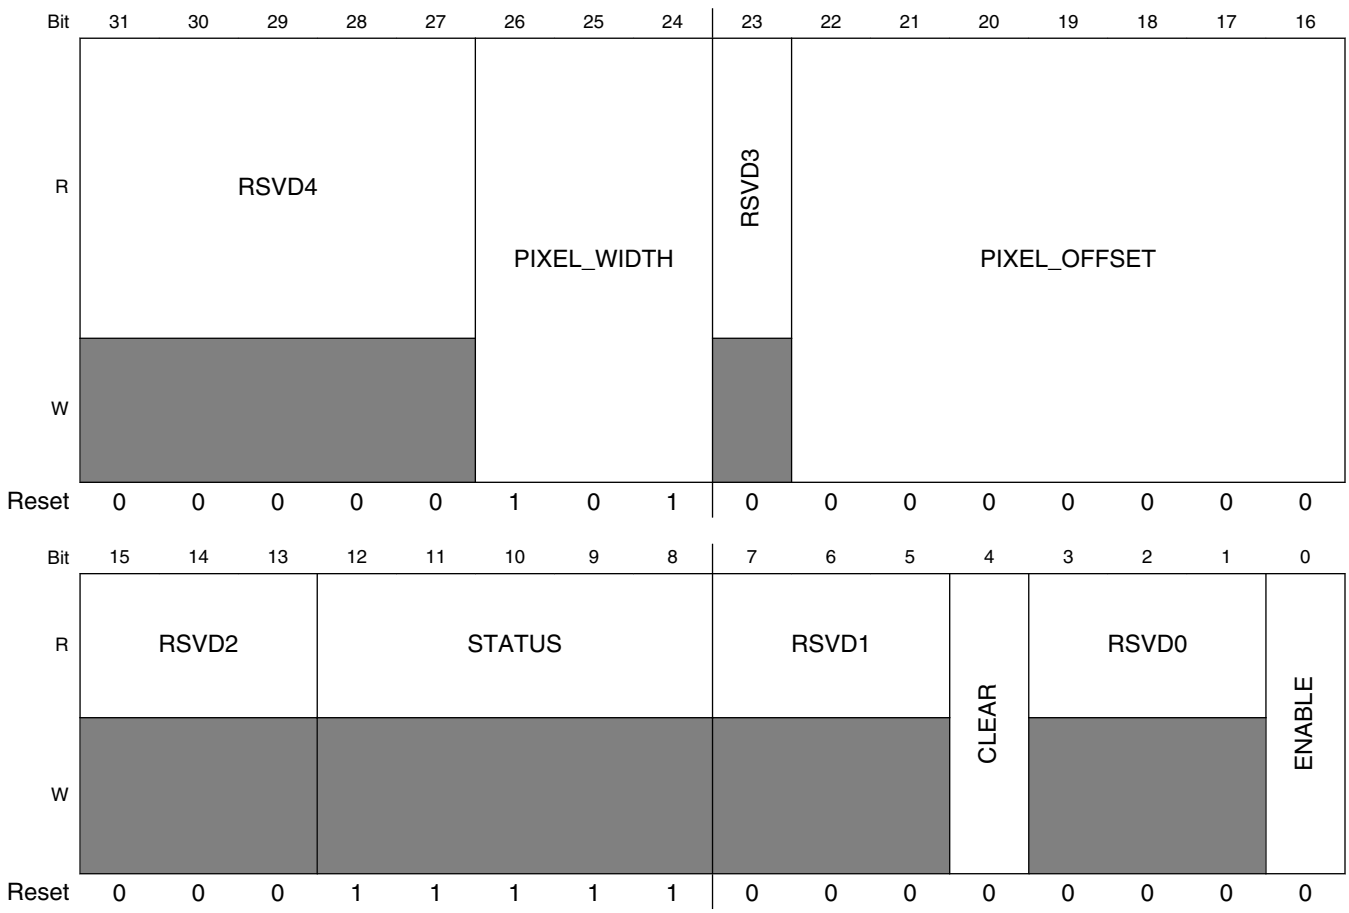
PXP_HW_PXP_HIST_A_RAW_STAT1 field descriptions

Field	Description
STAT1	Higher 32-bit result fo the histogram calculation

13.6.12.191 Histogram Control Register. (PXP_HW_PXP_HIST_B_CTRL)

Provides control and status registers for the PXP's histogram classification algorithm.

Address: 3070_0000h base + 2A80h offset = 3070_2A80h



PXP_HW_PXP_HIST_B_CTRL field descriptions

Field	Description
31–27 RSVD4	Reserved, always set to zero.
26–24 PIXEL_WIDTH	The width of the pixel to be used for histogram calculation
23 RSVD3	Reserved, always set to zero.
22–16 PIXEL_OFFSET	The offset of the pixel to be used for histogram calculation
15–13 RSVD2	Reserved, always set to zero.

Table continues on the next page...

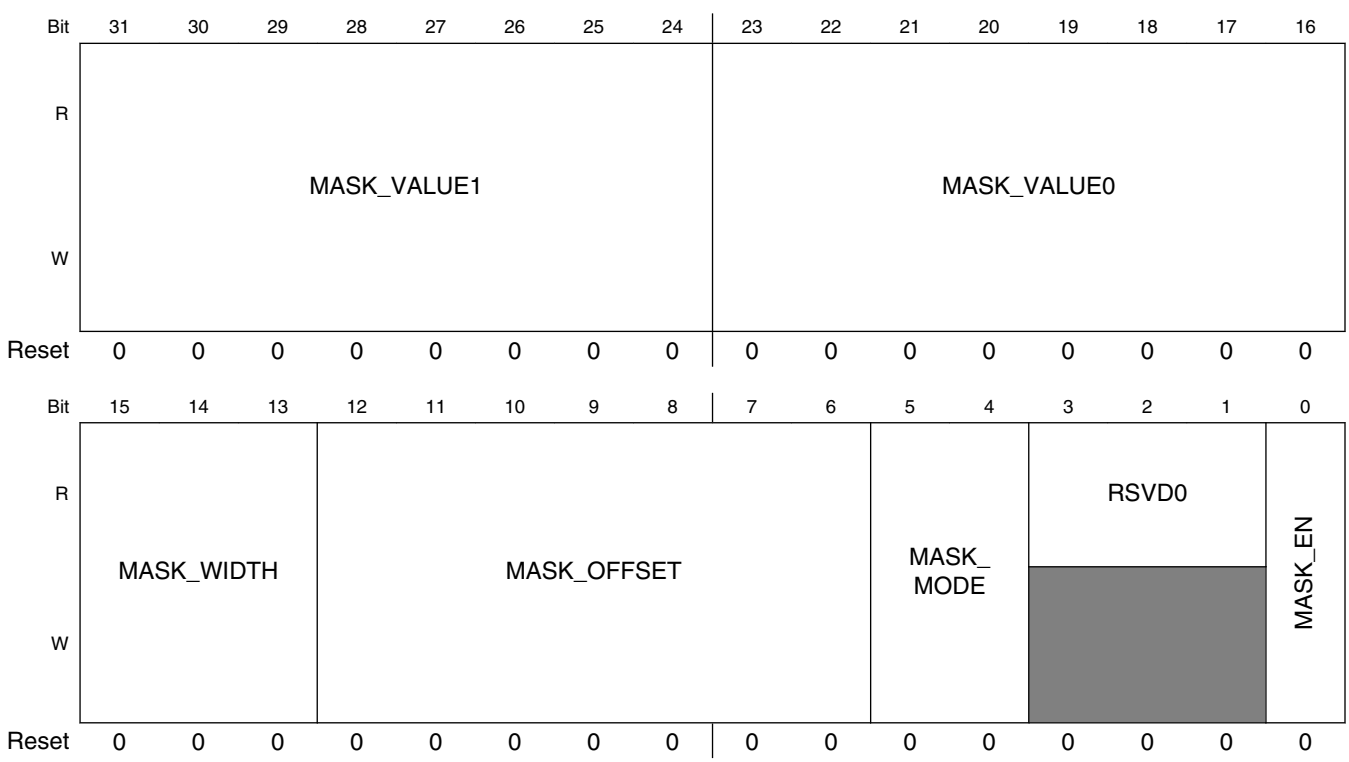
PXP_HW_PXP_HIST_B_CTRL field descriptions (continued)

Field	Description
12–8 STATUS	Indicates which histogram matched the processed bitmap. Bit[0] indicates that the bitmap pixels were fully contained within the HIST2 (black / white) histogram. Bit[1] indicates that the bitmap pixels were fully contained within the HIST4 (2-bit grayscale) histogram. Bit[2] indicates that the bitmap pixels were fully contained within the HIST8 (3-bit grayscale) histogram. Bit[3] indicates that the bitmap pixels were fully contained within the HIST16 (4-bit grayscale) histogram. Bit[4] indicates that the bitmap pixels were fully contained within the HIST32 (5-bit grayscale) histogram.
7–5 RSVD1	Reserved, always set to zero.
4 CLEAR	Write 1 to clear the histogram result and will be self-clear after clear function finished
3–1 RSVD0	Reserved, always set to zero.
0 ENABLE	Enable the Histogram Engine

13.6.12.192 Histogram Pixel Mask Register. (PXP_HW_PXP_HIST_B_MASK)

Provides control registers for the pixel masking in PXP's histogram.

Address: 3070_0000h base + 2A90h offset = 3070_2A90h



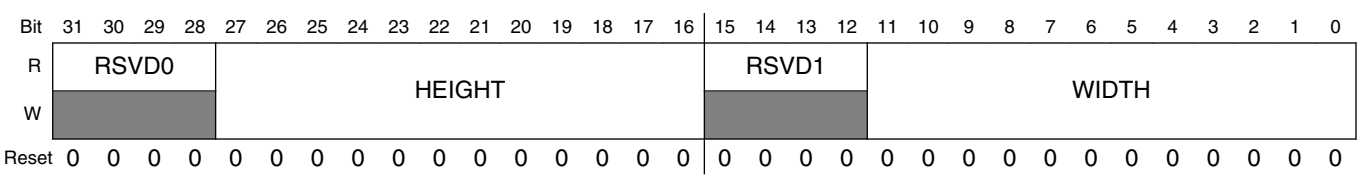
PXP_HW_PXP_HIST_B_MASK field descriptions

Field	Description
31–24 MASK_VALUE1	The value1 for mask condition checking
23–16 MASK_VALUE0	The value0 for mask condition checking
15–13 MASK_WIDTH	The width of the field to be checked against mask condition
12–6 MASK_OFFSET	The offset of the field to be checked against mask condition
5–4 MASK_MODE	Operation mode of pixel mask function 0x0 **EQUAL** — Run histogram for pixels equal to value0 0x1 **NOT_EQUAL** — Run histogram for pixels not equal to value0 0x2 **INSIDE** — Run histogram for pixels within the range of value0 to value1 0x3 **OUTSIDE** — Run histogram for pixels outside of the rang of value0 to value1
3–1 RSVD0	Reserved, always set to zero.
0 MASK_EN	Enable the Pixel Mask Function in Histogram

13.6.12.193 Histogram Pixel Buffer Size Register. (PXP_HW_PXP_HIST_B_BUF_SIZE)

This register defines the size of the buffer to be processed by the histogram engine.

Address: 3070_0000h base + 2AA0h offset = 3070_2AA0h



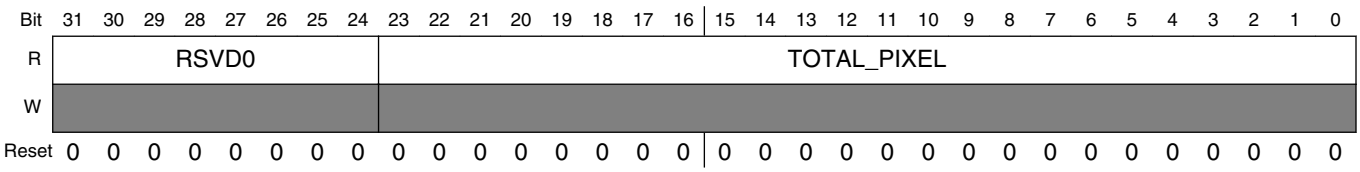
PXP_HW_PXP_HIST_B_BUF_SIZE field descriptions

Field	Description
31–28 RSVD0	Reserved. This field always reads 0.
27–16 HEIGHT	This indicate the buffer height in pixels
15–12 RSVD1	Reserved. This field always reads 0.
WIDTH	This indicate the buffer width in pixels

13.6.12.194 Total Number of Pixels Used by Histogram Engine. (PXP_HW_PXP_HIST_B_TOTAL_PIXEL)

This register shows the total number of pixels used by histogram engine

Address: 3070_0000h base + 2AB0h offset = 3070_2AB0h



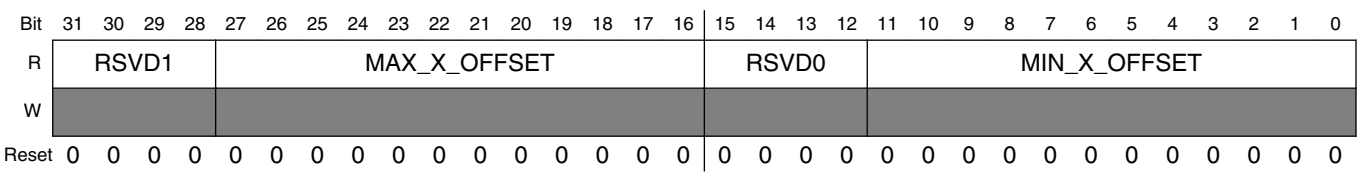
PXP_HW_PXP_HIST_B_TOTAL_PIXEL field descriptions

Field	Description
31–24 RSVD0	Reserved. This field always reads 0.
TOTAL_PIXEL	Total number of pixels used by histogram engine, the pixels got masked will be skipped

13.6.12.195 The X Coordinate Offset for Active Area. (PXP_HW_PXP_HIST_B_ACTIVE_AREA_X)

This register shows the minimal and maximum X coordinate offset for the active area in histogram processing

Address: 3070_0000h base + 2AC0h offset = 3070_2AC0h



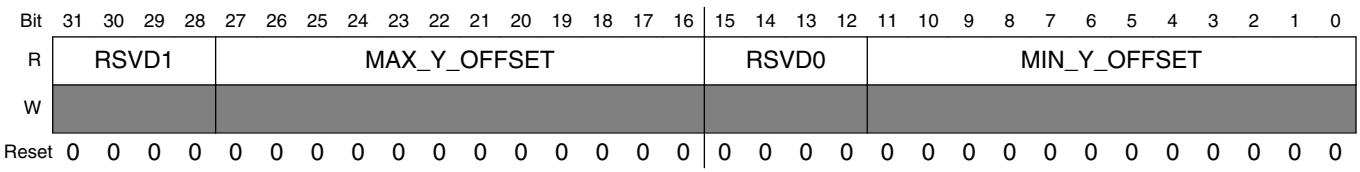
PXP_HW_PXP_HIST_B_ACTIVE_AREA_X field descriptions

Field	Description
31–28 RSVD1	Reserved. This field always reads 0.
27–16 MAX_X_OFFSET	Maximum X coordinate offset for the active area in histogram processing
15–12 RSVD0	Reserved. This field always reads 0.
MIN_X_OFFSET	Minimul X coordinate offset for the active area in histogram processing

13.6.12.196 The Y Coordinate Offset for Active Area. (PXP_HW_PXP_HIST_B_ACTIVE_AREA_Y)

This register shows the minimal and maximum Y coordinate offset for the active area in histogram processing

Address: 3070_0000h base + 2AD0h offset = 3070_2AD0h



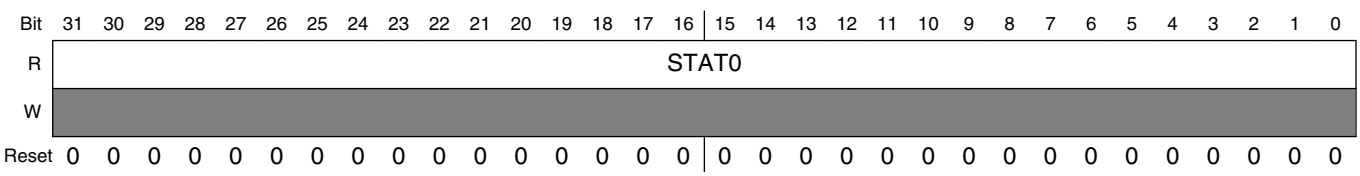
PXP_HW_PXP_HIST_B_ACTIVE_AREA_Y field descriptions

Field	Description
31–28 RSVD1	Reserved. This field always reads 0.
27–16 MAX_Y_OFFSET	Maximum Y coordinate offset for the active area in histogram processing
15–12 RSVD0	Reserved. This field always reads 0.
MIN_Y_OFFSET	Minimul Y coordinate offset for the active area in histogram processing

13.6.12.197 Histogram Result Based on RAW Pixel Value. (PXP_HW_PXP_HIST_B_RAW_STAT0)

This register shows the lower 32-bit of the histogram result based on raw pixel value

Address: 3070_0000h base + 2AE0h offset = 3070_2AE0h



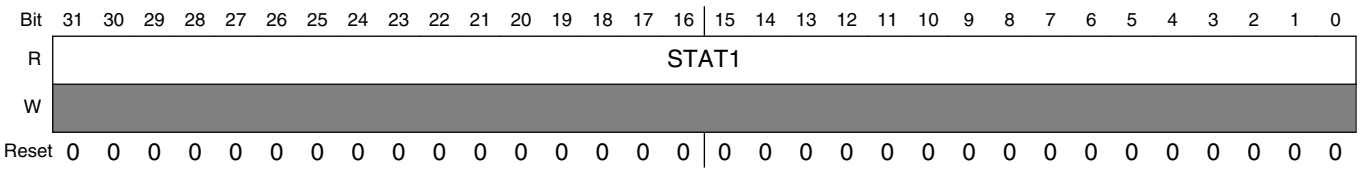
PXP_HW_PXP_HIST_B_RAW_STAT0 field descriptions

Field	Description
STAT0	Lower 32-bit result fo the histogram calculation

13.6.12.198 Histogram Result Based on RAW Pixel Value. (PXP_HW_PXP_HIST_B_RAW_STAT1)

This register shows the higher 32-bit of the histogram result based on raw pixel value

Address: 3070_0000h base + 2AF0h offset = 3070_2AF0h



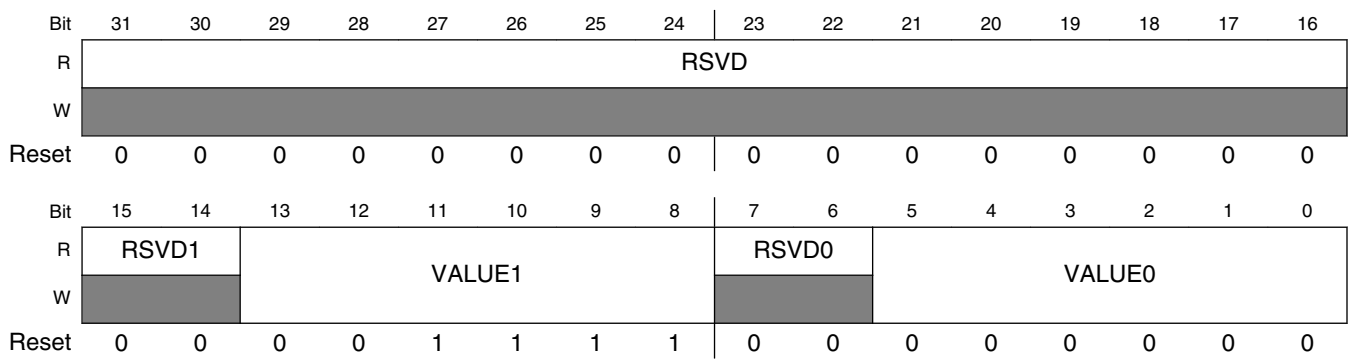
PXP_HW_PXP_HIST_B_RAW_STAT1 field descriptions

Field	Description
STAT1	Higher 32-bit result fo the histogram calculation

13.6.12.199 2-level Histogram Parameter Register. (PXP_HW_PXP_HIST2_PARAM)

This register specifies the valid values for a 2-level histogram. If all pixels in a bitmap match the 2-level histogram values, STATUS[0] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2B00h offset = 3070_2B00h



PXP_HW_PXP_HIST2_PARAM field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.

Table continues on the next page...

PXP_HW_PXP_HIST2_PARAM field descriptions (continued)

Field	Description
15–14 RSVD1	Reserved, always set to zero.
13–8 VALUE1	White value for 2-level histogram
7–6 RSVD0	Reserved, always set to zero.
VALUE0	Black value for 2-level histogram

13.6.12.200 4-level Histogram Parameter Register. (PXP_HW_PXP_HIST4_PARAM)

This register specifies the valid values for a 4-level histogram. If all pixels in a bitmap match the 4-level histogram values, STATUS[1] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2B10h offset = 3070_2B10h

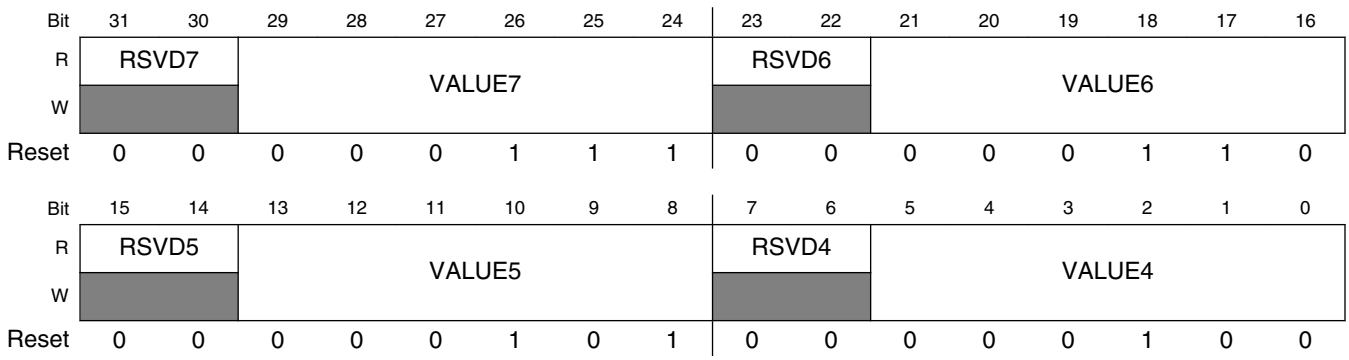
PXP_HW_PXP_HIST16_PARAM0 field descriptions

Field	Description
31–30 RSVD3	Reserved, always set to zero.
29–24 VALUE3	GRAY3 value for 16-level histogram
23–22 RSVD2	Reserved, always set to zero.
21–16 VALUE2	GRAY2 value for 16-level histogram
15–14 RSVD1	Reserved, always set to zero.
13–8 VALUE1	GRAY1 value for 16-level histogram
7–6 RSVD0	Reserved, always set to zero.
VALUE0	GRAY0 (Black) value for 16-level histogram

13.6.12.204 16-level Histogram Parameter 1 Register. (PXP_HW_PXP_HIST16_PARAM1)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2B50h offset = 3070_2B50h



PXP_HW_PXP_HIST16_PARAM1 field descriptions

Field	Description
31–30 RSVD7	Reserved, always set to zero.
29–24 VALUE7	GRAY7 value for 16-level histogram
23–22 RSVD6	Reserved, always set to zero.
21–16 VALUE6	GRAY6 value for 16-level histogram
15–14 RSVD5	Reserved, always set to zero.
13–8 VALUE5	GRAY5 value for 16-level histogram
7–6 RSVD4	Reserved, always set to zero.
VALUE4	GRAY4 value for 16-level histogram

13.6.12.205 16-level Histogram Parameter 2 Register. (PXP_HW_PXP_HIST16_PARAM2)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2B60h offset = 3070_2B60h

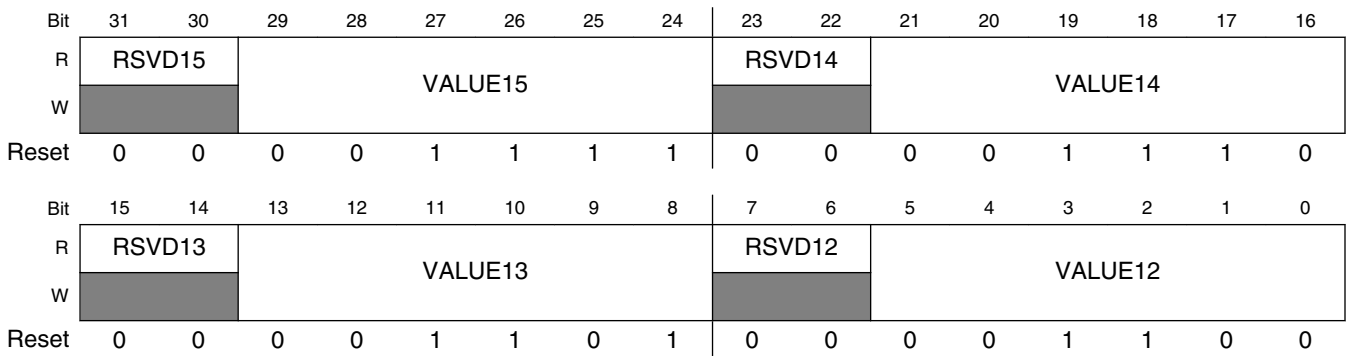
PXP_HW_PXP_HIST16_PARAM2 field descriptions

Field	Description
31–30 RSVD11	Reserved, always set to zero.
29–24 VALUE11	GRAY11 value for 16-level histogram
23–22 RSVD10	Reserved, always set to zero.
21–16 VALUE10	GRAY10 value for 16-level histogram
15–14 RSVD9	Reserved, always set to zero.
13–8 VALUE9	GRAY9 value for 16-level histogram
7–6 RSVD8	Reserved, always set to zero.
VALUE8	GRAY8 value for 16-level histogram

13.6.12.206 16-level Histogram Parameter 3 Register. (PXP_HW_PXP_HIST16_PARAM3)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match the 16-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2B70h offset = 3070_2B70h



PXP_HW_PXP_HIST16_PARAM3 field descriptions

Field	Description
31–30 RSVD15	Reserved, always set to zero.
29–24 VALUE15	GRAY15 (White) value for 16-level histogram
23–22 RSVD14	Reserved, always set to zero.
21–16 VALUE14	GRAY14 value for 16-level histogram
15–14 RSVD13	Reserved, always set to zero.
13–8 VALUE13	GRAY13 value for 16-level histogram
7–6 RSVD12	Reserved, always set to zero.
VALUE12	GRAY12 value for 16-level histogram

13.6.12.207 32-level Histogram Parameter 0 Register. (PXP_HW_PXP_HIST32_PARAM0)

This register specifies four of the valid values for a 32-level histogram. If all pixels in a bitmap match the 32-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

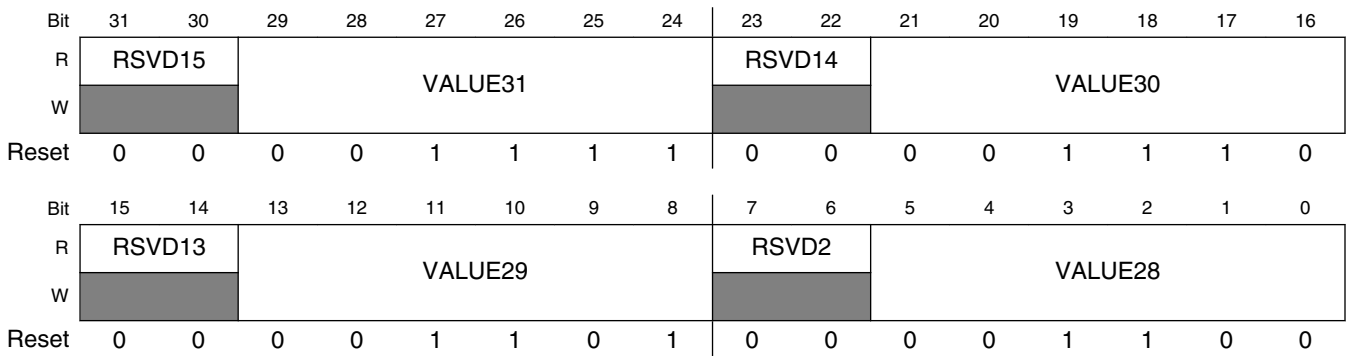
PXP_HW_PXP_HIST32_PARAM6 field descriptions

Field	Description
31–30 RSVD11	Reserved, always set to zero.
29–24 VALUE27	GRAY27 value for 32-level histogram
23–22 RSVD10	Reserved, always set to zero.
21–16 VALUE26	GRAY26 value for 32-level histogram
15–14 RSVD9	Reserved, always set to zero.
13–8 VALUE25	GRAY25 value for 32-level histogram
7–6 RSVD8	Reserved, always set to zero.
VALUE24	GRAY24 value for 32-level histogram

13.6.12.214 32-level Histogram Parameter 3 Register. (PXP_HW_PXP_HIST32_PARAM7)

This register specifies four of the valid values for a 32-level histogram. If all pixels in a bitmap match the 32-level histogram values, STATUS[3] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with the PANEL_MODE control field.

Address: 3070_0000h base + 2BF0h offset = 3070_2BF0h



PXP_HW_PXP_HIST32_PARAM7 field descriptions

Field	Description
31–30 RSVD15	Reserved, always set to zero.
29–24 VALUE31	GRAY31 (White) value for 32-level histogram
23–22 RSVD14	Reserved, always set to zero.
21–16 VALUE30	GRAY30 value for 32-level histogram
15–14 RSVD13	Reserved, always set to zero.
13–8 VALUE29	GRAY29 value for 32-level histogram
7–6 RSVD2	Reserved, always set to zero.
VALUE28	GRAY28 value for 32-level histogram

13.6.12.215 PXP_HW_PXP_COMP_CTRL

This register defines the control bits for the pxp compression sub-block.

HW_PXP_COMP_CTRL: 0x2C00

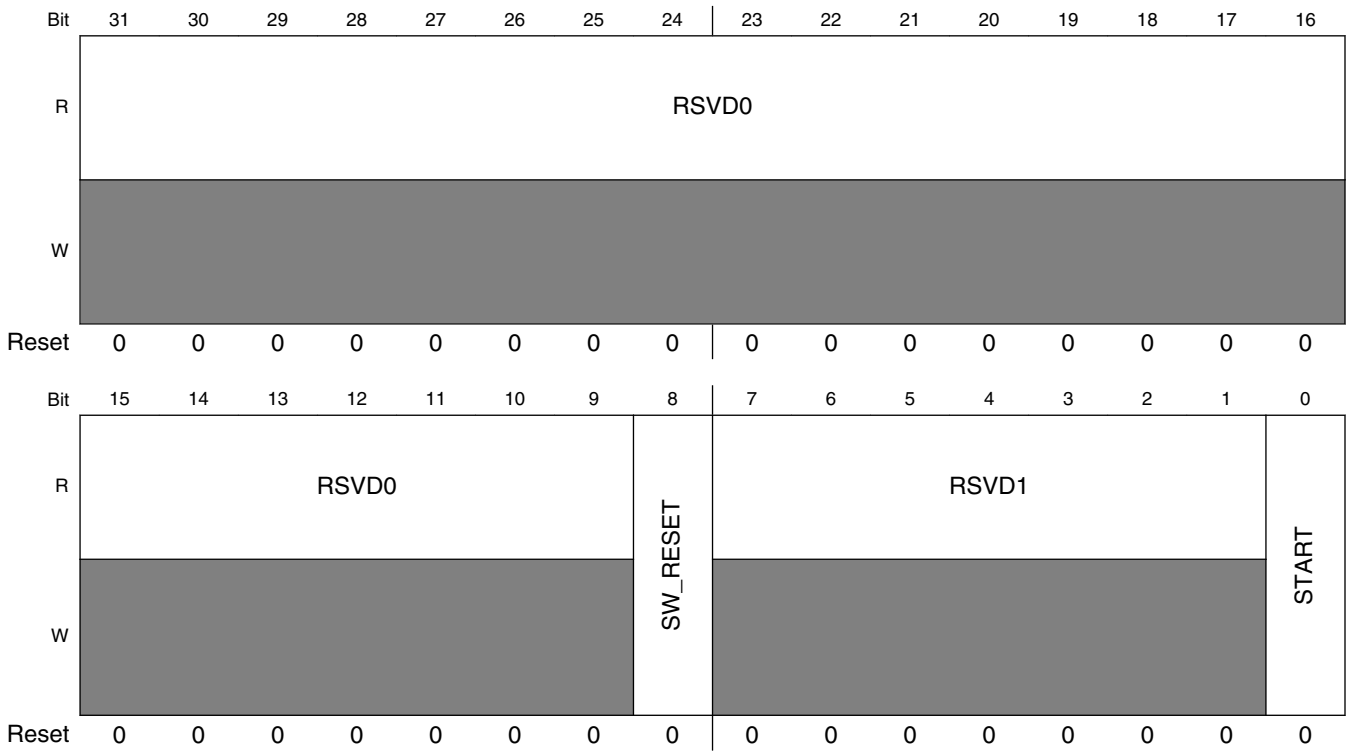
HW_PXP_COMP_CTRL_SET: 0x2C04

HW_PXP_COMP_CTRL_CLR: 0x2C08

HW_PXP_COMP_CTRL_TOG: 0x2C0C

EXAMPLE

Address: 3070_0000h base + 2C00h offset = 3070_2C00h



PXP_HW_PXP_COMP_CTRL field descriptions

Field	Description
31–9 RSVD0	Reserved. This field always reads 0.
8 SW_RESET	Write to 1 to do a software reset to the engine, self-clear.
7–1 RSVD1	Reserved. This field always reads 0.
0 START	Write to 1 to start operation, self-clear

13.6.12.216 PXP_HW_PXP_COMP_FORMAT0

This register defines the format bits for the pxp compression sub-block.

HW_PXP_COMP_FORMAT0: 0x2C10

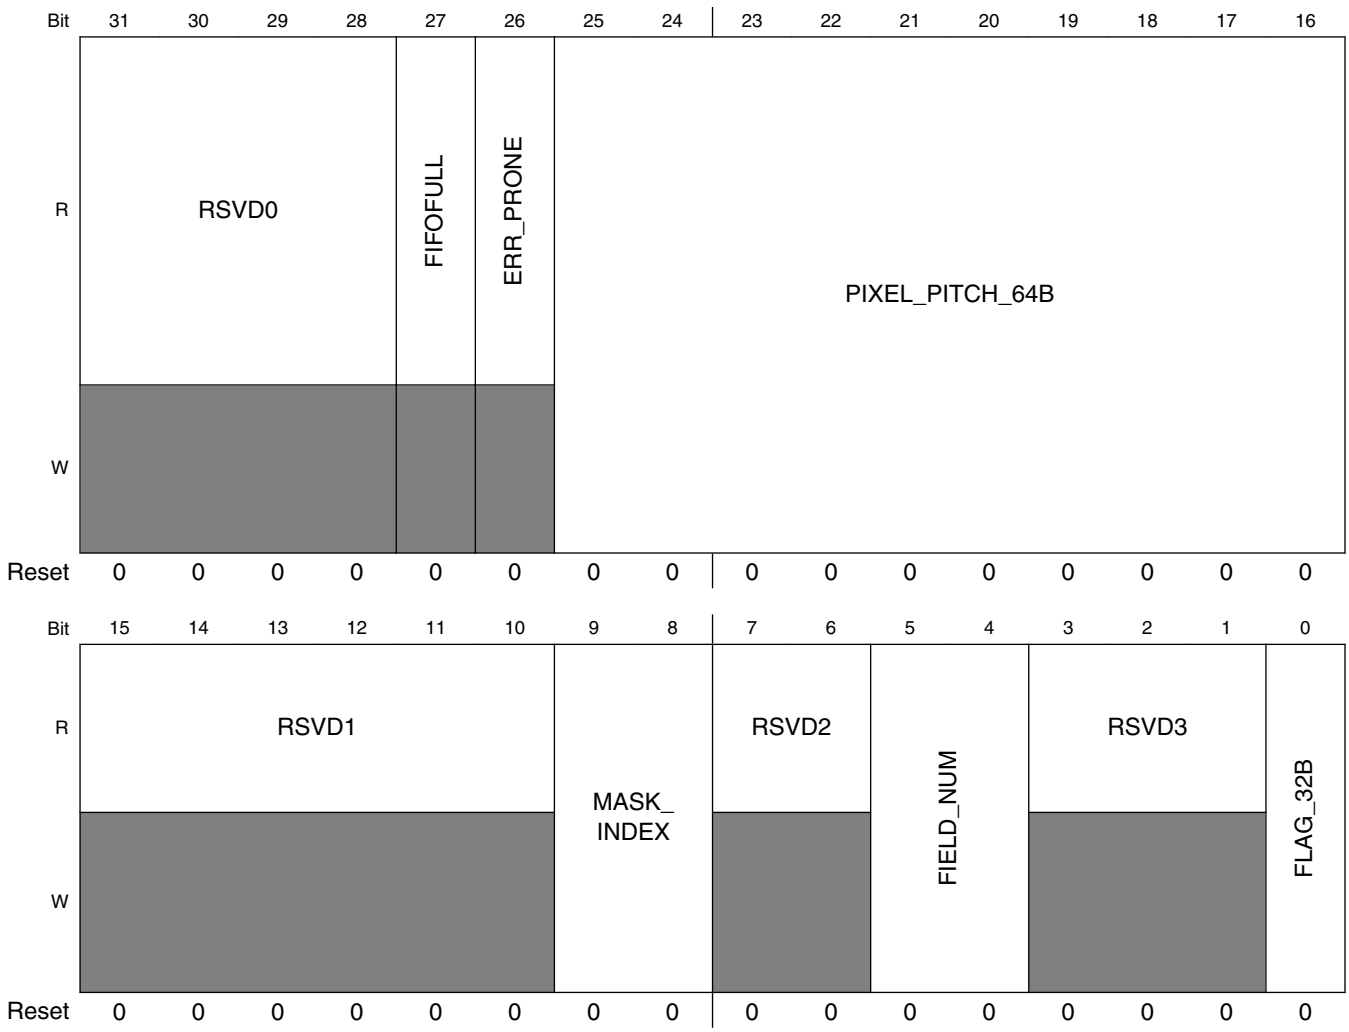
HW_PXP_COMP_FORMAT0_SET: 0x2C14

HW_PXP_COMP_FORMAT0_CLR: 0x2C18

HW_PXP_COMP_FORMAT0_TOG: 0x2C1C

EXAMPLE

Address: 3070_0000h base + 2C10h offset = 3070_2C10h



PXP_HW_PXP_COMP_FORMAT0 field descriptions

Field	Description
31–28 RSVD0	Reserved. This field always reads 0.
27 FIFOFULL	step1 write fifo full

Table continues on the next page...

PXP_HW_PXP_COMP_FORMAT0 field descriptions (continued)

Field	Description
26 ERR_PRONE	step1 write fifo full. If detected, this bit is 1, there is data error in current frame.
25–16 PIXEL_PITCH_64B	extend each line to be 64-bit aligned
15–10 RSVD1	Reserved. This field always reads 0.
9–8 MASK_INDEX	which field is the mask,0 for A, 3 for D
7–6 RSVD2	Reserved. This field always reads 0.
5–4 FIELD_NUM	indicate how many fields in one pixel,0 for only A;3 for ABCD
3–1 RSVD3	Reserved. This field always reads 0.
0 FLAG_32B	1 indicate 32-bit for one pixel, 0 for 16-bit

13.6.12.217 PXP_HW_PXP_COMP_FORMAT1

This register defines the format bits for the pxp compression sub-block.

EXAMPLE

Address: 3070_0000h base + 2C20h offset = 3070_2C20h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	D_LEN			D_OFFSET					C_LEN			C_OFFSET					B_LEN			B_OFFSET					A_LEN			A_OFFSET				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_FORMAT1 field descriptions

Field	Description
31–29 D_LEN	length of field D, 0 for 1 byte, 7 for 8 bytes, length of the field plus the length of RLE(*_runlen) should not more than 16-bit
28–24 D_OFFSET	offset for field D, 0 means D start from bit0
23–21 C_LEN	length of field C, 0 for 1 byte, 7 for 8 bytes, length of the field plus the length of RLE(*_runlen) should not more than 16-bit
20–16 C_OFFSET	offset for field C, 0 means C start from bit0
15–13 B_LEN	length of field B, 0 for 1 byte, 7 for 8 bytes, length of the field plus the length of RLE(*_runlen) should not more than 16-bit

Table continues on the next page...

PXP_HW_PXP_COMP_FORMAT1 field descriptions (continued)

Field	Description
12–8 B_OFFSET	offset for field B, 0 means B start from bit0
7–5 A_LEN	length of field A, 0 for 1 byte, 7 for 8 bytes, length of the field plus the length of RLE(*_runlen) should not more than 16-bit
A_OFFSET	offset for field A, 0 means A start from bit0

13.6.12.218 PXP_HW_PXP_COMP_FORMAT2

This register defines the format bits for the pxp compression sub-block.

EXAMPLE

Address: 3070_0000h base + 2C30h offset = 3070_2C30h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD																D_RUNLEN				C_RUNLEN				B_RUNLEN				A_RUNLEN			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_FORMAT2 field descriptions

Field	Description
31–16 RSVD	Reserved. This field always reads 0.
15–12 D_RUNLEN	length of the RLE for field D, 12-bit(4095) max
11–8 C_RUNLEN	length of the RLE for field C, 12-bit(4095) max
7–4 B_RUNLEN	length of the RLE for field B, 12-bit(4095) max
A_RUNLEN	length of the RLE for field A, 12-bit(4095) max

13.6.12.219 PXP_HW_PXP_COMP_MASK0

This register defines the format bits for the pxp compress mask configure.

EXAMPLE

Address: 3070_0000h base + 2C40h offset = 3070_2C40h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VLD_MASK_LOW																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_MASK0 field descriptions

Field	Description
VLD_MASK_LOW	low 32bit of the valid mask, one of ABCD will be vld_flag,1 left shifted by vld_flag anded with vld_mask will be used to check whether this pixel is valid

13.6.12.220 PXP_HW_PXP_COMP_MASK1

This register defines the format bits for the pxp compress mask configure.

EXAMPLE

Address: 3070_0000h base + 2C50h offset = 3070_2C50h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VLD_MASK_HIGH																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_MASK1 field descriptions

Field	Description
VLD_MASK_HIGH	high 32bit of the valid mask

13.6.12.221 PXP_HW_PXP_COMP_BUFFER_SIZE

This register defines the format bits for the pxp compress mask configure.

EXAMPLE

Address: 3070_0000h base + 2C60h offset = 3070_2C60h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RSVD0			PIXEL_WIDTH													RSVD1			PIXEL_LENGTH												
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_BUFFER_SIZE field descriptions

Field	Description
31–29 RSVD0	Reserved. This field always reads 0.
28–16 PIXEL_WIDTH	pixel width of the input frame, 4096 max
15–13 RSVD1	Reserved. This field always reads 0.
PIXEL_LENGTH	pixel length of the input frame, 4096 max

13.6.12.222 PXP_HW_PXP_COMP_SOURCE

This register defines the pxp compress source buffer address register.

EXAMPLE

Address: 3070_0000h base + 2C70h offset = 3070_2C70h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SOURCE_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_SOURCE field descriptions

Field	Description
SOURCE_ADDR	source address of the input frame that located in the memory, should be 32-byte aligned

13.6.12.223 PXP_HW_PXP_COMP_TARGET

This register defines the pxp compress target buffer address register.

EXAMPLE

Address: 3070_0000h base + 2C80h offset = 3070_2C80h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TARGET_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_TARGET field descriptions

Field	Description
TARGET_ADDR	taget address of the output frmae that the pxp compress engine should write to the memory, should be 32-byte aligned

13.6.12.224 PXP_HW_PXP_COMP_BUFFER_A

This register defines the pxp compress field A buffer address register.

EXAMPLE

Address: 3070_0000h base + 2C90h offset = 3070_2C90h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	A_SRAM_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_BUFFER_A field descriptions

Field	Description
A_SRAM_ADDR	sram address used for inter-data saving of A filed,should be 32-bit aligned, SW should make sure the SRAM addr for 4 field will not overlap

13.6.12.225 PXP_HW_PXP_COMP_BUFFER_B

This register defines the pxp compress field B buffer address register.

EXAMPLE

Address: 3070_0000h base + 2CA0h offset = 3070_2CA0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	B_SRAM_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_BUFFER_B field descriptions

Field	Description
B_SRAM_ADDR	sram address used for inter-data saving of B filed,should be 32-bit aligned, SW should make sure the SRAM addr for 4 field will not overlap

13.6.12.226 PXP_HW_PXP_COMP_BUFFER_C

This register defines the pxp compress field C buffer address register.

EXAMPLE

Address: 3070_0000h base + 2CB0h offset = 3070_2CB0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	C_SRAM_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_BUFFER_C field descriptions

Field	Description
C_SRAM_ADDR	sram address used for inter-data saving of C filed,should be 32-bit aligned, SW should make sure the SRAM addr for 4 field will not overlap

13.6.12.227 PXP_HW_PXP_COMP_BUFFER_D

This register defines the pxp compress field D buffer address register.

EXAMPLE

Address: 3070_0000h base + 2CC0h offset = 3070_2CC0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	D_SRAM_ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PXP_HW_PXP_COMP_BUFFER_D field descriptions

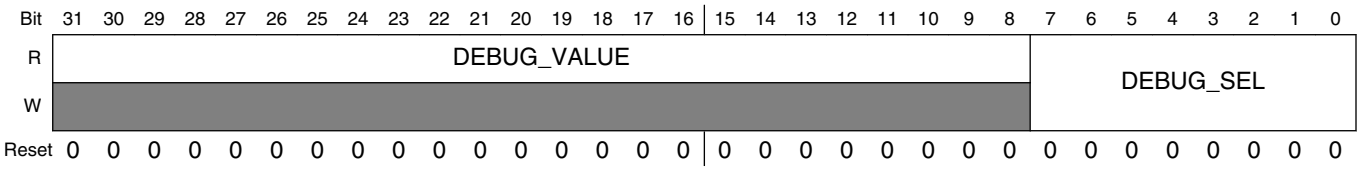
Field	Description
D_SRAM_ADDR	sram address used for inter-data saving of D filed,should be 32-bit aligned, SW should make sure the SRAM addr for 4 field will not overlap

13.6.12.228 PXP_HW_PXP_COMP_DEBUG

This register defines the pxp compress debug register.

EXAMPLE

Address: 3070_0000h base + 2CD0h offset = 3070_2CD0h



PXP_HW_PXP_COMP_DEBUG field descriptions

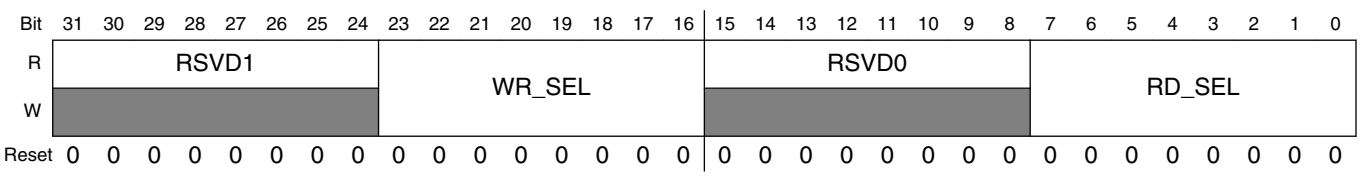
Field	Description
31–8 DEBUG_VALUE	value of selected debug signal
DEBUG_SEL	debug selection

13.6.12.229 PXP_HW_PXP_BUS_MUX

This register defines the pxp subblock bus mux on top level.

EXAMPLE

Address: 3070_0000h base + 2CE0h offset = 3070_2CE0h



PXP_HW_PXP_BUS_MUX field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–16 WR_SEL	Subblock BUS to AXI MUX, setting 0 to axi0 and setting 1 to axi1
15–8 RSVD0	Reserved, always set to zero.
RD_SEL	Subblock BUS to AXI MUX, setting 0 to axi0 and setting 1 to axi1

13.6.12.230 PXP_HW_PXP_HANDSHAKE_READY_MUX0

This register defines the pxp subblock handshake signals ready mux on top level.

EXAMPLE

Address: 3070_0000h base + 2CF0h offset = 3070_2CF0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7–4 HSK9	Subblock double buffer handshake signals MUX
HSK8	Subblock double buffer handshake signals MUX

13.6.12.234 PXP_HW_PXP_HANDSHAKE_CPU_FETCH

This register defines the pxp software handshake signals with CPU.

HW_PXP_HANDSHAKE_CPU_FETCH: 0x2D30

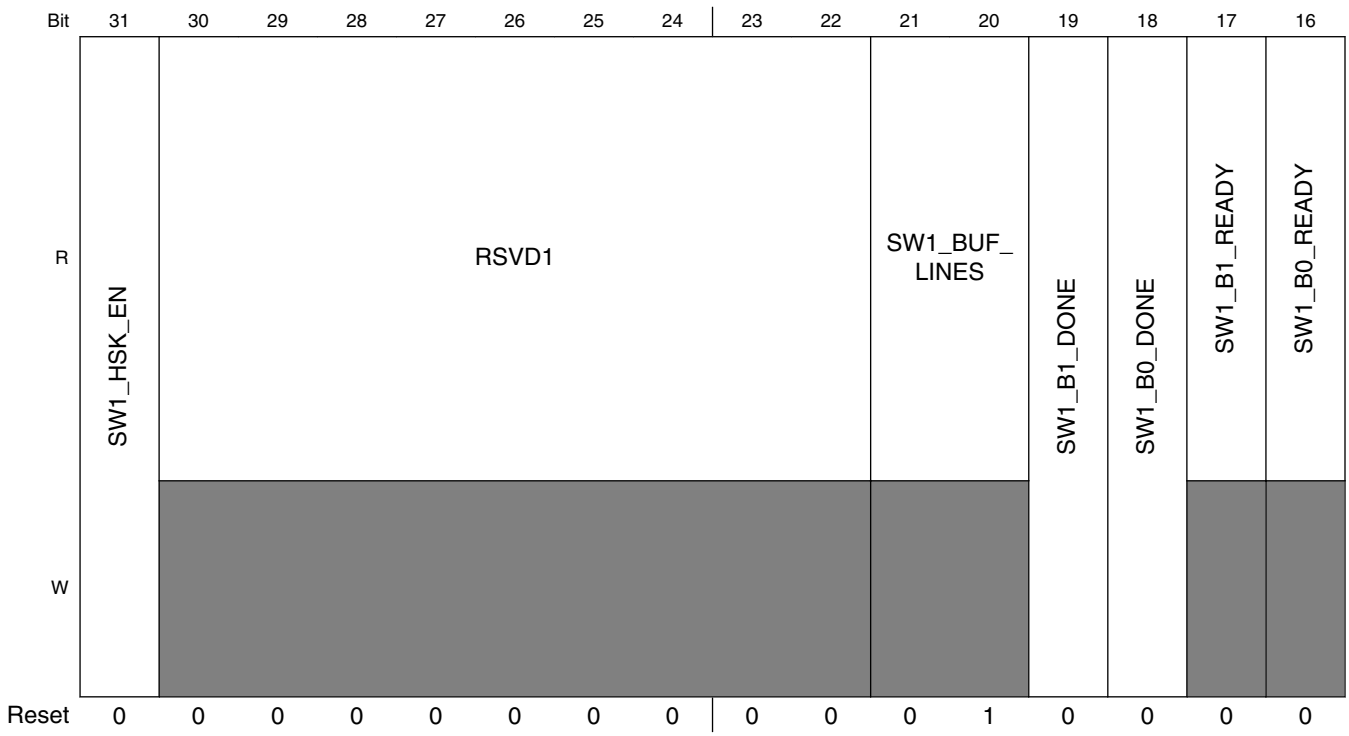
HW_PXP_HANDSHAKE_CPU_FETCH_SET: 0x2D34

HW_PXP_HANDSHAKE_CPU_FETCH_CLR: 0x2D38

HW_PXP_HANDSHAKE_CPU_FETCH_TOG: 0x2D3C

EXAMPLE

Address: 3070_0000h base + 2D30h offset = 3070_2D30h



PXP_HW_PXP_HANDSHAKE_CPU_FETCH field descriptions

Field	Description
31 SW1_HSK_EN	Enable software handshake 1 with CPU

Table continues on the next page...

PXP_HW_PXP_HANDSHAKE_CPU_FETCH field descriptions (continued)

Field	Description
30–22 RSVD1	Reserved, always set to zero.
21–20 SW1_BUF_ LINES	Buffer lines for software handshake 0x0 **LINE_4** — Buffer lines is 4 lines. 0x1 **LINE_8** — Buffer lines is 8 lines. 0x2 **LINE_16** — Buffer lines is 16 lines.
19 SW1_B1_DONE	CPU b1 buffer done to PXP
18 SW1_B0_DONE	CPU b0 buffer done to PXP
17 SW1_B1_ READY	PXP b1 buffer ready to CPU
16 SW1_B0_ READY	PXP b0 buffer ready to CPU
15 SW0_HSK_EN	Enable software handshake 0 with CPU
14–6 RSVD0	Reserved, always set to zero.
5–4 SW0_BUF_ LINES	Buffer lines for software handshake 0x0 **LINE_4** — Buffer lines is 4 lines. 0x1 **LINE_8** — Buffer lines is 8 lines. 0x2 **LINE_16** — Buffer lines is 16 lines.
3 SW0_B1_DONE	CPU b1 buffer done to PXP
2 SW0_B0_DONE	CPU b0 buffer done to PXP
1 SW0_B1_ READY	PXP b1 buffer ready to CPU
0 SW0_B0_ READY	PXP b0 buffer ready to CPU

13.6.12.235 PXP_HW_PXP_HANDSHAKE_CPU_STORE

This register defines the pxp software handshake signals with CPU.

HW_PXP_HANDSHAKE_CPU_STORE: 0x2D40

HW_PXP_HANDSHAKE_CPU_STORE_SET: 0x2D44

HW_PXP_HANDSHAKE_CPU_STORE_CLR: 0x2D48

HW_PXP_HANDSHAKE_CPU_STORE_TOG: 0x2D4C

EXAMPLE

Address: 3070_0000h base + 2D40h offset = 3070_2D40h

PXP_HW_PXP_HANDSHAKE_CPU_STORE field descriptions

Field	Description
31 SW1_HSK_EN	Enable software handshake 1 with CPU
30–22 RSVD1	Reserved, always set to zero.
21–20 SW1_BUF_ LINES	Buffer lines for software handshake 0x0 **LINE_4** — Buffer lines is 4 lines. 0x1 **LINE_8** — Buffer lines is 8 lines. 0x2 **LINE_16** — Buffer lines is 16 lines.
19 SW1_B1_DONE	CPU b1 buffer done to PXP
18 SW1_B0_DONE	CPU b0 buffer done to PXP
17 SW1_B1_ READY	PXP b1 buffer ready to CPU
16 SW1_B0_ READY	PXP b0 buffer ready to CPU
15 SW0_HSK_EN	Enable software handshake 0 with CPU
14–6 RSVD0	Reserved, always set to zero.
5–4 SW0_BUF_ LINES	Buffer lines for software handshake 0x0 **LINE_4** — Buffer lines is 4 lines. 0x1 **LINE_8** — Buffer lines is 8 lines. 0x2 **LINE_16** — Buffer lines is 16 lines.
3 SW0_B1_DONE	CPU b1 buffer done to PXP
2 SW0_B0_DONE	CPU b0 buffer done to PXP
1 SW0_B1_ READY	PXP b1 buffer ready to CPU
0 SW0_B0_ READY	PXP b0 buffer ready to CPU

13.7 Synchronous Audio Interface (SAI)

13.7.1 Overview

The synchronous audio interface (SAI) supports full-duplex serial interfaces with frame synchronization such as I^2S, AC97, TDM, and codec/DSP interfaces.

13.7.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 1 data line
- Receiver with independent bit clock and frame sync supporting 1 data line
- Maximum Frame Size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 × 32-bit FIFO for each transmit and receive channel
- Supports graceful restart after FIFO error

13.7.1.2 Block diagram

The following block diagram also shows the module clocks.

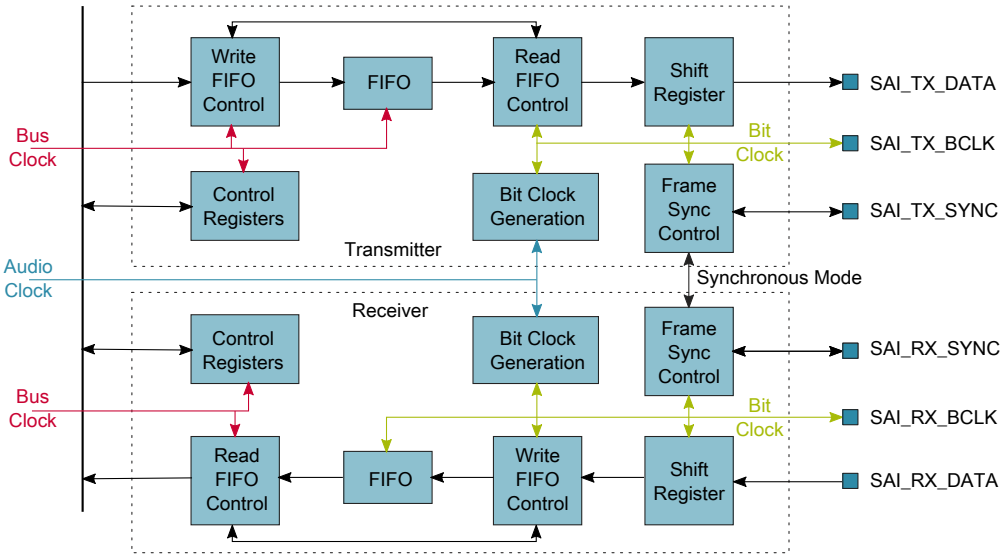

Figure 13-101. I²S/SAI block diagram

13.7.1.3 Modes of operation

The module operates in these power modes: Run mode, stop modes, and Debug mode.

13.7.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

13.7.1.3.2 Stop modes

In Stop mode, the transmitter is disabled after completing the current transmit frame, and, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented–not acknowledged–while waiting for the transmitter and receiver to be disabled at the end of the current frame.

13.7.1.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

13.7.2 External Signals

The following table describes the external signals of SAI:

Table 13-40. SAI External Signals

Signal	Description	Pad	Mode	Direction
SAI1_MCLK	Audio Master Clock. The master clock is an input when externally generated and an output when internally generated.	GPIO1_IO01	ALT3	IO
		SAI1_MCLK	ALT0	
SAI1_RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	ENET1_TXC	ALT2	IO
		SAI1_RXC	ALT0	
SAI1_RX_DATA	Receive Data. The receive data is sampled synchronously by the bit clock.	ENET1_TX_CLK	ALT2	I
		SAI1_RXD	ALT0	
SAI1_RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	ENET1_TX_CTL	ALT2	IO
		SAI1_RXFS	ALT0	
SAI1_TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	ENET1_RX_CLK	ALT2	IO
		SAI1_TXC	ALT0	
SAI1_TX_DATA	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	ENET1_COL	ALT2	O
		SAI1_TXD	ALT0	
SAI1_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	ENET1_CRS	ALT2	IO

SAI3_TX_DATA	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	SD1_DATA3	ALT1	O
		SD3_DATA3	ALT3	
		UART3_RTS	ALT2	
SAI3_TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	SD1_DATA2	ALT1	IO
		SD3_DATA2	ALT3	
		UART3_CTS	ALT2	

13.7.3 Functional description

This section provides a complete functional description of the block.

13.7.3.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

13.7.3.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

13.7.3.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

13.7.3.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

13.7.3.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

13.7.3.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

13.7.3.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

13.7.3.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

13.7.3.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

13.7.3.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

13.7.3.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32 × 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

13.7.3.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 13-102 for LSB First configurations and Figure 13-103 for MSB First configurations.

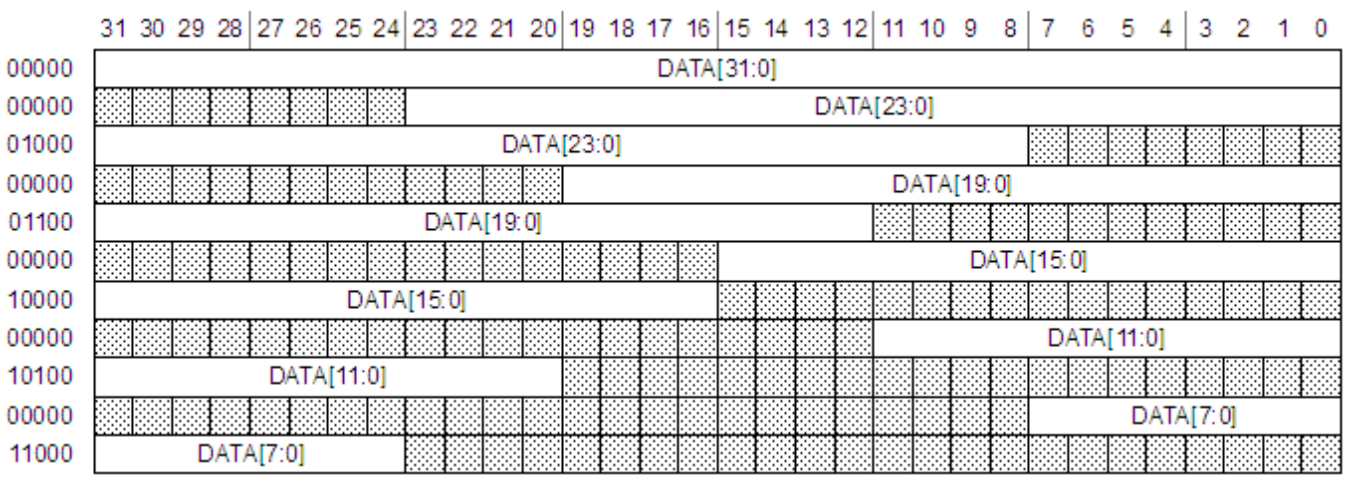

Figure 13-102. SAI first bit shifted, LSB first

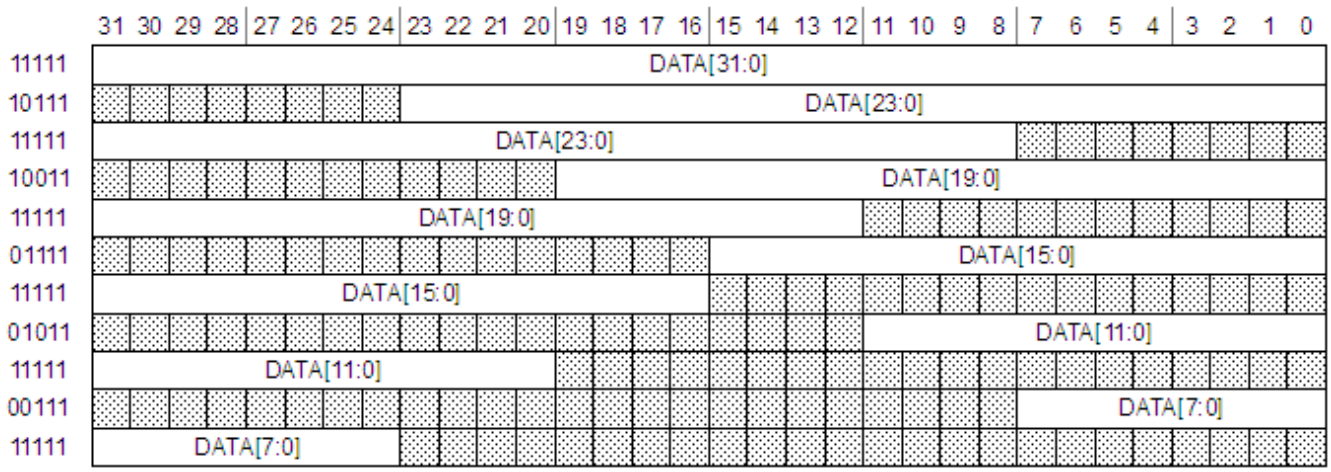

Figure 13-103. SAI first bit shifted, MSB first

13.7.3.5.2 FIFO pointers

When writing to a TDR, the WFP of the corresponding TFR increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the TDR and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data and 16-bit writes should only be used when transmitting up to 16-bit data.

Writes to a TDR are ignored if the corresponding bit of TCR3[TCE] is clear or if the FIFO is full. If the Transmit FIFO is empty, the TDR must be written at least three bit clocks before the start of the next unmasked word to avoid a FIFO underrun.

When reading an RDR, the RFP of the corresponding RFR increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data and 16-bit reads should only be used when receiving up to 16-bit data.

Reads from an RDR are ignored if the corresponding bit of RCR3[RCE] is clear or if the FIFO is empty. If the Receive FIFO is full, the RDR must be read at least three bit clocks before the end of an unmasked word to avoid a FIFO overrun.

13.7.3.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

13.7.3.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

13.7.3.7.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

13.7.3.7.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

13.7.3.7.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels repeat the last valid word read from the transmit FIFO until TCSR[FEF] is cleared and the next transmit frame starts. All enabled transmit FIFOs must be reset and initialized with new data before TCSR[FEF] is cleared.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

The FIFO error flag can generate only an interrupt.

13.7.3.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

13.7.3.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

13.7.4 Memory map and register definition

A read or write access to an address from offset and above will result in a bus error.

I2S memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0 Transmitter is disabled in Debug mode, after completing the current frame. 1 Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 Transmit bit clock is disabled. 1 Transmit bit clock is enabled.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 Transmit underrun not detected. 1 Transmit underrun detected.

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 No enabled transmit FIFO is empty. 1 Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 Transmit FIFO watermark has not been reached. 1 Transmit FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable

Table continues on the next page...

I2Sx_TCSR field descriptions (continued)

Field	Description
	Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

13.7.4.2 SAI Transmit Configuration 1 Register (I2Sx_TCR1)

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_TCR2 field descriptions

Field	Description
31–30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with receiver.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (SAI_RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (SAI_TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (SAI_TX_BCLK) but use the receiver frame sync (SAI_RX_SYNC). 0 Use the normal bit clock source. 1 Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.
27–26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00 Master Clock (MCLK) 1 option selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction

Table continues on the next page...

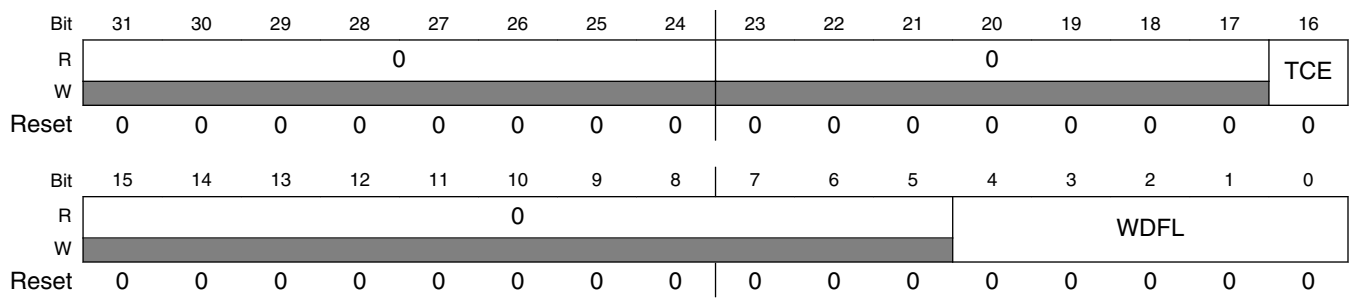
I2Sx_TCR2 field descriptions (continued)

Field	Description
	Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

13.7.4.4 SAI Transmit Configuration 3 Register (I2Sx_TCR3)

This register must not be altered when TCSR[TE] is set.

Address: Base address + Ch offset



I2Sx_TCR3 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. A channel must be enabled before its FIFO is accessed. 0 Transmit data channel N is disabled. 1 Transmit data channel N is enabled.
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
WDFL	Word Flag Configuration

Table continues on the next page...

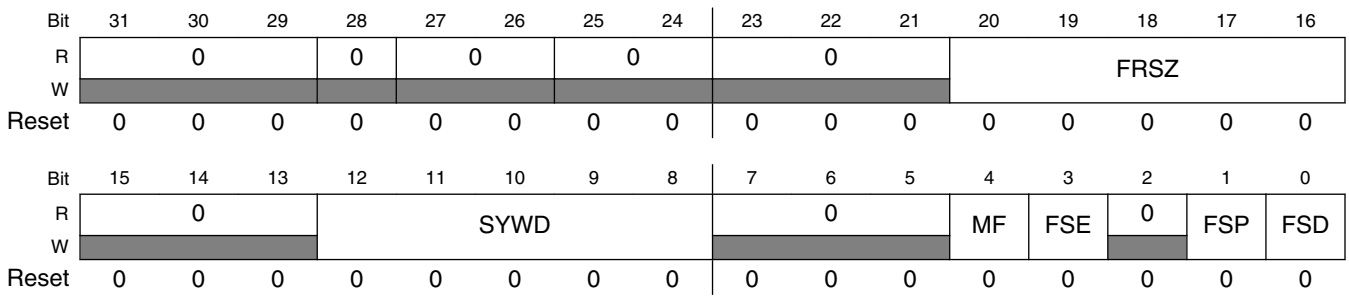
I2Sx_TCR3 field descriptions (continued)

Field	Description
	Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

13.7.4.5 SAI Transmit Configuration 4 Register (I2Sx_TCR4)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 10h offset



I2Sx_TCR4 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

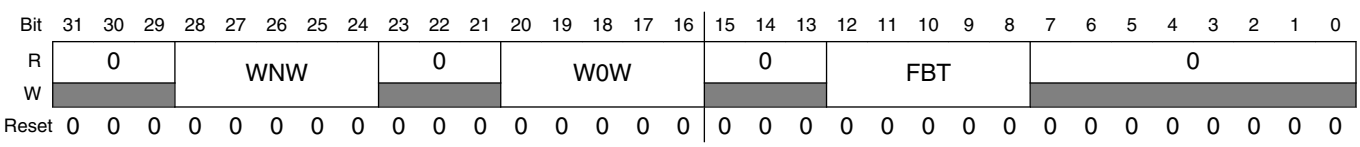
I2Sx_TCR4 field descriptions (continued)

Field	Description
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 LSB is transmitted first. 1 MSB is transmitted first.
3 FSE	Frame Sync Early 0 Frame sync asserts with the first bit of the frame. 1 Frame sync asserts one bit before the first bit of the frame.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 Frame sync is active high. 1 Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 Frame sync is generated externally in Slave mode. 1 Frame sync is generated internally in Master mode.

13.7.4.6 SAI Transmit Configuration 5 Register (I2Sx_TCR5)

This register must not be altered when TCSR[TE] is set.

Address: Base address + 14h offset



I2Sx_TCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

I2Sx_TCR5 field descriptions (continued)

Field	Description
20–16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

13.7.4.7 SAI Transmit Data Register (I2Sx_TDR*n*)

Address: Base address + 20h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																															
W	TDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

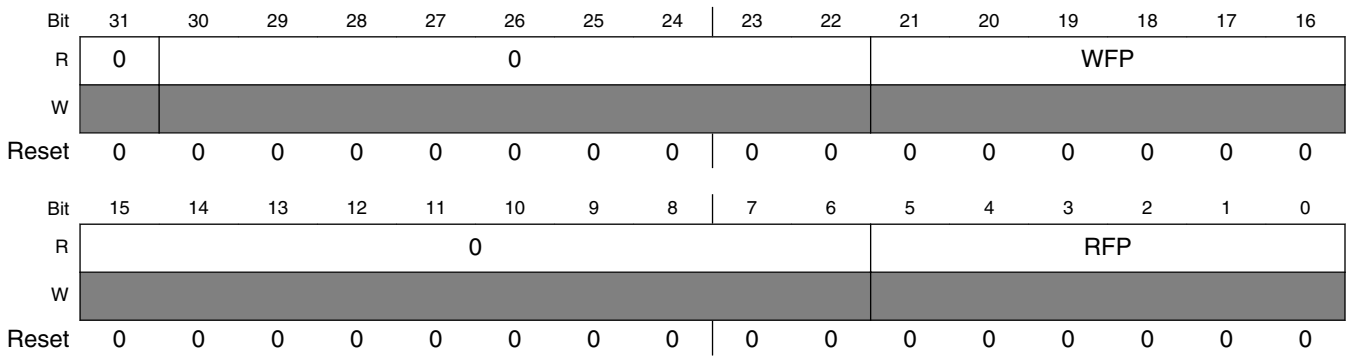
I2Sx_TDR*n* field descriptions

Field	Description
TDR	Transmit Data Register The corresponding TCR3[TCE] bit must be set before accessing the channel's transmit data register. Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

13.7.4.8 SAI Transmit FIFO Register (I2Sx_TFR*n*)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + 40h offset + (4d × i), where i=0d to 0d



I2Sx_TFR*n* field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

13.7.4.9 SAI Transmit Mask Register (I2Sx_TMR)

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

Address: Base address + 60h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_RCSR field descriptions

Field	Description
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0 Receiver is disabled. 1 Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 STOPE	Stop Enable Configures receiver operation in Stop mode. This bit is ignored and the receiver is disabled in all stop modes. 0 Receiver disabled in Stop mode. 1 Receiver enabled in Stop mode.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0 Receiver is disabled in Debug mode, after completing the current frame. 1 Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0 Receive bit clock is disabled. 1 Receive bit clock is enabled.
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 FR	FIFO Reset Resets the FIFO pointers. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0 No effect. 1 FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0 No effect. 1 Software reset.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.

Table continues on the next page...

I2Sx_RCSR field descriptions (continued)

Field	Description
	0 Start of word not detected. 1 Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 Sync error not detected. 1 Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0 Receive overflow not detected. 1 Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0 No enabled receive FIFO is full. 1 Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0 Receive FIFO watermark not reached. 1 Receive FIFO watermark has been reached.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 Disables interrupt. 1 Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 Disables interrupt. 1 Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts.

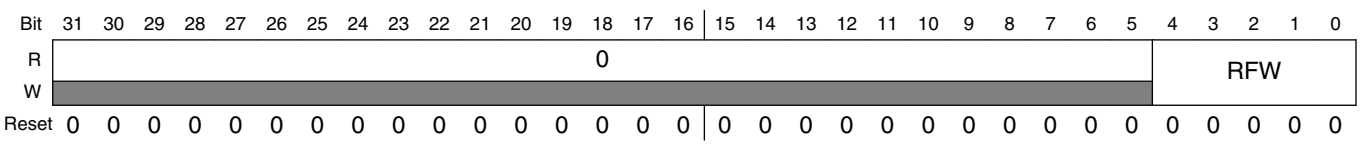
Table continues on the next page...

I2Sx_RCSR field descriptions (continued)

Field	Description
	0 Disables the interrupt. 1 Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 Disables the interrupt. 1 Enables the interrupt.
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 Disables the DMA request. 1 Enables the DMA request.

13.7.4.11 SAI Receive Configuration 1 Register (I2Sx_RCR1)

Address: Base address + 84h offset



I2Sx_RCR1 field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFW	Receive FIFO Watermark Configures the watermark level for all enabled receiver channels.

13.7.4.12 SAI Receive Configuration 2 Register (I2Sx_RCR2)

This register must not be altered when RCSR[RE] is set.

Address: Base address + 88h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

I2Sx_RCR2 field descriptions

Field	Description
31–30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation. 00 Asynchronous mode. 01 Synchronous with transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (SAI_TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (SAI_RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (SAI_RX_BCLK) but use the transmitter frame sync (SAI_TX_SYNC). 0 Use the normal bit clock source. 1 Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock . 0 No effect. 1 Internal logic is clocked as if bit clock was externally generated.
27–26 MSEL	MCLK Select

Table continues on the next page...

I2Sx_RCR2 field descriptions (continued)

Field	Description
	Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00 Bus Clock selected. 01 Master Clock (MCLK) 1 option selected. 10 Master Clock (MCLK) 2 option selected. 11 Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 Bit clock is generated externally in Slave mode. 1 Bit clock is generated internally in Master mode.
23–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.

13.7.4.13 SAI Receive Configuration 3 Register (I2Sx_RCR3)

This register must not be altered when RCSR[RE] is set.

Address: Base address + 8Ch offset

I2Sx_RCR5 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

13.7.4.16 SAI Receive Data Register (I2Sx_RDR*n*)

Reading this register introduces one additional peripheral clock wait state on each read.

Address: Base address + A0h offset + (4d × i), where i=0d to 0d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

I2Sx_RDRn field descriptions

Field	Description
RDR	Receive Data Register The corresponding RCR3[RCE] bit must be set before accessing the channel's receive data register. Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

13.7.4.17 SAI Receive FIFO Register (I2Sx_RFRn)

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

Address: Base address + C0h offset + (4d × i), where i=0d to 0d

I2Sx_RFRn field descriptions

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 WFP	Write FIFO Pointer FIFO write pointer for receive data channel.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

13.7.4.18 SAI Receive Mask Register (I2Sx_RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

Address: Base address + E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RWM																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Sx_RMR field descriptions

Field	Description
RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0 Word N is enabled. 1 Word N is masked.

13.8 Medium Quality Sound (MQS)

13.8.1 Overview

Medium quality sound (MQS) is used to generate medium quality audio via a standard GPIO in the pinmux, allowing the user to connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

MQS accepts 2-channel, LSB-valid 16bit, MSB shift-out first; frame sync asserting with the first bit of the frame, data shifted with the posedge of bit clock, 44.1 kHz or 48 kHz signals from SAI1 in left_justified format; and it provides the SNR target as no more than 20dB for the signals below 10 kHz. The signals above 10 kHz will have worse THD+N values.

MQS provides only simple audio reproduction. No internal pop, click or distortion artifact reduction methods are provided.

13.8.2 Block Diagram

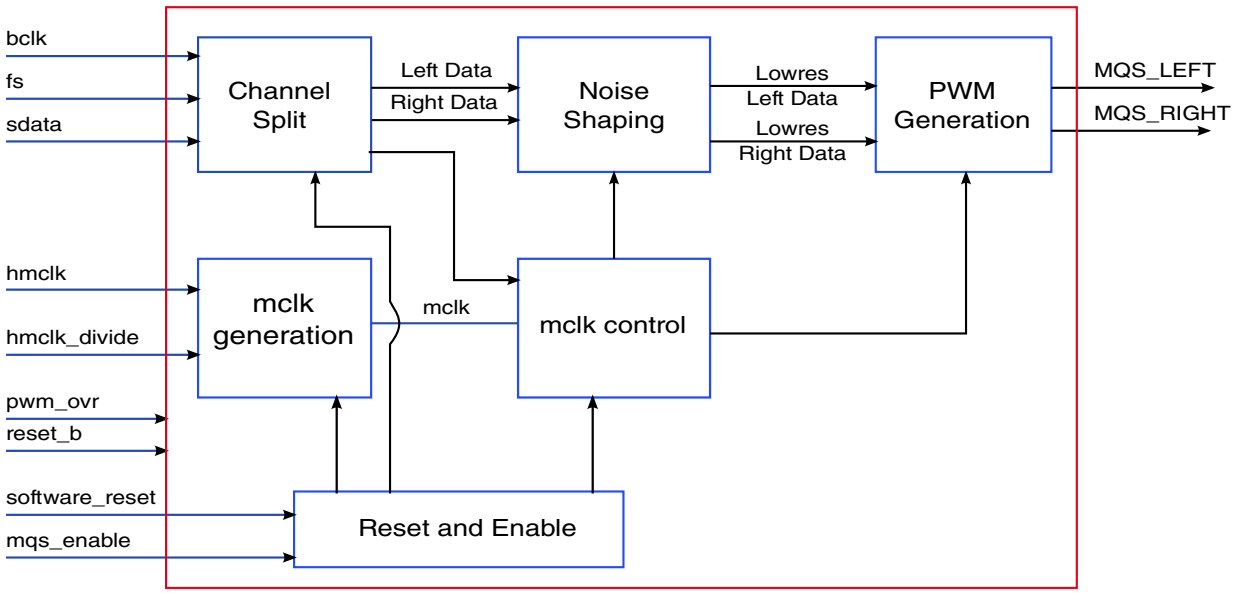

Figure 13-104. Block Diagram

MQS has the following sub-modules:

1. Channel Split: Splits the I2S signals into separate left channel and right channel audio data.
2. Noise Shaping: Uses the sigma-delta algorithm to generate low-resolution, very high sampling audio, while the audio sampling rate is increased.
3. PWM generation: Generates the bit stream to the GPIO, which is then used to drive the amplifier and then to drive the external speakers or headphones.
4. mclk generation: Used to generate the master clock (mclk). The frequency of mclk is determined by the final bit duration of PWM generation module.
5. mclk control:Used as a metronome to co-ordinate the different functional blocks working synchronously.
6. Reset and Enable: Used to generate the reset and enable logic to different clock domains.

13.8.3 External Signals

The following table describes the external signals of MQS:

Table 13-41. MQS External Signals

Signal	Description	Pad	Mode	Direction
MQS_LEFT	Left signal output	SAI1_RXC	ALT6	O
		SD2_CMD	ALT2	

Table continues on the next page...

Table 13-41. MQS External Signals (continued)

Signal	Description	Pad	Mode	Direction
MQS_RIGHT	Right signal output	SAI1_RXFS	ALT6	O
		SD2_CLK	ALT2	

13.8.4 Programmability

MQS has no internal programmable registers. But it does have some programmability from IOMUXC_GPR2.

Register Bits	Name	Description
IOMUXC_GPR2[26]	MQS_OVERSAMPLE	Used to control the PWM oversampling rate compared with mclk. 1—64, 0—32.
IOMUXC_GPR2[25]	MQS_EN	MQS enable. 1—Enable MQS, 0—Disable MQS
IOMUXC_GPR2[24]	MQS_SW_RST	MQS software reset. 1—Enable software reset for MQS 0—Exit software reset for MQS
IOMUXC_GPR2[23:16]	MQS_CLK_DIV[7:0]	Divider ration control for mclk from hmclk. 0—mclk frequency = hmclk frequency; 1—mclk frequency = ½*hmclk frequency; 2—mclk frequency = 1/3*hmclk frequency; …; n—mclk frequency = 1/(n+1)*hmclk frequency

13.8.5 Usage Model

The user needs to program SAI1 to output 2-channel LSB-16bit active left justified signal, and then to program the related IOMUXC_GPR2 bits.

Due to the different devices connected to MQS, and different high frequency behaviors of the connected analog circuits, customer need choose the appropriate MQS_CLK_DIV and MQS_OVERSAMPLE values for the best audible effects.

Chapter 14
ADC and Temperature Monitor

14.1 Analog-to-Digital Converter (ADC)

14.1.1 Overview

This block guide introduces the analog-to-digital converter (ADC). It discusses the architecture, functions and operating modes.

ADC is a 1.8 V 12-bit ADC with 16 channels analog input MUX and level-shifters for low-voltage digital interface. ADC supports conversion up to five logic groups (ChA / ChB / ChC / ChD / SW). Each group can select one channel from 0 - 15 physical channels.

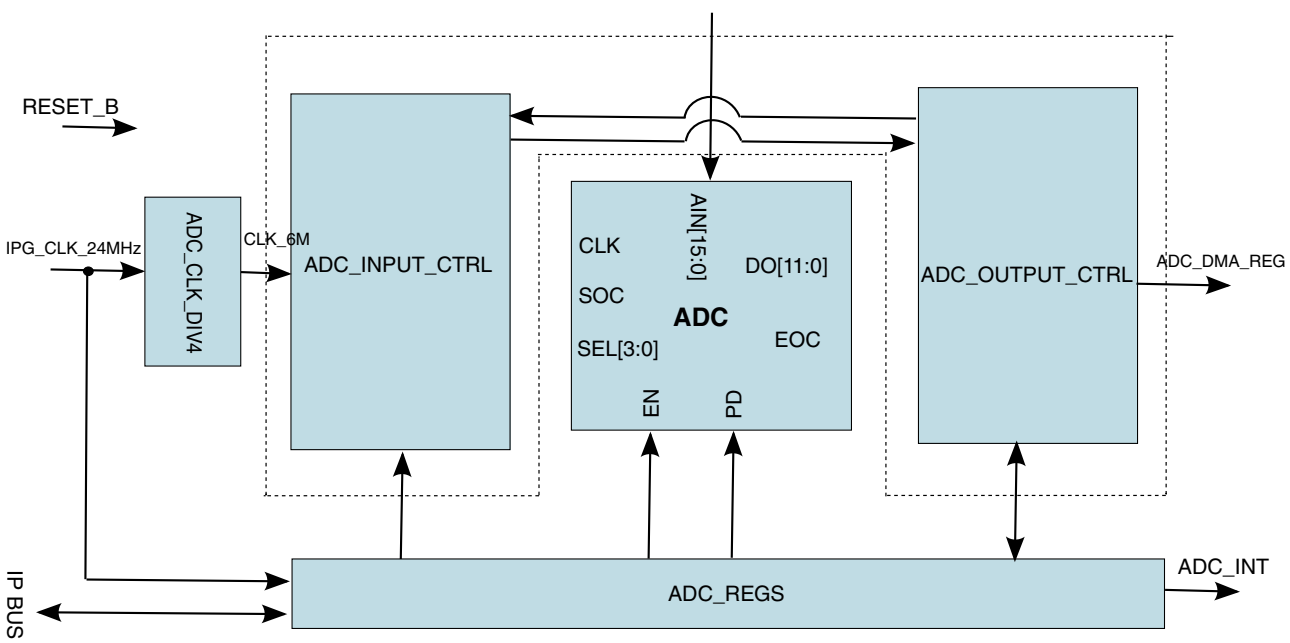

Figure 14-1. ADC Wrapper Hierarchy

14.1.1.1 Feature

The following list summarizes the key features of the ADC:

- Support up to 16 analog inputs
- Support five conversion pairs, can work simultaneously, with different conversion priority.
- Word size is 12-bits.
- Support Single and Continue conversion.
- Support Compare mode and channel auto disable if data match the requirement.
- Support Average conversion, Support flexible 4, 8, 16, 32 number of conversion data.
- Configurable sample time and conversion speed / power. The ADC core clock can vary from 300 kHz to 6 MHz, and the maximum sample rate is 1/6 ADC core clock.
- Conversion complete, hardware average complete, compare, DMA, time out flag and interrupt.
- Automatic compare with interrupt for less than, greater than, and equal to, within range, or out-of-range, programmable value.

14.1.2 Operation mode (ADC enable or disable)

By default, the ADC is in Disabled mode. In this state, no conversion or other actions occur. All of the ADC control registers are accessible in this state through an access bus interface. To enable the ADC, required configurations must be completed by programming the ADC configuration registers.

14.1.3 External signal description

The following table describes the external signals of ADC:

Table 14-1. ADC External Signals

Signal	Description	Pad	Mode	Direction
ADC1_IN0	Analog channel 1 input 0	ADC1_IN0	No muxing	I
ADC1_IN1	Analog channel 1 input 1	ADC1_IN1	No muxing	I
ADC1_IN2	Analog channel 1 input 2	ADC1_IN2	No muxing	I
ADC1_IN3	Analog channel 1 input 3	ADC1_IN3	No muxing	I
ADC1_VREFH	Voltage reference high	ADC1_VREFH	No muxing	I
ADC1_VREFL	Voltage reference low	ADC1_VREFL	No muxing	I

Table continues on the next page...

Table 14-1. ADC External Signals (continued)

Signal	Description	Pad	Mode	Direction
ADC2_IN0	Analog channel 2 input 0	ADC2_IN0	No muxing	I
ADC2_IN1	Analog channel 2 input 1	ADC2_IN1	No muxing	I
ADC2_IN2	Analog channel 2 input 2	ADC2_IN2	No muxing	I
ADC2_IN3	Analog channel 2 input 3	ADC2_IN3	No muxing	I
ADC2_VREFH	Voltage reference high	ADC2_VREFH	No muxing	I
ADC2_VREFL	Voltage reference low	ADC2_VREFL	No muxing	I

14.1.4 Clocks and timing

The following table describes the clock sources of ADC.

Table 14-2. ADC Clock Sources

Clock Name	Description
IPG_CLK_24MHZ	Global clock
IPG_CLK_24MHZ_S	Peripheral access clock

IPG_CLK_24MHZ can be divided by 4, 8, 16, 32, 64 or 128. Using the PRE_DIV bits to obtain the ADC analogue core clock. The ADC analogue core clock is vary from 300 kHz to 6 MHz.

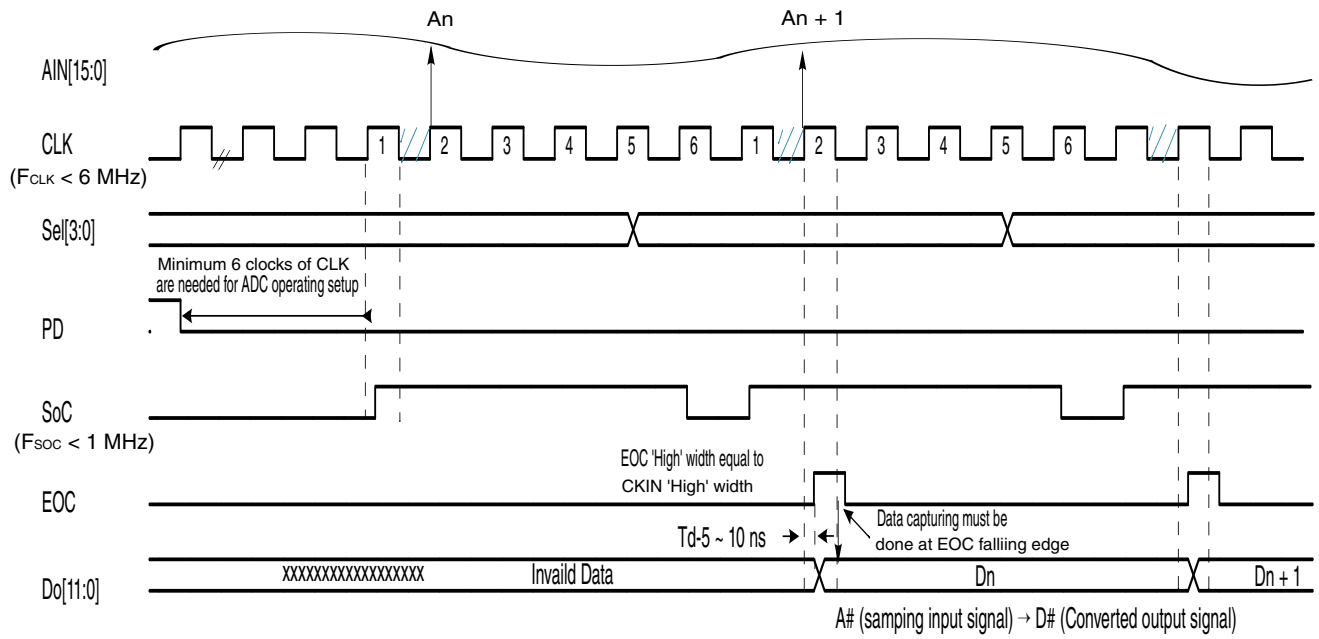

Figure 14-2. Timing

14.1.5 Functional description

This section provides a complete functional description of the ADC block.

14.1.5.1 Data FIFO

The size of ADC FIFO is 32 × 32-bit. The FIFO data are accessed by using the ADC FIFO Data Registers. Each data in the FIFO contains two ADC conversion data; each data is right aligned within the 12-bit wide.

When writing FIFO with an odd number of data, 0x0fff will be written into FIFO[31:16].

Table 14-3. Data FIFO

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

14.1.5.1.1 FIFO pointers

When writing of data into DMA_FIFO_DAT, the FIFO pointer increments one after every two valid write. Writing data of the DMA_FIFO_DAT will be ignored if FIFO is full.

When reading data from DMA_FIFO_DAT, the read FIFO pointer increments after each valid read. Reads from DMA_FIFO_DAT will be ignored if the FIFO is empty.

14.1.5.2 Interrupts and DMA requests

ADC generates interrupts or DMA requests when meet corresponding condition.

14.1.5.2.1 DMA requests

Only one channel can use DMA at a time. When more than one channel is enabled, it will be determined by its priority.

When the number of entries of ADC FIFO is less than or equal to the transmit FIFO watermark configuration, DMA request is generated. When the number of entries of FIFO is greater than FIFO watermark configuration, DMA request is cleared.

14.1.5.2.2 Flag and interrupt

Compare Flag

if enable the compare flag, the compare flag is set when conversion result matches the compare region. If enable compare interrupt, corresponding interrupt is generated.

Conversion Flag

If enable conversion flag, the Conversion Flag is set when one ADC conversion completed. If enable conversion interrupt, corresponding interrupt is generated.

Time Out Flag

If enable time out flag, the time out flag is set when conversion time out. If enable time out interrupt, corresponding interrupt is generated.

FIFO Overrun and Underrun

If enable fifo overrun or underrun flag, the fifo overrun or underrun flag is set when fifo overrun or underrun happens. If enable fifo overrun or underrun interrupt, corresponding interrupt is set.

14.1.5.2.3 Operating modes

Different modes can be programmed by several bits in the ADC register.

14.1.5.2.3.1 Single conversion

In Single conversion, ADC only starts a single conversion for enable channel. It stops when one conversion is finished.

14.1.5.2.3.2 Continue conversion

If continuous conversion is enabled, a new conversion is automatically initiated after the completion of the current conversion.

14.1.5.2.3.3 Average conversion

The hardware average function can be enabled (CH*_AVG_EN = 1) to perform a hardware average of multiple conversions. The number of conversions is determined by the CH*_AVG_NUMBER bit, which can average 4, 8, 16 or 32 conversions. If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions is completed.

If continuous conversion is also enabled, a new set of conversions (to be averaged) are initiated following the last of the selected number of conversions.

14.1.5.2.3.4 Compare mode

The compare function can be configured to check the result is less than, greater than, or equal to a single compare value, as well as the result falls within or outside a range determined by two compare values. The compare modes is determined by CH*_CMP_MODE. In compare mode, once one conversion is finished. ADC compares conversion with LOW_THRES and HIGH_THRES value to check whether the conversion result meet the requirement.

The following table shows six kinds of compare modes.

Table 14-4. Compare Modes

CH_*_CFG[31:29]	Compare Mode
X00	Disable compare
001	Compare true if the result is greater than **CHC_LOW_THRES**

Table continues on the next page...

Table 14-4. Compare Modes (continued)

CH_*_CFG[31:29]	Compare Mode
010	Compare true if the result is less than or equal to **CHC_LOW_THRES**
011	Compare true if the result is greater than **CHC_LOW_THRES** and less than **CHC_HIGH_THRES**
101	Compare true if the result is greater than or equal to **CHC_HIGH_THRES**
110	Compare true if the result is less than **CHC_HIGH_THRES**
111	Compare true if the result is less than or equal to **CHC_LOW_THRES**, or Compare true if the result is greater than or equal to **CHC_HIGH_THRES**

If compare mode and auto disable are enabled, the compare condition true can result in conversions discarded or conversion auto disabled.

14.1.5.2.3.5 Priority

When chA / chB / chC / chD / SW are all enabled, conflict may happen. To avoid this issue, ADC introduces priority mechanism. If chA / chB / chC / chD / SW start a conversion at the same time, chA will convert firstly, then ChB, ChC, chD, and SW at last. In worst condition, channel A blocks all chB / chC / chD / SW conversions.

The following table shows the priorities used in the conversion.

Table 14-5. Priority

Priority	Description
Highest	chA conversion
	chB conversion
	chC conversion
	chD conversion
Lowest	SW conversion

When ADC runs in Average and Priority mode simultaneously, ADC firstly consider the periodic, and then average time. When surplus timer between two chA conversion cannot complete a chB conversion, chB is blocked.

The same situation applies to other channels.

Constraints:

1. The conversion period of chA must be greater than total conversion time of chA + chB + chC + chD + SW. The conversion period of chB must be greater than total conversion time of chB + chC + chD + SW. The conversion period of channel with high priority must greater than total conversion time of low priority.

14.1.6 ADC Memory Map/Register Definition

ADC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3061_0000	Channel A configuration 1 (ADC1_CH_A_CFG1)	32	R/W	0000_0000h	14.1.6.1/ 4134

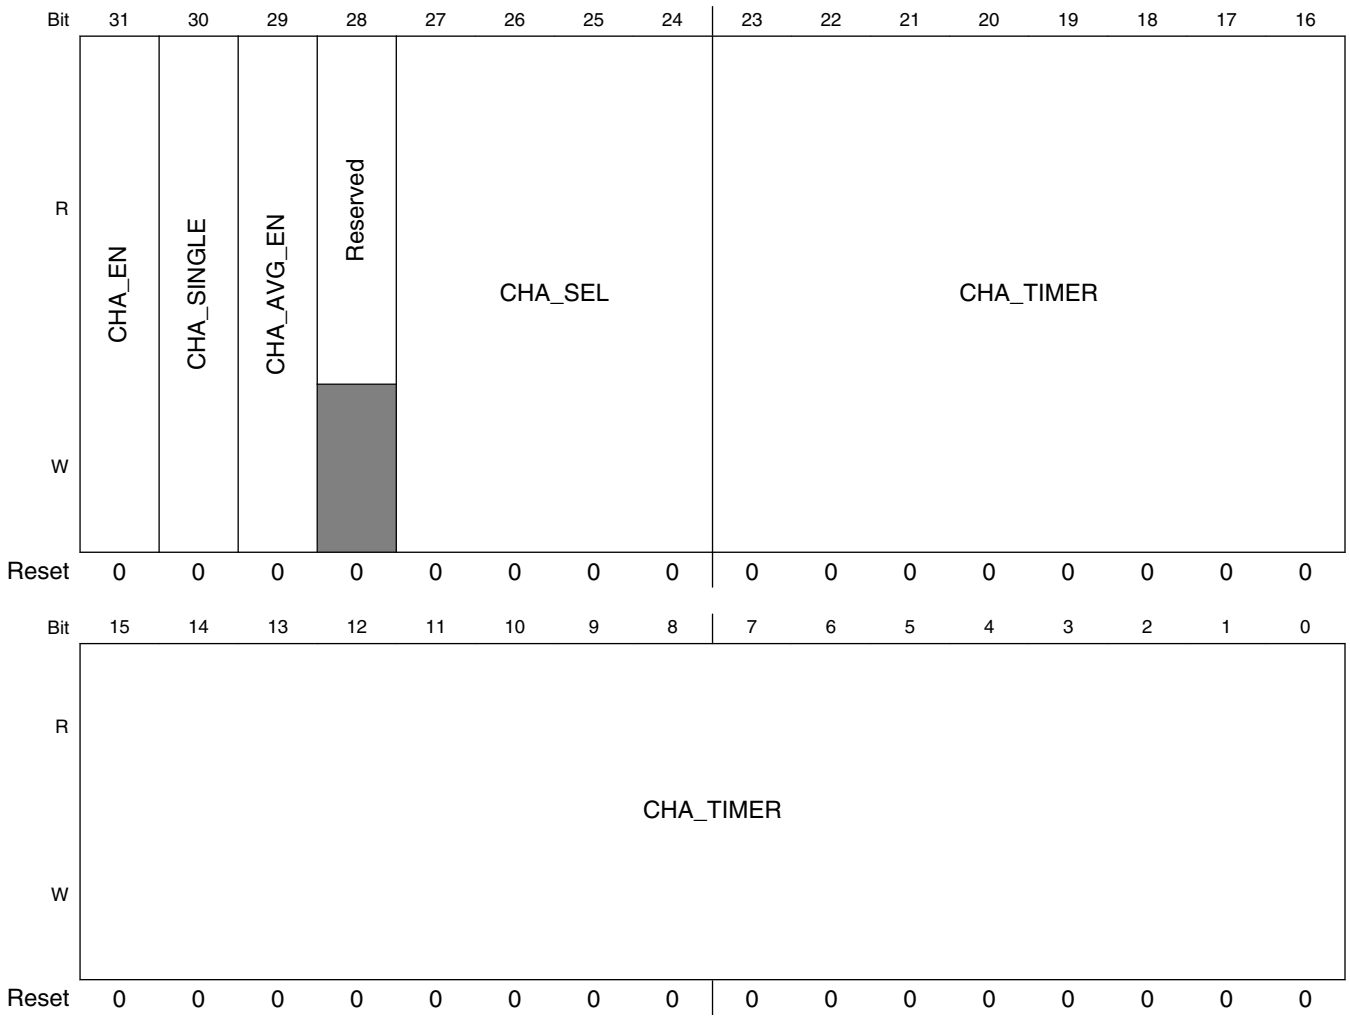
14.1.6.1 Channel A configuration 1 (ADCx_CH_A_CFG1)

CH_A_CFG1 defines the functions of channel A. Channel A has the highest priority of all four channels.

Address: Base address + 0h offset



ADCx_CH_A_CFG1 field descriptions

Field	Description
31 CHA_EN	Channel A Enable This bit controls the working mode of logical channel A. 1 Enable logical channel A. Logical channel A will work. 0 Disable logical channel A. Prevent logical channel A from working.
30 CHA_SINGLE	Channel A Signal Conversion

Table continues on the next page...

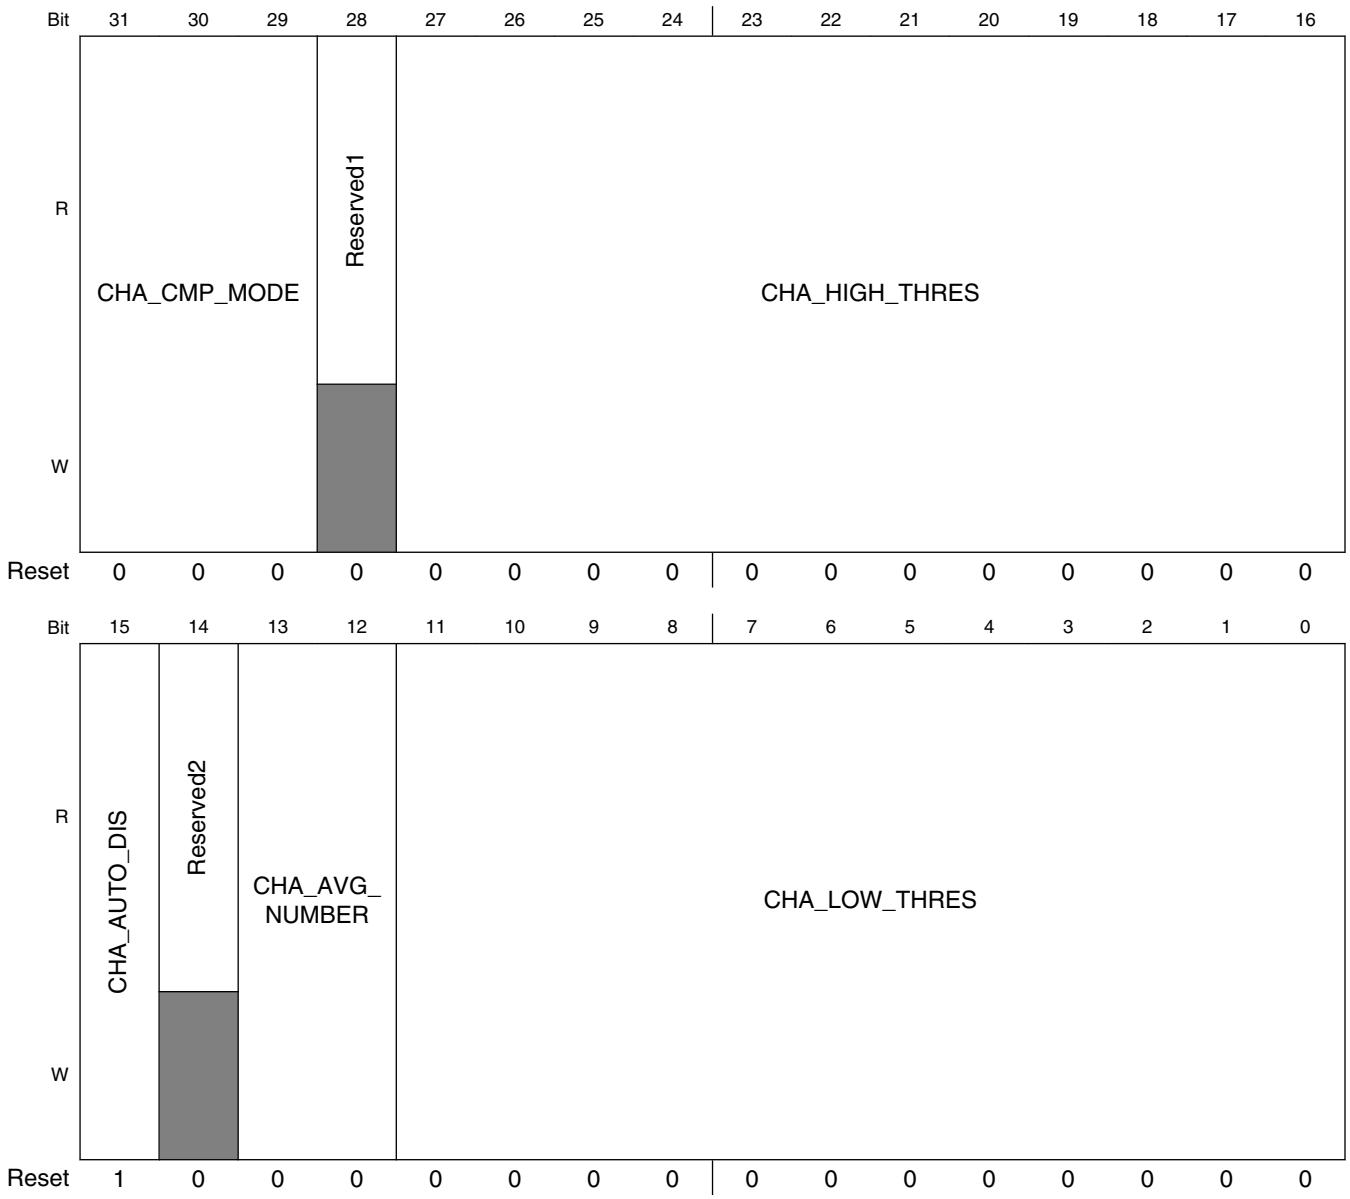
ADCx_CH_A_CFG1 field descriptions (continued)

Field	Description
	Start a single conversion from logical channel A. Switch between single and continuous conversion, it must disable CHA_EN first. When both CHA_EN and CHA_SINGLE are enabled, CHA_SIGNAL set CHA_EN to 0 and reset itself to 0. 1 Start a single conversion. Continuous conversion must stop. 0 No single conversion. Continuous conversion can start.
29 CHA_AVG_EN	Channel A Average Enable If enable this bit, channel A will do average for each conversion. 1 Enable average function. 0 Disable average function.
28 Reserved	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–24 CHA_SEL	Channel A Select Select input channel (from 16 channels) for the logical channel A. 0000 Channel 0 0001 Channel 1 0010 Channel 2 0011 Channel 3 0100 Channel 4 0101 Channel 5 0110 Channel 6 0111 Channel 7 1000 Channel 8 1001 Channel 9 1010 Channel 10 1011 Channel 11 1100 Channel 12 1101 Channel 13 1110 Channel 14 1111 Channel 15
CHA_TIMER	Channel A Timer This timer is for continuous conversion. The conversion rate = (CHA_TIMER + 1) times sample rate. 0x000 to 0xFFF timer value, every CHA_TIMER + 1 times sample rate, the ADC converts one data.

14.1.6.2 Channel A configuration 2 (ADCx_CH_A_CFG2)

CH_A_CFG2 defines the function of channel A. Channel A has the highest priority of all four channels.

Address: Base address + 10h offset



ADCx_CH_A_CFG2 field descriptions

Field	Description
31–29 CHA_CMP_ MODE	Channel A Compare Mode Select which compare mode the conversion result will take for channel A. X00 Disable compare function.

Table continues on the next page...

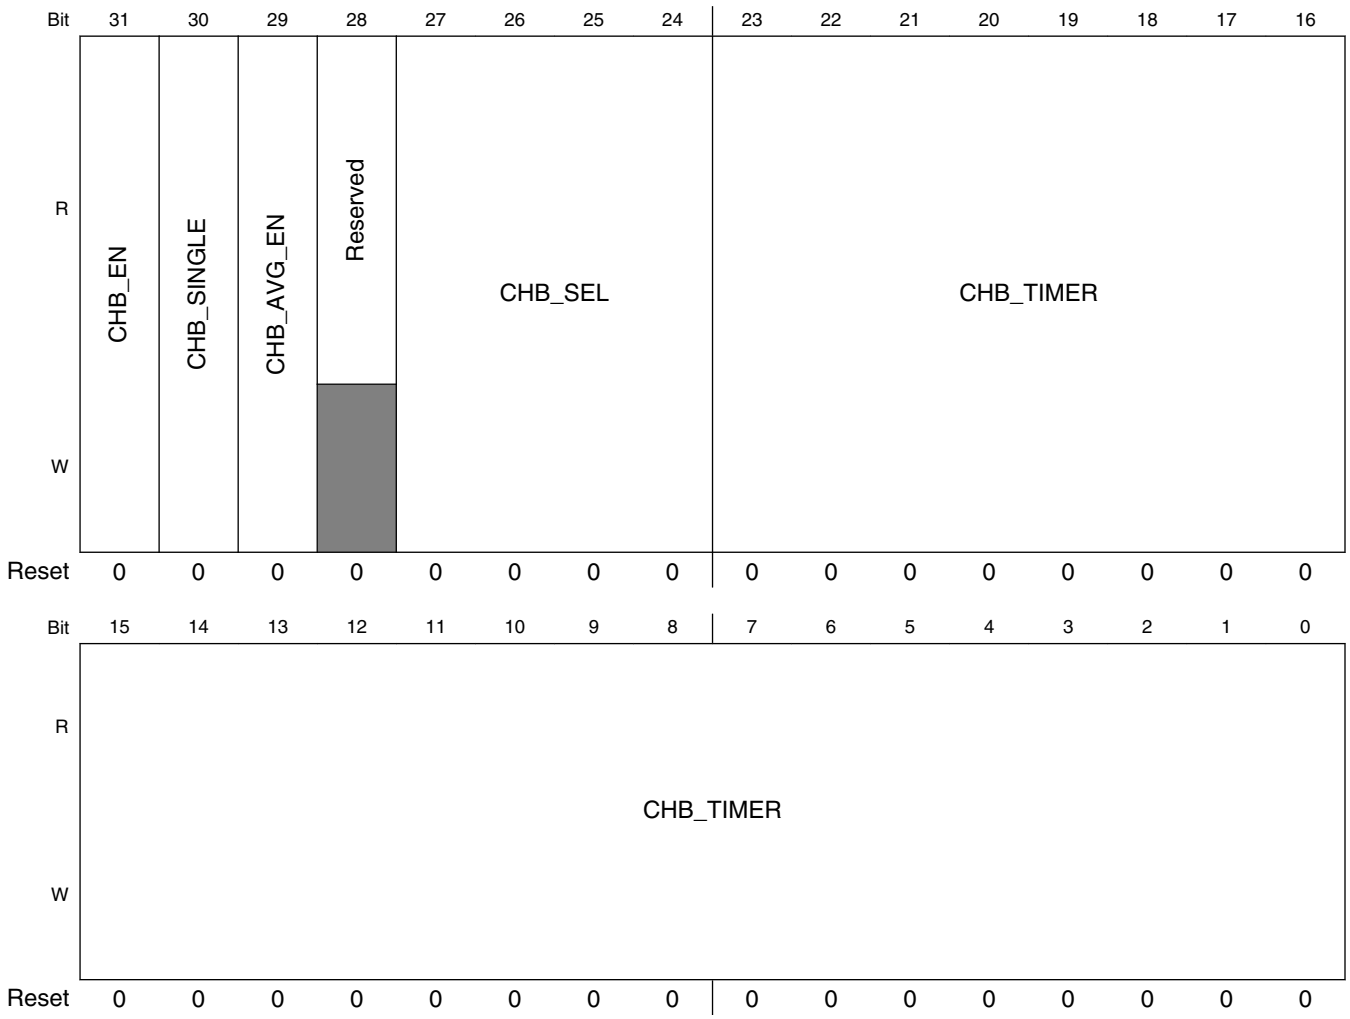
ADCx_CH_A_CFG2 field descriptions (continued)

Field	Description
	001 If channel A conversion result is greater than CHA_LOW_THRES, then an interrupt will be generated and the channel A flag will be set if they are enabled. 010 If channel A conversion result is less than or equal to CHA_LOW_THRES, then an interrupt will be generated and channel A flag will be set if they are enabled. 011 If channel A conversion result is greater than CHA_LOW_THRES and less than CHA_HIGH_THRES, then an interrupt will be generated and channel A flag will be set if they are enabled. 101 If channel A conversion result is greater than or equal to CHA_HIGH_THRES, then an interrupt will be generated and channel A flag will be set if they are enabled. 110 If channel A conversion result is less than CHA_HIGH_THRES, then an interrupt will be generated and channel A flag will be set if they are enabled. 111 If channel A conversion result is less than or equal to CHA_LOW_THRES, and at the same time, greater than or equal to CHA_HIGH_THRES, then an interrupt will be generated and channel A flag will be set if they are enabled.
28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–16 CHA_HIGH_ THRES	Channel A High Threshold Value Contains the high compare value to compare with the conversion result when a compare mode has been selected.
15 CHA_AUTO_DIS	Channel A Auto Disable During continuous conversion, if compare match a converted result, the ADC checks this bit. If CHA_AUTO_DIS = 1, then channel A stops continuous conversion, if CHA_AUTO_DIS = 0, then channel A keeps continuous working, and the conversion result overwrites the result registers. The default value is 1.
14 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13–12 CHA_AVG_ NUMBER	Channel A Average Number If enable average function, this bit contains channel A average number. 00 Average number = 4 01 Average number = 8 10 Average number = 16 11 Average number = 32
CHA_LOW_ THRES	Channel A Low Threshold Value Contains the lower compare value to compare with the conversion result when a compare mode has been selected.

14.1.6.3 ADCx_CH_B_CFG1

CH_B_CFG1 defines the functions of channel B. Channel B has the second highest priority of all four channels.

Address: Base address + 20h offset



ADCx_CH_B_CFG1 field descriptions

Field	Description
31 CHB_EN	Channel B Enable Controls the usable of logical channel B. 1 Enable logical channel B. Logical channel B will work. 0 Disable logical channel B. Prevent logical channel B from working.
30 CHB_SINGLE	Channel B Single Conversion

Table continues on the next page...

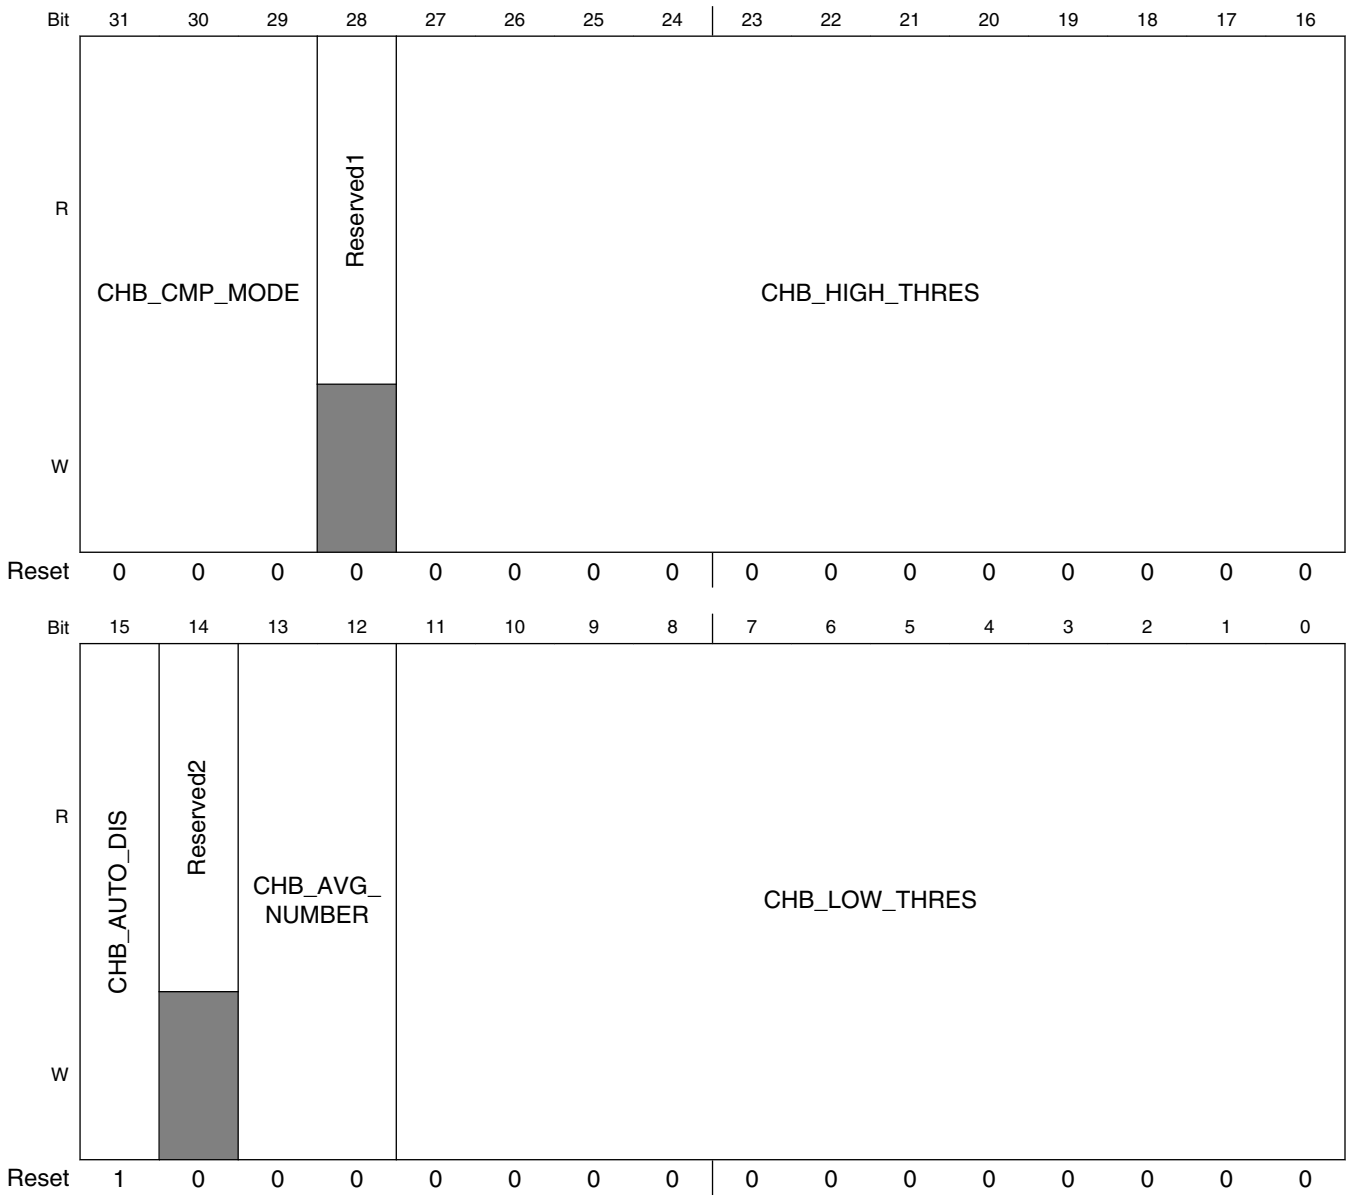
ADCx_CH_B_CFG1 field descriptions (continued)

Field	Description
	Start a single conversion from logical channel B. Switch between single and continuous conversion, it must disable CHB_EN first. When both CHB_EN and CHB_SINGLE are enabled, CHB_SIGNAL set CHB_EN to 0 and reset itself to 0. 1 Start a single conversion. Continuous conversion must stop. 0 No single conversion. Continuous conversion can start.
29 CHB_AVG_EN	Channel B Average Enable If enable this bit, channel B will do average for each conversion. 1 Enable average function. 0 Disable average function.
28 Reserved	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–24 CHB_SEL	Channel B Select Select input channel (from 16 channels) for the logical channel B. 0000 Channel 0 0001 Channel 1 0010 Channel 2 0011 Channel 3 0100 Channel 4 0101 Channel 5 0110 Channel 6 0111 Channel 7 1000 Channel 8 1001 Channel 9 1010 Channel 10 1011 Channel 11 1100 Channel 12 1101 Channel 13 1110 Channel 14 1111 Channel 15
CHB_TIMER	Channel B Timer This timer is for continuous conversion. The conversion rate = (CHB_TIMER + 1) times sample rate + offset. Offset is due to channel B obtains lower priority than channel A. In worst condition, all channel B's conversions are blocked by channel A's. 0x000 to 0xFFF timer value, every CHB_TIMER + 1 times sample rate + offset, the ADC converts one data.

14.1.6.4 Channel B Configuration 2 (ADCx_CH_B_CFG2)

CH_B_CFG2 defines the functions of channel B. Channel B has the second highest priority of all four channels.

Address: Base address + 30h offset



ADCx_CH_B_CFG2 field descriptions

Field	Description
31–29 CHB_CMP_ MODE	Channel B Compare Mode Select which compare mode the conversion result will take for channel B. X00 Disable compare function

Table continues on the next page...

ADCx_CH_B_CFG2 field descriptions (continued)

Field	Description
	001 If channel B conversion result is greater than CHB_LOW_THRES, then an interrupt will be generated and the channel B flag will be set if they are enabled. 010 If channel B conversion result is less than or equal to CHB_LOW_THRES, then an interrupt will be generated and channel B flag will be set if they are enabled. 011 If channel B conversion result is greater than CHB_LOW_THRES and less than CHB_HIGH_THRES, then an interrupt will be generated and channel B flag will be set if they are enabled. 101 If channel B conversion result is greater than or equal to CHB_HIGH_THRES, then an interrupt will be generated and channel B flag will be set if they are enabled. 110 If channel B conversion result is less than CHB_HIGH_THRES, then an interrupt will be generated and channel B flag will be set if they are enabled. 111 If channel B conversion result is less than or equal to CHB_LOW_THRES, and at the same time, is greater than or equal to CHB_HIGH_THRES, then an interrupt will be generated and channel B flag will be set.
28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–16 CHB_HIGH_ THRES	Channel B High Threshold Value Contains the bigger compare value to compare with the conversion result when a compare mode has been selected.
15 CHB_AUTO_DIS	Channel B Auto Disable During continuous conversion, if compare match a converted result, the ADC checks this bit. If CHB_AUTO_DIS = 1, then channel B stops continuous conversion, if CHB_AUTO_DIS = 0, then channel B keeps continuous working, and the conversion result overwrites the result registers. The default value is 1.
14 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13–12 CHB_AVG_ NUMBER	Channel B Average Number If enable average function, this bit contains channel B average number. 00 Average number = 4 01 Average number = 8 10 Average number = 16 11 Average number = 32
CHB_LOW_ THRES	Channel B Low Threshold Value Contains the smaller compare value to compare with the conversion result when a compare mode has been selected.

14.1.6.5 Channel C Configuration 1 (ADCx_CH_C_CFG1)

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CHC_EN	CHC_SINGLE	CHC_AVG_EN	Reserved	CHC_SEL				CHC_TIMER

R	CHC_TIMER															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADCx_CH_C_CFG1 field descriptions

Field	Description
31 CHC_EN	Channel C Enable Controls the usable of logical channel C. 1 Enable logical channel C. Logical channel C will work. 0 Disable logical channel C. Prevent logical channel C from working.
30 CHC_SINGLE	Channel C Single Conversion Start a single conversion from logical channel C. Switch between single and continuous conversion, it must disable CHC_EN. When both CHC_EN and CHC_SINGLE are enabled, CHC_SIGNAL set CHC_EN to 0 and reset itself to 0. Controls the usable of logical channel C. 1 Start a single conversion. Continuous conversion must stop. 0 No single conversion. Continuous conversion can start.
29 CHC_AVG_EN	Channel C Average Enable If enable this bit, channel C will do average for each conversion. 1 Enable average function. 0 Disable average function.
28 Reserved	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–24 CHC_SEL	Channel C Select Select input channel (from 16 channels) for the logical channel C.

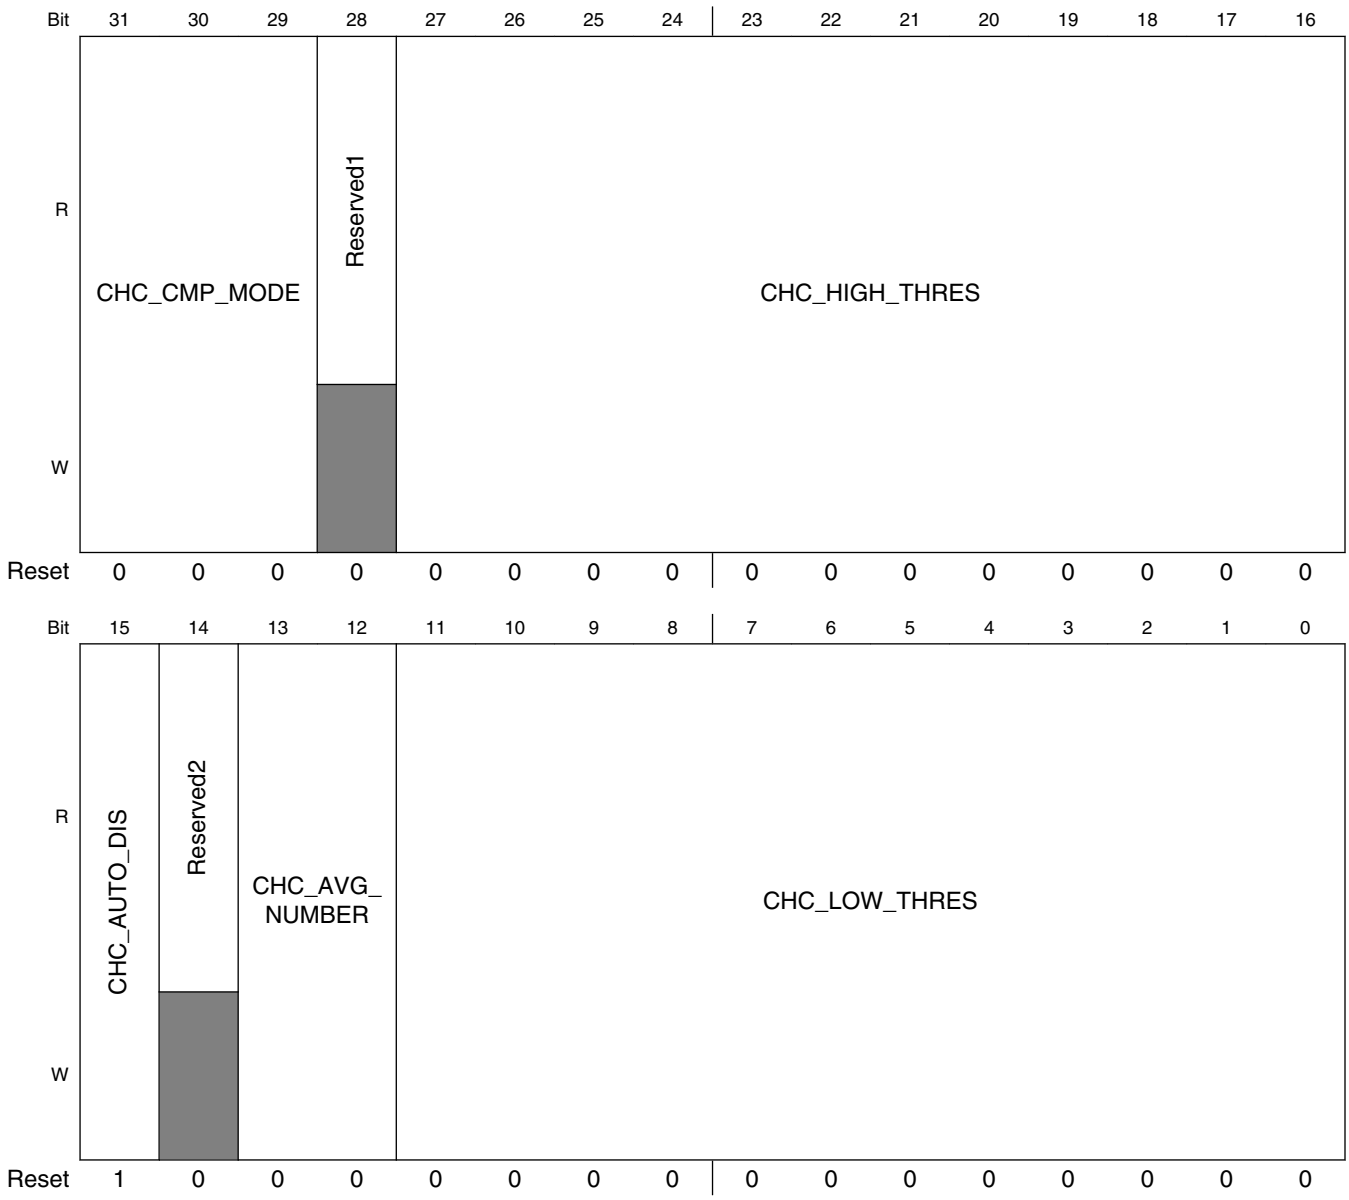
Table continues on the next page...

ADCx_CH_C_CFG1 field descriptions (continued)

Field	Description
	0000 Channel 0 0001 Channel 1 0010 Channel 2 0011 Channel 3 0100 Channel 4 0101 Channel 5 0110 Channel 6 0111 Channel 7 1000 Channel 8 1001 Channel 9 1010 Channel 10 1011 Channel 11 1100 Channel 12 1101 Channel 13 1110 Channel 14 1111 Channel 15
CHC_TIMER	Channel C Timer This timer is for continuous conversion. The conversion rate = (CHC_TIMER + 1) times sample rate + offset. The offset is due to channel C has lower priority than channel A and channel B. In worst condition, all channel C conversions are blocked by channel A and channel B's. 0x000 to 0xFFF timer value, every CHC_TIMER + 1 times sample rate + offset, the ADC converts one data.

14.1.6.6 Channel C Configuration 2 (ADCx_CH_C_CFG2)

Address: Base address + 50h offset



ADCx_CH_C_CFG2 field descriptions

Field	Description
31–29 CHC_CMP_ MODE	Channel C Compare Mode Select which compare mode the conversion result will take (for channel C). X00 Disable compare function. 001 If channel C conversion result bigger than CHC_LOW_THRES, then an interrupt will be generated and the channel C flag will be set if they are enabled.

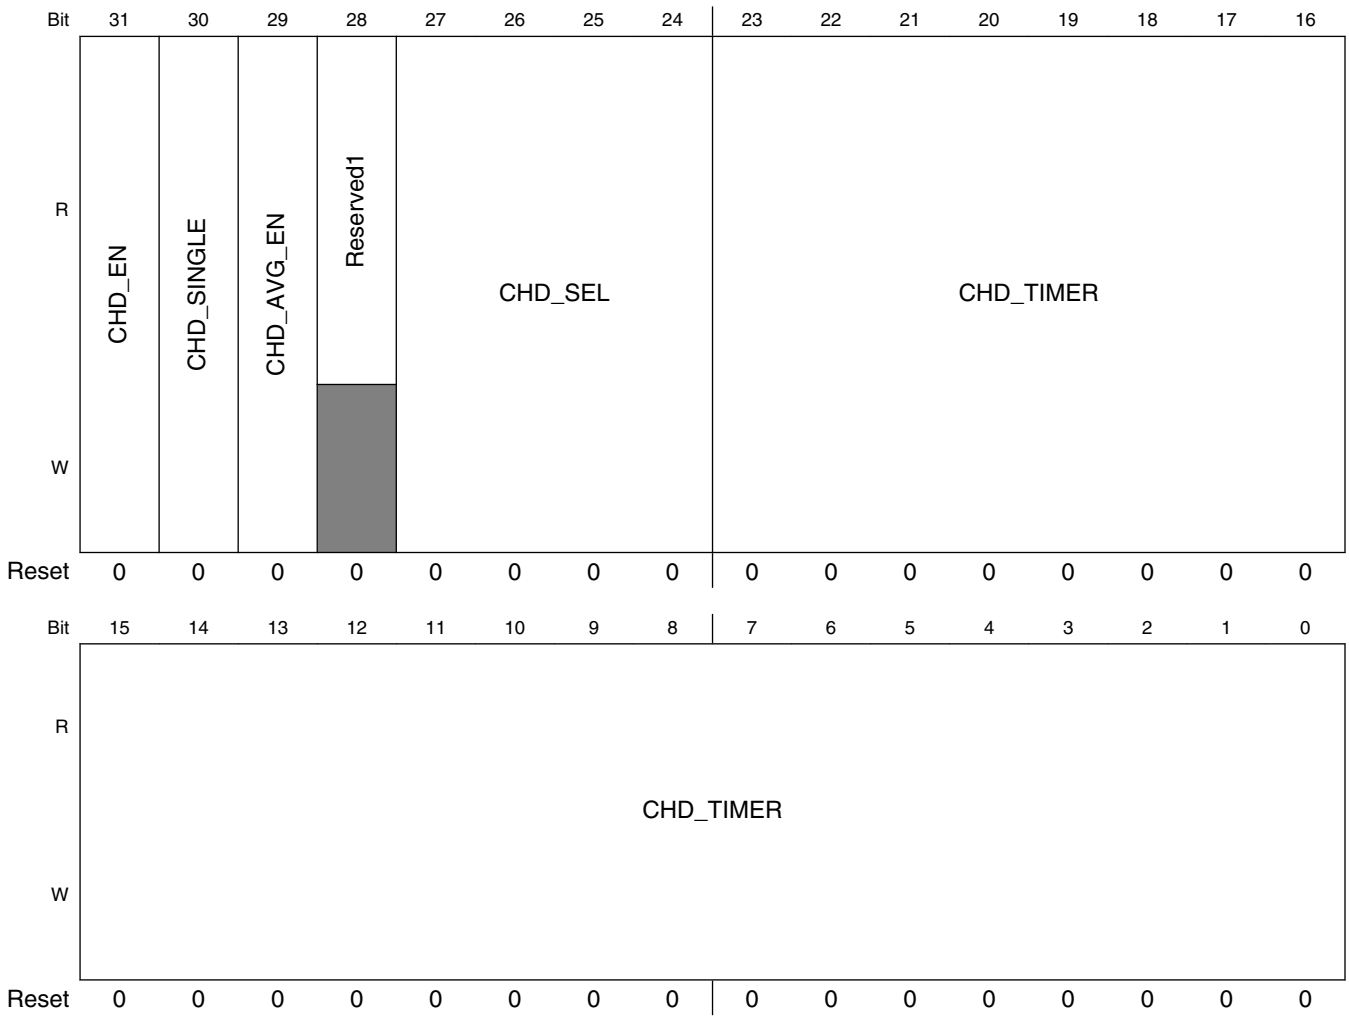
Table continues on the next page...

ADCx_CH_C_CFG2 field descriptions (continued)

Field	Description
	010 If channel C conversion result smaller or equal to CHC_LOW_THRES, then an interrupt will be generated and channel C flag will be set if they are enabled. 011 If channel C conversion result bigger than CHC_LOW_THRES and smaller than CHC_HIGH_THRES, then an interrupt will be generated and channel C flag will be set if they are enabled. 101 If channel C conversion result bigger or equal to CHC_HIGH_THRES, then an interrupt will be generated and channel C flag will be set if they are enabled. 110 If channel C conversion result smaller than CHC_HIGH_THRES, then an interrupt will be generated and channel C flag will be set if they are enabled. 111 If channel C conversion result smaller or equal to CHC_LOW_THRES, and at the same time, bigger or equal to CHC_HIGH_THRES, then an interrupt will be generated and channel C flag will be set if they are enabled.
28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–16 CHC_HIGH_ THRES	Channel C High Threshold Value Contains the bigger compare value to compare with the conversion result when a compare mode has been selected.
15 CHC_AUTO_DIS	Channel C Auto Disable During continuous conversion, if compare match a converted result, the ADC checks this bit. If CHC_AUTO_DIS = 1, then channel C stops continuous conversion, if CHC_AUTO_DIS = 0, then channel C keeps continuous working, and the conversion result overwrites the result registers. The default value is 1.
14 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13–12 CHC_AVG_ NUMBER	Channel C Average Number If enable average function, this bit contains channel C average number. 00 Average number = 4 01 Average number = 8 10 Average number = 16 11 Average number = 32
CHC_LOW_ THRES	Channel C Low Threshold Value Contains the smaller compare value to compare with the conversion result when a compare mode has been selected.

14.1.6.7 Channel D Configuration 1 (ADCx_CH_D_CFG1)

Address: Base address + 60h offset



ADCx_CH_D_CFG1 field descriptions

Field	Description
31 CHD_EN	Channel D Enable Controls the usable of logical channel D. 1 Enable logical channel D. Logical channel D will work. 0 Disable logical channel D. Prevent logical channel D from working.
30 CHD_SINGLE	Channel D Single Conversion Start a single conversion from logical channel D. Switch between single and continuous conversion, it must disable channel D first. When both CHD_EN and CHD_SINGLE are enabled, CHD_SIGNAL set CHD_EN to 0 and reset itself to 0.

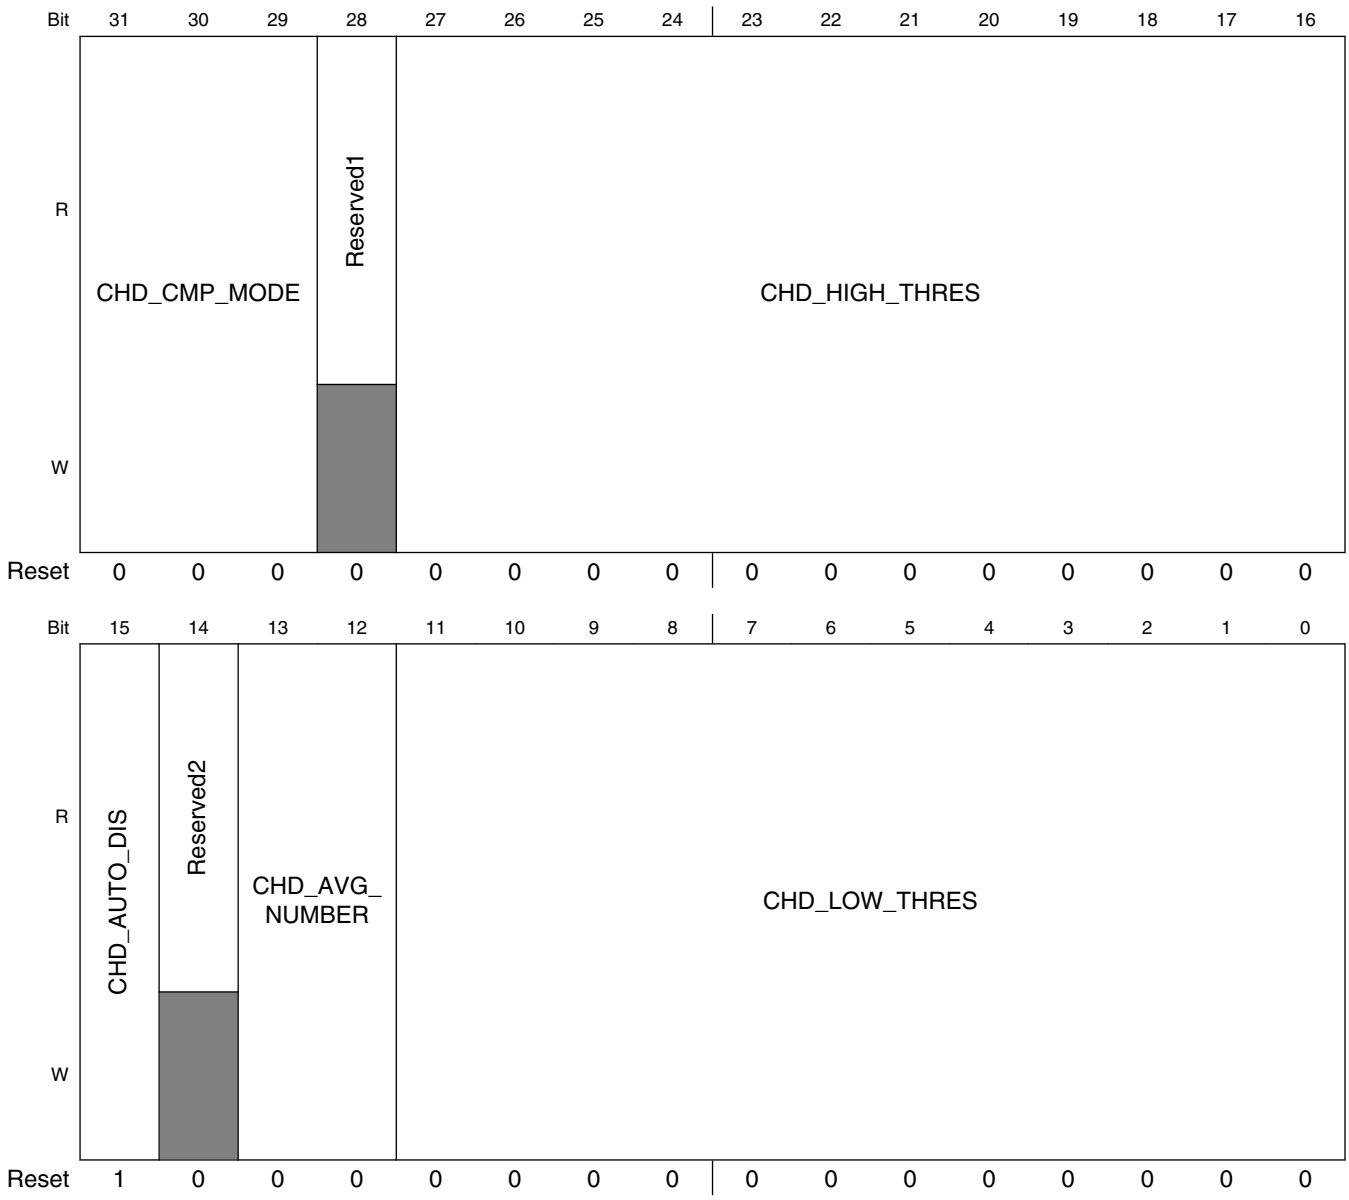
Table continues on the next page...

ADCx_CH_D_CFG1 field descriptions (continued)

Field	Description
	1 Start a single conversion. Continuous conversion must stop. 0 No single conversion. Continuous conversion can start.
29 CHD_AVG_EN	Channel D Average Enable If enable this bit, channel D will do average for each conversion. 1 Enable average function. 0 Disable average function.
28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–24 CHD_SEL	Channel D Select Select input channel (from 16 channels) for the logical channel D. 0000 Channel 0 0001 Channel 1 0010 Channel 2 0011 Channel 3 0100 Channel 4 0101 Channel 5 0110 Channel 6 0111 Channel 7 1000 Channel 8 1001 Channel 9 1010 Channel 10 1011 Channel 11 1100 Channel 12 1101 Channel 13 1110 Channel 14 1111 Channel 15
CHD_TIMER	Channel D Timer This timer is for continuous conversion. The conversion rate = (CHD_TIMER + 1) times sample rate + offset. The offset is due to channel D has lower priority than Channel A, B, and C. In worst case, all channel D's conversion are blocked by channel A, channel B and channel C's. 0x000 to 0xFFF timer value, every CHD_TIMER + 1 times sample rate + offset, the ADC converts one data.

14.1.6.8 Channel D Configuration 2 (ADCx_CH_D_CFG2)

Address: Base address + 70h offset



ADCx_CH_D_CFG2 field descriptions

Field	Description
31–29 CHD_CMP_ MODE	Channel D Compare Mode Select which compare mode the conversion result will take (for channel D). X00 Disable compare function 001 If channel D conversion result bigger than CHD_LOW_THRES, then an interrupt will be generated and the channel D flag will be set if they are enabled.

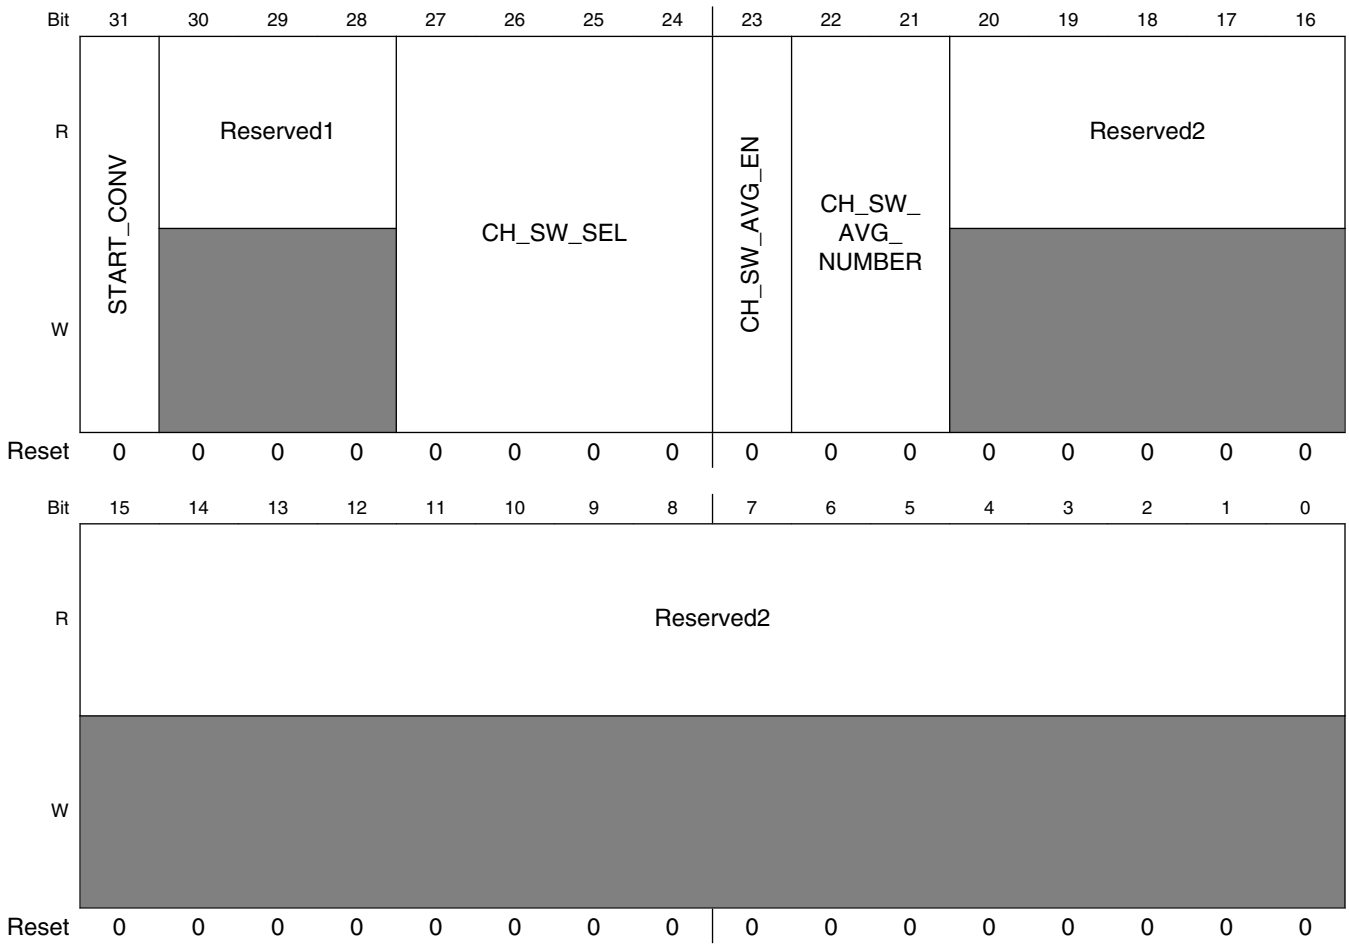
Table continues on the next page...

ADCx_CH_D_CFG2 field descriptions (continued)

Field	Description
	010 If channel D conversion result smaller or equal to CHD_LOW_THRES, then an interrupt will be generated and channel D flag will be set if they are enabled. 011 If channel D conversion result bigger than CHD_LOW_THRES and smaller than CHD_HIGH_THRES, then an interrupt will be generated and channel D flag will be set if they are enabled. 101 If channel D conversion result bigger or equal to CHD_HIGH_THRES, then an interrupt will be generated and channel D flag will be set if they are enabled. 110 If channel D conversion result smaller than CHD_HIGH_THRES, then an interrupt will be generated and channel D flag will be set if they are enabled. 111 If channel D conversion result smaller or equal to CHD_LOW_THRES, and at the same time, bigger or equal to CHD_HIGH_THRES, then an interrupt will be generated and channel D flag will be set if they are enabled.
28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–16 CHD_HIGH_ THRES	Channel D High Threshold Value Contains the bigger compare value to compare with the conversion result when a compare mode has been selected.
15 CHD_AUTO_DIS	Channel D Auto Disable During continuous conversion, if compare match a converted result, the ADC checks this bit. If CHD_AUTO_DIS = 1, then channel D stops continuous conversion, if CHD_AUTO_DIS = 0, then channel D keeps continuous working, and the conversion result overwrites the result registers. The default value is 1.
14 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
13–12 CHD_AVG_ NUMBER	Channel D Average Number If enable average function, this bit contains channel D average number. 00 Average number = 4 01 Average number = 8 10 Average number = 16 11 Average number = 32
CHD_LOW_ THRES	Channel D Low Threshold Value Contains the smaller compare value to compare with the conversion result when a compare mode has been selected.

14.1.6.9 Channel Software Configuration (ADCx_CH_SW_CFG)

Address: Base address + 80h offset



ADCx_CH_SW_CFG field descriptions

Field	Description
31 START_CONV	Start Software Trigger Conversion To start a software trigger, it must wait until the last software trigger finish. 0 Not start a new software trigger conversion. 1 Start a new software trigger conversion.
30–28 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
27–24 CH_SW_SEL	Software Trigger Channel Select Select 1 from 16 (physical) channels to be the software trigger channel. 0000 Channel 0

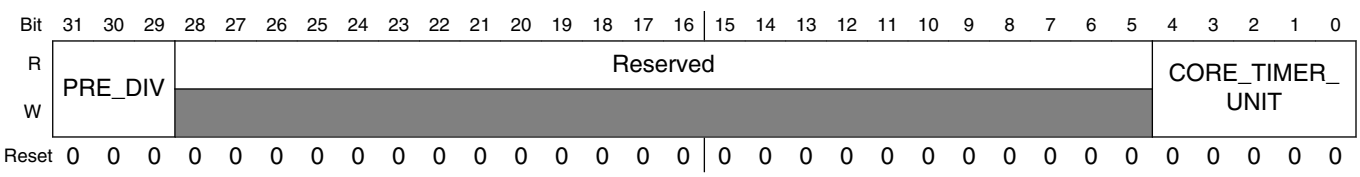
Table continues on the next page...

ADCx_CH_SW_CFG field descriptions (continued)

Field	Description
	0001 Channel 1 0010 Channel 2 0011 Channel 3 0100 Channel 4 0101 Channel 5 0110 Channel 6 0111 Channel 7 1000 Channel 8 1001 Channel 9 1010 Channel 10 1011 Channel 11 1100 Channel 12 1101 Channel 13 1110 Channel 14 1111 Channel 15
23 CH_SW_AVG_EN	Channel Software Average Enable If enable this bit, channel Software will do average for each conversion. 1 Enable average function. 0 Disable average function.
22–21 CH_SW_AVG_NUMBER	Channel Software Average Number If enable average function, this bit contains channel Software average number. 00 Average number = 4 01 Average number = 8 10 Average number = 16 11 Average number = 32
Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.

14.1.6.10 Timer Unit (ADCx_TIMER_UNIT)

Address: Base address + 90h offset

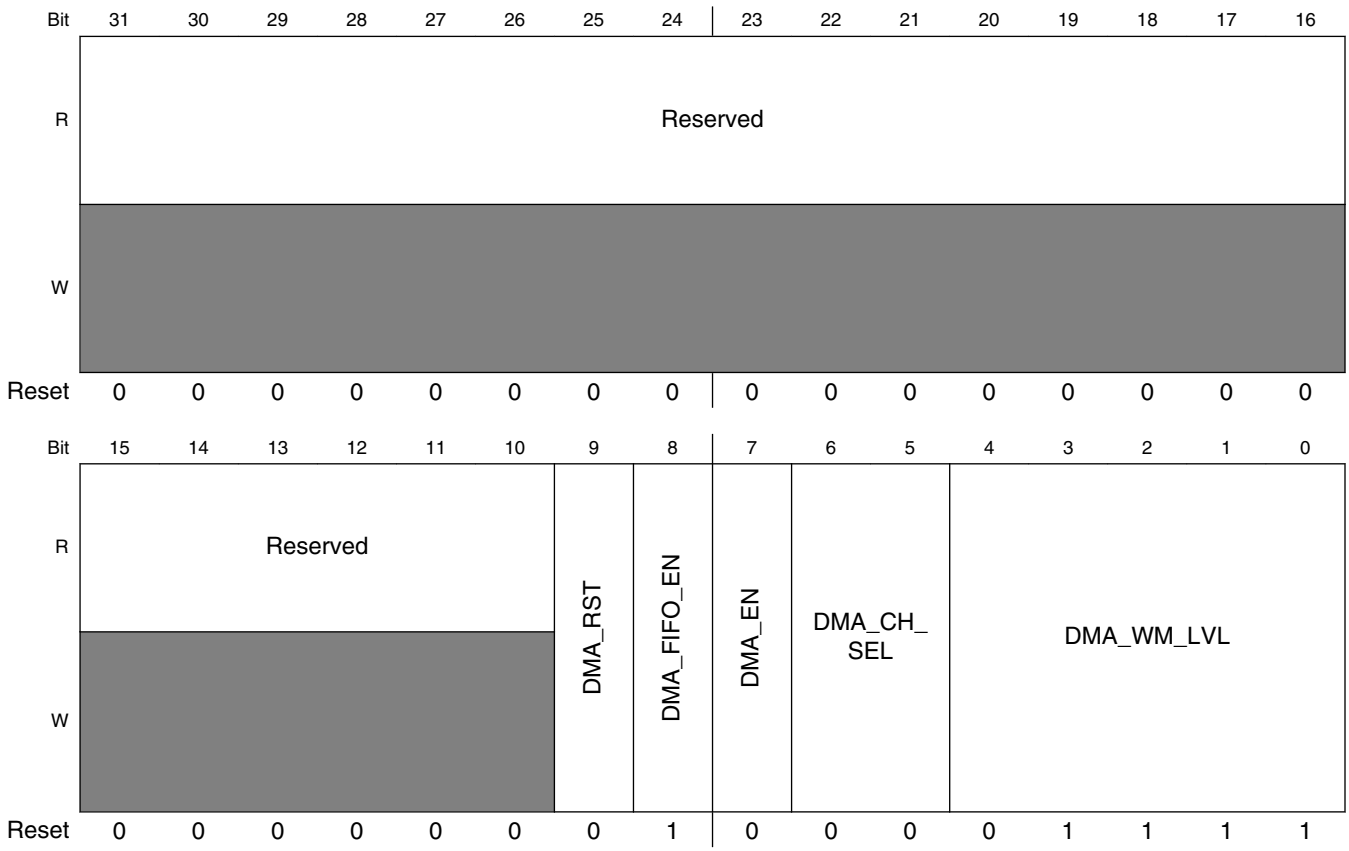


ADCx_TIMER_UNIT field descriptions

Field	Description
31–29 PRE_DIV	Pre-divide The ADC analogue core clock can vary from 300 kHz to 6 MHz. This parameter defines ADC core clock (and sample rate). The ADC analogue clock is default 1/4 of ADC digital input clock. All pre-divide is 1/4 ADC digital input clock. Warning: Before set this parameter, make sure analogue clock is from 300 kHz to 6 MHz. 000 No divide, analogue clock = 1/4 ADC digital input clock 001 Divide 2, analogue clock = 1/8 ADC digital input clock 010 Divide 4, analogue clock = 1/16 ADC digital input clock 011 Divide 8, analogue clock = 1/32 ADC digital input clock 100 Divide 16, analogue clock = 1/64 ADC digital input clock 101 Divide 32, analogue clock = 1/128 ADC digital input clock
28–5 Reserved	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
CORE_TIMER_ UNIT	Core_Timer_Unit This parameter defines sample rate. The maximum sample rate is 1/6 ADC analogue core clock. Sample rate = analogue core clock frequency (MHz) * 1 /((CORE_TIMER_UNIT + 1) * 6). If changing SAMPLE_RATE, please disable logical channel A, B, C, and D. Otherwise, the first A, B, C, and D conversion after change the sample rate may not follow exact sample rate interval.

14.1.6.11 DMA FIFO (ADC*x*_DMA_FIFO)

Address: Base address + A0h offset



ADC*x*_DMA_FIFO field descriptions

Field	Description
31–10 Reserved	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9 DMA_RST	DMA Reset This bit contains reset information. If reset, the DMA and DMA FIFO return to its reset value. The DMA FIFO data is lost. 0 Not reset 1 Reset
8 DMA_FIFO_EN	DMA FIFO Enable If enable DMA_FIFO_EN, ADC conversion result can store into DMA FIFO. If disable, no ADC conversion result will store in DMA FIFO. 0 Disable DMA FIFO. 1 Enable DMA FIFO.

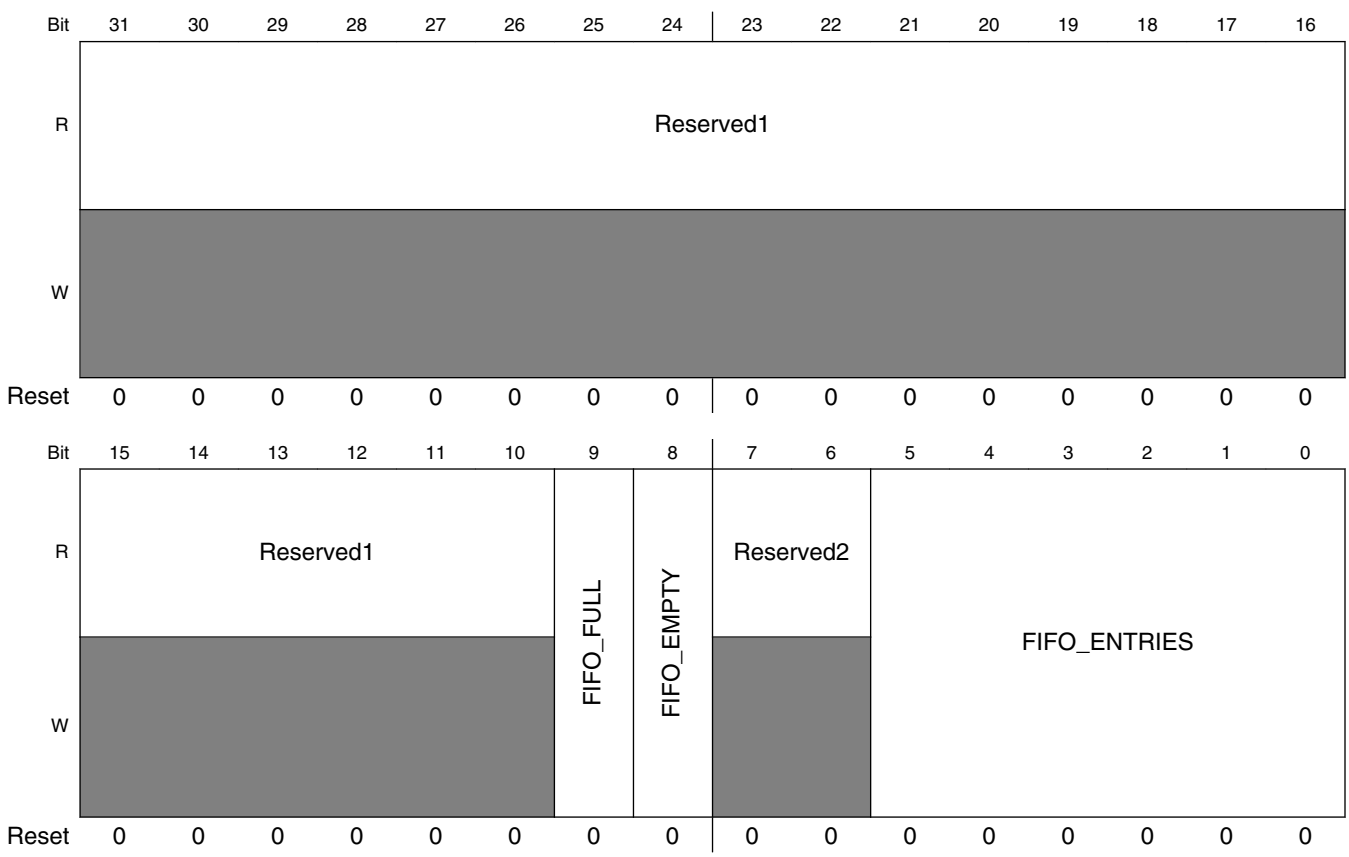
Table continues on the next page...

ADCx_DMA_FIFO field descriptions (continued)

Field	Description
7 DMA_EN	DMA Enable This bit defines data in DMA FIFO is moved by SDMA or moved by CPU. 0 Disable DMA, the data in DMA FIFO can only move by CPU. 1 Enable DMA, the data in DMA FIFO should move by SDMA.
6–5 DMA_CH_SEL	DMA Channel Select Select DMA FIFO source from Channel A, Channel B, Channel C, and Channel D. 00 Channel A 01 Channel B 10 Channel C 11 Channel D
DMA_WM_LVL	DMA Water Mark Level Once the DMA FIFO data reach water mark level, a DMA request or interrupt is generated (if enabled), and transfer data through DMA or CPU. 00000-11111 represents DMA water mark level value

14.1.6.12 FIFO Status (ADCx_FIFO_STATUS)

Address: Base address + B0h offset

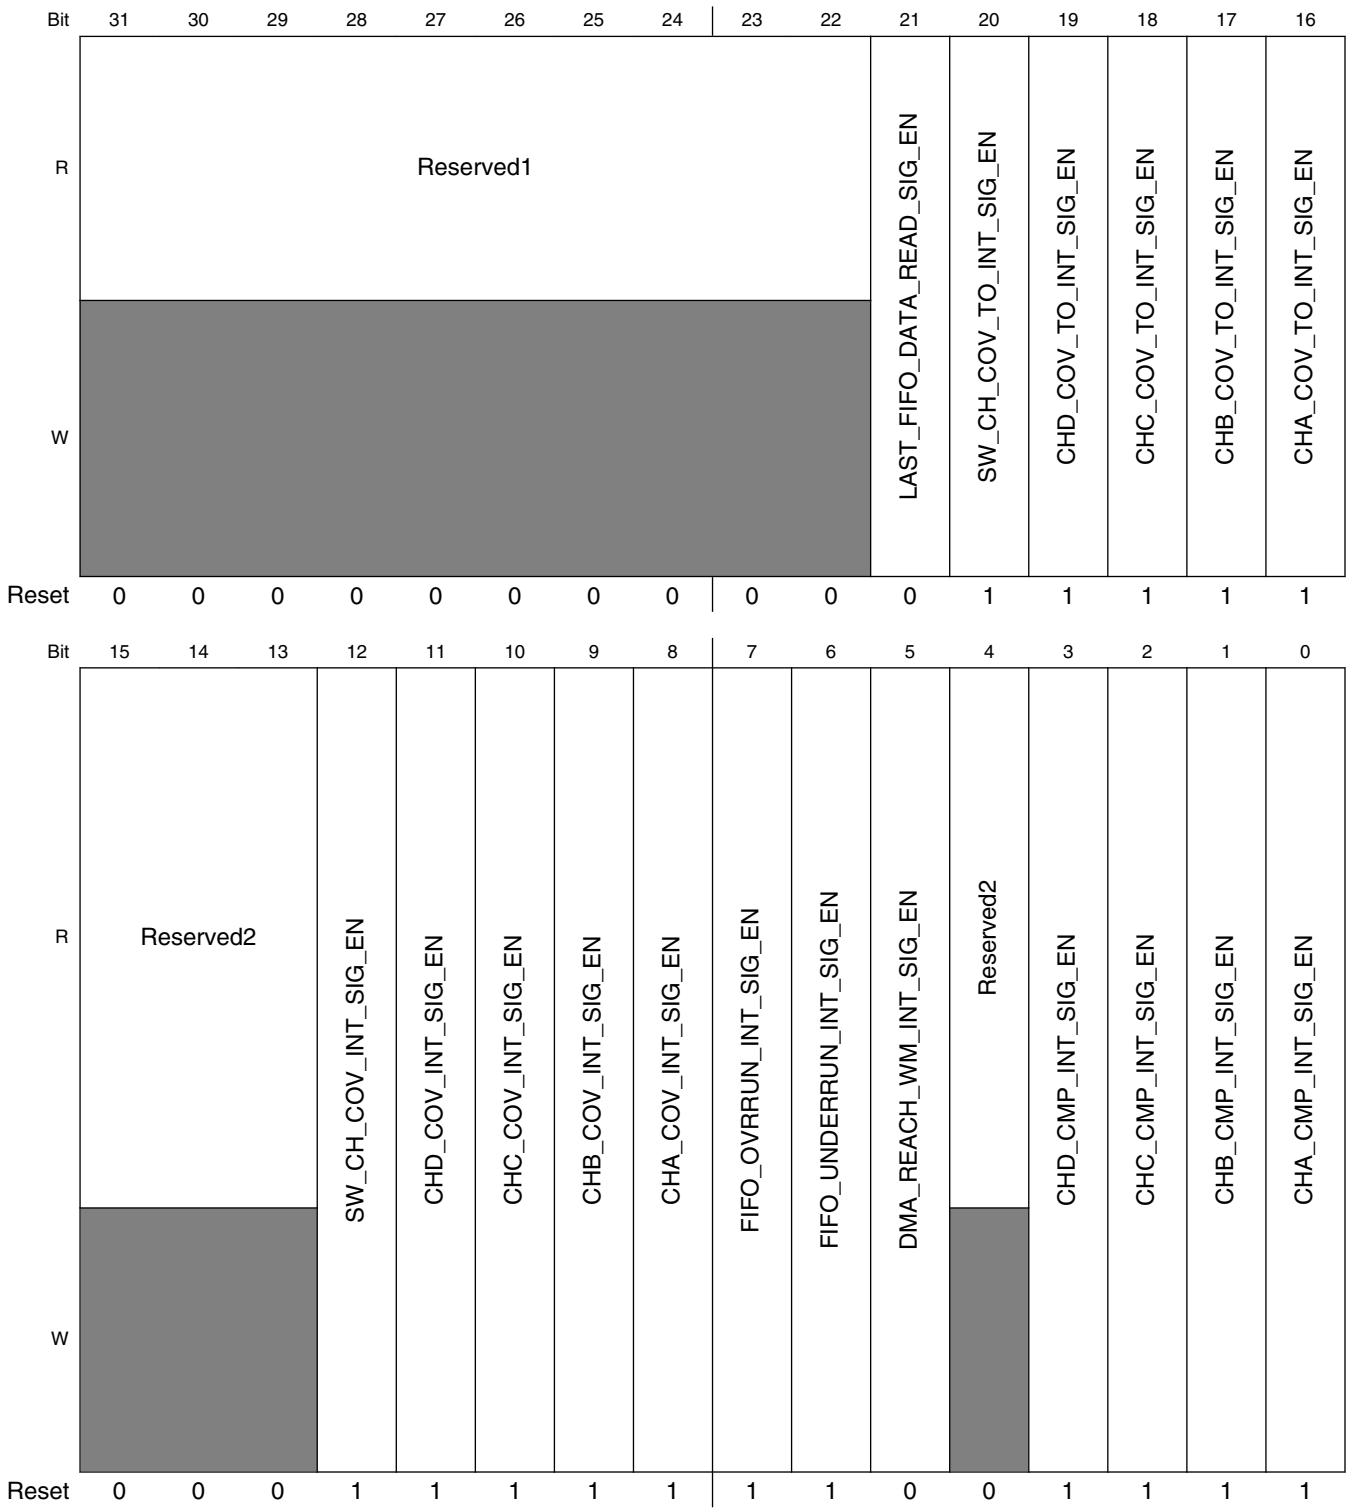


ADCx_FIFO_STATUS field descriptions

Field	Description
31–10 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
9 FIFO_FULL	This read-only bit represents the status of DMA FIFO. If FIFO is full, the DMA stop pushing data, set this bit, and generates an interrupt. 0 FIFO is not full. 1 FIFIO is full.
8 FIFO_EMPTY	FIFO Empty This read-only bit represents the status of DMA FIFO. If FIFO is empty, the DMA stops pop data, set this bit, and generates an interrupt. 0 FIFO is not empty. 1 FIFO is empty.
7–6 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
FIFO_ENTRIES	FIFO Entries This read-only bit represents the numbers of data in DMA FIFO. 00000 to 11111 The numbers of data stored in DMA FIFO.

14.1.6.13 ADCx_INT_SIG_EN

Address: Base address + C0h offset



ADCx_INT_SIG_EN field descriptions

Field	Description
31–22 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
21 LAST_FIFO_ DATA_READ_ SIG_EN	Last FIFO Data Read Signal Enable Define whether enable flag when the last data read out of FIFO (the last of whole continuous result) 0 Disable last FIFO read signal enable 1 Enable last FIFO read signal enable
20 SW_CH_COV_ TO_INT_SIG_EN	Software Channel Conversion Time Out Interrupt Signal Enable Define whether software channel conversion time out interrupt signal is enabled. 0 Disable software channel conversion time out interrupt signal. 1 Enable software channel conversion time out interrupt signal.
19 CHD_COV_TO_ INT_SIG_EN	Channel D Conversion Time Out Interrupt Signal Enable Define whether logical channel D conversion time out interrupt signal is enabled. 0 Disable logical channel D conversion time out interrupt signal. 1 Enable logical channel D conversion time out interrupt signal.
18 CHC_COV_TO_ INT_SIG_EN	Channel C Conversion Time Out Interrupt Signal Enable Define whether logical channel C conversion time out interrupt signal is enabled. 0 Disable logical channel C conversion time out interrupt signal. 1 Enable logical channel C conversion time out interrupt signal.
17 CHB_COV_TO_ INT_SIG_EN	Channel B Conversion Time Out Interrupt Signal Enable Define whether logical channel B conversion time out interrupt signal is enabled. 0 Disable logical channel B conversion time out interrupt signal. 1 Enable logical channel B conversion time out interrupt signal.
16 CHA_COV_TO_ INT_SIG_EN	Channel A Conversion Time Out Interrupt Signal Enable Define whether logical channel A conversion time out interrupt signal is enabled. 0 Disable logical channel A conversion time out interrupt signal. 1 Enable logical channel A conversion time out interrupt signal.
15–13 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 SW_CH_COV_ INT_SIG_EN	Software Channel Conversion Interrupt Signal Enable Define whether software trigger interrupt flag is enabled. 0 Disable software channel conversion signal interrupt flag. 1 Enable software channel conversion signal interrupt flag.
11 CHD_COV_INT_ SIG_EN	Channel D Conversion Interrupt Signal Enable

Table continues on the next page...

ADCx_INT_SIG_EN field descriptions (continued)

Field	Description
	Define whether channel D conversion interrupt flag is enabled. If enable interrupt flag, an interrupt flag is set once Channel D finish a new conversion. 0 Disable channel D conversion Interrupt flag. 1 Enable channel D conversion Interrupt flag.
10 CHC_COV_INT_SIG_EN	Channel C Conversion Interrupt Signal Enable Define whether channel C conversion interrupt flag is enabled. If enable interrupt flag, an interrupt flag is set once Channel C finish a new conversion. 0 Disable channel C conversion Interrupt flag. 1 Enable channel C conversion Interrupt flag.
9 CHB_COV_INT_SIG_EN	Channel B Conversion Interrupt Signal Enable Define whether channel B conversion interrupt flag is enabled. If enable interrupt flag, an interrupt flag is generated once Channel B finish a new conversion. 0 Disable channel B conversion Interrupt flag. 1 Enable channel B conversion Interrupt flag.
8 CHA_COV_INT_SIG_EN	Channel A Conversion Interrupt Signal Enable Define whether channel A round conversion interrupt flag enable. If enable interrupt flag, an interrupt flag is generated once Channel A finish a new conversion. 0 Disable channel A conversion Interrupt flag. 1 Enable channel A conversion Interrupt flag.
7 FIFO_OVRRUN_INT_SIG_EN	FIFO overrun Interrupt Signal Enable Define whether DMA FIFO overrun interrupt flag is enabled. If DMA FIFO overrun interrupt flag enabled and DMA FIFO has overrun condition, then an interrupt flag is generated. 0 Enable FIFO Interrupt flag. 1 Disable FIFO Interrupt flag.
6 FIFO_UNDERRUN_INT_SIG_EN	FIFO Underrrun Interrupt Signal Enable Define whether DMA FIFO underrun interrupt flag is enabled. If DMA FIFO underrun interrupt flag is enabled and DMA FIFO has underrun condition, then an interrupt flag is generated. 0 Enable FIFO underrun Interrupt flag 1 Disable FIFO underrun Interrupt flag
5 DMA_REACH_WM_INT_SIG_EN	DMA Reach Watermark Level Interrupt Signal (Flag) Enable Define whether the number of data in DMA FIFO is greater than DMA watermark level. If it is greater, then a flag is set. 0 Enable DMA watermark level interrupt signal (flag). 1 Disable DMA watermark level interrupt signal (flag).
4 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.

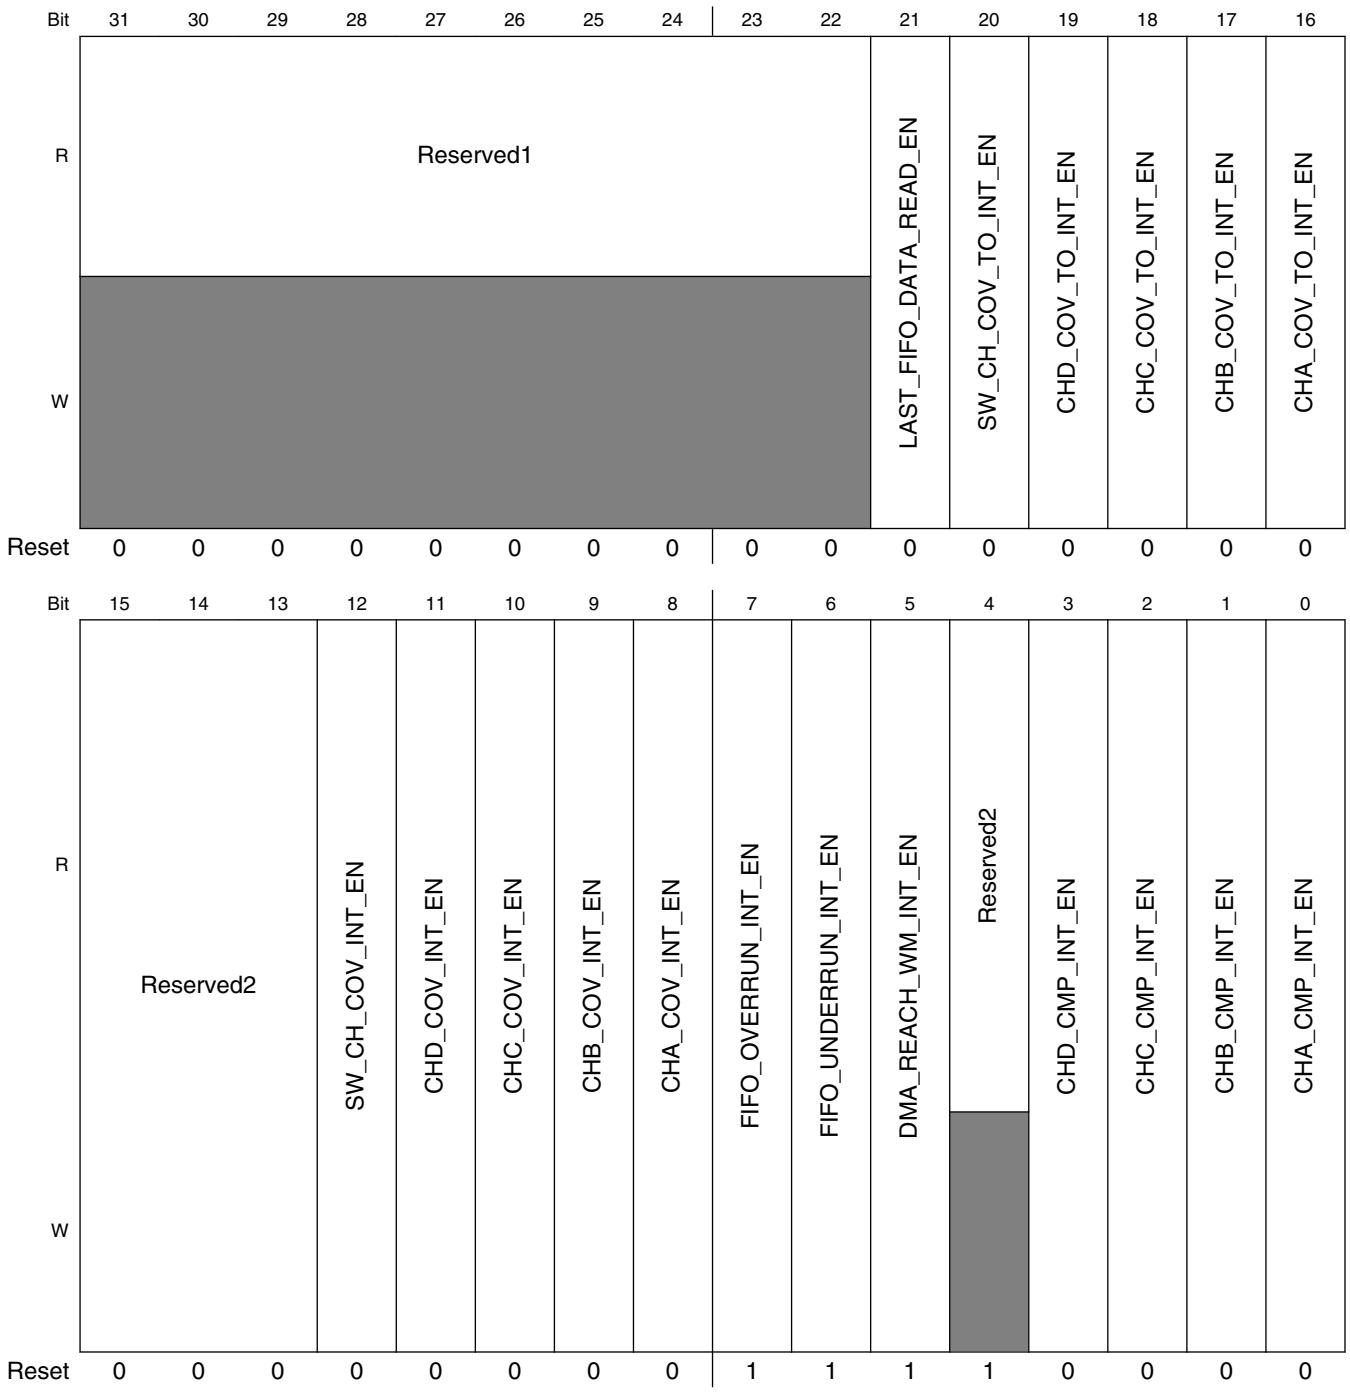
Table continues on the next page...

ADCx_INT_SIG_EN field descriptions (continued)

Field	Description
3 CHD_CMP_INT_SIG_EN	Channel D Compare Interrupt Signal Enable Define whether channel D compare interrupt flag is enabled. If enable the interrupt flag, an interrupt flag is set once channel D conversion result matches the compare region. 0 Disable Channel D Compare Interrupt flag 1 Enable Channel D Compare Interrupt flag
2 CHC_CMP_INT_SIG_EN	Channel C Compare Interrupt Signal Enable Define whether channel C compare interrupt flag is enabled. If enable the interrupt flag, an interrupt flag is set once channel C conversion result matches the compare region. 0 Disable Channel C Compare Interrupt flag. 1 Enable Channel C Compare Interrupt flag.
1 CHB_CMP_INT_SIG_EN	Channel B Compare Interrupt Signal Enable Define whether channel B compare interrupt flag is enabled. If enable the interrupt flag, an interrupt flag is set once channel B conversion result matches the compare region. 0 Disable Channel B Compare Interrupt flag. 1 Enable Channel B Compare Interrupt flag.
0 CHA_CMP_INT_SIG_EN	Channel A Compare Interrupt Signal Enable Define whether channel A compare interrupt flag is enabled. If enable the interrupt flag, an interrupt is set once channel A conversion result matches the compare region. 0 Disable Channel A Compare Interrupt flag. 1 Enable Channel A Compare Interrupt flag.

14.1.6.14 Interrupt Enable (ADCx_INT_EN)

Address: Base address + D0h offset



ADCx_INT_EN field descriptions

Field	Description
31–22 Reserved1	This field is reserved.

Table continues on the next page...

ADCx_INT_EN field descriptions (continued)

Field	Description
	This field is reserved. This read-only field is reserved and always has the value 0.
21 LAST_FIFO_ DATA_READ_EN	Last FIFO Data Read Enable Define whether generate an interrupt when the last data read out of FIFO (the last of whole continuous result) 0 Disable last FIFO read enable 1 Enable last FIFO read enable
20 SW_CH_COV_ TO_INT_EN	Software Channel Conversion Time Out Interrupt Enable Define whether software channel conversion time out interrupt is enabled. 0 Disable software channel conversion time out interrupt. 1 Enable software channel conversion time out interrupt.
19 CHD_COV_TO_ INT_EN	Channel D Conversion Time Out Interrupt Enable Define whether logical channel D conversion time out interrupt is enabled. 0 Disable logical channel D conversion time out interrupt. 1 Enable logical channel D conversion time out interrupt.
18 CHC_COV_TO_ INT_EN	Channel C Conversion Time Out Interrupt Enable Define whether logical channel C conversion time out interrupt is enabled. 0 Disable logical channel C conversion time out interrupt. 1 Enable logical channel C conversion time out interrupt.
17 CHB_COV_TO_ INT_EN	Channel B Conversion Time Out Interrupt Enable Define whether logical channel B conversion time out interrupt is enabled. 0 Disable logical channel B conversion time out interrupt. 1 Enable logical channel B conversion time out interrupt.
16 CHA_COV_TO_ INT_EN	Channel A Conversion Time Out Interrupt Enable Define whether logical channel A conversion time out interrupt is enabled. 0 Disable logical channel A conversion time out interrupt. 1 Enable logical channel A conversion time out interrupt.
15–13 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 SW_CH_COV_ INT_EN	Software Channel Conversion Interrupt Enable Define whether software trigger interrupt is enabled. 0 Disable software channel conversion interrupt. 1 Enable software channel conversion interrupt.
11 CHD_COV_INT_ EN	Channel D Conversion Interrupt Enable Define whether channel D conversion interrupt is enabled. If enable interrupt, an interrupt is generated once Channel D finish a new conversion.

Table continues on the next page...

ADCx_INT_EN field descriptions (continued)

Field	Description
	0 Disable channel D conversion Interrupt. 1 Enable channel D conversion Interrupt.
10 CHC_COV_INT_EN	Channel C Conversion Interrupt Enable Define whether channel C conversion interrupt is enabled. If enable interrupt, an interrupt is generated once Channel C finish a new conversion. 0 Disable channel C conversion Interrupt. 1 Enable channel C conversion Interrupt.
9 CHB_COV_INT_EN	Channel B Conversion Interrupt Enable Define whether channel B conversion interrupt is enabled. If enable interrupt, an interrupt is generated once Channel B finish a new conversion. 0 Disable channel B conversion Interrupt. 1 Enable channel B conversion Interrupt.
8 CHA_COV_INT_EN	Channel A Conversion Interrupt Enable Define whether channel A conversion interrupt is enabled. If enable interrupt, an interrupt is generated once Channel A finish a new conversion. 0 Disable channel A conversion Interrupt. 1 Enable channel A conversion Interrupt.
7 FIFO_OVERRUN_INT_EN	FIFO overrun Interrupt Enable Define whether DMA FIFO overrun interrupt is enabled. If DMA FIFO overrun interrupt is enabled and DMA FIFO has overrun condition, then an interrupt is generated. 0 Enable FIFO Interrupt. 1 Disable FIFO Interrupt.
6 FIFO_UNDERRUN_INT_EN	FIFO underrun Interrupt Enable Define whether DMA FIFO underrun interrupt is enabled. If DMA FIFO underrun interrupt is enabled and DMA FIFO has underrun condition, then an interrupt is generated. 0 Enable FIFO underrun Interrupt. 1 Disable FIFO underrun Interrupt.
5 DMA_REACH_WM_INT_EN	DMA Reach Watermark Level Interrupt Enable Define whether DMA watermark level interrupt is enabled. If enable the interrupt, an interrupt is generated. **NOTE:** This signal is for software read DMA FIFO. If SDMA read data, turn off both interrupt enable and signal (flag) enable. 0 Enable DMA reach watermark level interrupt. 1 Disable DMA reach watermark level interrupt.
4 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.

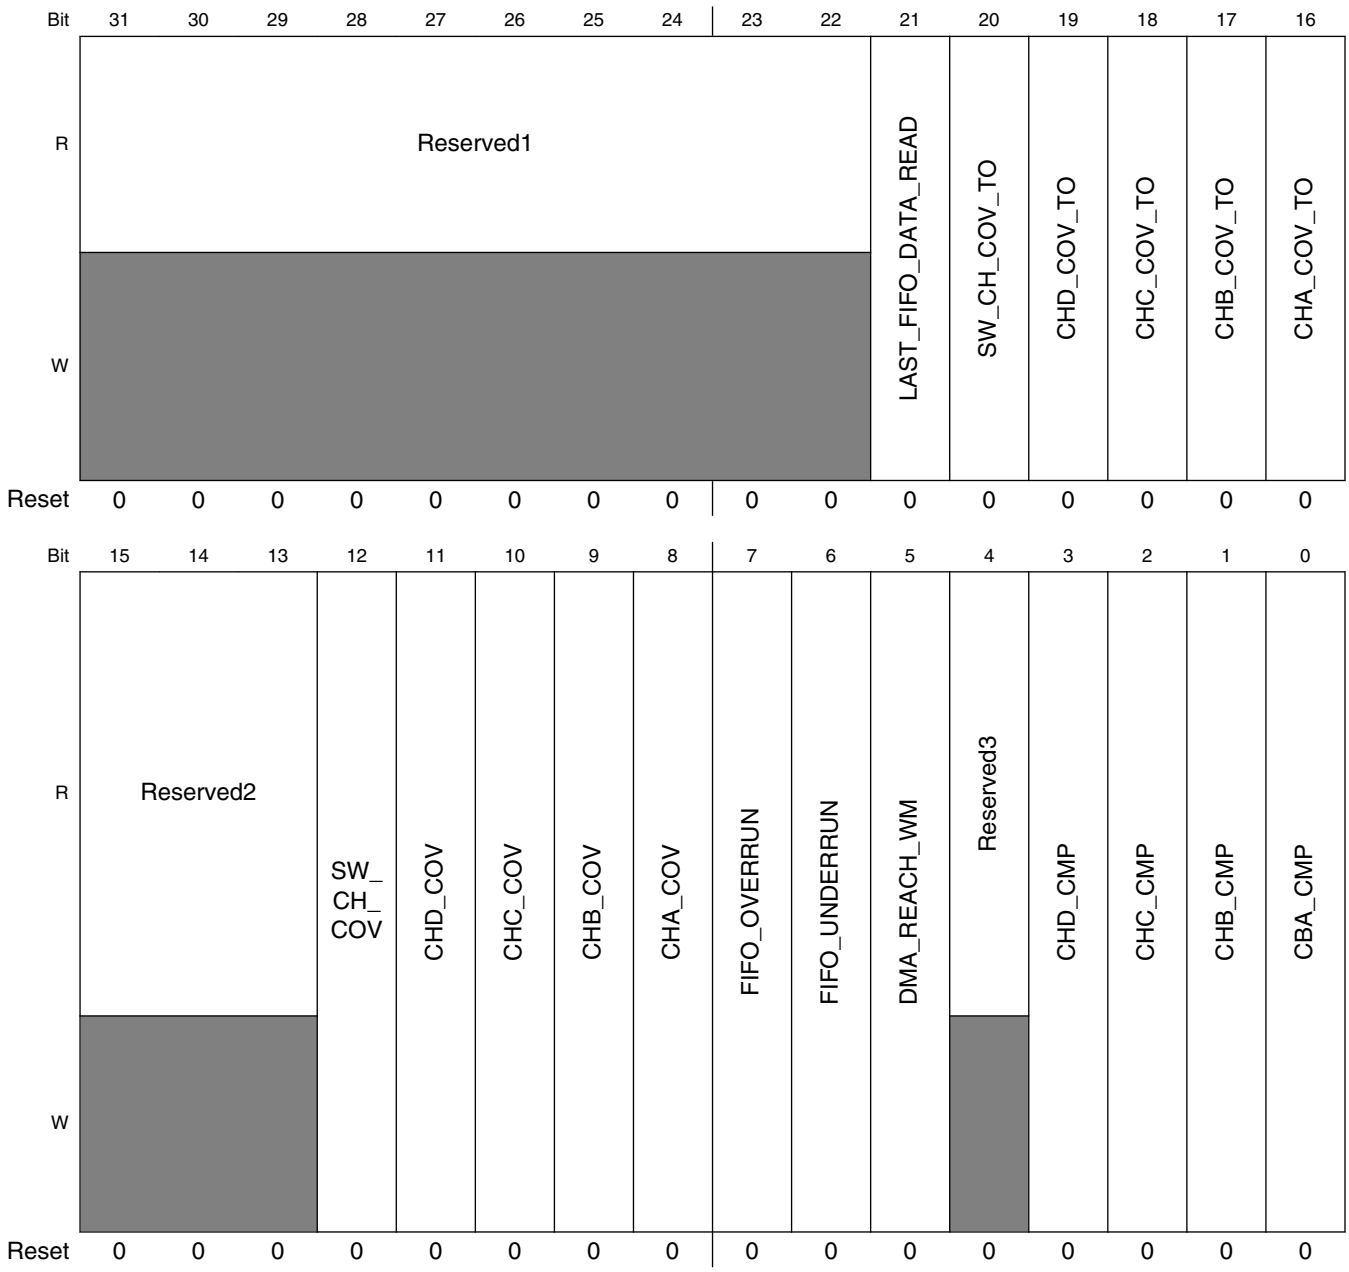
ADCx_INT_EN field descriptions (continued)

Field	Description
3 CHD_CMP_INT_EN	Channel D Compare Interrupt Enable Define whether channel D compare interrupt is enabled. If enable the interrupt, an interrupt is set once channel D conversion result matches the compare region. 0 Disable Channel D Compare Interrupt. 1 Enable Channel D Compare Interrupt.
2 CHC_CMP_INT_EN	Channel C Compare Interrupt Enable Define whether channel C compare interrupt is enabled. If enable the interrupt, an interrupt is set once channel C conversion result matches the compare region. 0 Disable Channel C Compare Interrupt. 1 Enable Channel C Compare Interrupt .
1 CHB_CMP_INT_EN	Channel B Compare Interrupt Enable Define whether channel B compare interrupt is enabled. If enable the interrupt, an interrupt is set once channel B conversion result matches the compare region. 0 Disable Channel B Compare Interrupt. 1 Enable Channel B Compare Interrupt.
0 CHA_CMP_INT_EN	Channel A Compare Interrupt Enable Define whether channel A compare interrupt is enabled. If enable the interrupt, an interrupt is set once channel A conversion result matches the compare region. 0 Disable Channel A Compare Interrupt. 1 Enable Channel A Compare Interrupt.

14.1.6.15 ADCx_INT_STATUS

Address: Base address + E0h offset



ADCx_INT_STATUS field descriptions

Field	Description
31–22 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADCx_INT_STATUS field descriptions (continued)

Field	Description
21 LAST_FIFO_ DATA_READ	Last FIFO Data Read Represents whether the last data read out of FIFO (the last of whole continuous result) 0 Last FIFO data has not been read out 1 Last FIFO data has been read out
20 SW_CH_COV_ TO	Software Channel Conversion Time Out Represents whether software channel conversion time out exist. 0 Software channel conversion time out does not exist. 1 Exist software channel conversion time out. Software clear / clear signal enable.
19 CHD_COV_TO	Channel D Conversion Time Out Represent whether logical channel D conversion time out exist. 0 Logical channel D conversion time out does not exist. 1 Exist logical channel D conversion time out. Software clear / clear signal enable.
18 CHC_COV_TO	Channel C Conversion Time Out Represent whether logical channel C conversion time out exist. 0 Logical channel C conversion time out does not exist. 1 Exist logical channel C conversion time out. Software clear / clear signal enable.
17 CHB_COV_TO	Channel B Conversion Time Out Represent whether logical channel B conversion time out exist. 0 Logical channel B conversion time out exist. 1 Exist logical channel B conversion time out. Software clear/clear signal enable.
16 CHA_COV_TO	Channel A Conversion Time Out Represent whether logical channel A conversion time exist. 0 Logical channel A conversion time out does not exist. 1 Exist logical channel A conversion time out. Software clear / clear signal enable.
15–13 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12 SW_CH_COV	Software Channel Conversion (Flag) This is the flag of software trigger. If SW_CH_COV_INT_SIG_EN is enabled and software trigger ADC conversion is finished, the SW_CH_COV (flag) is set. 0 Disable software channel conversion (Flag). 1 Enable software channel conversion (Flag).
11 CHD_COV	Channel D Conversion (Flag) This is the flag of channel D conversion. If CHD_COV_INT_SIG_EN is enabled and channel D ADC conversion is finished, the CHD_COV (flag) is set.

Table continues on the next page...

ADCx_INT_STATUS field descriptions (continued)

Field	Description
	0 Disable channel D conversion (Flag). 1 Enable channel D conversion (Flag).
10 CHC_COV	Channel C Conversion (Flag) This is the flag of channel C conversion. If CHC_COV_INT_SIG_EN is enabled and channel C ADC conversion is finished, the CHC_COV (flag) is set. 0 Disable channel C conversion (Flag). 1 Enable channel C conversion (Flag).
9 CHB_COV	Channel B Conversion (Flag) This is the flag of channel B conversion. If CHB_COV_INT_SIG_EN is enabled and channel B ADC conversion is finished, the CHB_COV (flag) is set. 0 Disable channel B conversion (Flag). 1 Enable channel B conversion (Flag).
8 CHA_COV	Channel A Conversion (Flag) This is the flag of channel A conversion. If CHA_COV_INT_SIG_EN is enabled and channel A ADC conversion is finished, the CHA_CONV (flag) is set. 0 Disable channel A conversion (Flag). 1 Enable channel A conversion (Flag).
7 FIFO_OVERRUN	FIFO Overrun (Flag) This is the flag of FIFO overrun. If FIFO_OVERRUN_INT_SIG_EN is enabled and FIFO overrun happens, the FIFO_OVERRUN (flag) is set. 0 Disable FIFO overrun (Flag). 1 Enable FIFO overrun (Flag).
6 FIFO_ UNDERRUN	FIFO Underrun (Flag) This is the flag of FIFO underrun. If FIFO_UNDERRUN_INT_SIG_EN is enabled and FIFO underrun happens, the FIFO_UNDERRUN (flag) is set. 0 Do not exist FIFO underrun (Flag). 1 Exist FIFO underrun (Flag). Software clear / clear signal enable.
5 DMA_REACH_ WM	DMA Reach Watermark Level (Flag) This is the flag of DMA reach watermark level. Setting this flag indicates the number of data in the DMA FIFO reach the watermark level. **NOTE:** This bit is for software read DMA FIFO, if SDMA read DMA FIFO, please disable both interrupt and interrupt signal (flag). 0 The numbers of data in DMA FIFO has not reach the watermark level. 1 The numbers of data in DMA FIFO has reach the watermark level. Software clear / clear signal enable.
4 Reserved3	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADCx_INT_STATUS field descriptions (continued)

Field	Description
3 CHD_CMP	Channel D Compare (Flag) This is the flag of channel D compare. If CHD_CMP_INT_SIG_EN is enabled and channel D conversion result matches the compare region, the CHD_CMP (Flag) is set. 0 Disable Channel D Compare (Flag). 1 Enable Channel D Compare (Flag).
2 CHC_CMP	Channel C Compare (Flag) This is the flag of channel C compare. If CHC_CMP_INT_SIG_EN is enabled and channel C conversion result matches the compare region, the CHC_CMP (Flag) is set. 0 Disable Channel C Compare (Flag). 1 Enable Channel C Compare (Flag).
1 CHB_CMP	Channel B Compare (Flag) This is the flag of channel B compare. If CHB_CMP_INT_SIG_EN is enabled and channel B conversion result matches the compare region, the CHB_CMP (Flag) is set. 0 Disable Channel B Compare (Flag). 1 Enable Channel B Compare (Flag).
0 CBA_CMP	Channel A Compare (Flag) This is the flag of channel A compare. If CHA_CMP_INT_SIG_EN is enabled and channel A conversion result matches the compare region, the CHA_CMP (Flag) is set. 0 Disable Channel A Compare (Flag). 1 Enable Channel A Compare (Flag).

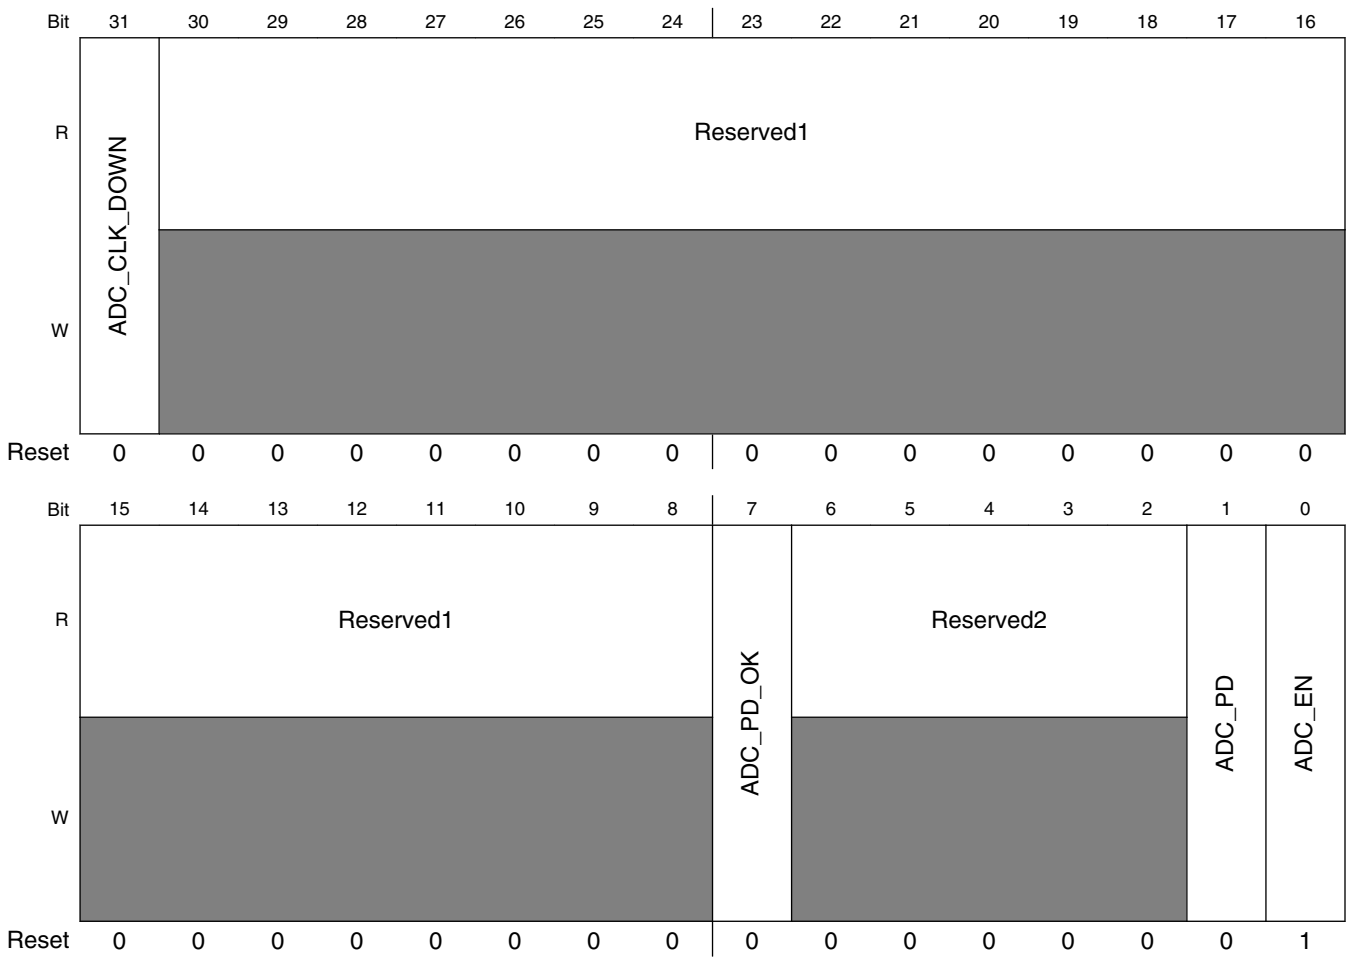
14.1.6.20 ADC Configuration (ADCx_ADC_CFG)

Address: Base address + 130h offset



ADCx_ADC_CFG field descriptions

Field	Description
31 ADC_CLK_ DOWN	ADC Clock Down This bit is for low power design. Set this bit to stop all digital part power. Warning: Before set this bit, all conversion must be finished.

Table continues on the next page...

ADCx_ADC_CFG field descriptions (continued)

Field	Description
	0 Clock running. 1 Clock down, no clock.
30–8 Reserved1	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
7 ADC_PD_OK	ADC Power Down OK This bit represents whether power down or to start conversion. After power up the ADC analogue core, system has to wait ADC_PD_OK = 1 before start a conversion or power down again. If violate this rule, the ADC may enter an unknown state. Clock cannot stop until this bit equals to 0. This bit will automatically set to 1 if ADC_PD = 0 and ADC_EN = 0 for the specific time period. 0 ADC has not power up completely. Cannot start a conversion. 1 ADC power up completely. Can start a conversion.
6–2 Reserved2	This field is reserved. This field is reserved. This read-only field is reserved and always has the value 0.
1 ADC_PD	ADC Power Down Power Down ADC analogue core. Before entering into stop-mode, power down ADC analogue core first. 0 Do not power down the ADC analogue core. 1 Power down the ADC analogue core.
0 ADC_EN	ADC Level Shifter Enable The level shifter provides 1.8 V to 1.1 V converter. The level shifter is embedded in ADC analogue. The ADC analogue ports voltage level must same with ADC digital part ports voltage level. During low power mode, also reset this bit to 1'b0 to save power. 0 Disable level shifter, the ADC analogue core ports using 1.8 V voltage level. 1 Enable level shifter, the ADC analogue core ports using 1.1 V voltage level.

14.2 Temperature Monitor (TEMPMON)

14.2.1 Overview

The temperature sensor module implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

The high-level implementation of the temperature sensor is shown in the figure below.

Figure 14-3. High Level Temp Sensor System Diagram

As shown in the figure above, the temperature sensor uses and assumes that the bandgap reference, 480MHz PLL and 32KHz RTC modules are properly programmed and fully settled for correct operation.

14.2.2 Software Usage Guidelines

During normal system operation software can use the temperature sensor counter output (TEMP_CNT) in conjunction with the fused temperature calibration data to determine the on-die operational temperature or to set an over-temperature interrupt alarm to within a couple of °C.

Based on calibration, two sets of temperature and counter values will be available via fuses on the device. These data points will correspond to the points (N_1, T_1) and (N_2, T_2) in the curve below.

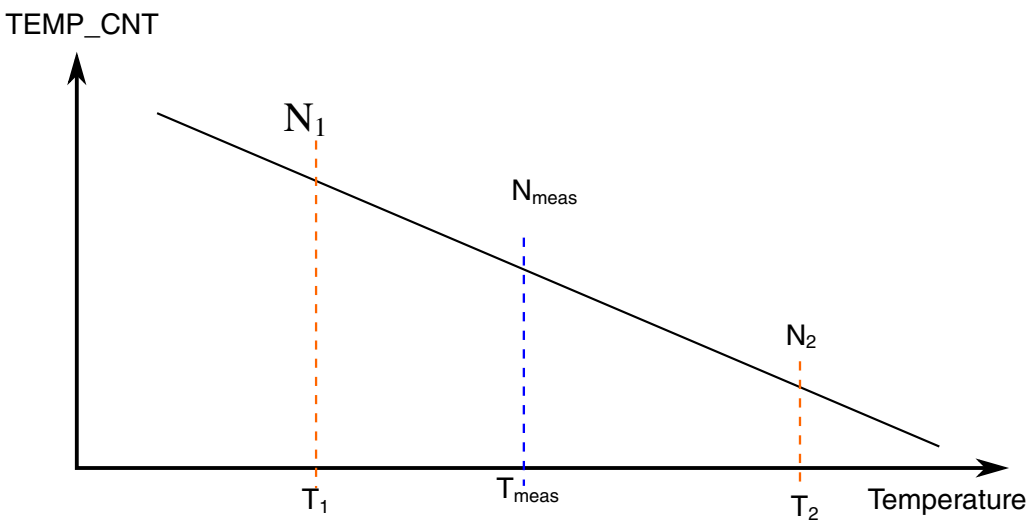


Figure 14-4. Temperature Measurement Cycle

After a temperature measurement cycle, software should use the calibration points in conjunction with the temperature code value in the TEMPMON_TEMPSENSE0[TEMP_CNT] bitfield to calculate the temperature for the device using the following equation:

$$T_{meas} = T_2 - (N_{meas} - N_2) * ((T_2 - T_1) / (N_1 - N_2))$$

Likewise, to determine the alarm counter value to be written in the TEMPMON_TEMPSENSE0 register for a temperature based interrupt, the above equation can be solved for the N_{meas} value that should be used based on the desired temperature trigger.

The temperature calibration point fuse values are available in the OCOTP_ANA1 register. The temperature calibration values are fused individually for each part in the product testing process. The fields of this register are described in the following table.

Table 14-6. OCOTP_ANA1 Temperature Sensor Calibration Data

Bit Range	Bit Mask	Name	Description
[31:20]	FFF0_0000h	ROOM_COUNT	Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at room temperature (25.0 °C).
[19:8]	000F_FF00h	HOT_COUNT	Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at the hot temperature, i.e. HOT_TEMP.
[7:0]	0000_00FFh	HOT_TEMP	The hot temperature test point. Each LSB equals 1 °C.

The points on the calibration curve are as follows.

- (N_1, T_1) = (ROOM_COUNT, 25.0)
- (N_2, T_2) = (HOT_COUNT, HOT_TEMP)
- (N_{meas}, T_{meas}) = (TEMP_CNT, T_{meas})

Substituting the fields from OCOTP_ANA1 into the earlier equation results in the following:

T_{meas} = HOT_TEMP - (N_{meas} - HOT_COUNT) * ((HOT_TEMP - 25.0) / (ROOM_COUNT – HOT_COUNT))

14.2.3 TEMPMON Memory Map/Register Definition

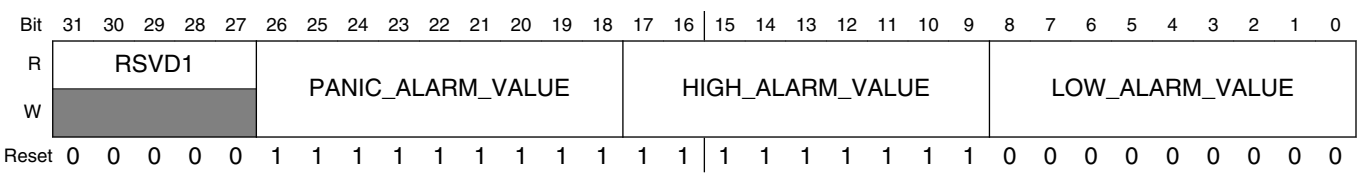
14.2.3.1 Anadig Tempsensor Control Register 0 (TEMPMON_HW_ANADIG_TEMPSENSE0*n*)

This register defines the alarm and panic functions for the temperature sensor.

Address: 3036_0000h base + 300h offset + (4d × i), where i=0d to 3d



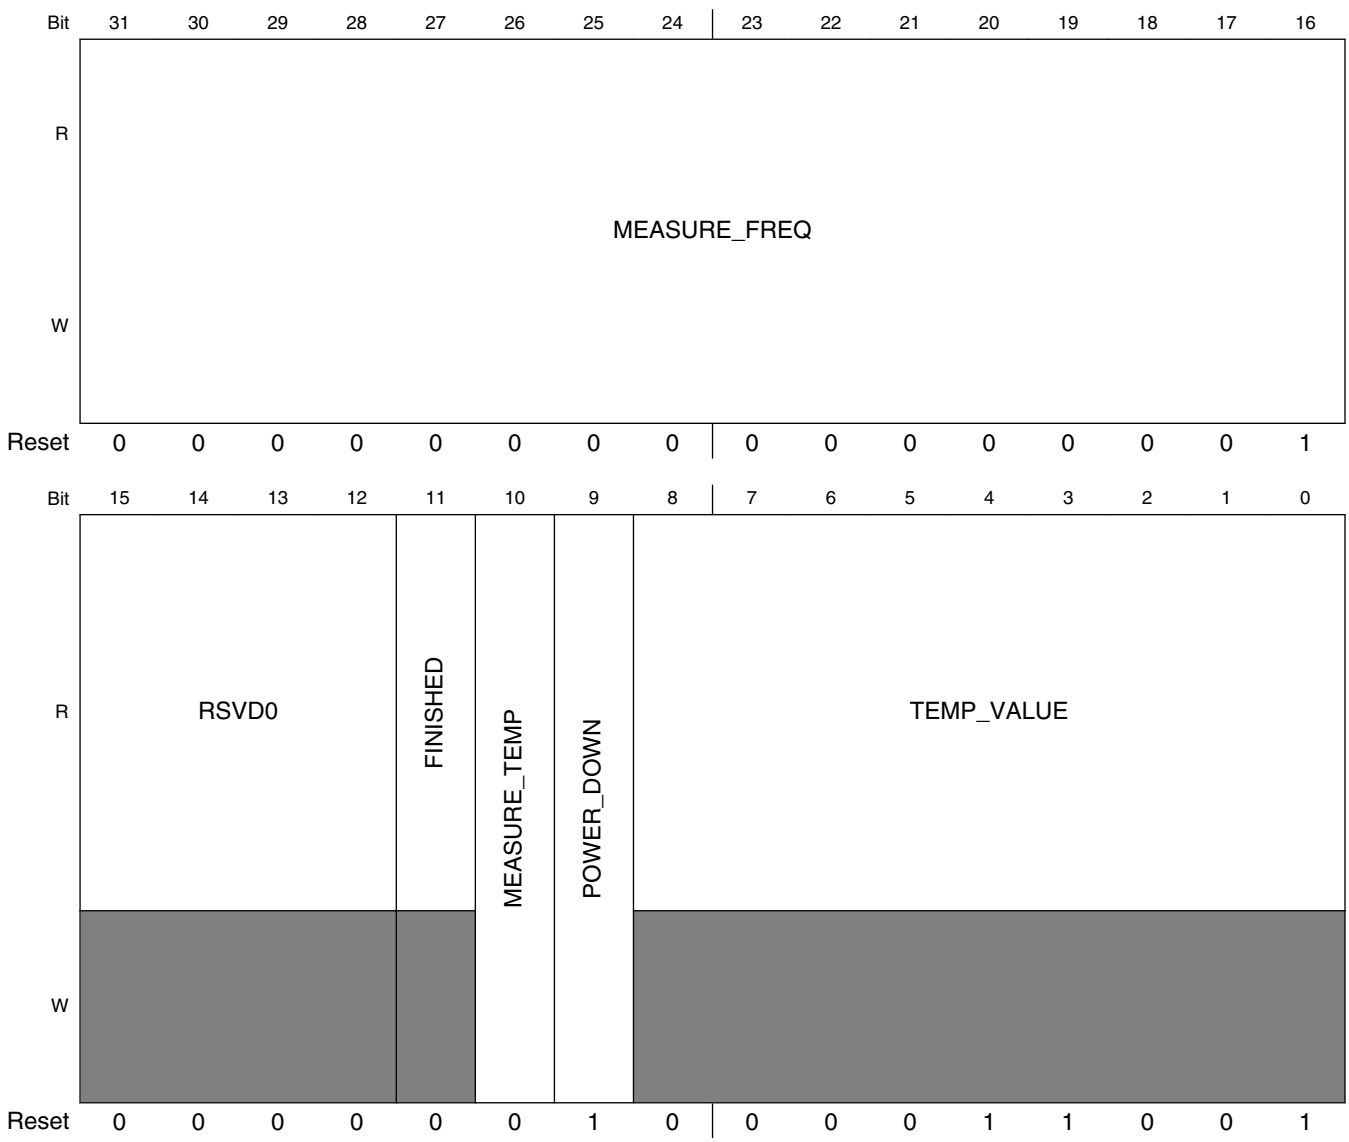
TEMPMON_HW_ANADIG_TEMPSENSE0*n* field descriptions

Field	Description
31–27 RSVD1	This bit field contains the last measured temperature.
26–18 PANIC_ALARM_ VALUE	This bit field contains the temperature measurement that will cause a panic and reset the chip.
17–9 HIGH_ALARM_ VALUE	This bit field contains the temperature measurement that will issue a high temperature interrupt
LOW_ALARM_ VALUE	This bit field contains the temperature measurement that will issue a low temperature interrupt.

14.2.3.2 Anadig Tempsensor Control Register 1 (TEMPMON_HW_ANADIG_TEMPSENSE1*n*)

This register defines the automatic repeat time of the temperature sensor.

Address: 3036_0000h base + 310h offset + (4d × i), where i=0d to 3d



TEMPMON_HW_ANADIG_TEMPSENSE1*n* field descriptions

Field	Description
31–16 MEASURE_ FREQ	This bits determines how many RTC clocks to wait before automatically repeating a temperature measurement. 0x0000 - defines a single measurement with no repeat. 0xFFFF determines a two second sample rate with a 32.768KHz RTC clock. Exact timings depend on the accuracy of the RTC clock.

Table continues on the next page...

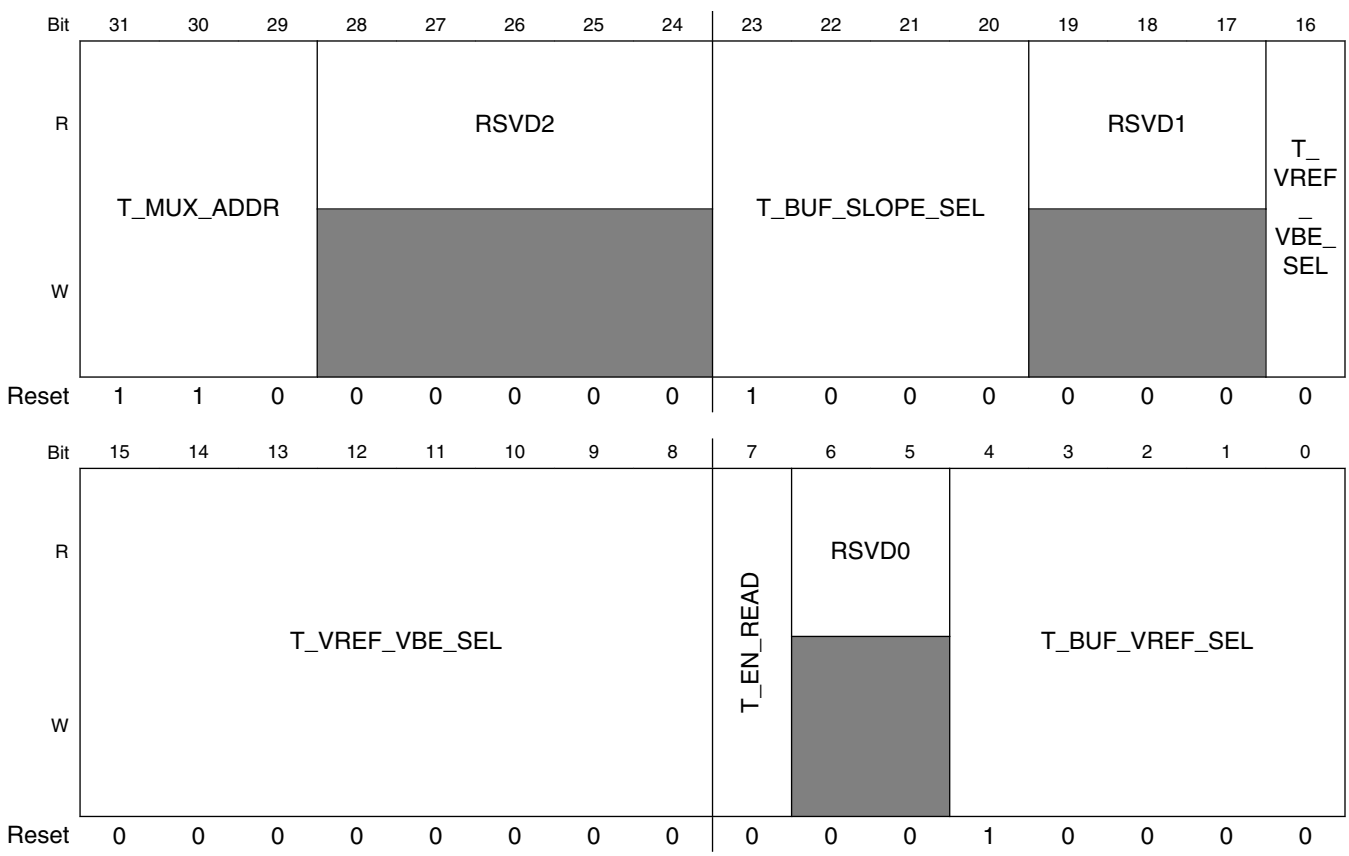
TEMPMON_HW_ANADIG_TEMPSENSE1*n* field descriptions (continued)

Field	Description
15–12 RSVD0	Always set to zero (0).
11 FINISHED	Indicates that the latest temp is valid. This bit should be cleared by the sensor after the start of each measurement.
10 MEASURE_ TEMP	Starts the measurement process. If the measurement frequency is zero in the tempsens_1 register. This results in a single conversion.
9 POWER_DOWN	This bit powers down the temperature sensor.
TEMP_VALUE	This bit field contains the temperature measurement.

14.2.3.3 Anadig Tempsensor Trim Control Register (TEMPMON_HW_ANADIG_TEMPSENSE_TRIM*n*)

This register defines the automatic repeat time of the temperature sensor.

Address: 3036_0000h base + 320h offset + (4d × i), where i=0d to 3d



TEMPMON_HW_ANADIG_TEMPSENSE_TRIM*n* field descriptions

Field	Description
31–29 T_MUX_ADDR	Test MUX address setting bits. Only for de-bugging purpose. Default: 110 Other Values : TBD
28–24 RSVD2	Always set to zero (0).
23–20 T_BUF_SLOPE_SEL	Amplifier gain setting bits. Default: 1000 This value can be changed by BJT characteristics. It will be fixed after temperature test.
19–17 RSVD1	Always set to zero (0).
16–8 T_VREF_VBE_SEL	Reference voltage setting bits for the am-plifier in the Positive-TC generator block. Default: 10000
7 T_EN_READ	Definition:TBD
6–5 RSVD0	Always set to zero (0).
T_BUF_VREF_SEL	Reference voltage setting bits for the am-plifier in the Positive-TC generator block. Default: 10000

Chapter 15
Low Speed Communication and Interconnects

15.1 Flexible Controller Area Network (FLEXCAN)

15.1.1 Overview

The Flexible Controller Area Network (FLEXCAN) module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification.

The CAN protocol was primarily designed to be used as a vehicle serial data bus meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness and required bandwidth. The FLEXCAN module is a full implementation of the CAN protocol specification, which supports both standard and extended message frames. 64 Message Buffers are supported.

15.1.1.1 Block Diagram

A general block diagram is shown in the figure below,which describes the main sub-blocks implemented in the FLEXCAN module, including the associated memory for storing Mailboxes, Rx Global Mask Registers, Rx Individual Mask Registers, Rx FIFO and Rx FIFO ID Filters.

Support for 64 Mailboxes and 6-deep Rx FIFO is provided. The functions of the sub-modules are described in subsequent sections.

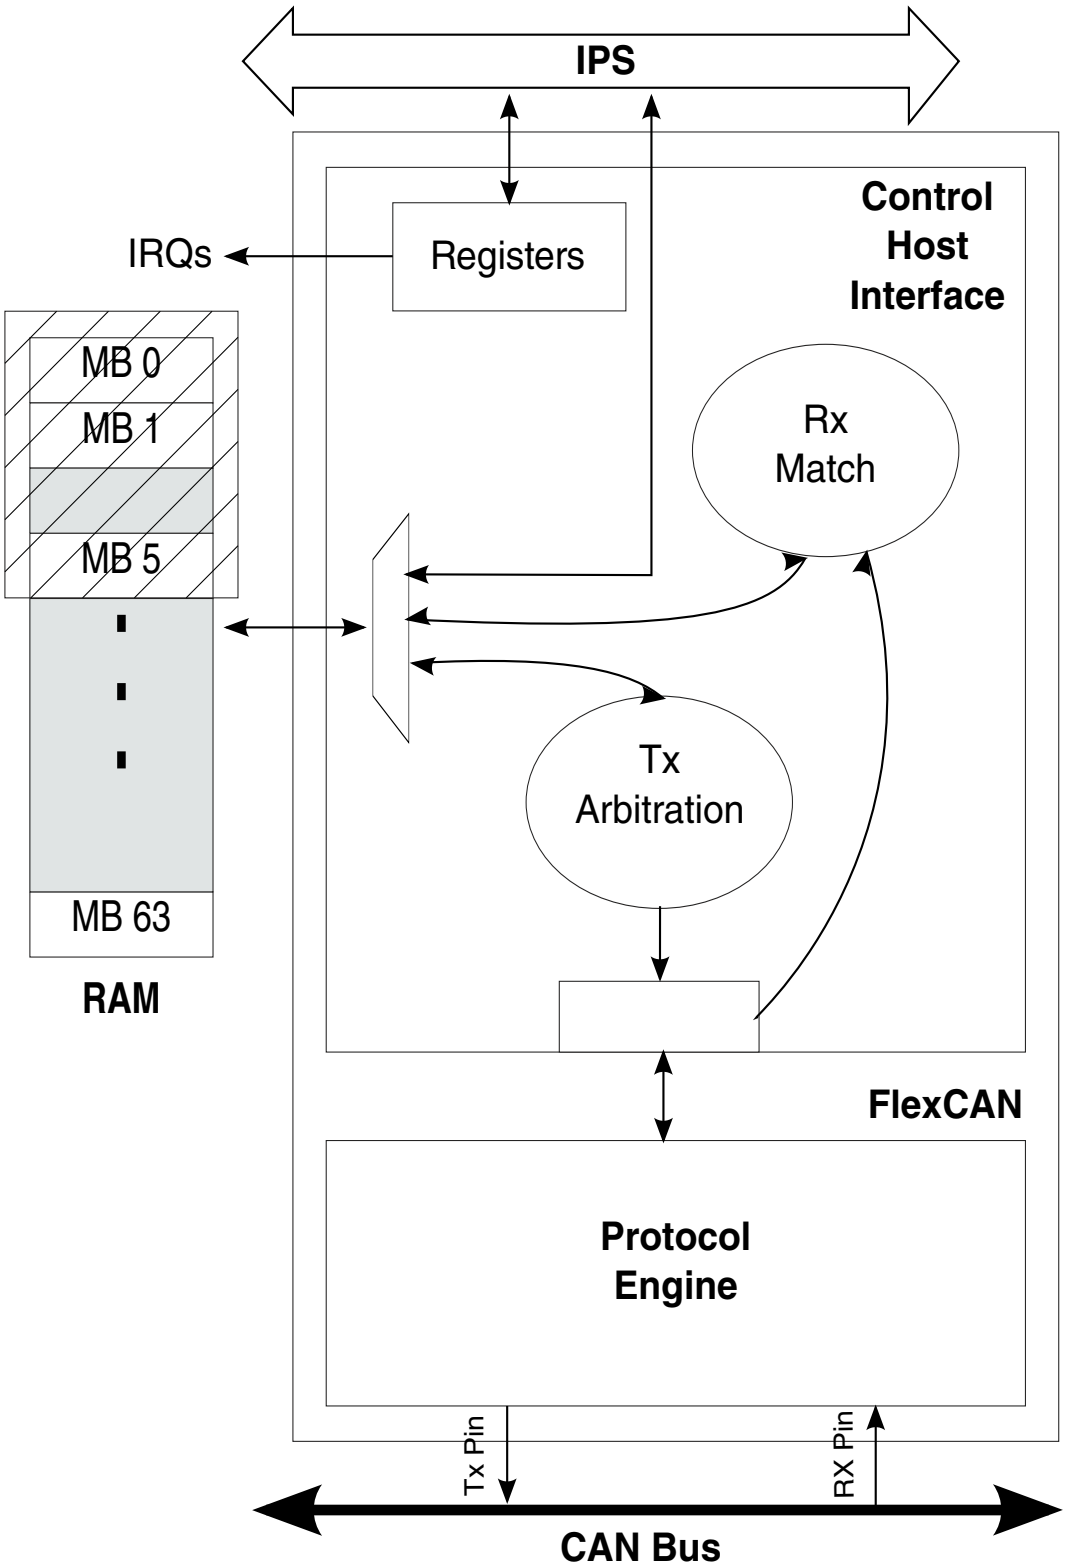


Figure 15-1. FLEXCAN Block Diagram

15.1.1.2 FLEXCAN Module Features

The FLEXCAN module includes these distinctive legacy features:

- Version 2.0B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Flexible Mailboxes of eight bytes data length
- Each Mailbox is configurable as Rx or Tx, all supporting standard and extended messages
- Individual Rx Mask Registers per Mailbox
- Full featured Rx FIFO with storage capacity for 6 frames and internal pointer handling
- Transmission abort capability
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard or 512 partial (8 bits) IDs, with up to 32 individual masking capability
- 100% backwards compatibility with previous FLEXCAN version
- Unused structures space can be used as general purpose RAM space
- Listen only mode capability
- Programmable loop-back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number or highest priority
- Time Stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts independent of the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Configurable Glitch filter width to filter the noise on CAN bus when waking up
- Remote request frames may be handled automatically or by software.
- ID filter configuration in Normal Mode
- CAN bit time settings and configuration bits can only be written in Freeze Mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- SYNC bit status to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Selectable priority between Mailboxes and Rx FIFO during matching process

15.1.1.3 Modes of Operation

The FLEXCAN module has four functional modes: Normal Mode (User and Supervisor), Freeze Mode, Listen-Only Mode and Loop-Back Mode. There are also two low power modes: Disable Mode and Stop Mode.

- Normal Mode (User or Supervisor):

In Normal Mode, the module operates receiving and/or transmitting message frames, errors are handled normally and all the CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze Mode:

It is enabled when the FRZ bit in the MCR Register is asserted. If enabled, Freeze Mode is entered when the HALT bit in MCR is set or when Debug Mode is requested at MCU level and the FRZ_ACK bit in the MCR Register is asserted by the FlexCAN . In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze Mode for more information.

- Listen-Only Mode:

The module enters this mode when the LOM bit in the Control Register is asserted. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back Mode:

The module enters this mode when the LPB bit in the Control Register is asserted. In this mode, FLEXCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The FLEXCAN_RX input pin is ignored and the FLEXCAN_TX output goes to the recessive state (logic '1'). FLEXCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FLEXCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Module Disable Mode:

This low power mode is entered when the MDIS bit in the MCR Register is asserted and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. Exit from this mode is done by negating the MDIS bit in the MCR Register. See Module Disable Mode for more information.

- Stop Mode:

This low power mode is entered when Stop Mode is requested at ARM level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the ARM that the clocks can be shut down globally. Exit from this mode happens when the Stop Mode request is removed or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Stop Mode for more information.

15.1.2 External Signals

The FLEXCAN module has two I/O signals.

Table 15-1. FLEXCAN External Signals

Signal	Description	Pad	Mode	Direction
FLEXCAN1_RX	FLEXCAN receive pin. This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	ENET1_RDATA2	ALT1	I
		GPIO1_IO12	ALT3	
		I2C1_SCL	ALT2	
		SAI1_RXD	ALT3	
		SD3_DATA7	ALT4	
FLEXCAN1_TX	FLEXCAN transmit pin. This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	ENET1_RDATA3	ALT1	O
		GPIO1_IO13	ALT3	
		I2C1_SDA	ALT2	
		SAI1_TXC	ALT3	
		SD3_DATA5	ALT4	
FLEXCAN2_RX	FLEXCAN receive pin. This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	ENET1_TDATA2	ALT1	I
		GPIO1_IO14	ALT3	
		I2C3_SCL	ALT2	
		SAI1_TXFS	ALT3	
		SD3_DATA4	ALT4	
FLEXCAN2_TX	FLEXCAN transmit pin. This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level '0'. Recessive state is represented by logic level '1'.	ENET1_TDATA3	ALT1	O
		GPIO1_IO15	ALT3	
		I2C3_SDA	ALT2	
		SAI1_TXD	ALT3	
		SD3_DATA6	ALT4	

15.1.3 Clocks

The table found here describes the clock sources for FLEXCAN.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-2. FLEXCAN Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_chi	ipg_clk_root	CHI clock
ipg_clk_pe	can_clk_root	Protocol Engine clock
ipg_clk_pe_nogate	can_clk_root	Protocol Engine clock (no gating)
ipg_clk_s	ipg_clk_root	Peripheral access clock
mem_ram_CLK	ipg_clk_root	RAM clock

15.1.4 Message Buffer Structure

Message Buffer Address: Base + 0x0080-0x047C

The Message Buffer structure used by the FLEXCAN module is represented in the figure found here.

Both Extended and Standard Frames (29-bit Identifier and 11-bit Identifier, respectively) used in the CAN specification are represented.

Table 15-3. Message Buffer Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0					CODE					SRR	IDE	RTR	DLC				TIME STAMP															
0x4	PRIO				ID Standard												ID Extended															
0x8	DATA BYTE 0								DATA BYTE 1								DATA BYTE 2								DATA BYTE 3							
0xC	DATA BYTE 4								DATA BYTE 5								DATA BYTE 6								DATA BYTE 7							

CODE - Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FLEXCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in the following tables. See Functional Description for additional information.

Table 15-4. Message Buffer Code for Rx buffers

CODE Description	Rx Code BEFORE receive New Frame	SRV[1]	Rx Code AFTER successful reception[2]	RRS[3]	Comment
0b0000: INACTIVE- MB is not active.	INACTIVE	-	-	-	MB does not participate in the matching process.
0b0100: EMPTY - MB is active and empty.	EMPTY	-	FULL	-	When a frame is received successfully (after move-in process. Refer to Move-in for details), the CODE field is automatically updated to FULL.
0b0010: FULL - MB is full.	FULL	Yes	FULL	-	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. Refer to Matching Process for matching details related to FULL code.
		No	OVERRUN	-	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. Refer to Matching Process for details about overrun behavior.
0b0110: OVERRUN - MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	-	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB, the code returns to FULL.
		No	OVERRUN	-	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. Refer to Matching Process for details about overrun behavior.
0b1010: RANSWER[4] - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.	RANSWER	-	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received, after that a MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). Refer to Matching Process for details. If CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
			-	1	This code is ignored during matching and arbitration process. Refer to Matching Process for details.

Table continues on the next page...

Table 15-4. Message Buffer Code for Rx buffers (continued)

CODE Description	Rx Code BEFORE receive New Frame	SRV[1]	Rx Code AFTER successful reception[2]	RRS[3]	Comment
CODE[0]=1b1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[5]	-	FULL	-	Indicates that the MB is being updated, it will be negated automatically and does not interfere on the next CODE.
			OVERRUN	-	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered successful reception after the frame to be moved to MB (move-in process). Refer to Move-in for details)
3. Remote Request Stored bit from CTRL2 register. Refer to CTRL2 for details.
4. Code 4'b1010 is not considered as a Tx and a MB with this code should not to be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 15-5. Message Buffer Code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE - MB is not active	INACTIVE	-	-	MB does not participate in the arbitration process.
0b1001: ABORT - MB is aborted	ABORT	-	-	MB does not participate in the arbitration process. .
0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	-	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of match to a remote request frame. The remote response frame will be transmitted unconditionally once and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. Refer to Matching Process and Arbitration process for details.

SRR - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to '1' by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FLEXCAN receives this bit as dominant, then it is interpreted as arbitration loss.

1= Recessive value is compulsory for transmission in Extended Format frames

0= Dominant is not a valid value for transmission in Extended Format frames

IDE - ID Extended Bit

This bit identifies whether the frame format is standard or extended. It is also used as part of the reception filter.

1= Frame format is extended

0= Frame format is standard

RTR - Remote Transmission Request

This bit affects the behavior of Remote Frames and is part of the reception filter. Refer to the tables above and RRS bit in Control 2 Register (FLEXCAN_CTRL2) for additional details.

If FLEXCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FLEXCAN module treats it as bit error. If the value received matches the value transmitted, it is considered as a successful bit transmission.

1= Indicates the current MB has a Remote Frame to be transmitted if MB is Tx. If the MB is Rx then incoming Remote Request Frames may be stored.

0= Indicates the current MB has a Data Frame to be transmitted. In Rx MB it may be considered in matching processes.

DLC - Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x08 through 0x0F of the MB space (see the first table above). In reception, this field is written by the FLEXCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the ARM and corresponds to the DLC field value of the frame to be transmitted. When RTR=1, the Frame to be transmitted is a Remote Frame and does not include the data field, regardless of the Length field. The DLC field indicates which DATA BYTEs are valid as shown in the table below.

TIME STAMP - Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO - Local priority

This 3-bit field is only used when MCR[LPRIO_EN] bit is asserted and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID - Frame Identifier

In Standard Frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In Extended Frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0-7 - Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (n) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

Table 15-6. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0-1
3	DATA BYTE 0-2
4	DATA BYTE 0-3
5	DATA BYTE 0-4
6	DATA BYTE 0-5
7	DATA BYTE 0-6
8	DATA BYTE 0-7

15.1.5 Rx FIFO Structure

When the MCR[RFEN] bit is set, the memory area from $80 to $DC (which is normally occupied by MBs 0 to 5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a Message Buffer. This output contains the oldest message received and not read yet. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, that starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 up to 37) depending on the CTRL2[RFFN] field setting, contains the ID Filter Table (configurable from 8 to 128 memory positions) that specifies filtering criteria for accepting frames into the FIFO.Table 15-7 shows the Rx FIFO data structure.

Each ID Filter Table Element occupies an entire 32-bit word and can be compounded by one, two or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. Table 15-8, Table 15-9 and Table 15-10 show the IDAF indexation. Table 15-11 show the three different formats that the IDAF can assume, depending on the MCR[IDAM] field setting. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Out of reset, the ID Filter Table flexible memory area defaults to 0xE0 and only extends to 0xFC, which corresponds to MBs 6 to 7 for RFFN=0.

Table 15-7. Rx FIFO Structure

Table 15-11. Identifier Acceptance Filter Format A,B and C

	(Std/Ext = 31-24)	(Std/Ext = 23-16)	(Std/Ext = 15-8)	(Std/Ext = 7-0)

RTR - Remote Frame

This bit specifies whether Remote Request Frames are accepted into the FIFO if they match the target ID in Formats A and B. If Format C is chosen the acceptance does not depend on whether the frame is a Remote Request Frame or not.

1= Remote Frames can be accepted and data frames are rejected

0= Remote Frames are rejected and data frames can be accepted

IDE - Extended Frame

Specifies if either Extended or Standard Format frames are accepted into the FIFO if they match the target ID in Formats A and B. If Format C is chosen the acceptance does not depend on whether the frame is of the Extended or Standard Format.

1= Extended frames can be accepted and standard frames are rejected

0= Extended frames are rejected and standard frames can be accepted

RXIDA - Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), only the 11 most significant bits (29 to 19) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all bits are used.

RXIDB_0, RXIDB_1 - Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), the 11 most significant bits (29 to 19 and 13 to 3) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all 14 bits of the field are compared with the 14 most significant bits of the Identifier of the incoming frame. The 15 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 - Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both Standard Format and Extended Format, all 8 bits of the field are compared to the 8 most significant bits of the Identifier of the incoming frame. The 3 least significant bits of the Identifier of an incoming Standard Format frame and the 21 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

15.1.6 Functional Description

This section provides a complete functional description of the block.

15.1.6.1 Functional Overview

The FLEXCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames.

The mailbox system consists of a set of 64 Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message Buffer Structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a *matching* algorithm makes it possible to store received frames only into MBs that have the same ID. A masking scheme makes it possible to match the ID programmed on the MB with a range of Identifiers on received CAN frames. For transmission, an *arbitration* algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 15-4). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 15-5).

15.1.6.2 Transmit Process

In order to transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the procedure found here.

1. Check if the respective interruption bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission Abort Mechanism). If backwards compatibility is desired (MCR[AEN]

bit negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Message Buffer Inactivation).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control and Code fields of the Control and Status word to activate the MB.

Once the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority.

At the end of the successful transmission, the value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the MB's Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB in step four (see Table 15-4 and Table 15-5 in Message Buffer Structure)

When the Abort feature is enabled (MCR[AEN] bit is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until it negates the Interrupt Flag. It means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

15.1.6.3 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest Mailbox number and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value. See Control 2 Register (FLEXCAN_CTRL2) for details.
- During the error delimiter field of the CAN frame
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When ARM write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and ARM writes to the C/S word of any MB.

- When FlexCAN exits Bus Off state
- Upon leaving Freeze Mode or Low Power Mode

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIO_EN] bits settings.

15.1.6.3.1 Lowest Mailbox number first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIO_EN] bit has no effect when CTRL1[LBUF] is asserted.

15.1.6.3.2 Highest Mailbox priority first

If CTRL1[LBUF] bit is negated then the arbitration process searches the active Tx Mailbox with the highest priority, and this Mailbox would have a higher probability to win the arbitration on CAN bus.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest priority Tx Mailbox is the one that has the least arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values the lowest Mailbox number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIO_EN] bit setting.

15.1.6.3.2.1 Local Priority disabled

If MCR[LPRIO_EN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see Table 15-12) in such a way that the Local Priority is disabled.

Table 15-12. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

15.1.6.3.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIO_EN] must be asserted.

In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the table below).

Table 15-13. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18](11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

Once the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called "move-out" and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze Mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the DLC (Data Length Code) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. Arbitration start point depends on instantiation parameters NUMBER_OF_MB and TASD. Additionally, TASD value may be changed (see Control 2 Register (FLEXCAN_CTRL2)) to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. Arbitration start point depends on instantiation parameters NUMBER_OF_MB and TASD. Additionally,

TASD value may be changed (see Control 2 Register (FLEXCAN_CTRL2)) to optimize the arbitration start point.

- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze Mode. If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned.
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process. For instance, a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus.
- Low Power or Freeze Mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB which number is lower than the Tx arbitration pointer.
- Any C/S write if there is no Tx Arbitration process in progress.
- Rx Match has just updated a Rx Code to Tx Code.
- Entering Bus off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- C/S write during arbitration if write is performed in a MB which number is higher than the Tx arbitration pointer.

15.1.6.4 Receive Process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the steps listed here.

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Message Buffer Inactivation), preferably with a *safe inactivation* (see Transmission Abort Mechanism);
2. Write the ID word;
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

Once the Mailbox is activated in the third step, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in process* (see Move-in) as follows:

1. The received Data field (8 bytes at most) is stored;
2. The received Identifier field is stored;
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox Time Stamp field;
4. The received SRR, IDE, RTR and DLC fields are stored;
5. The CODE field in the Control and Status word is updated. (see Table 15-4 and Table 15-5 in Section Message Buffer Structure)
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU servicing (read) the frame received in a Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox;
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Message Buffer Lock Mechanism;
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in;
4. Acknowledge the proper flag at IFLAG registers;
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL. If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received message matching the filter of that Mailbox may be lost.

In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in a Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRX_DIS] bit is not asserted. If MCR[SRX_DIS] bit is asserted, FlexCAN will not store messages transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN messages through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze Mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see Interrupt Masks 1 Register (FLEXCAN_IMASK1), bit IFLAG[BUF5I] - Frames available in Rx FIFO), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional - needed only if a mask was used for IDE and RTR bits);
2. Read the ID field (optional - needed only if a mask was used);
3. Read the Data field;
4. Read the RXFIR register (optional);
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory - releases the MB and allows the CPU to read the next Rx FIFO entry)

15.1.6.5 Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus.

If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- if the received frame is a remote frame, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame;

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures* . The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. Please, refer to the following table for details.

Table 15-14. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID][1]	MB[CODE]
Mailbox	0	-	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO[5]	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). In case of SMB[IDE] to be negated, the ID is only 11 bits (ID Standard). Please, refer to Message Buffer Structure for ID details. For FIFO structure, the ID depends on IDAM. Please, refer to Rx FIFO Structure for IDAM details.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no_cmp: The SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- the CODE field of the Mailbox is EMPTY;
- the CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the ARM and unlocked as described in Message Buffer Lock Mechanism);

- the CODE field of the Mailbox is either FULL or OVERRUN and an inactivation is performed. (see Message Buffer Inactivation)
- the Rx FIFO is not full.

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- if the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes;
- otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above.

If the selected priority is Mailboxes first:

- if a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO;
- if no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO;
- if both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - if MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox;
  - if MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox.

Please, refer to the table below for a summary of matching possibilities.

If a non-safe Mailbox inactivation (see Message Buffer Inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor

restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

Table 15-15. Matching Possibilities and Resulting Reception Structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception Structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	-[3]	None	Frame lost by no match
0	0	X	Free[4]	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMB	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMB	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull[6]	FIFO	
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMB	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)

Table continues on the next page...

Table 15-15. Matching Possibilities and Resulting Reception Structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception Structure	Description
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMB	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMB	Overrun

1. It is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. It is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for ARM to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. ARM can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Please refer to Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK) . During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze Mode , otherwise they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RGXMASK, RX14MASK, RX15MASK and RXFGMASK) for backward compatibility. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

15.1.6.6 Move Process

There are two types of move process, namely move-in and move-out.

15.1.6.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead.

The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching Process) and all of the following conditions are true:

- the CAN bus has reached or let past either:
  - the second bit of Intermission field next to the frame that carried the message that is in the Rx SMB;
  - the first bit of an overload frame next to the frame that carried the message that is in the Rx SMB;
- there is no ongoing matching process;
- the destination Mailbox is not locked by ARM;
- there is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the document and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- the destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished;
- there is a previous pending move-in to the same destination Mailbox.
- the Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled;
- any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters in Freeze or Low Power Mode. It only stays on hold waiting for exiting Low Power Mode and to be unlocked. If an MB is unlocked during Freeze Mode, the move-in happens immediately.

The move-in process consists of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;

5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field according to Table 15-4.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Message Buffer Inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed in such a way that ARM beware that the Message Buffer content is temporarily incoherent.

15.1.6.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process).

The move-out occurs in the following conditions:

- the first bit of Intermission field;
- during Bus off field when TX Error Counter is in the 124 to 128 range;
- during BusIdle field
- during Wait For Bus Idle field

The move-out process is not atomic. Only ARM has priority to access the memory concurrently out of BusIdle state. In BusIdle, the move-out has the lowest priority to the concurrent memory accesses.

15.1.6.7 Data Coherence

In order to maintain data coherency and FlexCAN proper operation, the ARM must obey the rules described in

Any form of ARM accessing an MB structure within FlexCAN other than those specified may cause FlexCAN to behave in an unpredictable way.

15.1.6.7.1 Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform ARM if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

In order to abort a transmission, ARM must write a specific abort code (0b1001) to the CODE field of the Control and Status word. The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze Mode
- The module enters in BusOff state
- There is an overload frame

If none of conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register and an interrupt to the ARM is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. In the other hand, if one of the above conditions is reached, the frame is not transmitted, therefore the abort code is written into the CODE field, the interrupt flag is set in the IFLAG and an interrupt is (optionally) generated to ARM.

If ARM writes the ABORT code before the transmission begins internally, then the write operation is not blocked, therefore the MB is updated and the interrupt flag is set. In this way ARM just needs to read the abort code to make sure the active MB was *safely inactivated* . Although the AEN bit is asserted and ARM wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

1. ARM checks the corresponding IFLAG and clears it, if asserted.
2. ARM writes 0b1001 into the CODE field of the C/S word.
3. ARM waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
4. ARM reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
5. It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

15.1.6.7.2 Message Buffer Inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing ARM to rely on Mailbox data coherence after having updated it, even in Normal Mode.

If a Mailbox is inactivated it does not participate neither in the arbitration nor in the matching process until it is reactivated. See Transmit Process and Receive Process for more detailed instruction on how to inactivate and reactivate a Mailbox.

In order to inactivate a Mailbox ARM must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

As the user is not able to synchronize the CODE field update with the FlexCAN internal processes an inactivation can lead to undesirable results:

- a frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter;
- a frame containing the message within the inactivated Tx Mailbox may be transmitted without notice.

In order to eliminate such risk and perform a *safe inactivation* ARM must use the following mechanism along with the inactivation itself:

- for Tx Mailboxes, the Transmission Abort (see Transmission Abort Mechanism);

The inactivation automatically unlocks the Mailbox (see Message Buffer Lock Mechanism).

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on FIFO region by FlexCAN. ARM must keep the data coherence into FIFO region when RFEN is asserted.

15.1.6.7.3 Message Buffer Lock Mechanism

Besides MB inactivation, FlexCAN has another data coherence mechanism for the receive process. When ARM reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that ARM wants to read the whole MB in an atomic operation, and thus it sets an internal lock flag for that MB. The lock is released when ARM reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code or when ARM writes into C/S word from locked MB. The MB locking is done to prevent a new frame to be written into the MB while ARM is reading it.

The locking mechanism only applies to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY[1] (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the ARM decides to read MB number 5 and at the same time another message with the same ID is arriving. When ARM reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB. If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If ARM reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If ARM inactivates a locked Rx Mailbox, then its lock status is negated and the Mailbox is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the Mailbox.An MB is unlocked when ARM reads the Free Running Timer Register (see Free Running Timer Register (FLEXCAN_TIMER)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during any of the low power modes (see in Modes of Operation specific information on Module Disable or Stop modes) and it will take place only when the module resumes to Normal or Freeze modes.

15.1.6.8 Rx FIFO

The receive-only FIFO is enabled by asserting the RFEN bit in the MCR.

1. In previous FlexCAN versions, reading the C/S word locks the MB even if it is EMPTY. This behavior is maintained when the IRMQ bit is negated.

The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep, therefore when the FIFO is enabled, the memory region occupied by the first 6 Message Buffers is reserved for use of the FIFO engine (see Rx FIFO Structure). ARM can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, ARM can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to ARM. Otherwise, the flag remains negated. The output of the FIFO is only valid when the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until ARM clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the ARM clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, thus reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO Structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid whilst

the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to thirty two elements of the ID Filter Table are individually affected by the Individual Mask Registers (RXIMR0 - RXIMR31), according to CTRL2[RFFN] setting (refer to Control 2 Register (FLEXCAN_CTRL2)), allowing very powerful filtering criteria to be defined. If the MCR[IRMQ] bit is negated (or if the RXIMR are not available for the particular MCU), then the FIFO ID Filter Table is affected by RXFGMASK.

15.1.6.9 CAN Protocol Related Features

15.1.6.9.1 Remote Frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No

automatic remote response frame will be generated. The mask registers are used in the matching process.

- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the ARM. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID).Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

15.1.6.9.2 Overload Frames

FLEXCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

15.1.6.9.3 Time Stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

Note that the Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. Refer to TSYN description in Control 1 Register (FLEXCAN_CTRL1).

15.1.6.9.4 Protocol Timing

The FLEXCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See Control 1 Register (FLEXCAN_CTRL1) .

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler value})}$$

A bit time is subdivided into three segments[2] (reference Table 15-16):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL Register (plus 1) to be 2 to 8 time quanta long

$$\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}$$

2. For further explanation of the underlying concepts please refer to ISO/DIS 11519-1, Section 10.3. Reference also the Bosch CAN 2.0A/B protocol specification dated September 1991 for bit timing.

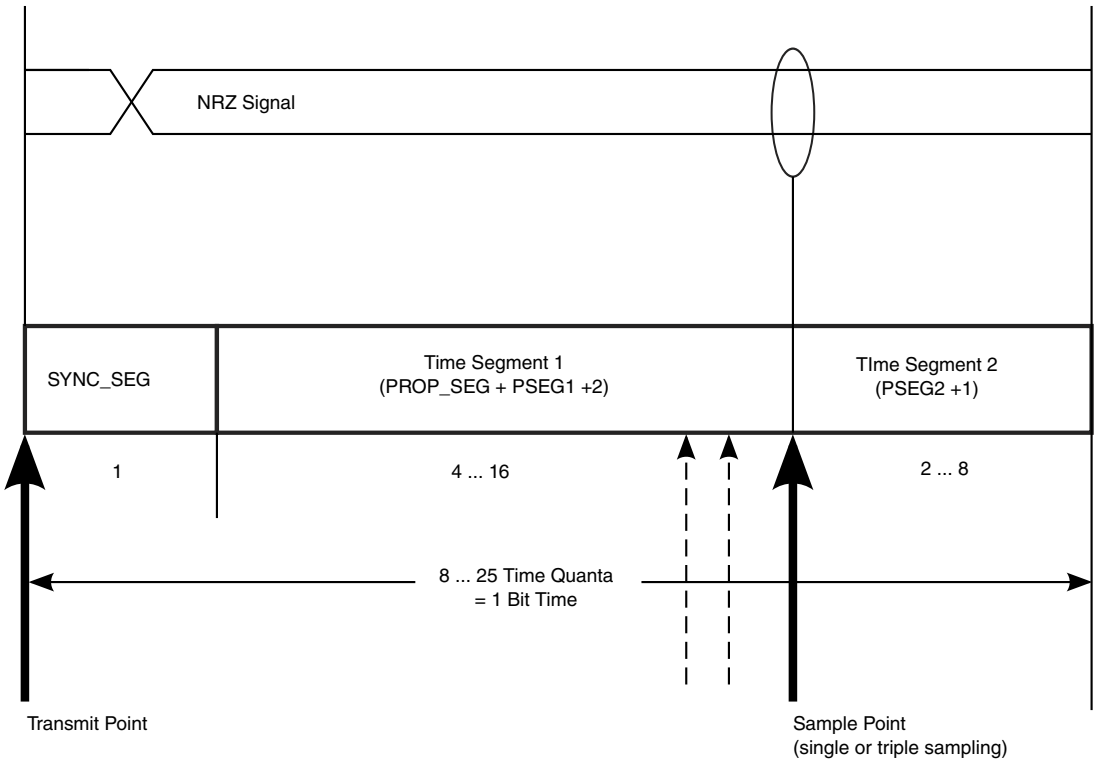

Figure 15-2. Segments within the Bit Time

Whenever CAN bit is used as a measure of duration (e.g. MCR[FRZ_ACK] and MCR[LPM_ACK] in Module Configuration Register (FLEXCAN_MCR)), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{sys} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRESDIV + 1)}{f_{CANCLK}}$$

where:

NCCP is the number of peripheral clocks in one CAN bit;

f_{CANCLK} is the Protocol Engine (PE) Clock in Hz;

f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;

PSEG1 is the value in CTRL1[PSEG1] field;

PSEG2 is the value in CTRL1[PSEG2] field;

PROPSEG is the value in CTRL1[PROPSEG] field;

PRESDIV is the value in CTRL1[PRESDIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

Figure 15-2 gives an overview of the CAN compliant segment settings and the related parameter values.

Table 15-16. Time Segment Syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

Table 15-17. CAN Standard Compliant Bit Time Segment Settings

Time Segment 1	Time Segment 2	Re-synchronization Jump Width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

15.1.6.9.5 Arbitration and Matching Timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

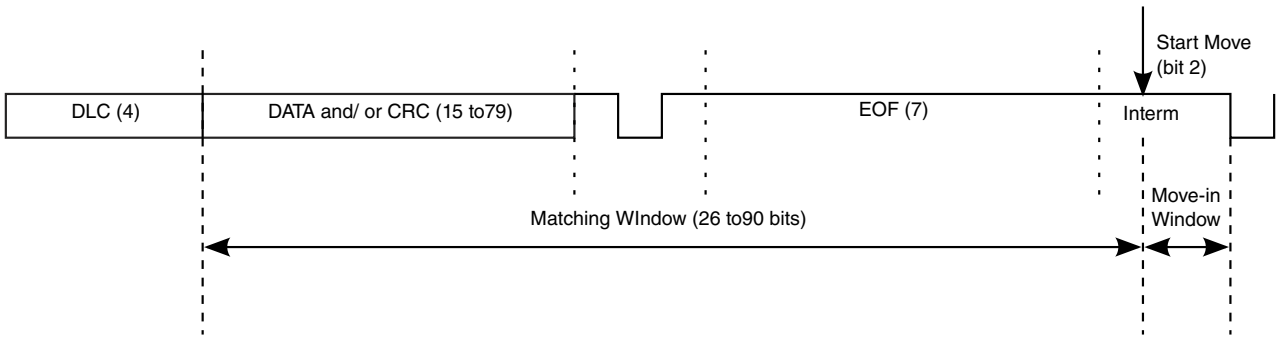

Figure 15-3. Matching and Move-In Time Windows

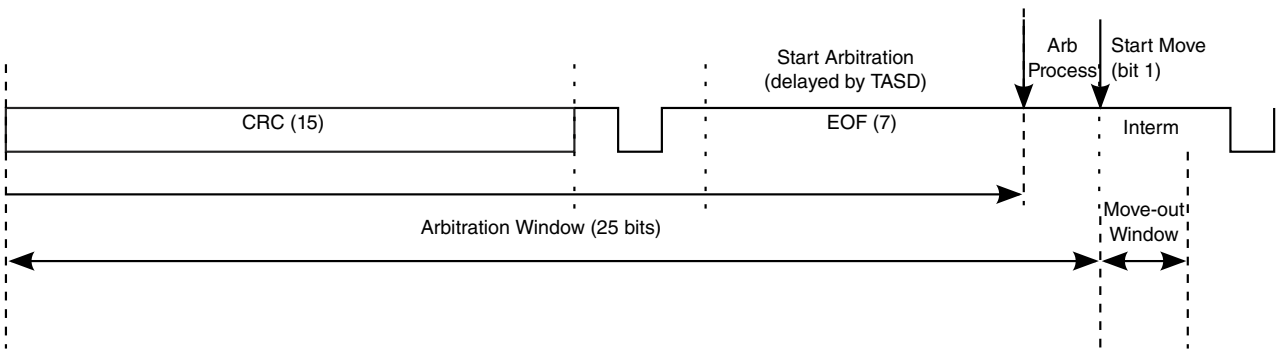

Figure 15-4. Arbitration and Move-Out Time Windows

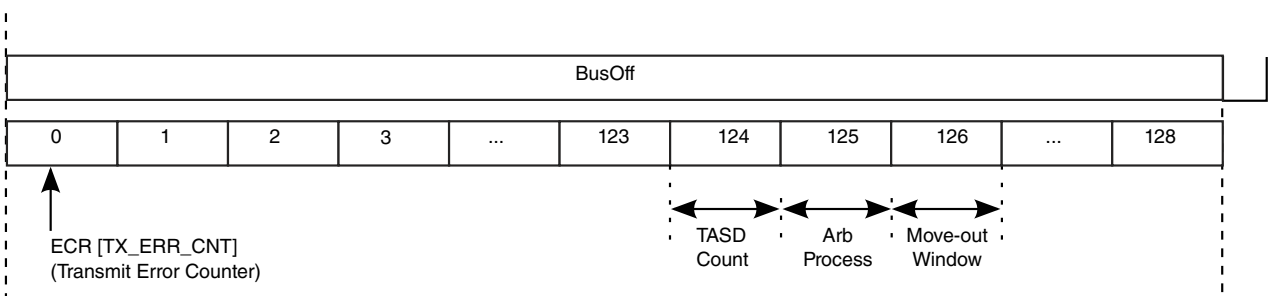

Figure 15-5. Arbitration at the end of Bus Off and Move-Out Time Windows

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time window. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in Table 15-17
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, i.e. the PLL can not be programmed to divide down the oscillator clock
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table.

Table 15-18. Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate

Number of Message Buffers	RFEN	Minimum Number of Peripheral Clocks per CAN bit
16 and 32	0	16
64	0	25
16	1	16
32	1	17
64	1	30

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, so the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in Table 15-18 can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRESDIV, PROPSEG, PSEG1, PSEG2). As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRESDIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

15.1.6.10 Modes of Operation Details

The FlexCAN module has four functional modes (Normal Mode, Freeze Mode, Listen-Only Mode and Loop-Back Mode) and two low power modes (Disable Mode and Stop Mode).

See in Modes of Operation an introductory description of all these modes of operation. The following sub-sections bring functional details on Freeze mode and the low power modes.

15.1.6.10.1 Freeze Mode

This mode is requested by ARM through the assertion of the HALT bit in the MCR Register or when the MCU is put into Debug Mode . In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in any of the low power modes (Disable, Stop). The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The ARM must only consider the FlexCAN in Freeze Mode when both request and acknowledgement conditions are satisfied.

When Freeze Mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
- Ignores the FLEXCAN_RX input pin and drives the FLEXCAN_TX pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in MCR

After requesting Freeze Mode, the user must wait for the FRZ_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK_SRC] bit that can be read but cannot be written.

Exiting Freeze Mode is done in one of the following ways:

- ARM negates the FRZ bit in the MCR Register
- The ARM is removed from Debug Mode and the HALT bit is negated

The FRZ_ACK bit is negated after protocol engine recognizes the negation of freeze request. Once out of Freeze Mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

15.1.6.10.2 Module Disable Mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the ARM through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM_ACK bit in the same register. The ARM must only consider the FlexCAN in Disable Mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze Mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM_ACK bit and negates the FRZ_ACK bit. The ability to shut down the clocks depends on how FlexCAN is integrated into the MCU. If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
- Ignores its FLEXCAN_RX input pin and drives its FLEXCAN_TX pin as recessive

- May shut down the clocks to the PE and CHI sub-modules, depending on how FlexCAN is integrated into the MCU
- Sets the NOT_RDY and LPM_ACK bits in MCR

The Bus Interface Unit continues to operate, enabling the ARM to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode depending on how FlexCAN RAM is integrated into the ARM. Exiting from this mode is done by negating the MDIS bit by ARM, which make FlexCAN requests to resume the clocks and negates the LPM_ACK bit after CAN protocol engine recognizes the negation of disable mode requested by ARM.

15.1.6.10.3 Stop Mode

This is a system low power mode in which system clocks can be stopped for maximum power savings.. To enter stop mode, the CPU should manually assert a global Stop Mode request (see the CAN1_STOP_REQ and CAN2_STOP_REQ bit in the register IOMUXC_GPR4)and check the acknowledgement asserted by the FlexCAN (see the CAN1_STOP_ACK and CAN2_STOP_ACK in the register IOMUXC_GPR4) . The CPU must only consider the FlexCAN in Stop Mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop Mode request during Freeze Mode, it sets the LPM_ACK bit, negates the FRZ_ACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally. If Stop Mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish.Pending move-in is not taken in account
- Ignores its FLEXCAN_RX input pin and drives its FLEXCAN_TX pin as recessive
- Sets the NOT_RDY and LPM_ACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Exiting Stop Mode is done in one of the following ways:

- ARM resuming the clocks and removing the Stop Mode request
- ARM resuming the clocks and Stop Mode request as a result of the Self Wake mechanism

In the Self Wake mechanism, if the SLF_WAK bit in MCR Register was set at the time FlexCAN entered Stop Mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAK_INT bit in the ESR Register and, if enabled by the WAK_MSK bit in MCR, generates a Wake Up interrupt to the ARM. Upon receiving the interrupt, the ARM should resume the clocks and remove the Stop Mode request manually. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the FLEXCAN_RX input line while in Stop Mode. See the WAK_SRC bit in Module Configuration Register (FLEXCAN_MCR) . This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments, the glitch filter width can be set in Glitch Filter Width Register (FLEXCAN_GFWR).

15.1.6.11 Interrupts

The module can generate up to 70 interrupt sources (64 interrupts due to message buffers and 6 interrupts due to Ored interrupts from MBs, Bus Off, Error, Tx Warning, Rx Warning and Wake Up)).

The number of actual sources depends on the configured number of message buffers.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG Registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the ARM writes it to '1' (unless another interrupt is generated at the same time).

If the Rx FIFO is enabled (bit RFEN on MCR set), the interrupts corresponding to MBs 0 to 7 have a different behavior. Bit 7 of the IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag" and bits 4-0 are unused. See Interrupt Flags 1 Register (FLEXCAN_IFLAG1) for more information.

A combined interrupt for all MBs is also generated by an Or of all the interrupt sources from MBs. This interrupt gets generated when any of the Mailboxes or FIFO generates an interrupt. The ARM must read the IFLAG Registers to determine which MB or FIFO caused the interrupt.

The other 5 interrupt sources (Bus Off, Error, Tx Warning, Rx Warning and Wake Up generate interrupts like the MB ones, and can be read from both the Error and Status Register 1 and 2. The Bus Off, Error, Tx Warning and Rx Warning interrupt mask bits are located in the Control 1 Register and the Wake-Up interrupt mask bit is located in the MCR.

15.1.7 Initialization/Application Information

This section provide instructions for initializing the FLEXCAN module.

15.1.7.1 FLEXCAN Initialization Sequence

The FLEXCAN module may be reset in two ways:

- SOC level hard reset which resets all memory mapped registers asynchronously
- SOFT_RST bit in MCR, which resets some of the memory mapped registers synchronously

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFT_RST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in any of the low power modes. The low power mode should be exited and the clocks resumed before applying soft reset.

After the module is enabled (MDIS bit negated), FLEXCAN automatically goes to Freeze Mode. In Freeze Mode, FLEXCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZ_ACK and NOT_RDY bits in the MCR Register are set. The FLEXCAN_TX pin is in recessive state and FLEXCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FLEXCAN is put into Freeze Mode. The following is a generic initialization sequence applicable to the FLEXCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRN_EN bit
  - If required, disable frame self reception by setting the SRX_DIS bit

    - Enable the FIFO by setting the RFEN bit
    - Enable the abort mechanism by setting the AEN bit
    - Enable the local priority feature by setting the LPRIO_EN bit
- Initialize the Control Register
    - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
    - Determine the bit rate by programming the PRESDIV field
    - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
    - The Control and Status word of all Message Buffers must be initialized
    - If FIFO was enabled, the 8-entry ID table must be initialized
    - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts), in CTRL Register (for Bus Off and Error interrupts) and in MCR Register for Wake-Up interrupt
- Negate the HALT bit in MCR

Starting with the last event, FLEXCAN attempts to synchronize to the CAN bus.

15.1.8 FLEXCAN Memory Map/Register Definition

The complete memory map for a FLEXCAN module with 64 MBs capability is shown in the following table. Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV bit in the MCR Register. The MCR register allows only Supervisor access regardless the SUPV bit state.

The FLEXCAN module stores CAN messages for transmission and reception using a Mailboxes and Rx FIFO structure.

FLEXCANx_MCR field descriptions

Field	Description
31 MDIS	This bit controls whether FLEXCAN is enabled or not. When disabled, FLEXCAN shuts down the clocks to the CAN Protocol Interface and Message Buffer Management sub-modules. This is the only bit in MCR not affected by soft reset. See Module Disable Mode for more information. 1 Disable the FLEXCAN module 0 Enable the FLEXCAN module
30 FRZ	The FRZ bit specifies the FLEXCAN behavior when the HALT bit in the MCR Register is set or when Debug Mode is requested at ARM level. When FRZ is asserted, FLEXCAN is enabled to enter Freeze Mode. Negation of this bit field causes FLEXCAN to exit from Freeze Mode. 1 Enabled to enter Freeze Mode 0 Not enabled to enter Freeze Mode
29 RFEN	This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements.RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 15-18 (see Arbitration and Matching Timing).This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 FIFO enabled 0 FIFO not enabled
28 HALT	Assertion of this bit puts the FLEXCAN module into Freeze Mode. The ARM should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FLEXCAN before this bit is cleared. Freeze Mode can not be entered while FLEXCAN is in any of the low power modes.See Freeze Mode for more information 1 Enters Freeze Mode if the FRZ bit is asserted. 0 No Freeze Mode request.
27 NOT_RDY	This read-only bit indicates that FLEXCAN is either in Disable Mode, Stop Mode or Freeze Mode. It is negated once FLEXCAN has exited these modes. 1 FLEXCAN module is either in Disable Mode, Stop Mode or Freeze Mode 0 FLEXCAN module is either in Normal Mode, Listen-Only Mode or Loop-Back Mode
26 WAK_MSK	This bit enables the Wake Up Interrupt generation. 1 Wake Up Interrupt is enabled 0 Wake Up Interrupt is disabled
25 SOFT_RST	When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER, ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, RXIMR0_RXIMR63, RXGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR and all Message Buffers The SOFT_RST bit can be asserted directly by the ARM when it writes to the MCR Register. It may take some time to fully propagate its effect. The SOFT_RST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in any of the low power modes. The module should be first removed from low power mode, and then soft reset can be applied.

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
	1 Reset the registers 0 No reset request
24 FRZ_ACK	This read-only bit indicates that FLEXCAN is in Freeze Mode and its prescaler is stopped. The Freeze Mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZ_ACK bit to know when FLEXCAN has actually entered Freeze Mode. If Freeze Mode request is negated, then this bit is negated once the FLEXCAN prescaler is running again. If Freeze Mode is requested while FLEXCAN is in any of the low power modes, then the FRZ_ACK bit will only be set when the low power mode is exited. See Freeze Mode for more information 1 FLEXCAN in Freeze Mode, prescaler stopped 0 FLEXCAN not in Freeze Mode, prescaler running
23 SUPV	This bit configures some of the FLEXCAN registers to be either in Supervisor or User Mode. Reset value of this bit is '1', so the affected registers start with Supervisor access allowance only. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 FlexCAN is in Supervisor Mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location 0 FlexCAN is in User Mode. Affected registers allow both Supervisor and Unrestricted accesses
22 SLF_WAK	This bit enables the Self Wake Up feature when FLEXCAN is in Stop Mode. If this bit had been asserted by the time FLEXCAN entered Stop Mode, then FLEXCAN will look for a recessive to dominant transition on the bus during these modes. If a transition from recessive to dominant is detected during Stop Mode, then FLEXCAN generates, if enabled to do so, a Wake Up interrupt to the ARM so that it can resume the clocks globally and FlexCAN can request to resume the clocks. This bit can not be written while the module is in Stop Mode. 1 FLEXCAN Self Wake Up feature is enabled 0 FLEXCAN Self Wake Up feature is disabled
21 WRN_EN	When asserted, this bit enables the generation of the TWRN_INT and RWRN_INT flags in the Error and Status Register. If WRN_EN is negated, the TWRN_INT and RWRN_INT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated.This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 TWRN_INT and RWRN_INT bits are set when the respective error counter transition from <96 to ≥ 96. 0 TWRN_INT and RWRN_INT bits are zero, independent of the values in the error counters.
20 LPM_ACK	This read-only bit indicates that FLEXCAN is either in Disable Mode or Stop Mode. Either of these low power modes can not be entered until all current transmission or reception processes have finished, so the ARM can poll the LPM_ACK bit to know when FLEXCAN has actually entered low power mode. See Module Disable Mode, and Stop Mode for more information 1 FLEXCAN is either in Disable Mode, or Stop mode 0 FLEXCAN not in any of the low power modes
19 WAK_SRC	This bit defines whether the integrated low-pass filter is applied to protect the FLEXCAN_RX input from spurious wake up. See Stop Mode for more information. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 FLEXCAN uses the filtered FLEXCAN_RX input to detect recessive to dominant edges on the CAN bus 0 FLEXCAN uses the unfiltered FLEXCAN_RX input to detect recessive to dominant edges on the CAN bus.
18 -	This field is reserved. Reserved

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
17 SRX_DIS	This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Self reception disabled 0 Self reception enabled
16 IRMQ	This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Individual Rx masking and queue feature are enabled. 0 Individual Rx masking and queue feature are disabled.For backward compatibility, the reading of C/S word locks the MB even if it is EMPTY.
15–14 -	This field is reserved. Reserved
13 LPRIO_EN	This bit is provided for backwards compatibility reasons. It controls whether the local priority feature is enabled or not. It is used to extend the ID used during the arbitration process. With this extended ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames.This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Local Priority enabled 0 Local Priority disabled
12 AEN	This bit is supplied for backwards compatibility reasons. When asserted, it enables the Tx abort feature. This feature guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.Write Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted. 1 Abort enabled 0 Abort disabled
11–10 -	This field is reserved. Reserved
9–8 IDAM	This 2-bit field identifies the format of the elements of the Rx FIFO filter table, as shown below. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Rx FIFO Structure. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 00 Format A One full ID (standard or extended) per ID filter Table element. 01 Format B Two full standard IDs or two partial 14-bit extended IDs per ID filter Table element. 10 Format C Four partial 8-bit IDs (standard or extended) per ID filter Table element. 11 Format D All frames rejected.
7 -	This field is reserved. Reserved
MAXMB	This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to 16 MB configuration. This field can only be written in Freeze Mode as it is blocked by hardware in other modes Number of the last MB = MAXMB.

Table continues on the next page...

FLEXCANx_MCR field descriptions (continued)

Field	Description
	NOTE: Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN] MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 15-18 (see Arbitration and Matching Timing).

15.1.8.2 Control 1 Register (FLEXCANx_CTRL1)

This register is defined for specific FLEXCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back Mode, Listen Only Mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: Base address + 4h offset

FLEXCANx_CTRL1 field descriptions

Field	Description
31–24 PRESDIV	This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this register is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256.For more information refer to Protocol Timing. This field can only be written in Freeze mode as it is blocked by hardware in other modes.

Table continues on the next page...

FLEXCANx_CTRL1 field descriptions (continued)

Field	Description
	Sclock frequency = CPI clock frequency / (PRESDIV+1)
23–22 RJW	This 2-bit field defines the maximum number of time quanta[1] that a bit time can be changed by one re-synchronization. The valid programmable values are 0-3. This field can only be written in Freeze mode as it is blocked by hardware in other modes Resync Jump Width = RJW + 1.
21–19 PSEG1	This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes Phase Buffer Segment 1 = (PSEG1 + 1) x Time-Quanta.
18–16 PSEG2	This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes Phase Buffer Segment 2 = (PSEG2 + 1) x Time-Quanta.
15 BOFF_MSK	This bit provides a mask for the Bus Off Interrupt. 1 Bus Off interrupt enabled 0 Bus Off interrupt disabled
14 ERR_MSK	This bit provides a mask for the Error Interrupt. 1 Error interrupt enabled 0 Error interrupt disabled
13 -	This field is reserved. Reserved
12 LPB	This bit configures FlexCAN to operate in Loop-Back Mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The FLEXCAN_RX input pin is ignored and the FLEXCAN_TX output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Loop Back enabled 0 Loop Back disabled
11 TWRN_MSK	This bit provides a mask for the Tx Warning Interrupt associated with the TWRN_INT flag in the Error and Status Register. This bit is read as zero when MCR[WRN_EN] bit is negated. This bit can only be written if MCR[WRN_EN] bit is asserted. 1 Tx Warning Interrupt enabled 0 Tx Warning Interrupt disabled
10 RWRN_MSK	This bit provides a mask for the Rx Warning Interrupt associated with the RWRN_INT flag in the Error and Status Register. This bit is read as zero when MCR[WRN_EN] bit is negated. This bit can only be written if MCR[WRN_EN] bit is asserted. 1 Rx Warning Interrupt enabled 0 Rx Warning Interrupt disabled
9–8 -	This field is reserved. Reserved
7 SMP	This bit defines the sampling mode of CAN bits at the FLEXCAN_RX. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.

Table continues on the next page...

FLEXCANx_CTRL1 field descriptions (continued)

Field	Description
	1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples, a majority rule is used 0 Just one sample is used to determine the bit value
6 BOFF_REC	This bit defines how FLEXCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFF_REC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FLEXCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFF_REC bit can be re-asserted again during Bus Off, but it will only be effective the next time the module enters Bus Off. If BOFF_REC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 1 Automatic recovering from Bus Off state disabled 0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B
5 TSYN	This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FLEXCAN stations with a special "SYNC" message (i.e., global network time). If the RFEN bit in MCR is set (FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0.This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Timer Sync feature enabled 0 Timer Sync feature disabled
4 LBUF	This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIO_EN bit does not affect the priority arbitration.This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Lowest number buffer is transmitted first 0 Buffer with highest priority is transmitted first
3 LOM	This bit configures FLEXCAN to operate in Listen Only Mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message. Listen-Only Mode acknowledgement can be obtained by the state of ESR1[FLT_CONF] field which is Passive Error when Listen-Only Mode is entered. There can be some delay between the Listen-Only Mode request and acknowledge. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 FLEXCAN module operates in Listen Only Mode 0 Listen Only Mode is deactivated
PROP_SEG	This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0-7. This field can only be written in Freeze mode as it is blocked by hardware in other modes Propagation Segment Time = (PROPSEG + 1) * Time-Quanta. Time-Quantum = one Sclock period.

1. One time quantum is equal to the Sclock period.

15.1.8.3 Free Running Timer Register (FLEXCANx_TIMER)

This register represents a 16-bit free running counter that can be read and written by the ARM. The timer starts from $0000 after Reset, counts linearly to $FFFF, and wraps around.

The timer is clocked by the FLEXCAN bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. During Freeze Mode, disable, and stop mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

ARM can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure. For additional details, refer to Message Buffer Lock Mechanism.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15.1.8.4 Rx Mailboxes Global Mask Register (FLEXCANx_RXMGMASK)

RXMGMASK is provided for legacy support. Asserting the MCR[IRMQ] bit causes the RXMGMASK Register to have no effect on the module operation.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Table 15-19. Rx Mailboxes Global Mask usage

SMB[RTR][1]	CTRL2[RRS]	CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	reserved
0	-	0	- Note[2]	- Note[3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If CTRL2[EACEN] bit is negated the RTR bit of Mailbox is never compared with the RTR bit of the Incoming Frame (Rx SMB[RTR]).
3. If CTRL2[EACEN] bit is negated the IDE bit of Mailbox is always compared with the IDE bit of the Incoming Frame (Rx SMB[IDE]).

FLEXCANx_RXMGMASK field descriptions

Field	Description
MG31_MG0	These bits mask the Mailbox filter bits as shown in the figure above. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE which are located in the Control and Status word of the Mailbox. Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK) shows in detail which MG bits mask each Mailbox filter field. 1 The corresponding bit in the filter is checked against the one received 0 the corresponding bit in the filter is "don't care"

15.1.8.5 Rx Buffer 14 Mask Register (FLEXCANx_RX14MASK)

RX14MASK is provided for legacy support, asserting the MCR[IRMQ] bit causes the RX14MASK to have no effect on the module operation.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze Mode as it is blocked by hardware in other modes.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
RX15M31_ RX15M0	These bits mask Mailbox 15 filter bits in the same fashion as RXMGMASK masks other Mailboxes filters (see Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK)). 1 The corresponding bit in the filter is checked 0 the corresponding bit in the filter is "don't care"

15.1.8.7 Error Counter Register (FLEXCANx_ECR)

This register has 2 8-bit fields reflecting the value of two FLEXCAN error counters: Transmit Error Counter (Tx_Err_Counter field) and Receive Error Counter (Rx_Err_Counter field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FLEXCAN module. Both counters are read only except in Freeze Mode, where they can be written by the ARM.

FLEXCAN responds to any bus state as described in the protocol, e.g. transmit 'Error Active' or 'Error Passive' flag, delay its transmission start time ('Error Passive') and avoid any influence on the bus when in 'Bus Off' state. The following are the basic rules for FLEXCAN bus state transitions.

- If the value of Tx_Err_Counter or Rx_Err_Counter increases to be greater than or equal to 128, the FLT_CONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FLEXCAN state is 'Error Passive', and either Tx_Err_Counter or Rx_Err_Counter decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLT_CONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of Tx_Err_Counter increases to be greater than 255, the FLT_CONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of Tx_Err_Counter is then reset to zero.
- If FLEXCAN is in 'Bus Off' state, then Tx_Err_Counter is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, Tx_Err_Counter is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the Tx_Err_Counter. When Tx_Err_Counter reaches the value of 128, the FLT_CONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the Tx_Err_Counter value.
- If during system start-up, only one node is operating, then its Tx_Err_Counter increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACK_ERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the Tx_Err_Counter does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the Rx_Err_Counter increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next

successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

15.1.8.8 Error and Status 1 Register (FLEXCANx_ESR1)

This register reflects various error conditions, some general status of the device and it is the source of four interrupts to the ARM.

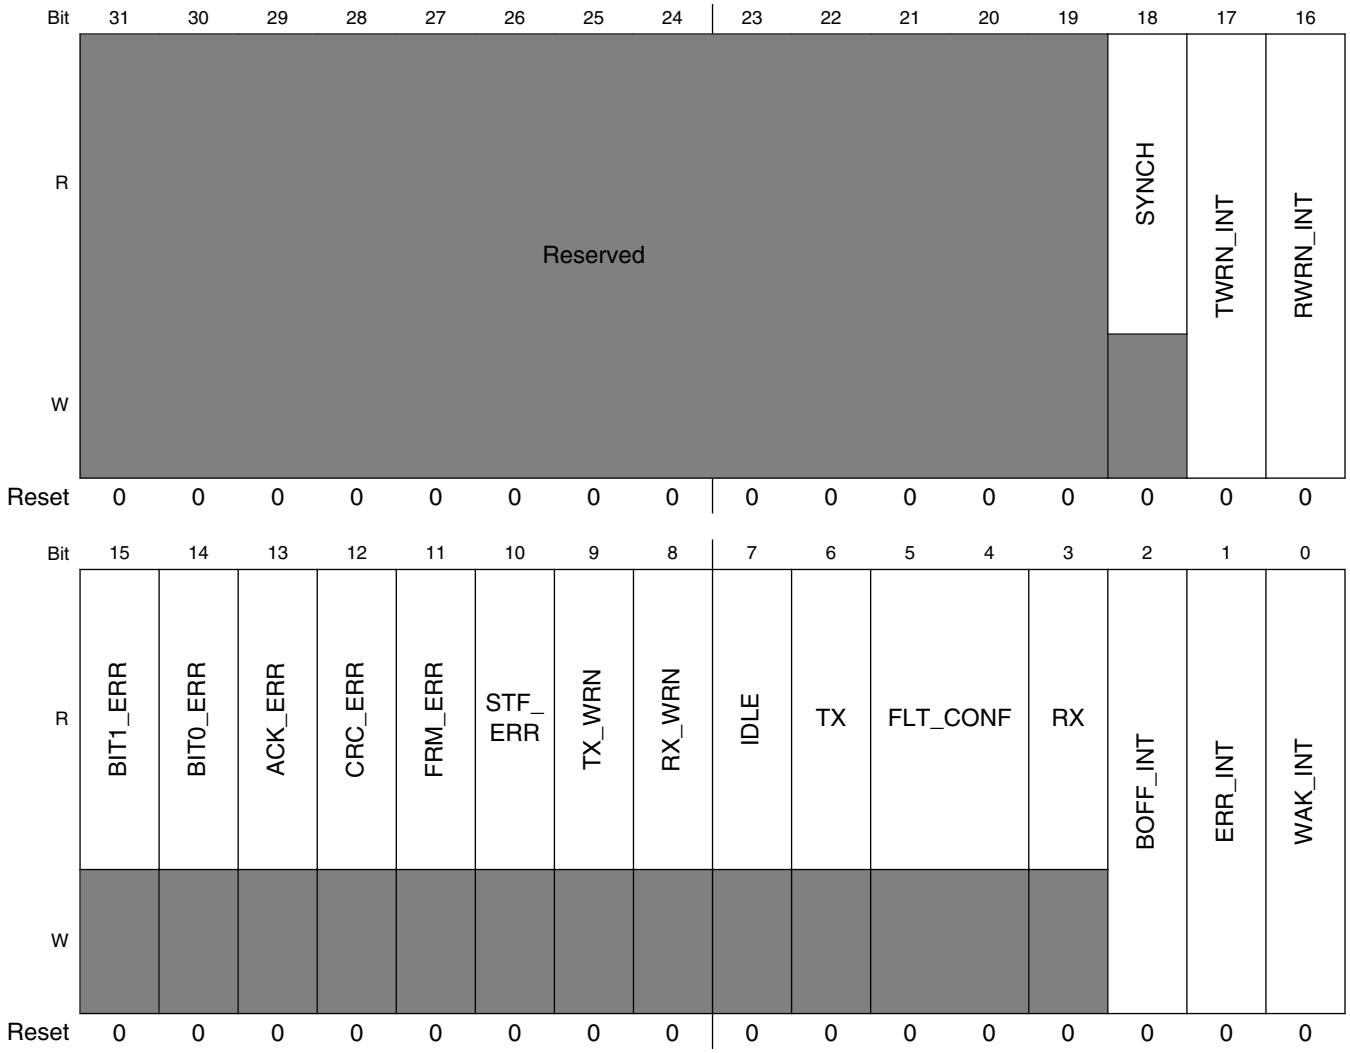
The ARM read action clears bits 15-10, therefore the reported *error conditions*(bits 15-10) are those that occurred since the last time the ARM read this register. Bits 9-3 are status bits.

Some bits in this register are read-only and some are not.

Table 15-20. FlexCAN State

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	x	x	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving
other combinations				Reserved

Address: Base address + 20h offset



FLEXCANx_ESR1 field descriptions

Field	Description
31–19 -	This field is reserved. Reserved
18 SYNCH	This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. Refer to Table 15-20 1 FlexCAN is synchronized to the CAN bus 0 FlexCAN is not synchronized to the CAN bus
17 TWRN_INT	If the WRN_EN bit in MCR is asserted, the TWRN_INT bit is set when the TX_WRN flag transition from '0' to '1', meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control Register (TWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. When WRN_EN is negated, this flag is masked. ARM must clear this flag before disabling the bit. Otherwise it will be set when the WRN_EN is set again. Writing '0' has no effect. This flag is not generated during "Bus Off" state. This bit is not updated during Freeze mode. 1 The Tx error counter transition from < 96 to >= 96 0 No such occurrence

Table continues on the next page...

FLEXCANx_ESR1 field descriptions (continued)

Field	Description
16 RWRN_INT	If the WRN_EN bit in MCR is asserted, the RWRN_INT bit is set when the RX_WRN flag transition from '0' to '1', meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control Register (RWRN_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. When WRN_EN is negated, this flag is masked. ARM must clear this flag before disabling the bit. Otherwise it will be set when the WRN_EN is set again. Writing '0' has no effect. This bit is not updated during Freeze mode. 1 The Rx error counter transition from < 96 to >= 96 0 No such occurrence
15 BIT1_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 1 At least one bit sent as recessive is received as dominant 0 No such occurrence
14 BIT0_ERR	This bit indicates when an inconsistency occurs between the transmitted and the received bit in a message. 1 At least one bit sent as dominant is received as recessive 0 No such occurrence
13 ACK_ERR	This bit indicates that an Acknowledge Error has been detected by the transmitter node, i.e., a dominant bit has not been detected during the ACK SLOT. 1 An ACK error occurred since last read of this register 0 No such occurrence
12 CRC_ERR	This bit indicates that a CRC Error has been detected by the receiver node, i.e., the calculated CRC is different from the received. 1 A CRC error occurred since last read of this register. 0 No such occurrence
11 FRM_ERR	This bit indicates that a Form Error has been detected by the receiver node, i.e., a fixed-form bit field contains at least one illegal bit. 1 A Form Error occurred since last read of this register 0 No such occurrence
10 STF_ERR	This bit indicates that a Stuffing Error has been detected. 1 A Stuffing Error occurred since last read of this register. 0 No such occurrence.
9 TX_WRN	This bit indicates when repetitive errors are occurring during message transmission. 1 TX_Err_Counter ≥ 96 0 No such occurrence
8 RX_WRN	This bit indicates when repetitive errors are occurring during message reception. 1 Rx_Err_Counter ≥ 96 0 No such occurrence
7 IDLE	This bit indicates when CAN bus is in IDLE state.Refer to Table 15-20.

Table continues on the next page...

FLEXCANx_ESR1 field descriptions (continued)

Field	Description
	1 CAN bus is now IDLE 0 No such occurrence
6 TX	This bit indicates if FLEXCAN is transmitting a message.Refer to Table 15-20. 1 FLEXCAN is transmitting a message 0 FLEXCAN is receiving a message
5–4 FLT_CONF	If the LOM bit in the Control Register is asserted, after some delay that depends on the CAN bit timing the FLT_CONF field will indicate "Error Passive". The very same delay affects the way how FLT_CONF reflects an update to ECR register by the ARM. It may be necessary up to one CAN bit time to get them coherent again. Since the Control Register is not affected by soft reset, the FLT_CONF field will not be affected by soft reset if the LOM bit is asserted. This 2-bit field indicates the Confinement State of the FLEXCAN module, as shown in below: 00 Error Active 01 Error Passive 1x Bus off
3 RX	This bit indicates if FlexCAN is receiving a message. Refer to Table 15-20. 1 FLEXCAN is transmitting a message 0 FLEXCAN is receiving a message
2 BOFF_INT	This bit is set when FLEXCAN enters 'Bus Off' state. If the corresponding mask bit in the Control Register (BOFF_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. Writing '0' has no effect. 1 FLEXCAN module entered 'Bus Off' state 0 No such occurrence
1 ERR_INT	This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit in the Control Register (ERR_MSK) is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'.Writing '0' has no effect. 1 Indicates setting of any Error Bit in the Error and Status Register 0 No such occurrence
0 WAK_INT	When FLEXCAN is Stop Mode and a recessive to dominant transition is detected on the CAN bus and if the WAK_MSK bit in the MCR Register is set, an interrupt is generated to the ARM. This bit is cleared by writing it to '1'. When SLF_WAK is negated, this flag is masked. ARM must clear this flag before disabling the bit. Otherwise it will be set when the SLF_WAK is set again. Writing '0' has no effect 1 Indicates a recessive to dominant transition received on the CAN bus when the FLEXCAN module is in Stop Mode 0 No such occurrence

15.1.8.9 Interrupt Masks 2 Register (FLEXCANx_IMASK2)

This register allows any number of a range of 32 Message Buffer Interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer, enabling the ARM to determine which buffer generates an interrupt after a successful transmission or reception (i.e. when the corresponding IFLAG2 bit is set).

Address: Base address + 24h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FLEXCANx_IMASK2 field descriptions

Field	Description
BUF63M_ BUF32M	Each bit enables or disables the respective FLEXCAN Message Buffer (MB32 to MB63) Interrupt. Setting or clearing a bit in the IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 1 The corresponding buffer Interrupt is enabled 0 The corresponding buffer Interrupt is disabled

15.1.8.10 Interrupt Masks 1 Register (FLEXCANx_IMASK1)

This register allows to enable or disable any number of a range of 32 Message Buffer Interrupts. It contains one interrupt mask bit per buffer, enabling the ARM to determine which buffer generates an interrupt after a successful transmission or reception (i.e., when the corresponding IFLAG1 bit is set).

Address: Base address + 28h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXCANx_IMASK1 field descriptions

Field	Description
BUF31M_BUF0M	Each bit enables or disables the respective FLEXCAN Message Buffer (MB0 to MB31) Interrupt. Setting or clearing a bit in the IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set

FLEXCANx_IMASK1 field descriptions (continued)

Field	Description
	1 The corresponding buffer Interrupt is enabled 0 The corresponding buffer Interrupt is disabled

15.1.8.11 Interrupt Flags 2 Register (FLEXCANx_IFLAG2)

This register defines the flags for 32 Message Buffer interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect.Before updating MCR[MAXMB] field, ARM must treat the IFLAG2 bits which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

Address: Base address + 2Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BUF63I_BUF32I																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FLEXCANx_IFLAG2 field descriptions

Field	Description
BUF63I_BUF32I	Each bit flags the respective FLEXCAN Message Buffer (MB32 to MB63) interrupt. 1 The corresponding buffer has successfully completed transmission or reception 0 No such occurrence

15.1.8.12 Interrupt Flags 1 Register (FLEXCANx_IFLAG1)

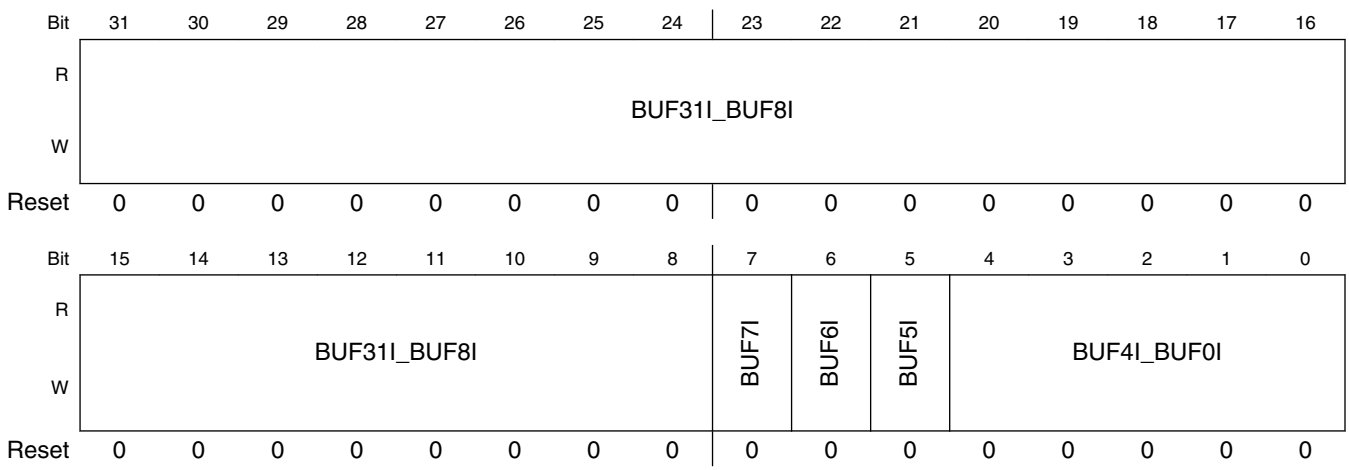
This register defines the flags for 32 Message Buffer interrupts and FIFO interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The Interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect.

When the RFEN bit in the MCR is set (Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) is changed to support the FIFO operation. BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, while BUF4I to BUF0I are not used. Before enabling the RFEN, ARM must service the IFLAGS asserted

in the Rx FIFO region (see Rx FIFO). Otherwise, these IFLAGS will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN is negated, the FIFO flags must be cleared. The same care must be taken when a RFFN value is selected extending Rx FIFO filters beyond MB7 (see Control 2 Register (FLEXCAN_CTRL2)). For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAGS must be cleared.

Before updating MCR[MAXMB] field, ARM must service the IFLAG1 which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

Address: Base address + 30h offset



FLEXCANx_IFLAG1 field descriptions

Field	Description
31–8 BUF31I_BUF8I	Each bit flags the respective FLEXCAN Message Buffer (MB8 to MB31) interrupt. 1 The corresponding MB has successfully completed transmission or reception 0 No such occurrence
7 BUF7I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB7. If the MCR[RFEN] bit is asserted, this flag indicates that a message was lost because Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by ARM writes. 1 MB7 completed transmission/reception or FIFO overflow 0 No such occurrence
6 BUF6I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB6. If the MCR[RFEN] bit is asserted, this flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4 it will not assert again until the number of unread messages within the Rx FIFO is decreased to equal or less than 4. This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by ARM writes.

Table continues on the next page...

FLEXCANx_IFLAG1 field descriptions (continued)

Field	Description
	1 MB6 completed transmission/reception or FIFO almost full 0 No such occurrence
5 BUF5I	If the Rx FIFO is not enabled, this bit flags the interrupt for MB5. If the Rx FIFO is enabled, this flag indicates that at least one frame is available to be read from the Rx FIFO. This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by ARM writes. 1 MB5 completed transmission/reception or frames available in the FIFO 0 No such occurrence
BUF4I_BUF0I	If the Rx FIFO is not enabled, these bits flag the interrupts for MB0 to MB4. If the Rx FIFO is enabled, these flags are not used and must be considered as reserved locations. These flags are cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by ARM writes. 1 Corresponding MB completed transmission/reception 0 No such occurrence

15.1.8.13 Control 2 Register (FLEXCANx_CTRL2)

This register contains control bits for CAN errors, FIFO features and mode selection.

Table 15-21. Rx FIFO Filters

RFFN[3:0]	Number of Rx FIFO filters	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes[1]	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks[2]	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask[2]

0xF	128	MB 0-37	MB 38-63	Elements 0-31	Elements 32-127

1. The number of the last remaining available mailboxes is defined by the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.

Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:

$$(SETUP\_MB - 6) \times 4$$

where SETUP_MB is MAXMB.

The number of remaining Mailboxes available will be:

$$SETUP\_MB - 8 - (RFFN \times 2)$$

If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value, the exceeding ones will not be functional.Unshaded regions in Table 15-22 indicate the valid combinations of MAXMB, RFEN and RFFN, shaded regions are not functional.

Table 15-22. Valid Combinations of MAXMB, RFEN and RFFN

FLEXCANx_CTRL2 field descriptions

Field	Description
31 -	must be written as 0
30–29 -	This field is reserved. Reserved

Table continues on the next page...

FLEXCANx_CTRL2 field descriptions (continued)

Field	Description
28 WRMFRZ	Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. 1 Enable unrestricted write access to FlexCAN memory 0 Keep the write access restricted in some regions of FlexCAN memory
27–24 RFFN	This 4-bit field defines the number of Rx FIFO filters according to Table 15-21. The maximum selectable number of filters is determined by the ARM. This field can only be written in Freeze mode as it is blocked by hardware in other modes. RFFN defines a number of Message Buffers occupied by Rx FIFO and ID Filter (see Table 15-21) that **may not exceed** the number of available Mailboxes present in module, defined by MCR[MAXMB].Default RFFN value is 0x0, which leads to a total of 8 Rx FIFO filters, occupies the first 8 Message Buffers (MB 0-7) and makes available the next Message Buffers (MB 8-63) for Mailboxes. As a second example, when RFFN is set to 0xD, there will be 112 Rx FIFO filters, located in MB 0-33, and MB 34-63 are available for Mailboxes. Notice that, in this case, individual masks (RXIMR) will just cover Rx FIFO filters in 0-31 range, and filters 32-111 will use RXFGMASK. In case of reducing the number of last Message Buffers, MCR[MAXMB] (see Module Configuration Register (FLEXCAN_MCR)) can be adjusted by the application to minimum of 33, in order to give room to the Rx FIFO and its ID Filter Table defined by RFFN. On the contrary, if the application sets MCR[MAXMB] to 16, for instance, the maximum RFFN is limited to 0x4. RFFN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 15-18 (see Arbitration and Matching Timing).
23–19 TASD	This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency. The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa. If TASD is 0 then the arbitration start is not delayed, thus ARM has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. In the other hand, if TASD is 24 then ARM can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that ARM reconfigure some Tx MBs and the winner MB is not the best to be transmitted. The reset value is different on various platforms, according to their peripheral clock frequency, number of MBs and target CAN baud rate. The optimal configuration for TASD can be calculated as:

Table continues on the next page...

FLEXCANx_CTRL2 field descriptions (continued)

Field	Description
	$$TASD = 25 - \left\{ \frac{f_{CANCLK} \times [MAXMB + 3 - (RFEN \times 8) - (RFEN \times RFFN \times 2)] \times 2}{f_{sys} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRESDIV + 1)} \right\}$$ where: f_{CANCLK} is the Protocol Engine (PE) Clock in Hz; PE clock is derrived from CAN_CLK_ROOT in CCM. See Clock Root Generator f_{SYS} is the peripheral clock in Hz; MAXMB is the value in CTRL1[MAXMB] field; RFEN is the value in CTRL1[RFEN] bit; RFFN is the value in CTRL2[RFFN] field; PSEG1 is the value in CTRL1[PSEG1] field; PSEG2 is the value in CTRL1[PSEG2] field; PROPSEG is the value in CTRL1[PROPSEG] field; PRESDIV is the value in CTRL1[PRESDIV] field. Please refer to Arbitration process and Protocol Timing for more details.
18 MRP	If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Matching starts from Mailboxes and continues on Rx FIFO 0 Matching starts from Rx FIFO and continues on Mailboxes
17 RRS	If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated. If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Remote Request Frame is stored 0 Remote Response Frame is generated
16 EACEN	This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can only be written in Freeze mode as it is blocked by hardware in other modes. 1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply. 0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.
-	This field is reserved.

Table continues on the next page...

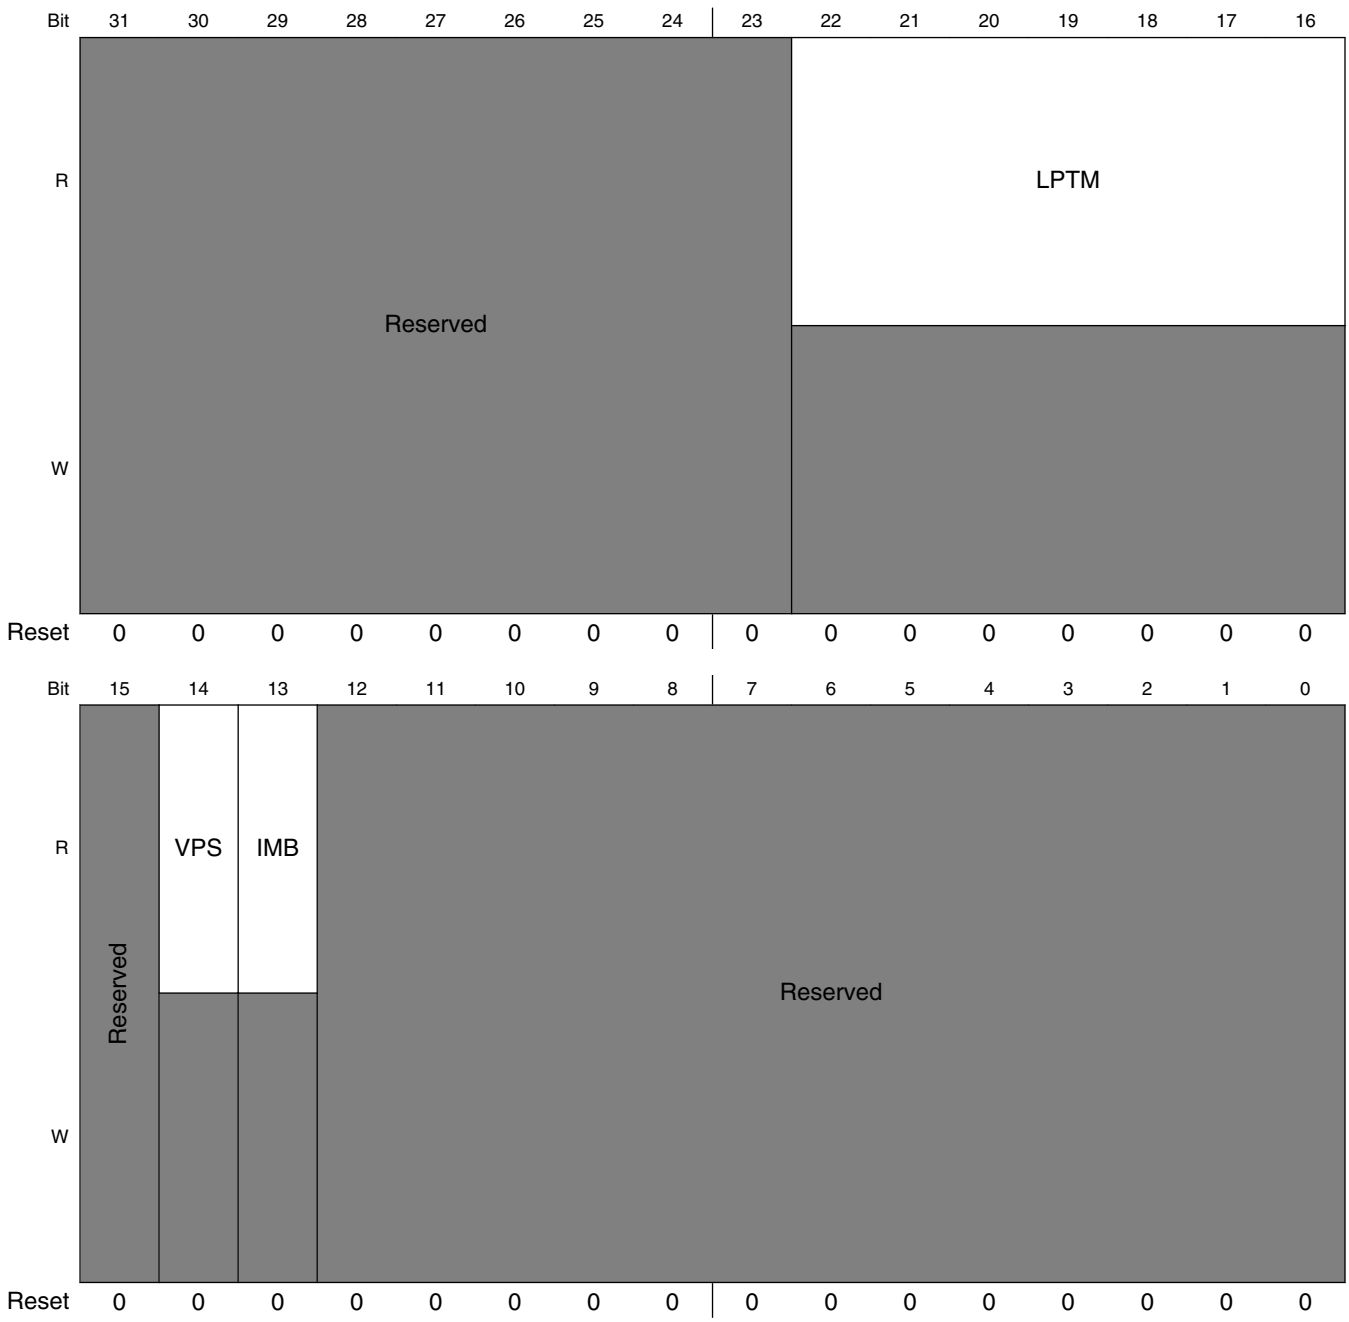
FLEXCANx_CTRL2 field descriptions (continued)

Field	Description
	Reserved

15.1.8.14 Error and Status 2 Register (FLEXCANx_ESR2)

This register reflects various interrupt flags and some general status.

Address: Base address + 38h offset



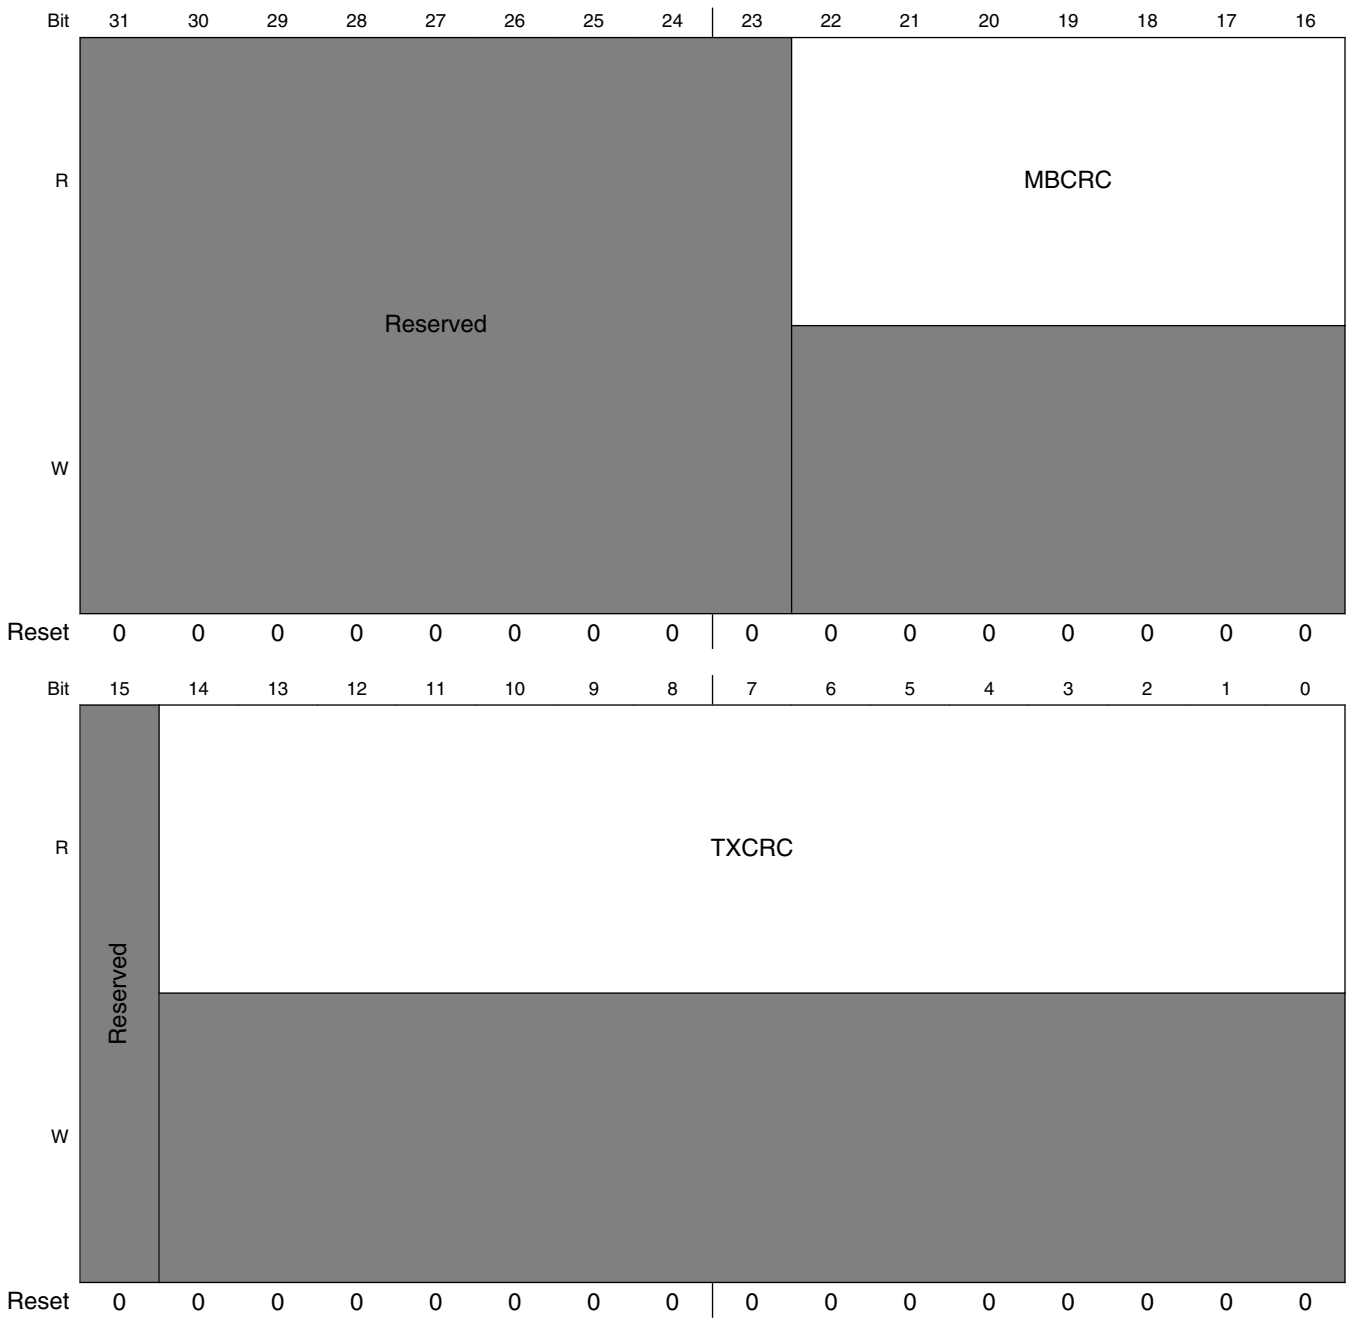
FLEXCANx_ESR2 field descriptions

Field	Description
31–23 -	This field is reserved. Reserved
22–16 LPTM	If ESR2[VPS] is asserted, his 7-bit field indicates the lowest number inactive Mailbox (refer to IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one which has the greatest arbitration value (see Highest Mailbox priority first). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
15 -	This field is reserved. Reserved
14 VPS	This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the ARM writes to Control and Status word of a Mailbox that has already been scanned (i.e. it is behind Tx Arbitration Pointer) during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox which is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.ESR2[VPS] is not affected by any ARM write into Control Status (C/S) of a MB which is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is been transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked. 1 Contents of IMB and LPTM are valid 0 Contents of IMB and LPTM are invalid
13 IMB	If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases: (1) During arbitration, if a LPTM is found and it is inactive. (2) If IMB is not asserted and a frame is transmitted successfully. (3) This bit is cleared in all start of arbitration (see Arbitration process). LPTM mechanism have the following behavior: if a MB is successfully transmitted and ESR2[IMB]=0 (no inactive Mailbox), then ESR2[VPS] and ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into ESR2[LPTM]. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox.
-	This field is reserved. Reserved

15.1.8.15 CRC Register (FLEXCANx_CRCR)

This register provides information about the CRC of transmitted messages

Address: Base address + 44h offset



FLEXCANx_CRCR field descriptions

Field	Description
31–23 -	This field is reserved. Reserved
22–16 MBCRC	This field indicates the number of the Mailbox corresponding to the value in TXCRC field.
15 -	This field is reserved. Reserved
TXCRC	This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.

15.1.8.16 Rx FIFO Global Mask Register (FLEXCANx_RXFGMASK)

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze Mode as it is blocked by hardware in other modes.

Table 15-23. Rx FIFO Global Mask usage

Rx FIFO ID Filter Table Elements Format (MCR[IDAM])	Identifier Acceptance Filter fields					
	RTR	IDE	RXIDA	RXIDB	RXIDC	reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31] FGM[15]	FGM[30] FGM[14]	-	FGM[29:16] FGM[13:0] 1		-
C	-	-		-	FGM[31:24] FGM[23:16] FGM[15:8] FGM[7:0] 2	

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

FLEXCANx_RXFGMASK field descriptions

Field	Description
FGM31_FGM0	These bits mask the ID Filter Table elements bits in a perfect alignment.Rx FIFO Global Mask Register (FLEXCAN_RXFGMASK) shows in detail which FGM bits mask each IDAF field. Clear this register has the effect of disabling the ID Filter. 1 The corresponding bit in the filter is checked 0 The corresponding bit in the filter is "don't care"

15.1.8.17 Rx FIFO Information Register (FLEXCANx_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which ARM accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. Refer to Rx FIFO to find instructions on reading this register.

Address: Base address + 4Ch offset

FLEXCANx_RXFIR field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
IDHIT	This 9-bit field indicates which Identifier Acceptance Filter (see Rx FIFO Structure) was hit by the received message that is in the output of the Rx FIFO. (refer to Rx FIFO for details) If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted.

15.1.8.18 Rx Individual Mask Registers (FLEXCANx_RXIMR0_RXIMR63)

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on CTRL2[RFFN] setting. Refer to Control 2 Register (FLEXCAN_CTRL2) for details.

RXIMR can only be written by the ARM while the module is in Freeze Mode, otherwise they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: Base address + 880h offset

FLEXCANx_RXIMR0_RXIMR63 field descriptions

Field	Description
MI31_MI0	These bits mask both Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. For Mailbox filter refer to Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK). For Rx FIFO ID Filter Table element refer to Rx FIFO Global Mask Register (FLEXCAN_RXFGMASK). 1 The corresponding bit in the filter is checked 0 the corresponding bit in the filter is "don't care"

15.1.8.19 Glitch Filter Width Registers (FLEXCANx_GFWR)

The Glitch Filter just takes effects when FLEXCAN enters the STOP mode.

Address: Base address + 9E0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FLEXCANx_GFWR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
GFWR	It determines the Glitch Filter Width. The width will be divided from Oscillator clock by GFWR values. By default, it is 5.33 µs when the oscillator is 24 MHz. Filter Pulse Width = [(GFWR FIELD + 1) x (1 / Osc. Frequency)]

15.2 I2C Controller (I2C)

15.2.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block-driver software developer. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following document:

- *The I2C Bus Specification*, Version 2.1, by Philips Semiconductor

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard NXP I2C bus protocol.

NOTE

independent I2C channels are available.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

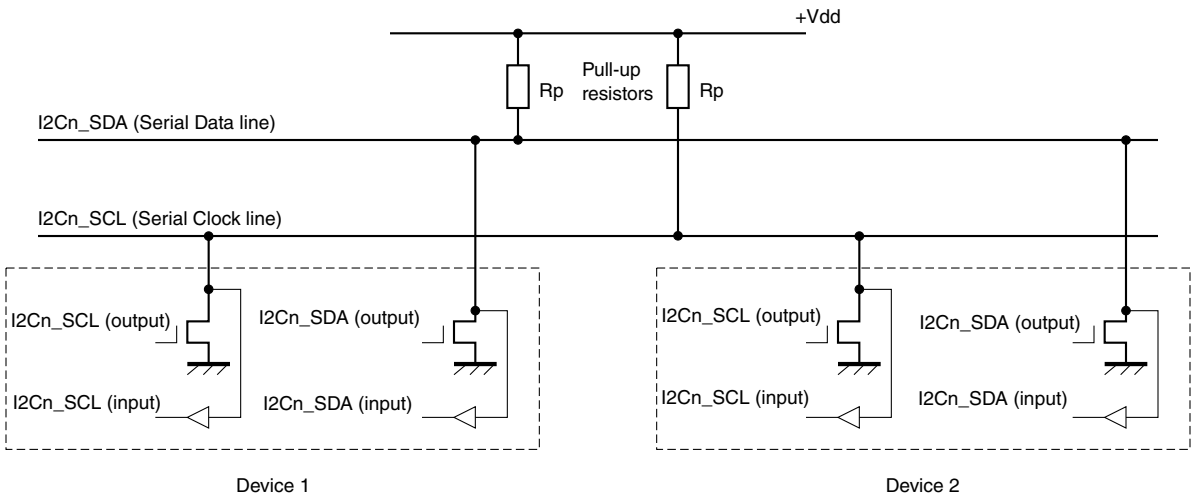

Figure 15-6. Connection of devices to I2C bus

The I2C interface speed is dependent on the I2C bus loading and timing characteristics. For pin requirement details, see *The I2C Bus Specification*. The I2C system is a true multimaster bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

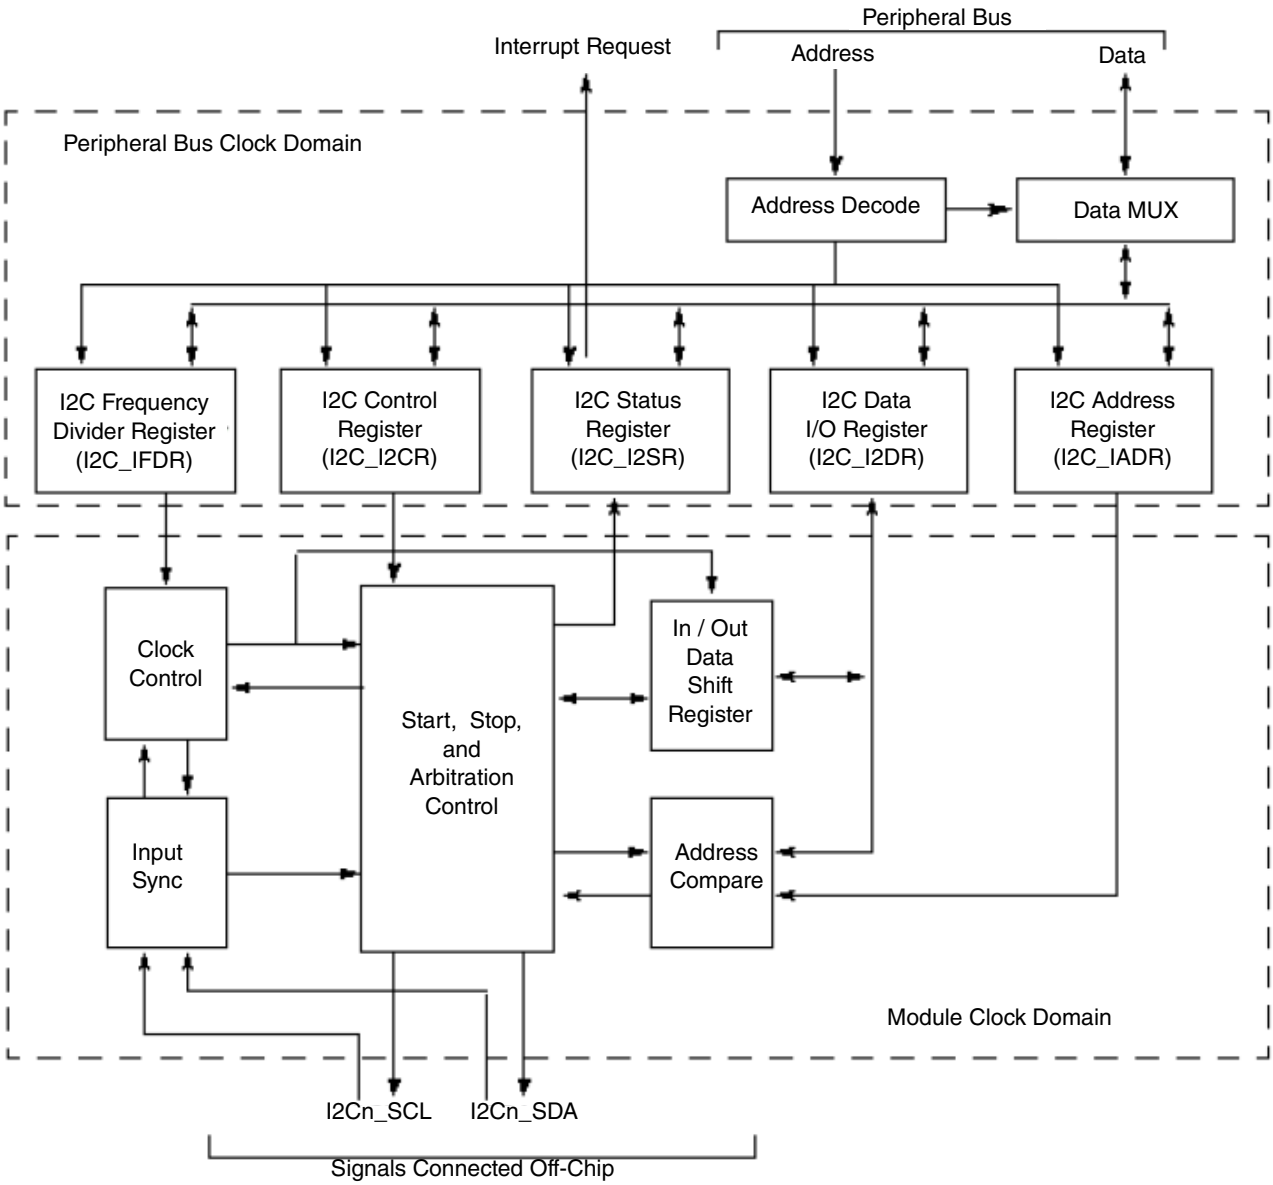

Figure 15-7. I2C block diagram

15.2.1.1 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multimaster operation
- Software programmability for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated Start signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

15.2.1.2 Modes and operations

The I2C operates primarily in two functional modes: Standard mode and Fast mode.

- In Standard mode, I2C supports the data transfer rates up to 100 kbits/s.
- In Fast mode, data transfer rates up to 400 kbits/s can be achieved. Per block operation, there is no special configuration required for Fast or Standard mode. It is the data transfer rate that distinguishes Standard and Fast mode.

15.2.2 External Signals

This section discusses I2C signals that connect off-chip.

For I2C compliance, all devices connected to the I2Cn_SCL and I2Cn_SDA signals must have open-drain or open-collector outputs. The logic AND function is implemented on both lines with external pull-up resistors.

Inputs of I2Cn_SCL and I2Cn_SDA also need to be manually enabled by setting the SION bit in the IOMUX after the corresponding PADs are selected as I2C function.

The table below describes all I2C signals that connect off-chip.

Table 15-24. I2C External Signals

Signal	Description	Pad	Mode	Direction
I2C1_SCL	Serial Clock	GPIO1_IO04	ALT4	IO
		I2C1_SCL	ALT0	
		UART1_RXD	ALT1	
I2C1_SDA	Serial Data	GPIO1_IO05	ALT4	IO
		I2C1_SDA	ALT0	
		UART1_TXD	ALT1	
I2C2_SCL	Serial Clock	GPIO1_IO06	ALT4	IO
		I2C2_SCL	ALT0	
		UART2_RXD	ALT1	
I2C2_SDA	Serial Data	GPIO1_IO07	ALT4	IO

Table continues on the next page...

Table 15-24. I2C External Signals (continued)

Signal	Description	Pad	Mode	Direction
		I2C2_SDA	ALT0	
		UART2_TXD	ALT1	
I2C3_SCL	Serial Clock	ENET1_RDATA0	ALT2	IO

		LCD1_DATA23	ALT6	
		SAI1_RXC	ALT3	

15.2.3 Clocks

There are two input clocks for I2C.

The following table describes the clock sources for I2C. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-25. I2C Clocks

Clock name	Clock Root	Description
ipg_clk_patref	I2C_CLK_ROOT	Module clock
ipg_clk_s	I2C_CLK_ROOT	Peripheral access clock

- Peripheral clock: This clock is used for peripheral bus register read/writes.
- Module clock: This is the functional clock of the I2C. The serial bit clock frequency is derived from the module clock. The module clock and peripheral clocks are synchronous with each other. The minimum frequency of the module clock should be 12.8 MHz for Fast mode to achieve 400-kbps operation.

15.2.4 Functional description

This section provides a complete functional description of the block.

15.2.4.1 I2C system configuration

After a reset, the I2C defaults to Slave Receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C defaults to the Slave Receive state.

For exceptions, see Initialization sequence.

NOTE

The I2C is designed to be compatible with the Philips™ I2C bus protocol. For information on system configuration, protocol, and restrictions, see the *I2C Bus Specification*, version 2.1, by Philips Semiconductors. The I2C supports Standard and Fast modes only.

15.2.4.2 Arbitration procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to Slave Receive mode and stops driving I2Cn_SDA. In this case, the transition from master to Slave mode does not generate a Stop condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

15.2.4.3 Clock synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the Clock High state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a High Wait state during this time (see Figure 15-8). When all devices involved have counted off their low periods, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

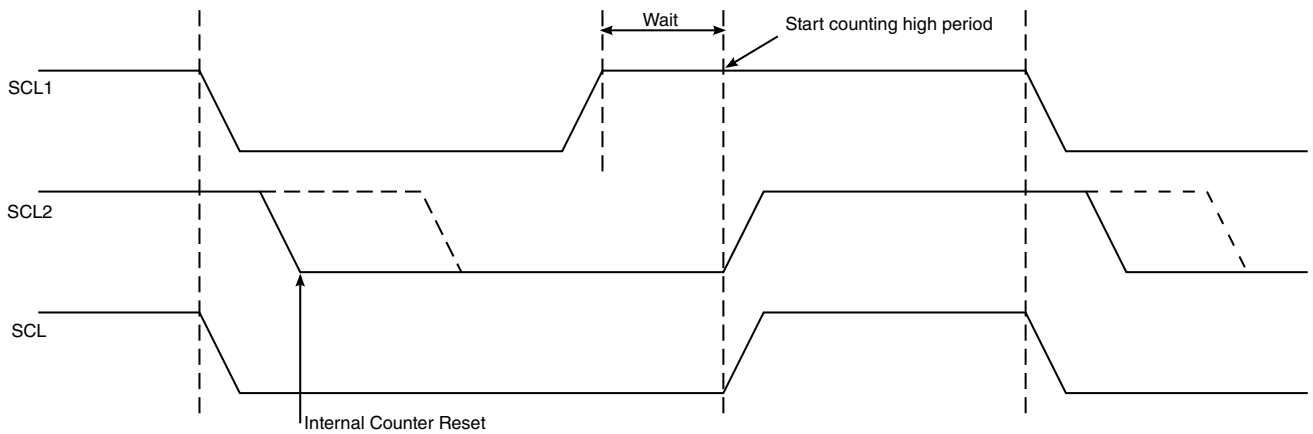

Figure 15-8. Synchronized clock SCL

15.2.4.4 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a Wait state until the slave releases SCL.

15.2.4.5 Clock stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

15.2.4.6 Peripheral bus accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

15.2.4.7 Generation of transfer error on IP bus

If an address is received on the peripheral slave bus interface but it is not implemented, an access error is generated.

15.2.4.8 Reset

The I2C can be reset in the following ways:

- Global reset: A hard asynchronous reset of the whole I2C
- Software reset: An internal reset for the whole I2C (except for I2C_IADR and I2C_IFDR registers) initiated by deasserting the I2C_I2CR[IEN] bit

15.2.4.9 Interrupts

There is only one interrupt from the block, which is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions:

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in Slave Receive mode.
- Arbitration is lost.

15.2.4.10 Byte order

The block only supports the Little-Endian mode.

15.2.5 Initialization

NOTE

Ensure the input select pins for IOMUXC are configured correctly for I2C.

15.2.5.1 Initialization sequence

Before the interface can transfer serial data, registers must be initialized, as listed here.

1. Set the data sampling rate (I2C_IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select Master/Slave mode, Transmit/Receive mode, and Interrupt-Enable or not.

15.2.5.2 Generation of Start

After completion of the initialization procedure, serial data can be transmitted by selecting the Master Transmit mode. On a multimaster bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the Start signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a Stop and the next Start condition is built into the hardware that generates the Start cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is not busy after writing the calling address to the data register (I2C_I2DR), before proceeding to load data into the data register (I2C_I2DR).

15.2.5.3 Post-transfer software response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte of communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

See the flow chart in Figure 15-10.

The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in Receive mode or by writing to this register in Transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled in the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in Transmit mode; that is, the address is sent. If Master Receive mode is required, then I2C_I2CR[MTX] should be toggled and a dummy read of the I2C_I2DR register must be executed to trigger receive data.

During Slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For Slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

15.2.5.4 Generation of Stop

A data transfer ends when the master signals a Stop, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a Stop signal must be generated.

15.2.5.5 Generation of Repeated Start

After the data transfer, if the master still requires the bus, it can signal another Start followed by another slave address without signaling a Stop.

15.2.5.6 Slave mode

In the slave interrupt service routine (see Figure 15-10), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the Transmit/Receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in Slave Receive mode. A dummy read of I2C_I2DR in Slave Receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from Transmit to Receiver mode. Reading the data register (I2C_I2DR) then releases SCL so the master can generate a Stop signal.

15.2.5.7 Arbitration lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to Slave Receive mode. Data output to 12Cn_SDA stops, but 12Cn_SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the Slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in Figure 15-10.

If a device that is not a master tries to transmit or do a Start, hardware inhibits the transmission, clears MSTA without signaling a Stop, generates an interrupt to the ARM platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multimaster mode, when an I2C is enabled when the bus is busy and asserts Start, the I2C_I2SR[IAL] bit gets set only for 12Cn_SDA=0, 12Cn_SCL=0/1, 12Cn_SDA=1, and 12Cn_SCL=0; but not for 12Cn_SDA=1 and I2Cn_SCL=1, which is the equivalent of Bus Idle state.

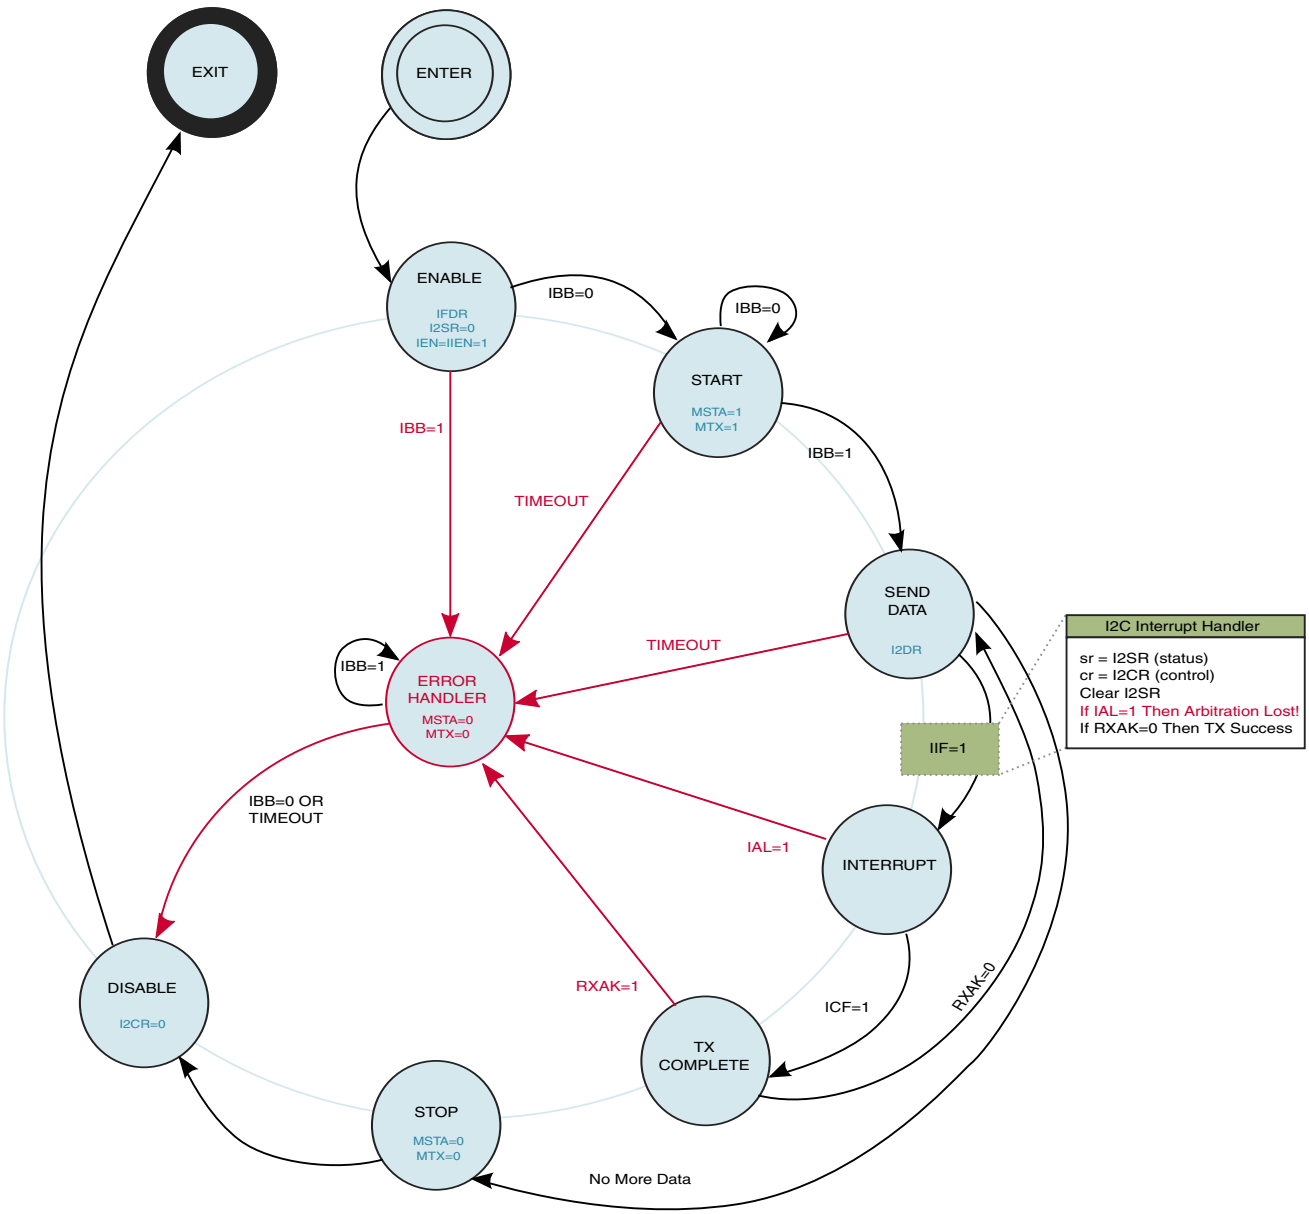

Figure 15-9. I2C Programming state diagram

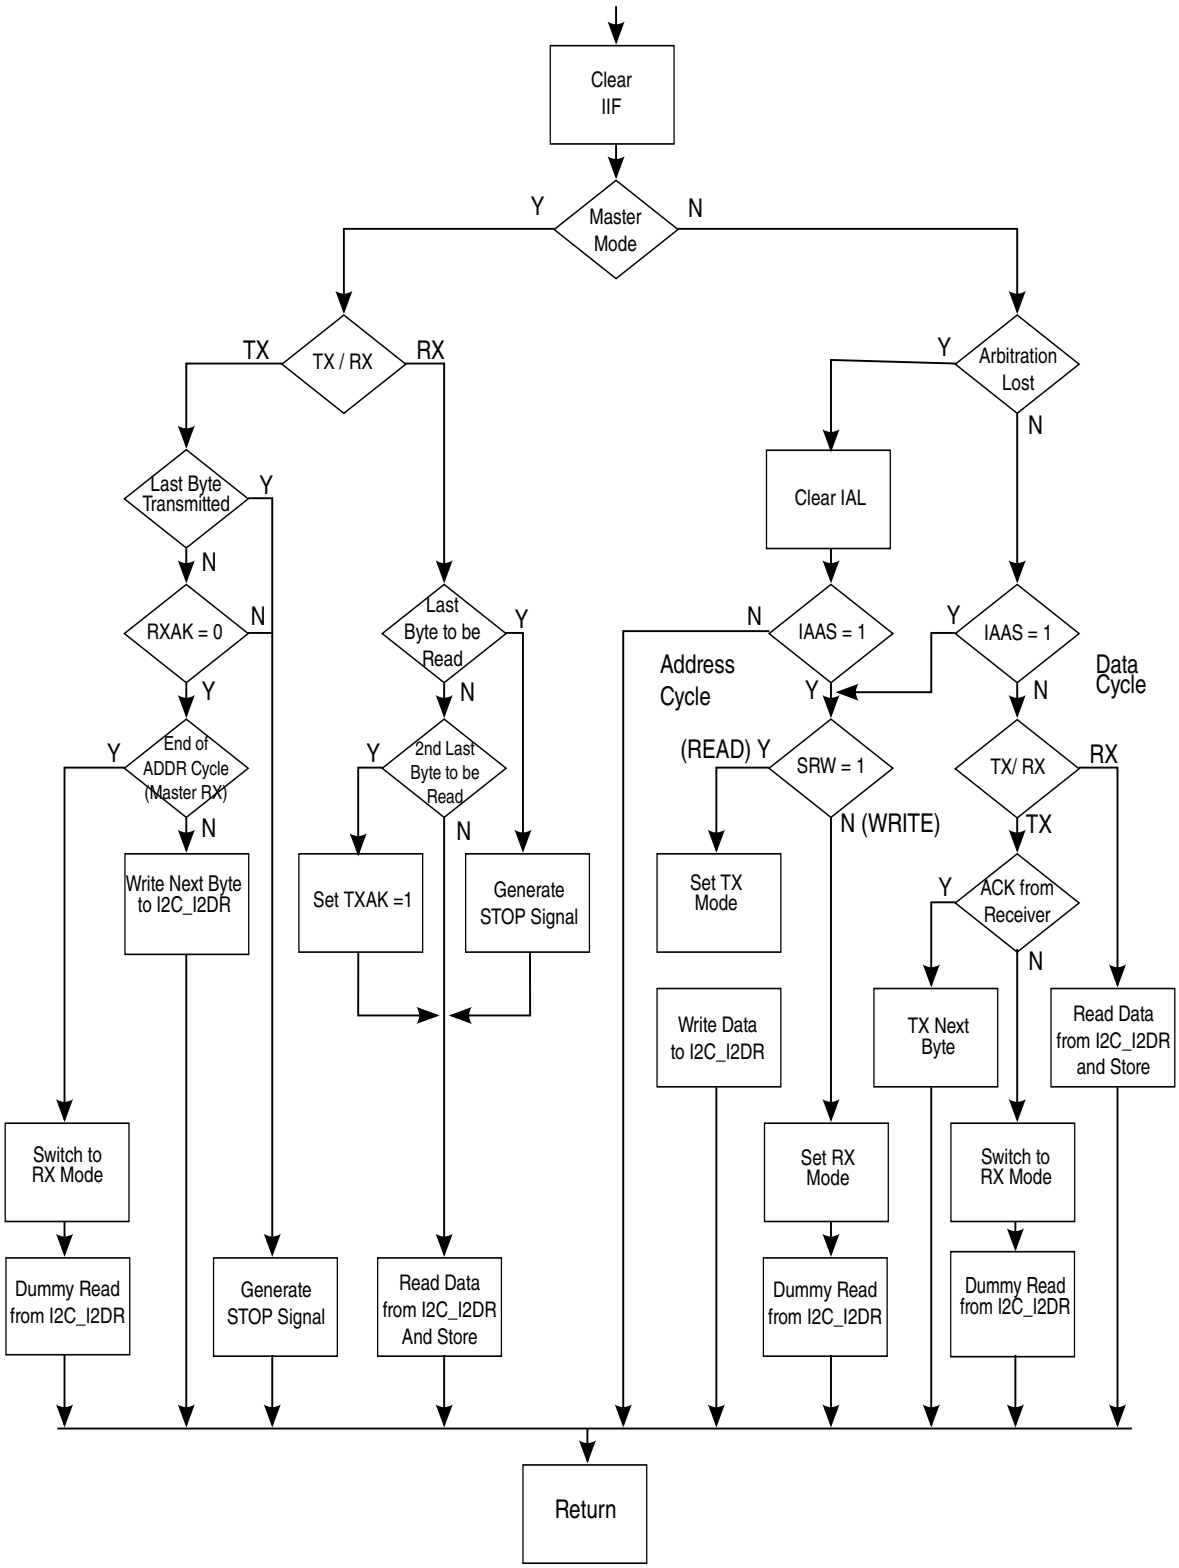

Figure 15-10. Flowchart of typical I2C interrupt routine

NOTE

For a Repeated Start only, the Stop-generation stage does not occur in Master mode. A loop repeats itself without stopping for the next start.

For Master Receive mode, I2C is programmed as Master Transmit during Address mode and after slave address transfer; the MTX bit should be cleared and a dummy read on the I2C_I2DR register should be performed so I2C can read the next receive data.

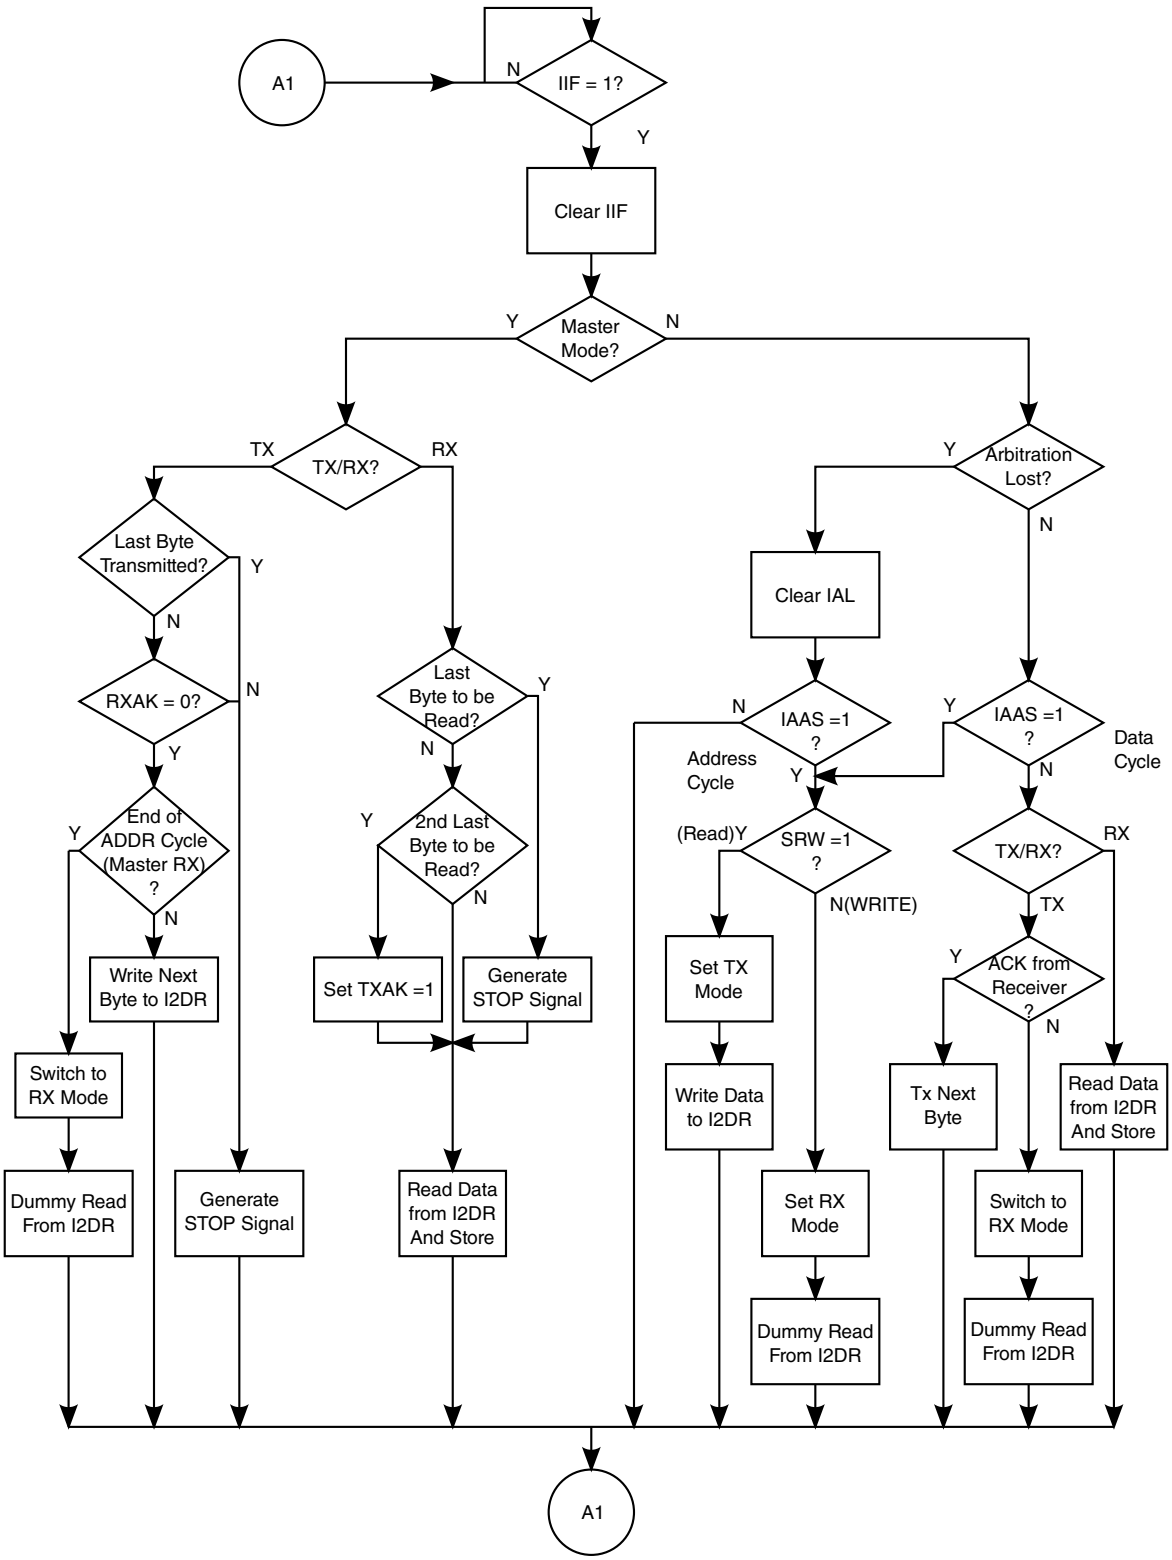

Figure 15-11. Flowchart for typical I2C polling routine

NOTE

The timeout value depends on the bus frequency at which I2C is operating. The minimum timeout for polling the IIF bit at a maximum I2C bus frequency of 400 kHz is T_{min} = 25 µs (=2.5 x 10 µs). This value can be calculated for any bus frequency. The formula is $T_{min} = 10/F_{SCL}$, where F_{SCL} is the frequency of the I2C clock (SCL).

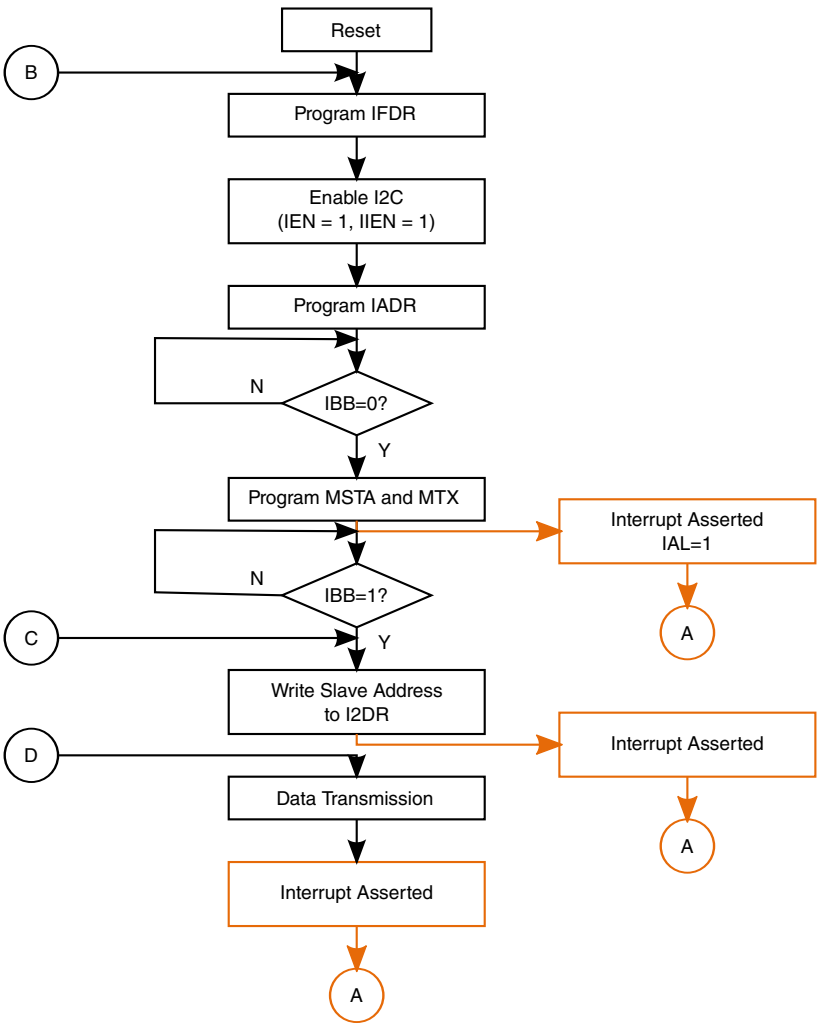

Figure 15-12. Detailed flowchart of a typical I2C Master Transmit mode, part 1

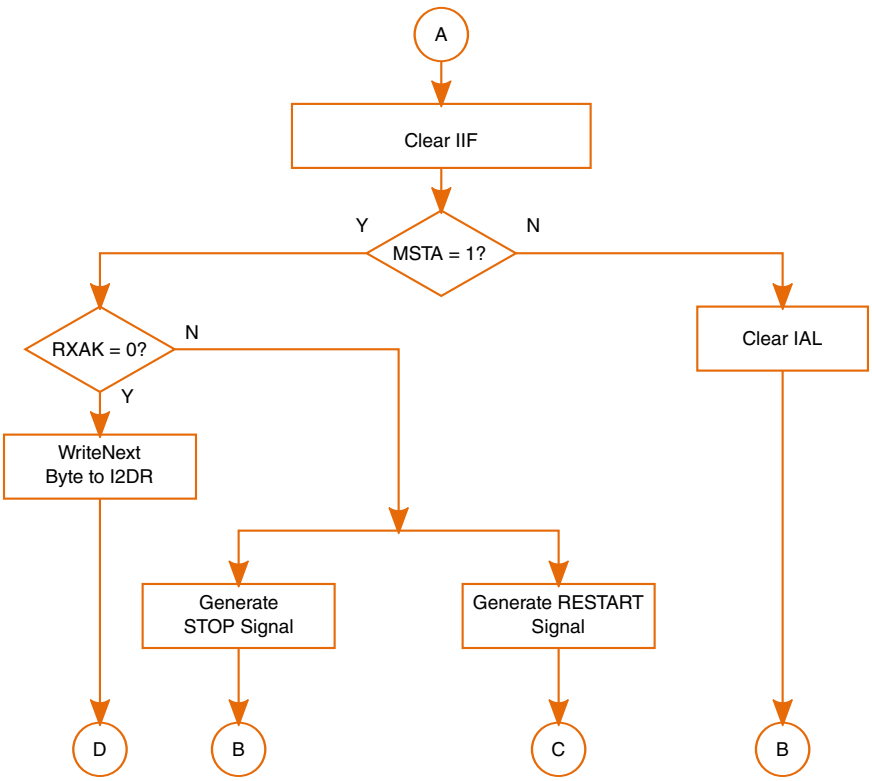

Figure 15-13. Detailed flowchart of a typical I2C Master Transmit mode, part 2

Figure 15-12 and Figure 15-13 show the Master Transmit mode operation with interrupt subroutine. If an interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear the IAL bit and reprogram I2C. If the MSTA bit is 1, then it is a transfer-generated interrupt. In this case, software can check the RXAK bit for a data receive acknowledgement by the slave and, accordingly, decide to do one of the following:

- Generate a STOP
- Generate a REPEATED START by writing to the I2C_I2CR register
- Perform the next data transfer by writing to the I2C_I2DR register

NOTE

The IBB bit is asserted by a Start condition on the bus, and it is deasserted by a Stop condition on the bus. Therefore, if arbitration is lost due to an unexpected Stop condition during transfer, then IBB is cleared. If arbitration is lost due to a data mismatch, then it is not cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

15.2.6 Software restriction

Software should ensure that there is a delay of at least two module clock cycles after it sets the I2C_I2CR[RSTA] bit and before writing to the I2C_I2DR register. The maximum possible clock period of the module clock is 78 ns.

15.2.7 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

I2C memory map

I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus. **NOTE:** The I2C_IADR holds the address to which the I2C responds when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value 0.

15.2.7.2 I2C Frequency Divider Register (I2Cx_IFDR)

The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by a software reset.

The following table describes the divider and register values for the register field "IC."

Table 15-26. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160
0x01	32		0x11	320		0x21	24		0x31	192

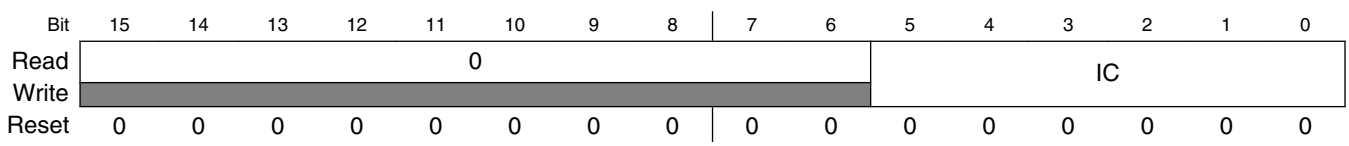
Address: Base address + 4h offset



I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value 0.
IC	I2C clock rate. Prescales the clock for bit-rate selection. Due to potentially slow I2Cn_SCL and I2Cn_SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency may be lower than IPG_CLK_ROOT divided by the divider shown in the I2C Data I/O Register. **NOTE:** The IC value should not be changed during the data transfer, however, it can be changed before a Repeat Start or Start programming sequence in I2C. The I2C protocol supports bit rates of up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

15.2.7.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 IEN	I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, Slave mode ignores the current bus transfer and starts operating when the next Start condition is detected. Master mode is not aware that the bus is busy, so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. Subsequently, bus operation returns to normal. 0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have an effect.
6 IIEN	I2C interrupt enable. **NOTE:** If data is written during the Start condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after Start. If data is written after the Start condition and falling edge of SCLK, then the ICF bit is cleared as soon as data is written. 0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an Interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.
5 MSTA	Master/Slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a Stop signal. **NOTE:** The module clock should be on for writing to the MSTA bit. **NOTE:** The MSTA bit is cleared by software to generate a Stop condition; it can also be cleared by hardware when the I2C loses the bus arbitration.

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	0 Slave mode. Changing MSTA from 1 to 0 generates a Stop and selects Slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a Start on the bus and selects Master mode.
4 MTX	Transmit/Receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In Master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto I2Cn_SDA during acknowledge cycles for both master and slave receivers. **NOTE:** Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a Repeated Start condition
Reserved	This read-only field is reserved and always has the value 0.

15.2.7.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Address: Base address + Ch offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
Write								
Reset	1	0	0	0	0	0	0	1

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The ARM platform is interrupted if the interrupt enable (I2C_I2CR[IIEN]) is set. The ARM platform must check the slave read/write bit (SRW) and set its Transfer/Receive mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. **NOTE:** When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDA) and clock (SCL) signals to determine a Start or Stop condition. 0 Bus is idle. If a Stop signal is detected, IBB is cleared. 1 Bus is busy. When Start is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): • I2Cn_SDA input samples low when the master drives high during an address or data-transmit cycle. • I2Cn_SDA input samples low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of the ninth I2Cn_SCL clock during the ACK cycle. • A Start cycle is attempted when the bus is busy. • A Repeated Start cycle is requested in Slave mode. • A Stop condition is detected when the master did not request it. **NOTE:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.
3 Reserved	This read-only field is reserved and always has the value 0.
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. **NOTE:** The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending.

Table continues on the next page...

I2Cx_I2SR field descriptions (continued)

Field	Description
	This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in Slave Receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received from the I2Cn_SDA input for the acknowledge bit during a bus cycle. 0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.

15.2.7.5 I2C Data I/O Register (I2Cx_I2DR)

In Master Receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In Slave mode, the same function is available after it is addressed.

Address: Base address + 10h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **NOTE:** The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.

15.3 Universal Asynchronous Receiver/Transmitter(UART)

15.3.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

Figure 15-14 is the UART block diagram.

The "Module Clock" is the UART_CLK which comes from CCM. The "Peripheral Clock" is the IPG_CLK which comes from CCM.

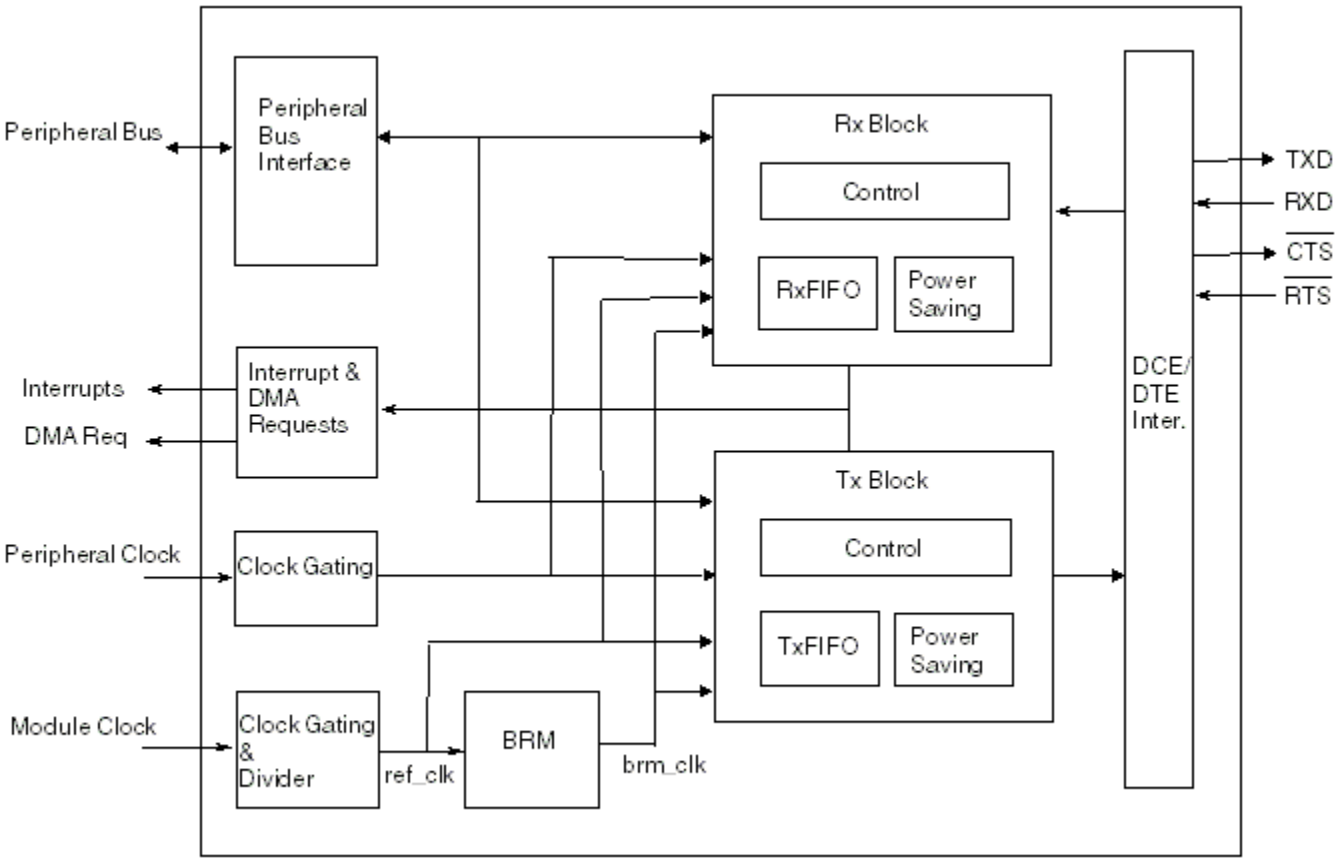

Figure 15-14. UART Block Diagram

15.3.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression

- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/ RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

15.3.1.2 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

To set UART in different modes, see the table below.

Table 15-27. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Descriptioin
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

15.3.2 External Signals

The chip-level IOMUX modifies the direction and routing of the UART signals based on whether the UART is operating in DCE mode (UARTn_UFCR[DCEDTE]=0) or DTE mode (UARTn_UFCR[DCEDTE]=1). The routing of the external signals to the UART module is shown in the figure below.

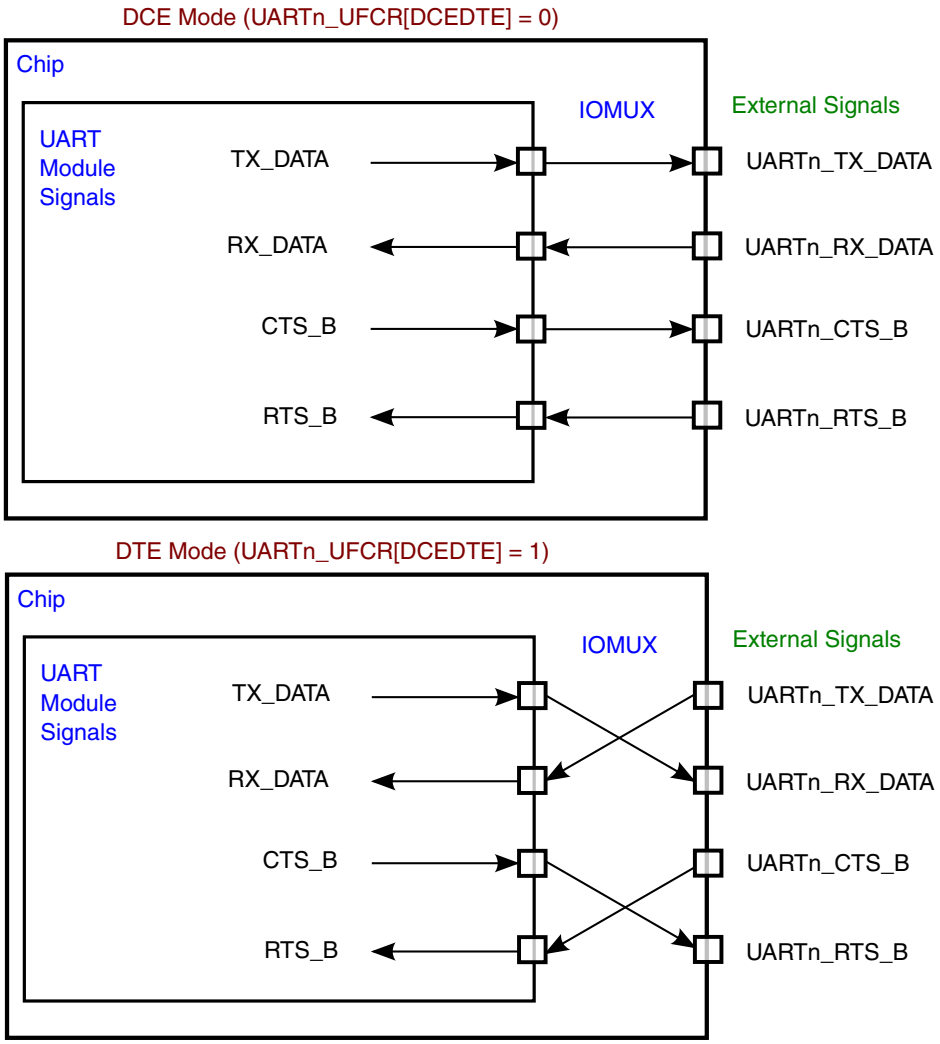

Figure 15-15. UART external signals to module signals routing with respect to DCE/DTE mode

The following table describes the external signals of UART:

Table 15-28. UART External Signals

Signal	Description	Pad	Mode	Direction
UART1_CTS_B	Clear to send	ENET1_RDATA0	ALT3	O
		SAI2_TXFS	ALT3	
UART1_RTS_B	Request to send	ENET1_RDATA1	ALT3	I
		SAI2_TXC	ALT3	
UART1_RX_DATA	Serial / infrared data receive	ENET1_RDATA2	ALT3	I
		UART1_RXD	ALT0	
UART1_TX_DATA	Serial / infrared data transmit	ENET1_RDATA3	ALT3	O
		UART1_TXD	ALT0

		EPDC1_DATA14	ALT3	
		SD1_DATA3	ALT2	
UART7_RX_DATA	Serial / infrared data receive	ECSPI2_SCLK	ALT1	I
		EPDC1_DATA12	ALT3	
		SD1_DATA0	ALT2	
UART7_TX_DATA	Serial / infrared data transmit	ECSPI2_MOSI	ALT1	O
		EPDC1_DATA13	ALT3	
		SD1_DATA1	ALT2	

The user must configure the input path to the UART by properly configuring the DAISY bits in the IOMUXC_UARTn_RX_DATA_INPUT and the IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT registers.

For IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_CTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

For IOMUXC_UARTn_UART_RX_DATA_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_TX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

15.3.2.1 Detailed Signal Descriptions

15.3.2.1.1 Interrupt Signals

15.3.2.1.1.1 *interrupt_uart* - UART Interrupt

Output interrupt request.

15.3.2.1.2 DMA Request Signals

15.3.2.1.2.1 *dma_req_rx* - Receiver DMA Request

Output DMA Request signal for receiver interface.

15.3.2.1.2.2 *dma_req_tx* - Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

15.3.2.1.3 Special Signals

15.3.2.1.3.1 *stop_req* - Stop Mode

Input stop mode. Indicates to UART that ARM platform is going to enter in Stop Mode and clocks are going to stop running.

See Low Power Modes for more information about Stop Mode.

15.3.2.1.3.2 *doze_req* - Doze Mode

Input doze mode. ARM platform requests UART to switch in doze mode (power saving mode).

See Low Power Modes for more information about Doze Mode.

15.3.2.1.3.3 *debug_req* - Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode.

See UART Operation in System Debug State, for more information about Debug Mode.

15.3.3 Clocks

The table found here describes the clock sources for UART.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-29. UART Clocks

Clock name	Clock Root	Description
ipg_clk	ipg_clk_root	Peripheral clock
ipg_clk_s	ipg_clk_root	Peripheral access clock
ipg_perclk	uart_clk_root	Module clock

15.3.4 Functional Description

This section provides a complete functional description of the block.

15.3.4.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 15-30. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
interrupt_uart	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)
	IDEN	UCR1 (bit 12)	IDLE	USR2 (bit 12)
	DREN	UCR4 (bit 0)	RDR	USR2 (bit 0)
	RXDSEN	UCR3 (bit 6)	RXDS	USR1 (bit 6)
	ATEN	UCR2 (bit 3)	AGTIM	USR1 (bit 8)
interrupt_uart	TXMPTYEN	UCR1 (bit 6)	TXFE	USR2 (bit 14)

Table continues on the next page...

Table 15-30. Interrupts and DMA (continued)

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
	TRDYEN	UCR1 (bit 13)	TRDY	USR1 (bit 13)
	TCEN	UCR4 (bit 3)	TXDC	USR2 (bit 3)
interrupt_uart	OREN	UCR4 (bit 1)	ORE	USR2 (bit 1)
	BKEN	UCR4 (bit 2)	BRCD	USR2 (bit 2)
	WKEN	UCR4 (bit 7)	WAKE	USR2 (bit 7)
	ADEN	UCR1 (bit 15)	ADET	USR2 (bit 15)
	ACIEN	UCR3 (bit 0)	ACST	USR2 (bit 11)
	ESCI	UCR2 (bit 15)	ESCF	USR1 (bit 11)
	ENIRI	UCR4 (bit 8)	IRINT	USR2 (bit 8)
	AIRINTEN	UCR3 (bit 5)	AIRINT	USR1 (bit 5)
	AWAKEN	UCR3 (bit 4)	AWAKE	USR1 (bit 4)
	FRAERREN	UCR3 (bit 11)	FRAERR	USR1 (bit 10)
	PARERREN	UCR3 (bit 12)	PARITYERR	USR1 (bit 15)
	RTSDEN	UCR1 (bit 5)	RTSD	USR1 (bit 12)
	RTSEN	UCR2 (bit 4)	RTSF	USR2 (bit 4)
	DTREN (DCE)	UCR3 (bit 13)	DTRF	USR2 (bit 13)
	RI (DTE)	UCR3 (bit 8)	RIDELT	USR2 (bit 10)
	DCD (DTE)	UCR3 (bit 9)	DCDDELT	USR2 (bit 6)
	DTRDEN	UCR3 (bit 3)	DTRD	USR1 (bit 7)
	SADEN	UMCR (bit 3)	SAD	USR1 (bit 3)
dma_req_rx	RXDMAEN	UCR1 (bit 8)	RRDY	USR1 (bit 9)
	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
dma_req_tx	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

15.3.4.2 Clocks

This section describes clocks and special clocking requirements of the UART.

15.3.4.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Clocking in Low-Power Modes).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. They can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M x 16 = 64 MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

15.3.4.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the module_clock.

For example, if the SoC can provide the fastest module_clock 66.5 MHz, the UART can transmit and receive serial data with the maximum baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, module_clock frequency must be higher or equal to 1.8432 MHz.

15.3.4.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the ARM platform with the asynchronous interrupts (see Low Power Modes).

- If before entering in STOP mode the software has enabled RTSDEN interrupt, when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in STOP mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling

edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock* .

15.3.4.3 General UART Definitions

Definitions of terms that occurs the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.
- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
- Framing Error-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However,

when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RX_DATA input. Parity error is calculated only after an entire frame is received.
- Idle-One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RX_DATA input.

15.3.4.3.1 RTS_B - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS_B pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the ARM platform from STOP mode on its assertion. When RTS_B is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

15.3.4.3.2 RTS Edge Triggered Interrupt

The input to the RTS_B pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the RTS_B pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the RTS_B edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the RTS_B input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 15-31. RTS_B Edge Triggered Interrupt Truth Table

RTS_B	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On…	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS_B interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS_B delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

15.3.4.3.3 CTS_B - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the CTS_B trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

15.3.4.3.4 Programmable CTS_B Deassertion

The CTS_B output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the CTS_B pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

15.3.4.3.5 TX_DATA - UART Transmit

This is the transmitter serial output. When operating in RS-232/RS-485 mode, NRZ encoded data is transmitted, and the data can be inverted (controlled by INVT (UCR3[1])) before transmitted. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232/RS-485 applications, this pin must be connected to an RS-232/RS-485 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 15-16.

15.3.4.3.6 RX_DATA - UART Receive

This is the receiver serial input. When operating in RS-232/RS-485 mode, NRZ encoded data is expected, and the data can be inverted (controlled by INVR (UCR4[9])) before sampled. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232/RS-485 applications require an external RS-232/RS-485 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

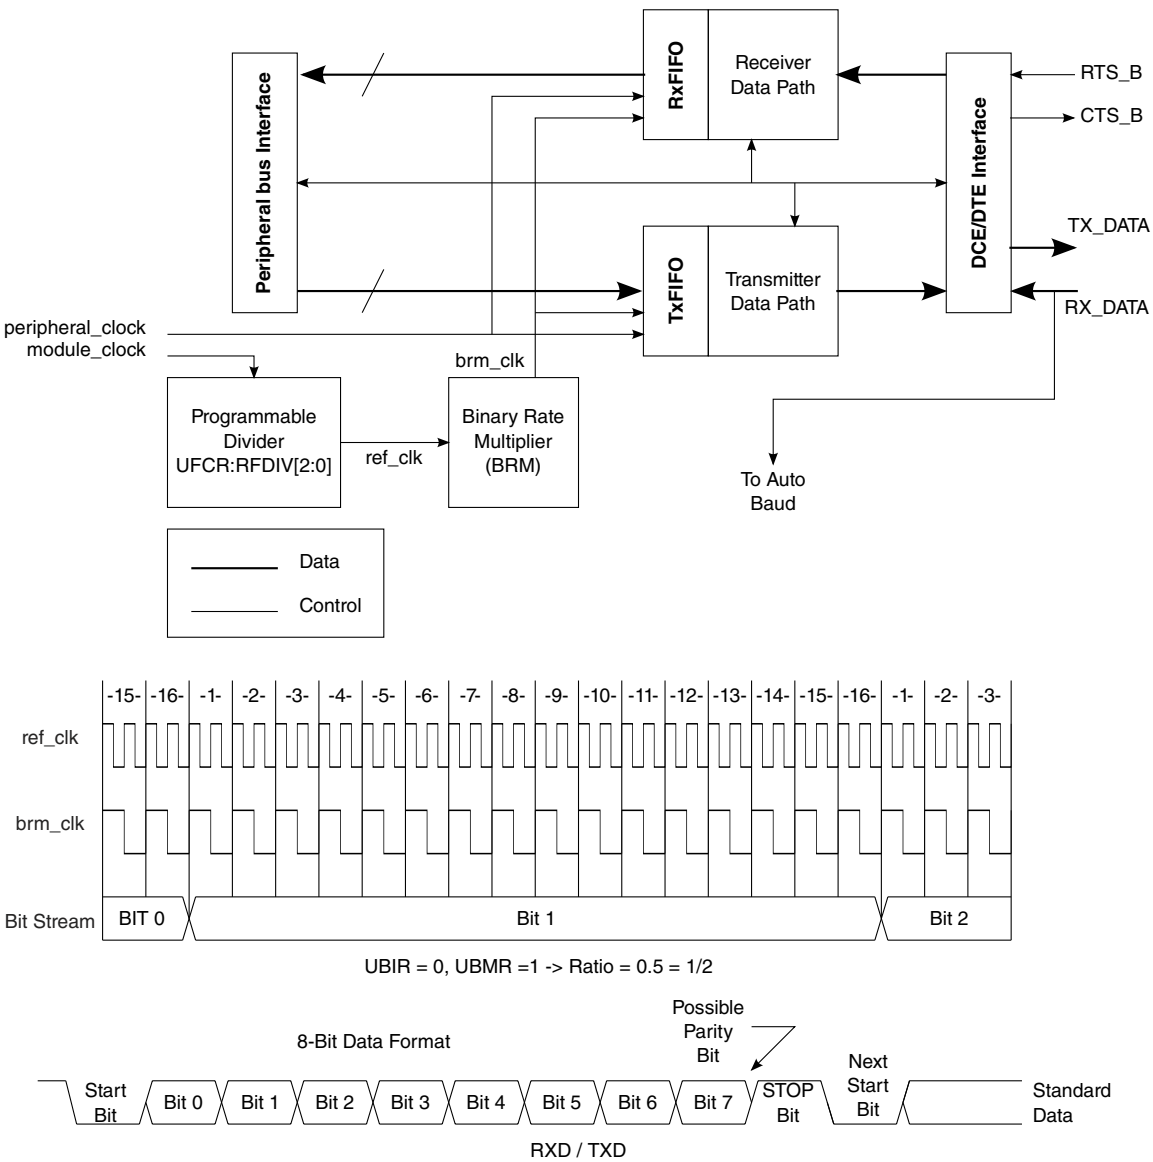

Figure 15-16. UART Simplified Block and Clock Generation Diagrams

15.3.4.4 UART Ports Mapping in DCE/DTE Mode

The table below shows UART signal mapping in DCE and DTE mode.

IO Pads Name	DCE mode		DTE mode	
	IO direction	Uart function port	IO direction	Uart function port
UART_CTS_B	O	CTS_B	I	RTS_B
UART_RTS_B	I	RTS_B	O	CTS_B
UART_TXD	O	TXD	I	RXD
UART_RXD	I	RXD	O	TXD

15.3.4.5 Transmitter

The transmitter accepts a parallel character from the ARM platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. RTS_B can be used to provide flow-control of the serial data. When RTS_B is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for RTS_B to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the Binary Rate Multiplier(BRM). Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

15.3.4.5.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the

transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset
- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

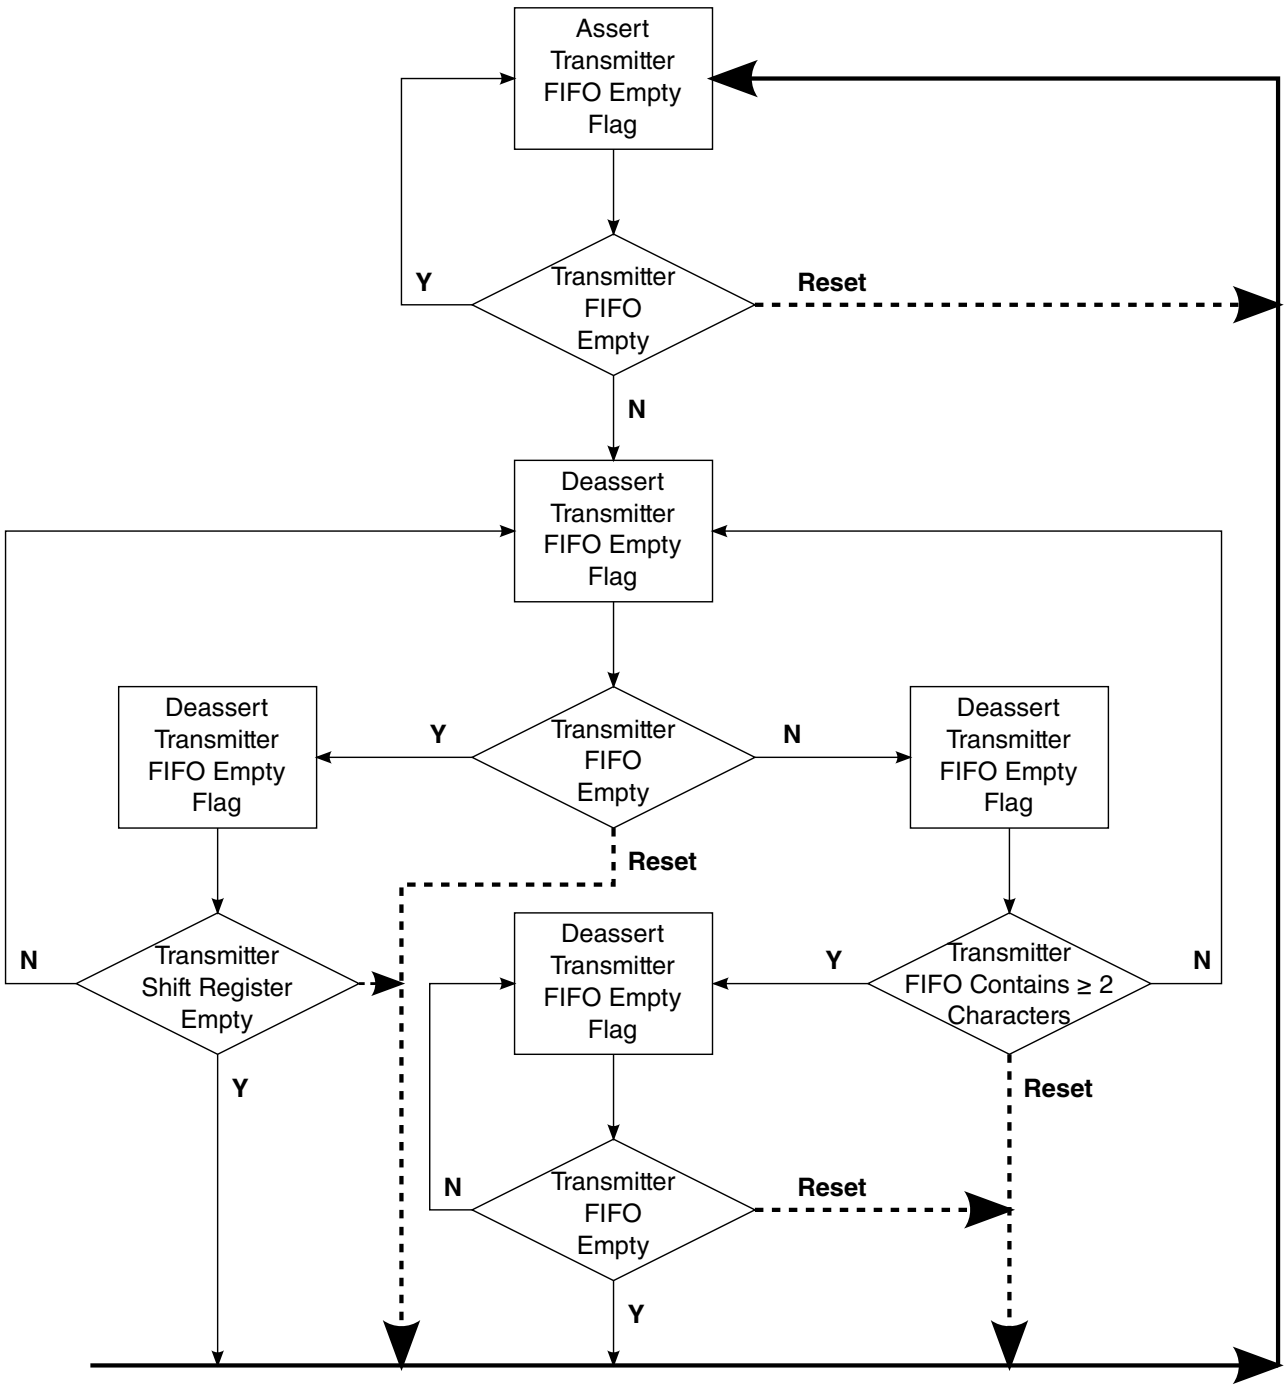

Figure 15-17. Transmitter FIFO Empty Interrupt Suppression Flow Chart

15.3.4.5.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

15.3.4.6 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center.

Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the ARM platform from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

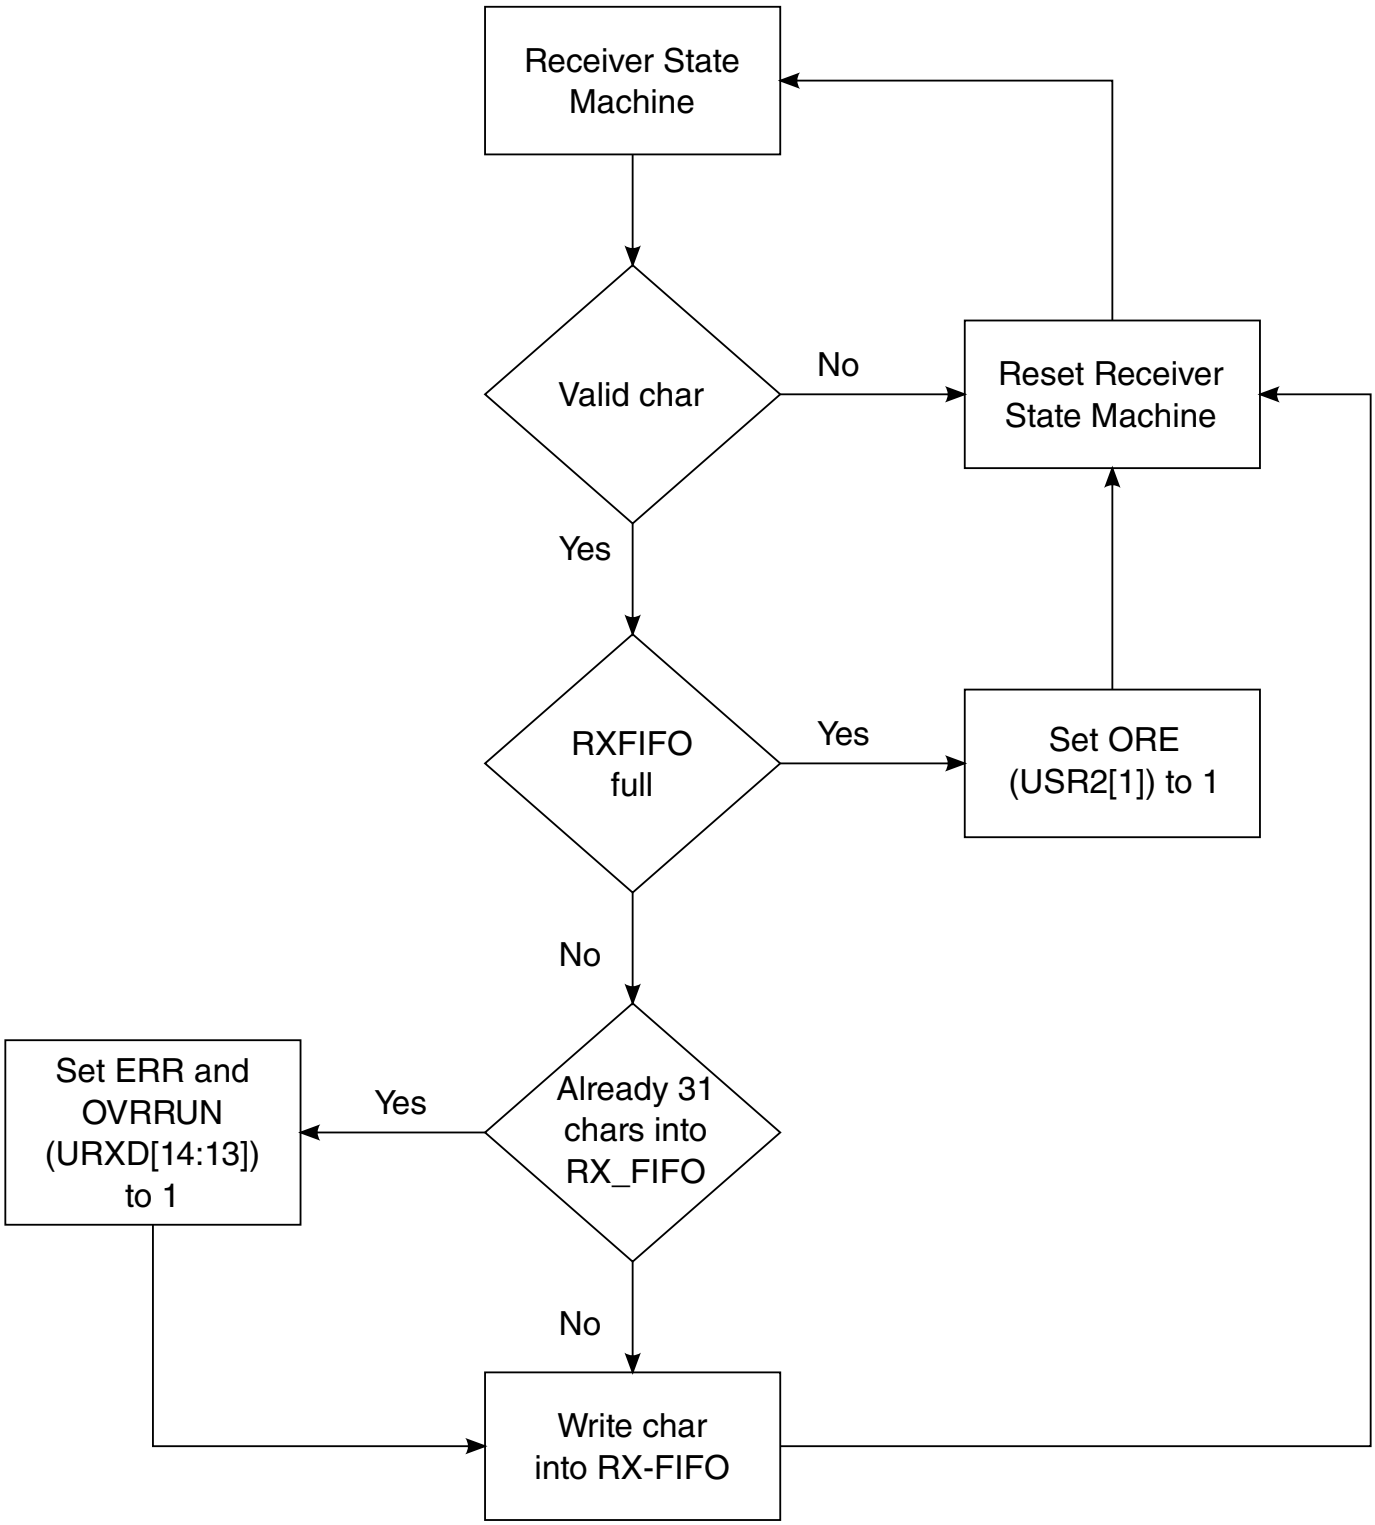

Figure 15-18. Receiver Flow Chart

15.3.4.6.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RX_DATA pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 15-32. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

15.3.4.6.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the ARM platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to ARM platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

15.3.4.6.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RX_DATA line must be detected and secondly the RX_DATA line must stays at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock* .

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the ARM platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RX_DATA) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the ARM platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the ARM platform is in STOP mode (UART clocks are off when ARM platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the ARM platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RX_DATA pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

15.3.4.6.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

15.3.4.6.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See Figure 15-19. The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 15-33. Majority Vote Results

Samples	Vote
000	0

Table continues on the next page...

Table 15-33. Majority Vote Results (continued)

Samples	Vote
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 15-33). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

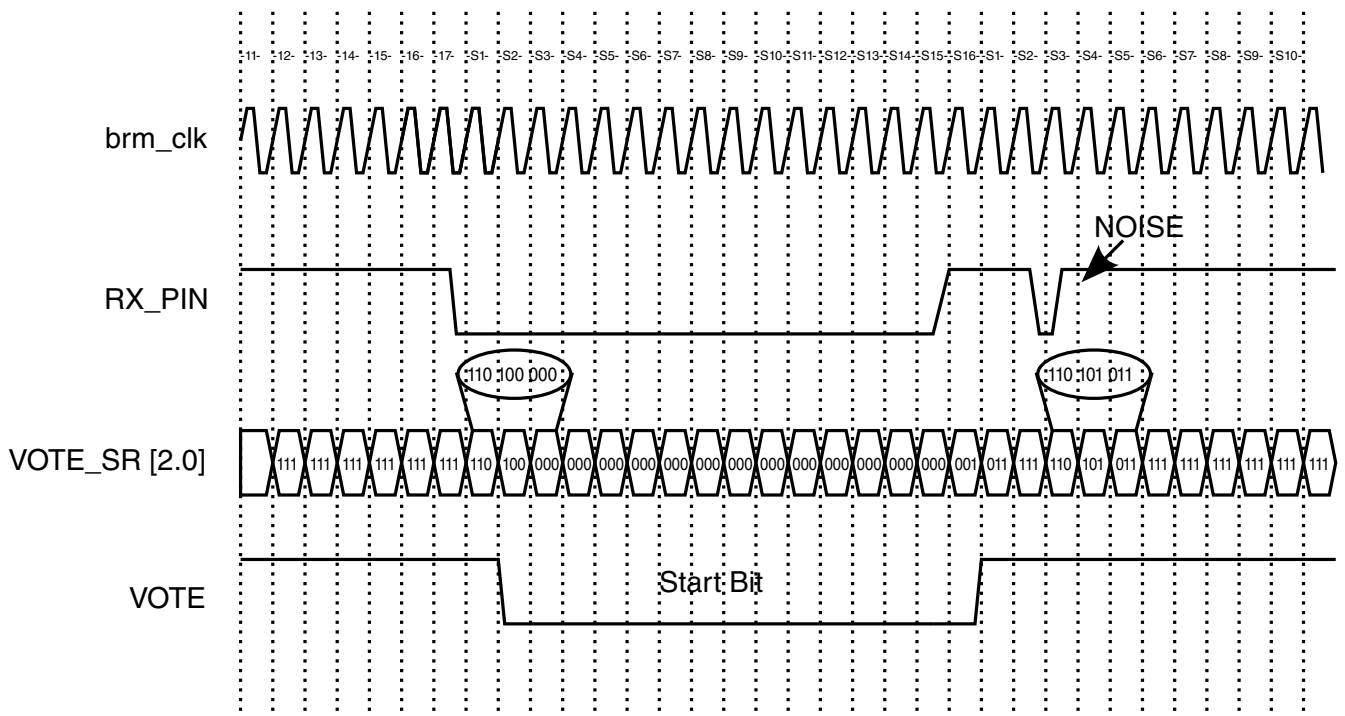

Figure 15-19. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RX_DATA line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to Infrared Interface for more details.

15.3.4.6.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RX_DATA) has been detected, UART starts a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RX_DATA), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```

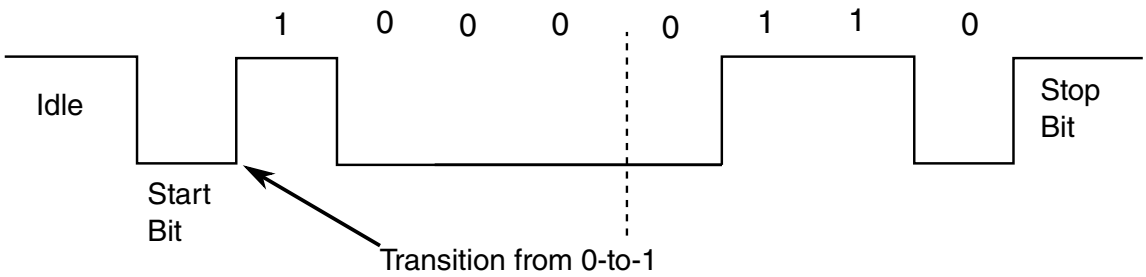
The updated values of the 3 registers can be read.

See Table 15-34 for list of parameters for baud rate detection and Figure 15-20 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 15-34. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	*interrupt_uart*
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal.			



Note: LSB Transmitted first.

Figure 15-20. Baud Rate Detection Protocol Diagram

15.3.4.6.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

15.3.4.6.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RX_DATA line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

15.3.4.6.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the ARM platform that the BRM has just been set with the result of the bit length measurement. If needed, the ARM platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the ARM platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

15.3.4.7 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence.

Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 15-35. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
NOTE: To calculate the time interval: (UTIM_Value + 1) x 0.002 = Time_Interval Example: (09C3 + 1) x 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider: UFCR[9:7] = 3'b100

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Figure 15-21. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1with the internal divider: UFCR[9:7] = 3'b101

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

Figure 15-22. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

15.3.5 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock .

The UART transmitte will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1} \right)}$$

Figure 15-23. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR + 1}{UBIR + 1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

15.3.6 Infrared Interface

15.3.6.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

15.3.6.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

15.3.6.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 µs.

But user must take into account the electrical MPD associated with the transceiver on the receiver path. Typically this value is 2.0 µs, but for some manufacturers MPD can go down to 1.0 µs.

In order to understand the meaning of IRSC bit, one must understand how the RX path works in IrDA mode.

When the UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means that at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. The pulse must last at least 2 BRM clock cycles. If this condition is not fulfilled, IRSC must be set to 1.

Let's examine two examples, for a Minimum Pulse Duration equal to the MPD from the IrDA SIR specification (i.e., 1.41 µs).

1: Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16*baud rate = 16 * 115.2K = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2* BRM_clock period is lower than 1.41 µs. Lets check:

BRM_clock period = 1/1843000 = 542 ns

So 2*BRM_clock period = 1.09 µs < 1.41 µs. It is fine.

2: Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to 16*19200 = 307.2 kHz. Let's check if 2* BRM_clock period < 1.41 µs:

1. BRM_clock period =1/307200 = 3.25 µs

   So 2*BRM_clock period = 6.50 µs >> 1.41 µs. It doesn't work.

   So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to Escape Sequence Detection.

15.3.6.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

15.3.6.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times BRMClockPeriod < MinPulseDuration$$

Figure 15-24. Calculation of Baud Rate

So,

$$BRMClockFrequency > \frac{2}{MPD}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$BaudRate > \frac{1}{8 \times MinPulseDuration}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to1.

15.3.6.6 Programming IrDA Interface

15.3.6.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

         UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to ARM platform when a character is received.

15.3.6.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to ARM platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to ARM platform when a character is received.

15.3.7 9-bit RS-485 Mode

15.3.7.1 Generalities

The UART provides a 9-bit mode to facilitate multidrop (RS-485) network communication. To enable this mode, set MDEN bit in the UMCR register to 1. When 9-bit RS-485 mode is enabled, UART transmitter can transmit the ninth bit (9^{th} bit) set by TXB8, and UART receiver can differentiate between data frames (9^{th} bit = 0) and address frames (9^{th} bit = 1).

The CTS_B pin can be used to control RS-485 output driver outside the chip.

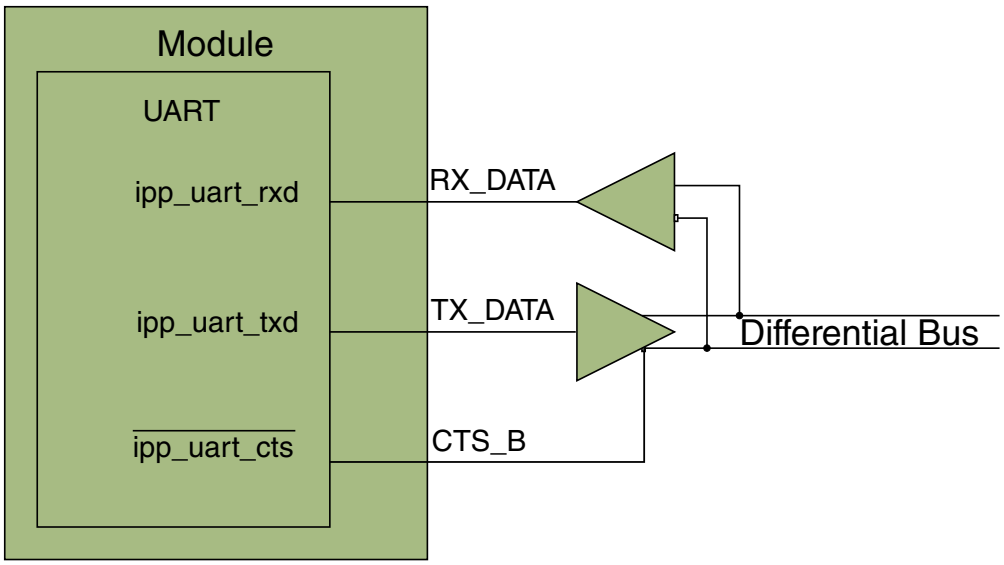


Figure 15-25. RS-485 driver connection (UART in DCE mode)

15.3.7.2 Transmit 9-bit RS-485 frames

To transmit 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable trasmitting the ninth data bit, set 8-bit data word size (WS=1), and write TXB8 (UMCR[2]) as the 9th bit (bit [8]) to be transmitted (write '0' to TXB8 to transmit a data frame, write '1' to transmit a address frame). The other data bit [7:0] is written to TxFIFO by writing to the UTXD same as normal RS-232 operation.

15.3.7.3 Receive 9-bit RS-485 frames

To receive 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable receiving the ninth data bit, set 8-bit data word size (WS=1). The receiver will save the 9-bit data to RxFIFO, and user should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

There are two slave address detect modes, normal detect mode and automatic detect mode, and can be selected by SLAM (UMCR[1]).

15.3.7.3.1 RS-485 Slave Address Normal Detect Mode

To enable Normal Detect mode, clear SLAM (UMCR[1] to 0). The receiver ignores all data frames (9th bit = 0) until an address frame is received (9th bit = 1). At that time, the slave address detected (SAD = USR1[3]) bit is asserted and the *interrupt_uart* interrupt is

generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. The UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL) if receive ready DMA (RXDMAEN = UCR1[8]) request is enabled.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

In this mode, once the UART has detected a 9th bit is equal to '1', it will always save the subsequent frames to RxFIFO. So the software must decide whether the address and data in RxFIFO are needed or not.

15.3.7.3.2 RS-485 Slave Address Automatic Detect Mode

To enable Automatic Detect Mode, set SLAM (UMCR[1]) to 1. The receiver tries to detect an address byte (frame 9th bit = 1) that matches the programmed SLADDR (UMCR[15:8]) character. If the received byte is a data or an address byte that does not match the programmed SLADDR character, the receiver will discard these data.

Once the UART receives a matching address byte, it will assert the slave address detected (SAD = USR1[3]) bit and the *interrupt_uart* interrupt will be generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. If receive ready DMA(RXDMAEN = UCR1[8]) request is enabled, the UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL).

If another address byte is received and this address byte does not match SLADDR character, the receiver will discard the address byte and subsequent data byte. If the address byte again matches SLADDR character, the receiver will put this address byte and subsequent data byte in the RxFIFO along with their 9th bit.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

See Initialization for 9-bit RS-485 programming guide.

15.3.8 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting in/out of low power modes.

Table 15-36. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

15.3.8.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

15.3.8.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the ARM platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the ARM platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

15.3.8.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

15.3.9 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
   - All writes into the RX FIFO are prevented.
   - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

     RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

15.3.10 Reset

This section describes how to reset the block and explains special requirements related to reset.

15.3.10.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

15.3.10.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will keep the software reset asserted for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the SRST_B bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

15.3.11 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

15.3.12 Functional Timing

This section includes timing diagrams for functional signaling.

15.3.12.1 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

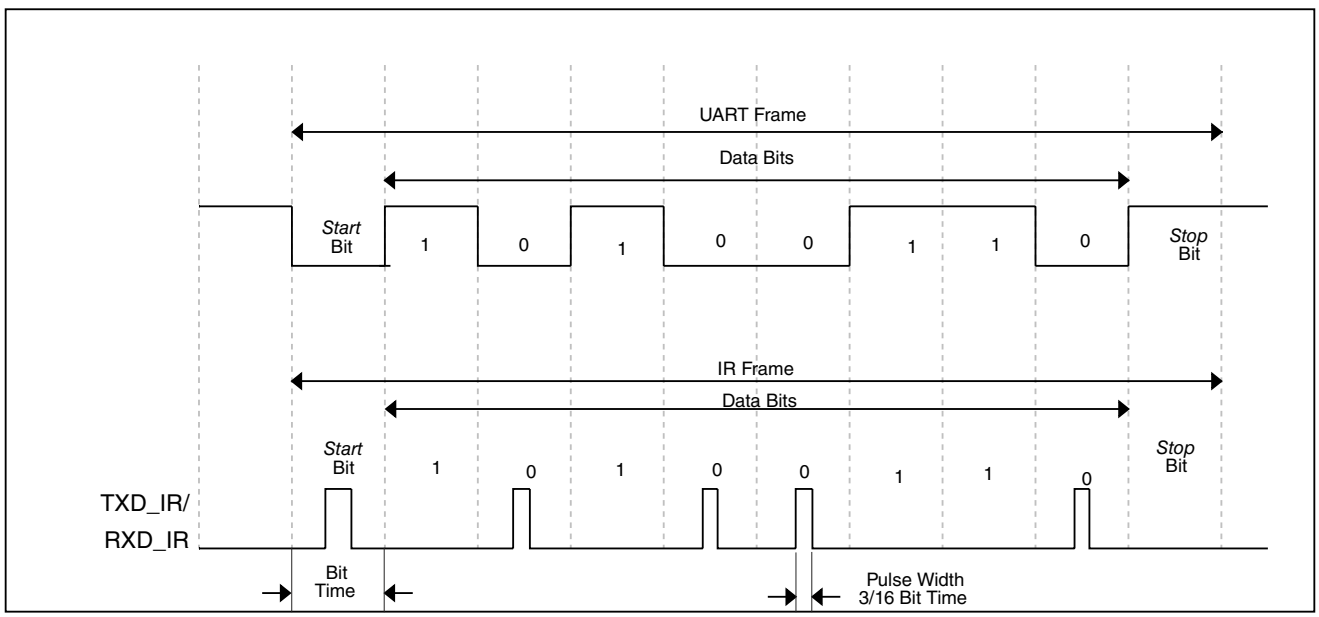

Figure 15-26. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

15.3.13 Initialization

15.3.13.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6 Kbps

- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x2127

   Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

   Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

   Set CTS trigger level to 31,

5. UFCR = 0x089E

   Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is 100 MHz/5 = 20 MHz.

   Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

   In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

   Enable the TRDY and RRDY interrupts.

9. UMCR = 0x0000

   UMCR stay at default value 0x0000

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

15.3.13.2 Programming the UART in 9-bit RS-485 mode

As an example, the following sequence can be used to program the UART in order to send and receive frames in RS-485 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 5 Mbps

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x4127

   Set software flow control ($\overline{\text{CTS}}$ pin is controlled by UCR2[12]), enable parity(enable 9^{th} bit rxd/txd), 8-bit word size , and enable transmitter and receiver.

3. UCR4 = 0x7C00

   Set CTS trigger level to 31,

4. UFCR = 0x0A9E

   Set RFDIV = 5 (divide input uart clock by 1), so the reference clock is 100 MHz. Set UART in DCE mode (RS-485 driver connection outside the chip is the same as Figure 15-25)

   Set TXTL = 2 and RXTL = 30.

5. UBIR = 0x0003
6. UBMR = 0x0004

   In the above two steps, set baud rate to 5 Mbps based on the 100 MHz reference clock.

7. UCR1 = 0x2001 when UART as a master ,

   or UCR1 = 0x0201 (or 0x0101) when UART as a slave.

Enable TRDY interrupt when UART as a master, enable RRDY interrupt or DMA request when UART as a slave.

8. UMCR = 0xA50B

   Enable 9-bit RS-485 mode, enable SAD interrupt, set automatic slave address detect mode, set slave address is 0xA5.

Interrupt service routine for the transmitter:

- Transmit data: write its ninth bit (bit[8]) to UMCR[2], write its bit [7:0] into UTXD[7:0]

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2.

Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Receive data: read its ninth bit (bit[8]) from URXD[10] , read its bit [7:0] from URXD[7:0].

Note: in RS-485 mode, URXD[10] bit is not the parity error, instead it holds the ninth bit (bit[8]) of the received data.

The SAD interrupt can not de-assert automatically, it needs MCU write 1 to USR1[3] to clear it . The RRDY interrupt or DMA request will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

15.3.15 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

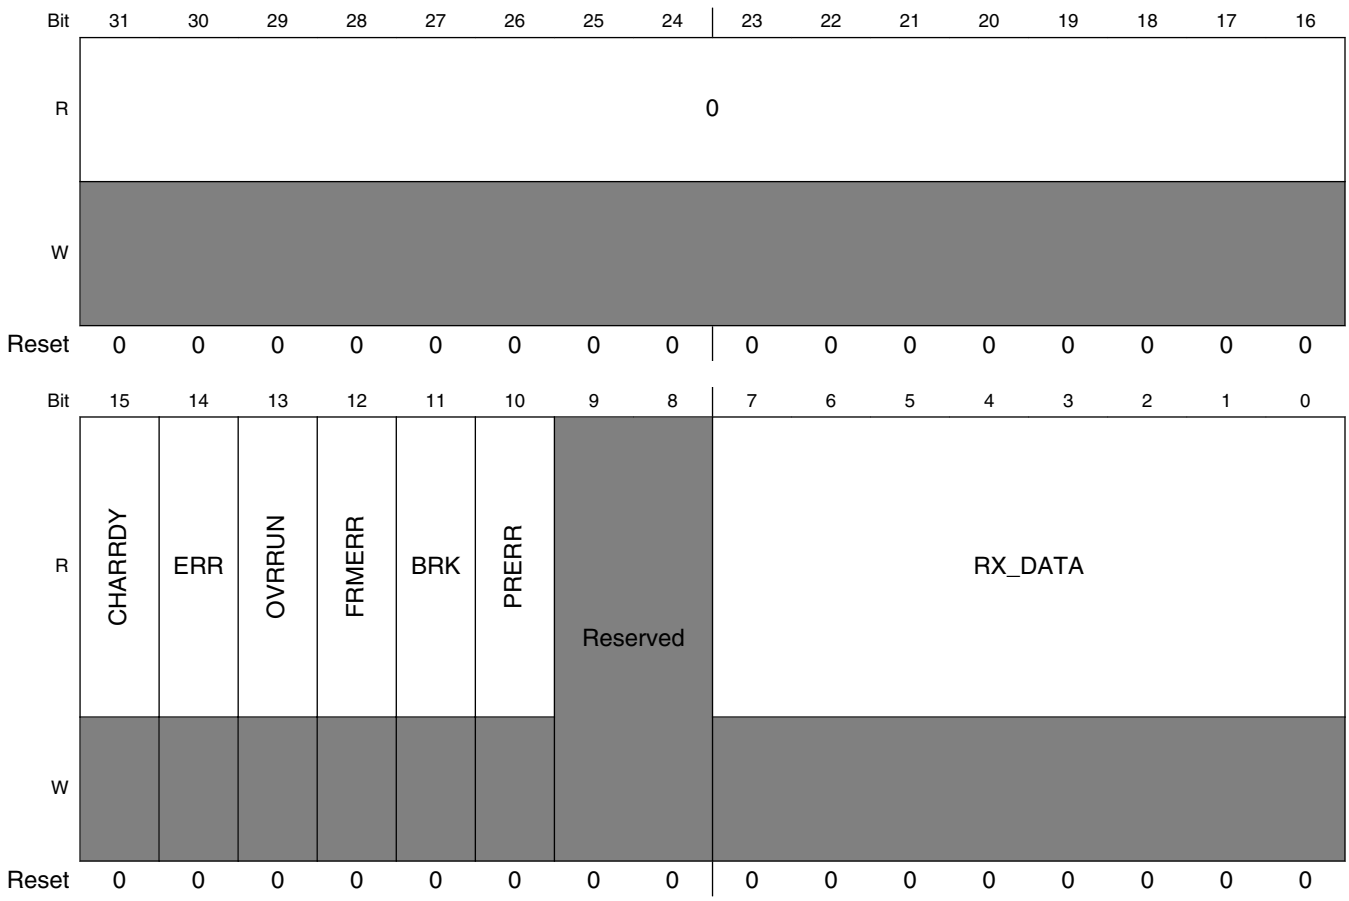
15.3.15.1 UART Receiver Register (UARTx_URXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Address: Base address + 0h offset



UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.

Table continues on the next page...

UARTx_URXD field descriptions (continued)

Field	Description
14 ERR	**Error Detect.** Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected
13 OVRRUN	**Receiver Overrun.** This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	**Frame Error.** Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	**BREAK Detect.** Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	**In RS-485 mode, it holds the ninth data bit (bit [8]) of received 9-bit RS-485 data** **In RS232/IrDA mode, it is the Parity Error flag**. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8 -	This field is reserved. **Reserved**
RX_DATA	**Received Data**. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.

15.3.15.2 UART Transmitter Register (UARTx_UTXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

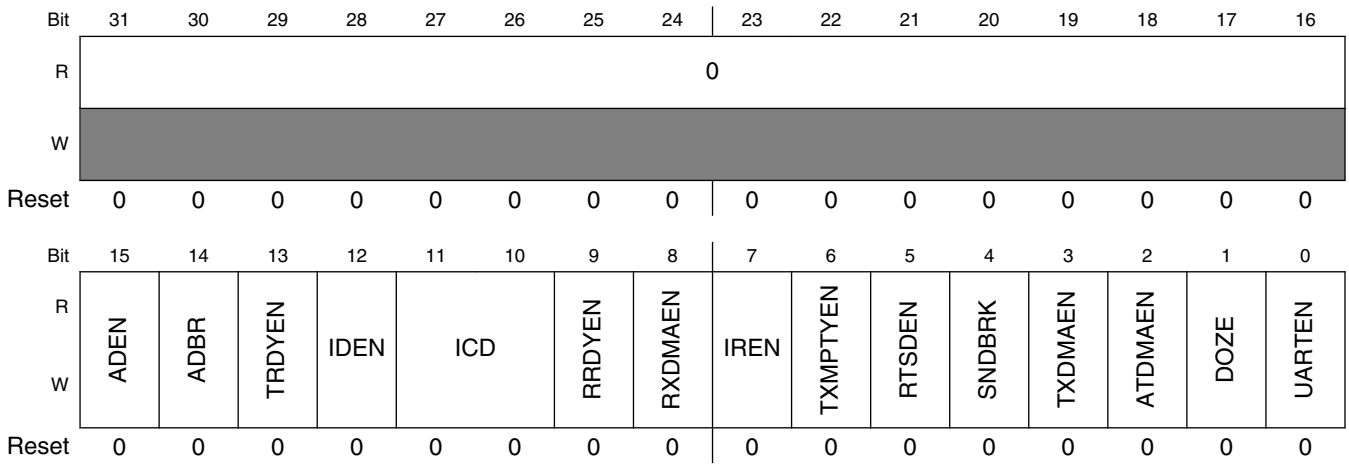
UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 Reserved	This read-only field is reserved and always has the value 0.
TX_DATA	**Transmit Data**. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

15.3.15.3 UART Control Register 1 (UARTx_UCR1)

Address: Base address + 80h offset



UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADEN	**Automatic Baud Rate Detection Interrupt Enable**. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	**Automatic Detection of Baud Rate**. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x41 or 0x61). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	**Transmitter Ready Interrupt Enable**. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **NOTE:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	**Idle Condition Detected Interrupt Enable**. Enables/Disables the IDLE bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
11–10 ICD	**Idle Condition Detect**. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	**Receiver Ready Interrupt Enable**. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	**Receive Ready DMA Enable**. Enables/Disables the receive DMA request *dma_req_rx* when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	**Infrared Interface Enable**. Enables/Disables the IR interface. See the IR interface description in Infrared Interface, for more information. Note: MDEN(UMCR[0]) must be cleared to 0 when using IrDA interface. See Table 15-27 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	**Transmitter Empty Interrupt Enable**. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. *interrupt_uart*. When negated, the TXFE interrupt is disabled. **NOTE:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	**RTS Delta Interrupt Enable**. Enables/Disables the RTSD interrupt. The current status of the RTS_B pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	**Send BREAK**. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	**Transmitter Ready DMA Enable**. Enables/Disables the transmit DMA request *dma_req_tx* when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the *dma_req_tx* is controlled by the TXTL bits.

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	NOTE: A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request
2 ATDMAEN	**Aging DMA Timer Enable**. Enables/Disables the receive DMA request *dma_req_rx* for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request
1 DOZE	**DOZE**. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the ARM Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes. 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	**UART Enable**. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

15.3.15.4 UART Control Register 2 (UARTx_UCR2)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ESCI	**Escape Sequence Interrupt Enable**. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	**Ignore RTS Pin**. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS **Pin Control**. Controls the operation of the CTS_B module output. When CTSC is asserted, the CTS_B module output is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the CTS_B module output is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the CTS_B module output is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the CTS_B pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the CTS_B signal is negated. 0 The CTS_B pin is controlled by the CTS bit 1 The CTS_B pin is controlled by the receiver
12 CTS	**Clear to Send**. Controls the CTS_B pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The CTS_B pin is high (inactive) 1 The CTS_B pin is low (active)
11 ESCEN	**Escape Enable**. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	**Request to Send Edge Control**. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 15-31). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	**Parity Enable**. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	**Parity Odd/Even**. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
6 STPB	**Stop**. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	**Word Size**. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)
4 RTSEN	**Request to Send Interrupt Enable.** Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the RTS_B pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (See Table 15-31.) 0 Disable request to send interrupt 1 Enable request to send interrupt
3 ATEN	**Aging Timer Enable**. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	**Transmitter Enable**. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	**Receiver Enable**. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 SRST	**Software Reset**. Once the software writes 0 to SRST_B, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts SRST_B. The software can only write 0 to SRST_B. Writing 1 to SRST_B is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC , URXD, UTXD and UTS[6-3]. 1 No reset

15.3.15.5 UART Control Register 3 (UARTx_UCR3)

Address: Base address + 88h offset

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 DPEC	This bit is not used in this chip.
13 DTREN	This bit is not used in this chip.
12 PARERREN	**Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt.** 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	**Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt.** 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	This bit is not used in this chip.
9 DCD	This bit is not used in this chip.
8 RI	This bit is not used in this chip.
7 ADNIMP	**Autobaud Detection Not Improved-. Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details).** 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism

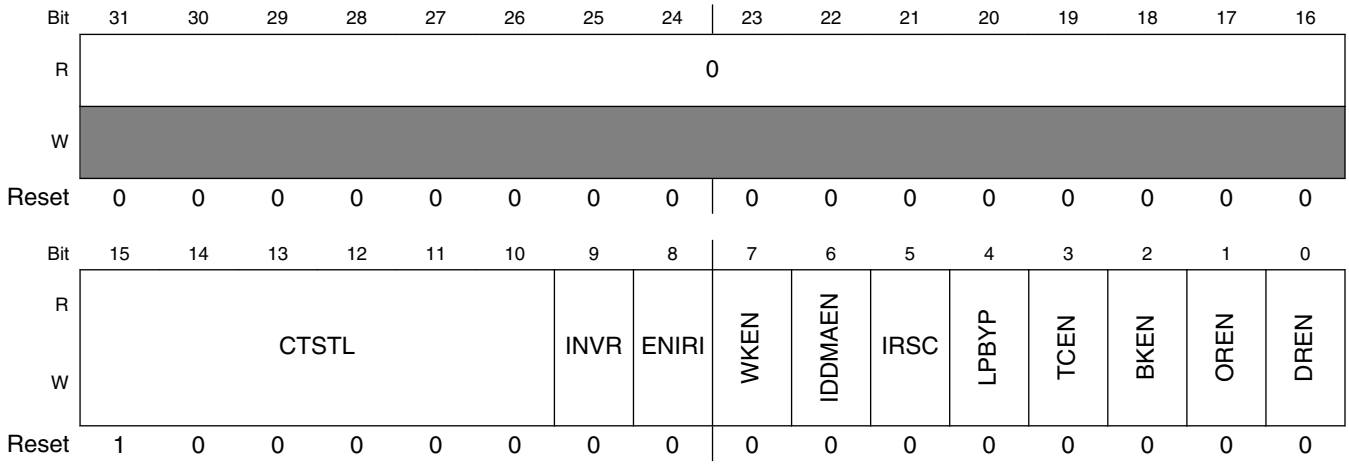
Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt (*interrupt_uart*). When this bit is enabled and RXDS status bit is set, the interrupt *interrupt_uart* will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	This bit is not used in this chip.
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. **NOTE:** In this chip, UARTs are used in MUXED mode, so that this bit should always be set.
1 INVT	Invert TXD output in RS-232/RS-485 mode, set TXD active level in IrDA mode. In RS232/RS-485 mode(UMCR[0] = 1), if this bit is set to 1, the TXD output is inverted before transmitted. In **IrDA mode**, when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 **TXD is not inverted** 1 **TXD is inverted** 0 **TXD** Active low transmission 1 **TXD** Active high transmission
0 ACIEN	**Autobaud Counter Interrupt Enable.** This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

15.3.15.6 UART Control Register 4 (UARTx_UCR4)

Address: Base address + 8Ch offset



UARTx_UCR4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 CTSTL	**CTS Trigger Level**. Controls the threshold at which the CTS_B pin is deasserted by the RxFIFO. After the trigger level is reached and the CTS_B pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 1 characters in the RxFIFO ... — ... — 100000 32 characters in the RxFIFO (maximum)
9 INVR	**Invert RXD input in RS-232/RS-485 Mode, d**etermine **RXD input** logic level being sampled in **In IrDA mode.** **In RS232/RS-485 Mode(UMCR[0] = 1), if this bit is set to 1, the RXD input is inverted before sampled.** **In IrDA mode**,when cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR 1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 **RXD input is not inverted** 1 **RXD input is inverted** 0 **RXD** active low detection 1 **RXD** active high detection
8 ENIRI	**Serial Infrared Interrupt Enable**. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled

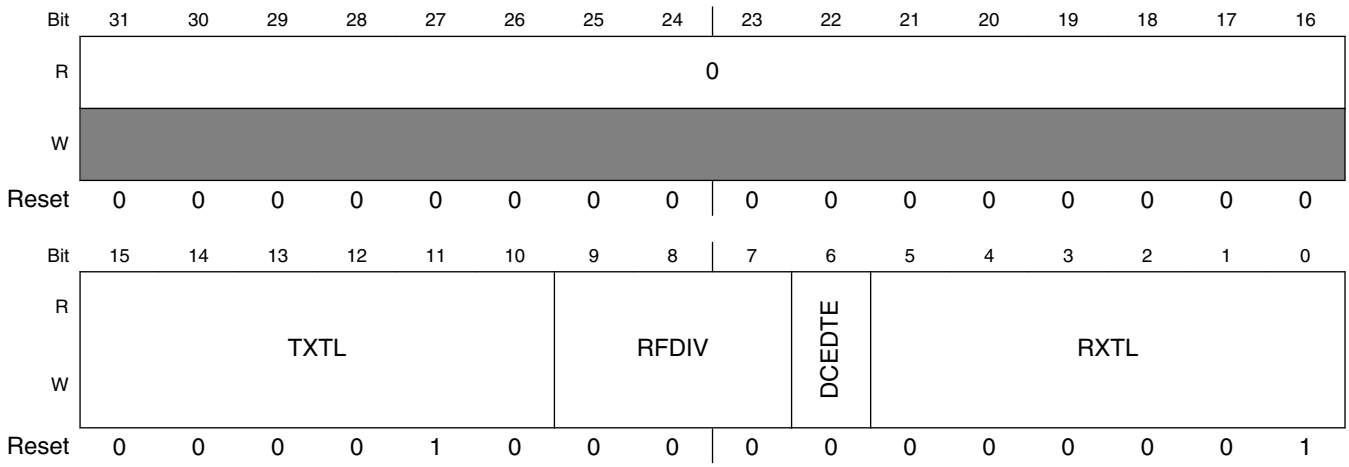
Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
7 WKEN	**WAKE Interrupt Enable**. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	**DMA IDLE Condition Detected Interrupt Enable** Enables/Disables the receive DMA request *dma_req_rx* for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	**IR Special Case**. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	**Low Power Bypass**. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	**TransmitComplete Interrupt Enable**. Enables/Disables the TXDC bit to generate an interrupt (*interrupt_uart* = 0) **NOTE:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	**BREAK Condition Detected Interrupt Enable**. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt
1 OREN	**Receiver Overrun Interrupt Enable**. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	**Receive Data Ready Interrupt Enable**. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

15.3.15.7 UART FIFO Control Register (UARTx_UFCR)

Address: Base address + 90h offset



UARTx_UFCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 TXTL	**Transmitter Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... — ... — 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum)
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	**DCE/DTE mode select**. Select UART as data communication equipment (DCE mode) or as data terminal equipment (DTE mode).

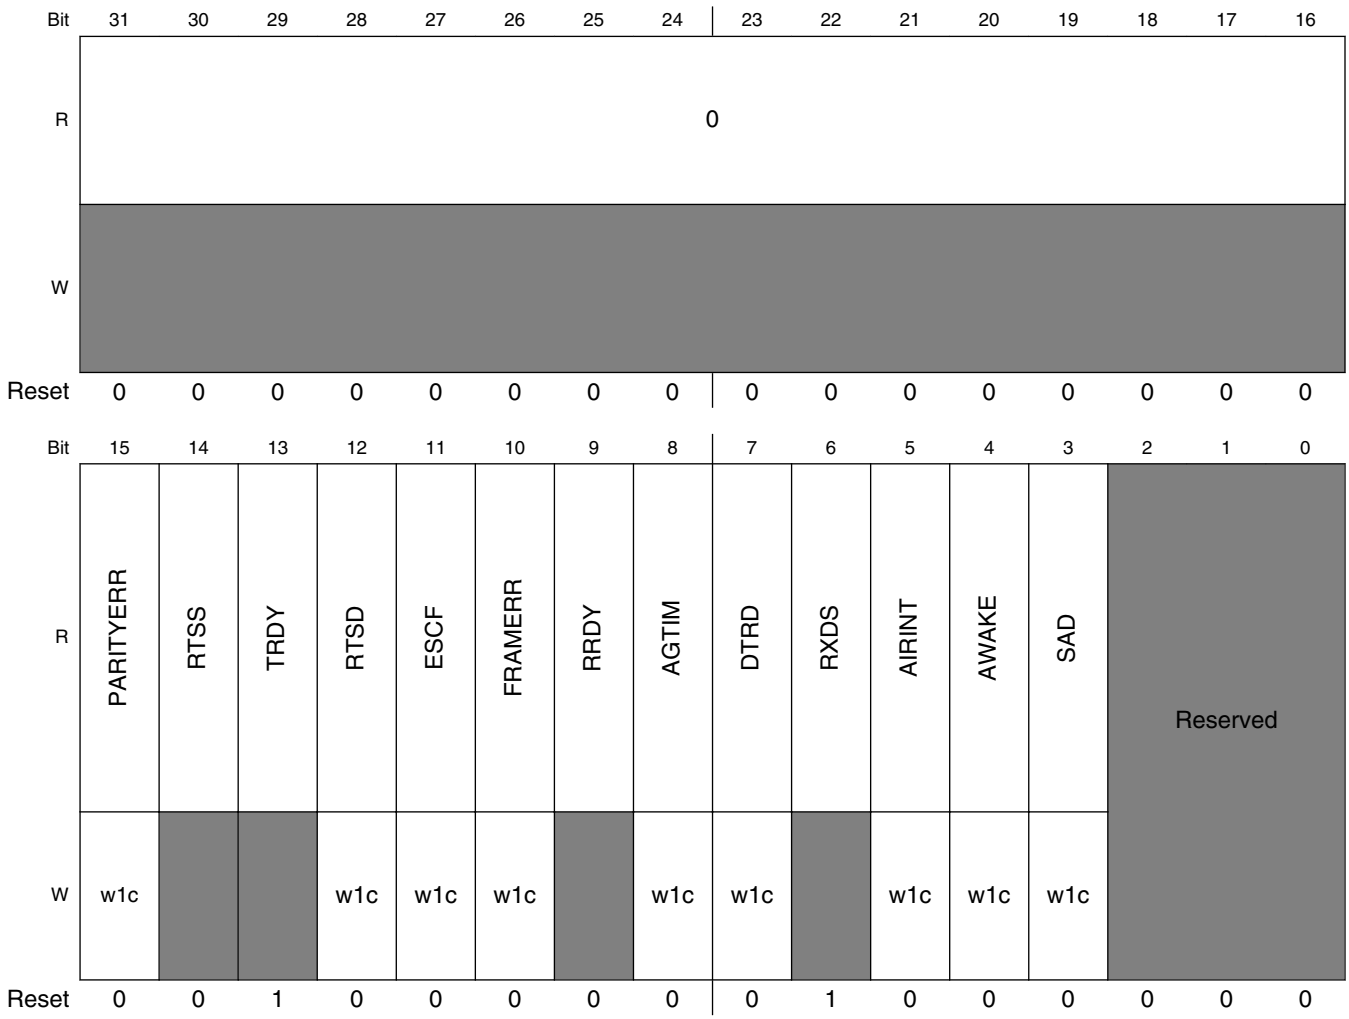
Table continues on the next page...

UARTx_UFCR field descriptions (continued)

Field	Description
	0 DCE mode selected 1 DTE mode selected
RXTL	**Receiver Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. Setting 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 RxFIFO has 1 character ... — ... — 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum)

15.3.15.8 UART Status Register 1 (UARTx_USR1)

Address: Base address + 94h offset



UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 PARITYERR	**Parity Error Interrupt Flag**. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	RTS_B **Pin Status**. Indicates the current status of the RTS_B pin. A "snapshot" of RTS_B is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 The RTS_B module input is high (inactive) 1 The RTS_B module input is low (active)
13 TRDY	**Transmitter Ready Interrupt / DMA Flag**. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	**RTS Delta.** Indicates whether the RTS_B pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the RTS_B pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 RTS_B pin did not change state since last cleared 1 RTS_B pin changed state (write 1 to clear)
11 ESCF	**Escape Sequence Interrupt Flag**. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	**Frame Error Interrupt Flag**. Indicates that a frame error is detected. The *interrupt_uart* interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	**Receiver Ready Interrupt / DMA Flag**. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	This bit is not used in this chip.
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE

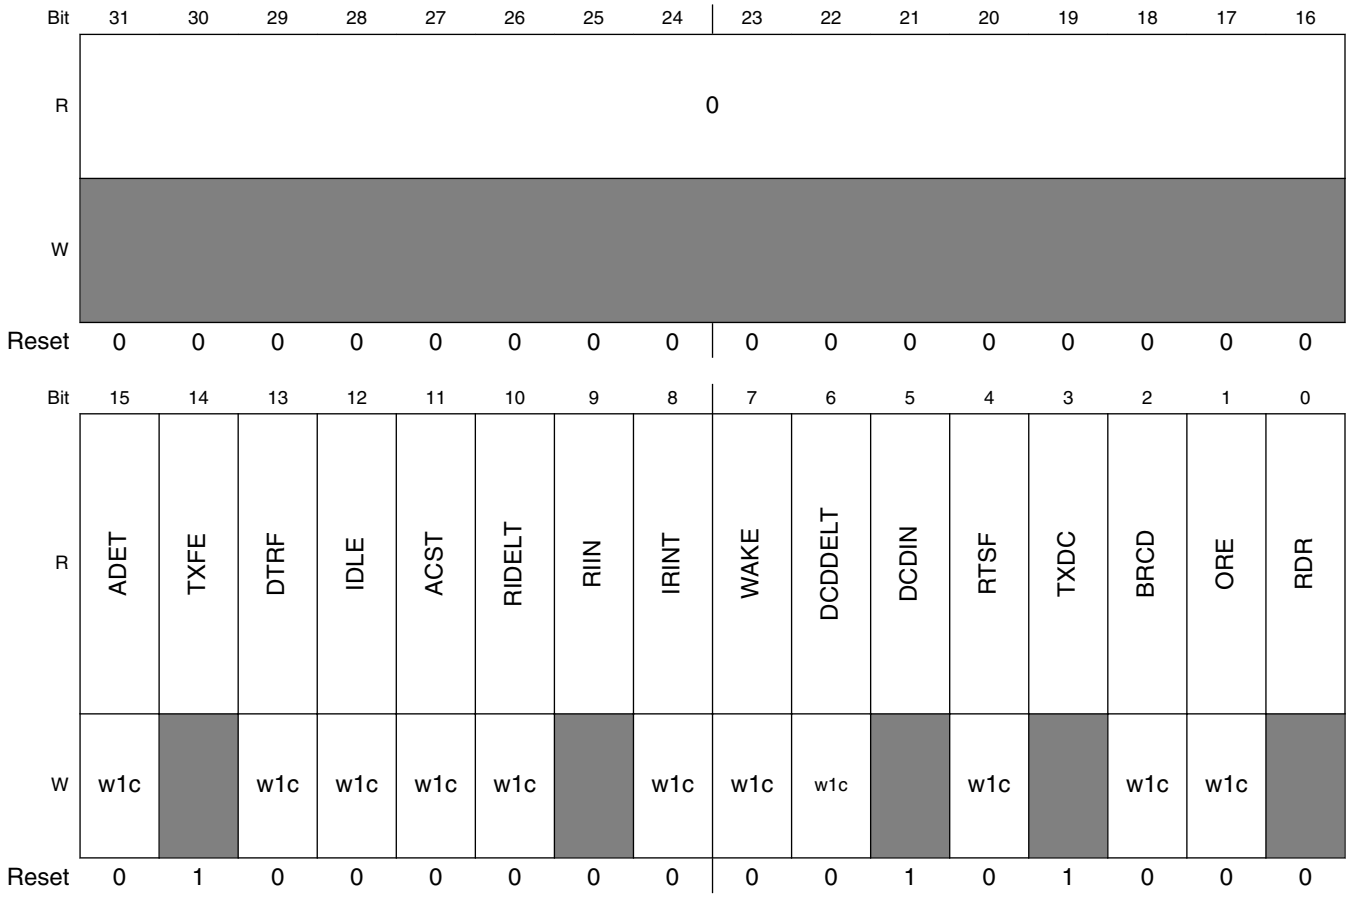
Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3 SAD	RS-485 Slave Address Detected Interrupt Flag. Indicates if RS-485 Slave Address was detected . SAD was asserted in RS-485 mode when the SADEN bit is set and Slave Address is detected in RxFIFO (in Nomal Address Detect Mode, the 9th data bit = 1; in Automatic Address Detect Mode, the received charater matches the programmed SLADDR). 0 No slave address detected 1 Slave address detected
-	This field is reserved. Reserved

15.3.15.9 UART Status Register 2 (UARTx_USR2)

Address: Base address + 98h offset



UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADET	**Automatic Baud Rate Detect Complete**. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	**Transmit Buffer FIFO Empty**. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	This bit is not used in this chip.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
12 IDLE	**Idle Condition**. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect. An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	**Autobaud Counter Stopped**. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt, for more details. An interrupt can be flagged on *interrupt_uart* if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	This bit is not used in this chip.
9 RIIN	This bit is not used in this chip.
8 IRINT	**Serial Infrared Interrupt Flag.** When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	**Wake**. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELT	This bit is not used in this chip.
5 DCDIN	This bit is not used in this chip.
4 RTSF	**RTS Edge Triggered Interrupt Flag. Indicates if** a programmed edge is detected on the RTS_B pin. The RTEC bits select the edge that generates an interrupt (see Table 15-31). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on RTS_B 1 Programmed edge detected on RTS_B (write 1 to clear)
3 TXDC	**Transmitter Complete**. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	**BREAK Condition Detected**. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	**Overrun Error**. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
	0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	**Receive Data Ready**-Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

15.3.15.10 UART Escape Character Register (UARTx_UESC)

Address: Base address + 9Ch offset

UARTx_UTIM field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 15-35 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

15.3.15.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[8].

Please note software reset will reset the register to its reset value.

Address: Base address + A4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UARTx_UBIR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

15.3.15.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[9].

Please note software reset will reset the register to its reset value.

Address: Base address + A8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UARTx_UBRC field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
BCNT	**Baud Rate Count Register.** This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

15.3.15.15 UART One Millisecond Register (UARTx_ONEMS)

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

Address: Base address + B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

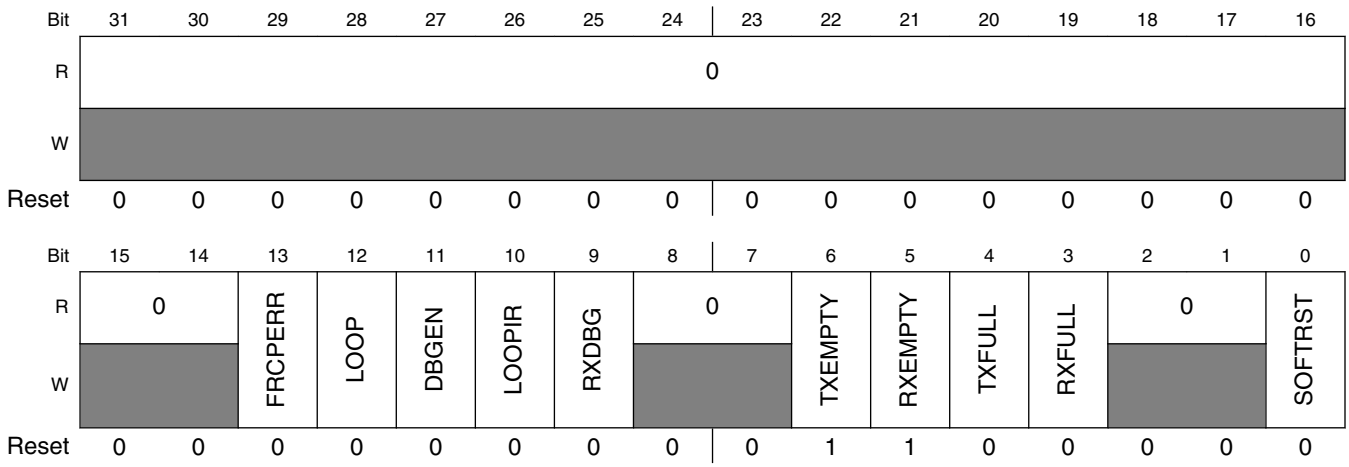
UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
ONEMS	**One Millisecond Register.** This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Figure 15-14) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F (*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.

15.3.15.16 UART Test Register (UARTx_UTS)

Address: Base address + B4h offset



UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	This bit is not used in this chip. debug_enable_B**.** This bit controls whether to respond to the *debug_req* input signal. 0 UART will go into debug mode when *debug_req* is HIGH 1 UART will not go into debug mode even if *debug_req* is HIGH
10 LOOPIR	**Loop TX and RX for IR Test (LOOPIR)**. This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	This bit is not used in this chip. **RX_fifo_debug_mode.** This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal

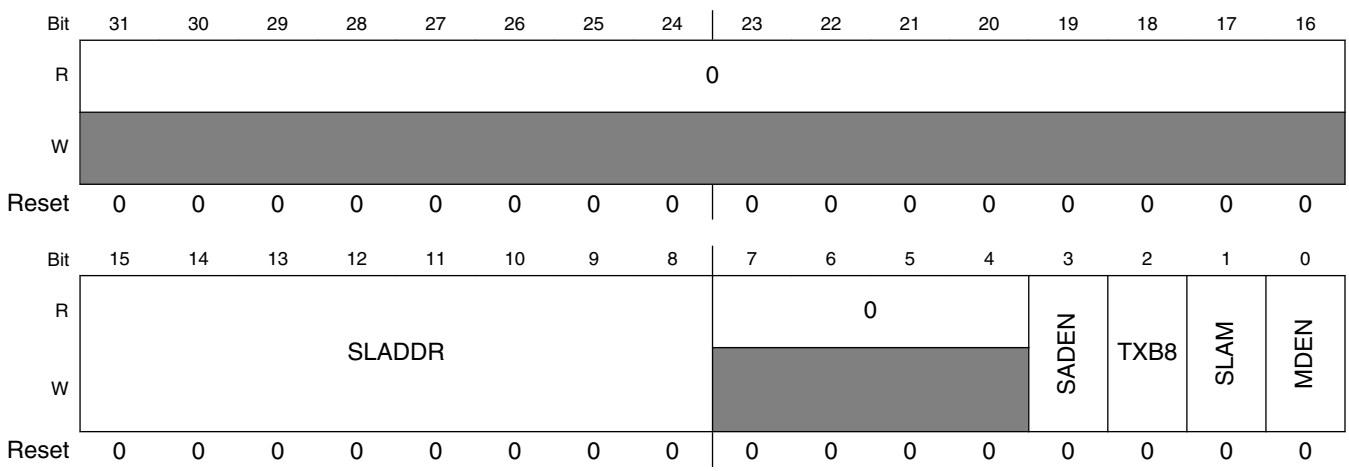
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SOFTRST	Software Reset. Indicates the status of the software reset (SRST_B bit of UCR2). 0 Software reset inactive 1 Software reset active

15.3.15.17 UART RS-485 Mode Control Register (UARTx_UMCR)

Address: Base address + B8h offset



UARTx_UMCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 SLADDR	RS-485 Slave Address Character. Holds the selected slave adress character that the receiver wil try to detect.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 SADEN	RS-485 Slave Address Detected Interrupt Enable. 0 Disable RS-485 Slave Address Detected Interrupt 1 Enable RS-485 Slave Address Detected Interrupt
2 TXB8	Transmit RS-485 bit 8 (the ninth bit or 9th bit). In RS-485 mode, software writes TXB8 bit as the 9th data bit to be transmitted. 0 0 will be transmitted as the RS485 9th data bit 1 1 will be transmitted as the RS485 9th data bit
1 SLAM	RS-485 Slave Address Detect Mode Selection. 0 Select Normal Address Detect mode 1 Select Automatic Address Detect mode
0 MDEN	9-bit data or Multidrop Mode (RS-485) Enable. 0 Normal RS-232 or IrDA mode, see Table 15-27 for detail. 1 Enable RS-485 mode, see Table 15-27 for detail

15.4 Keypad Port (KPP)

15.4.1 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O).

The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

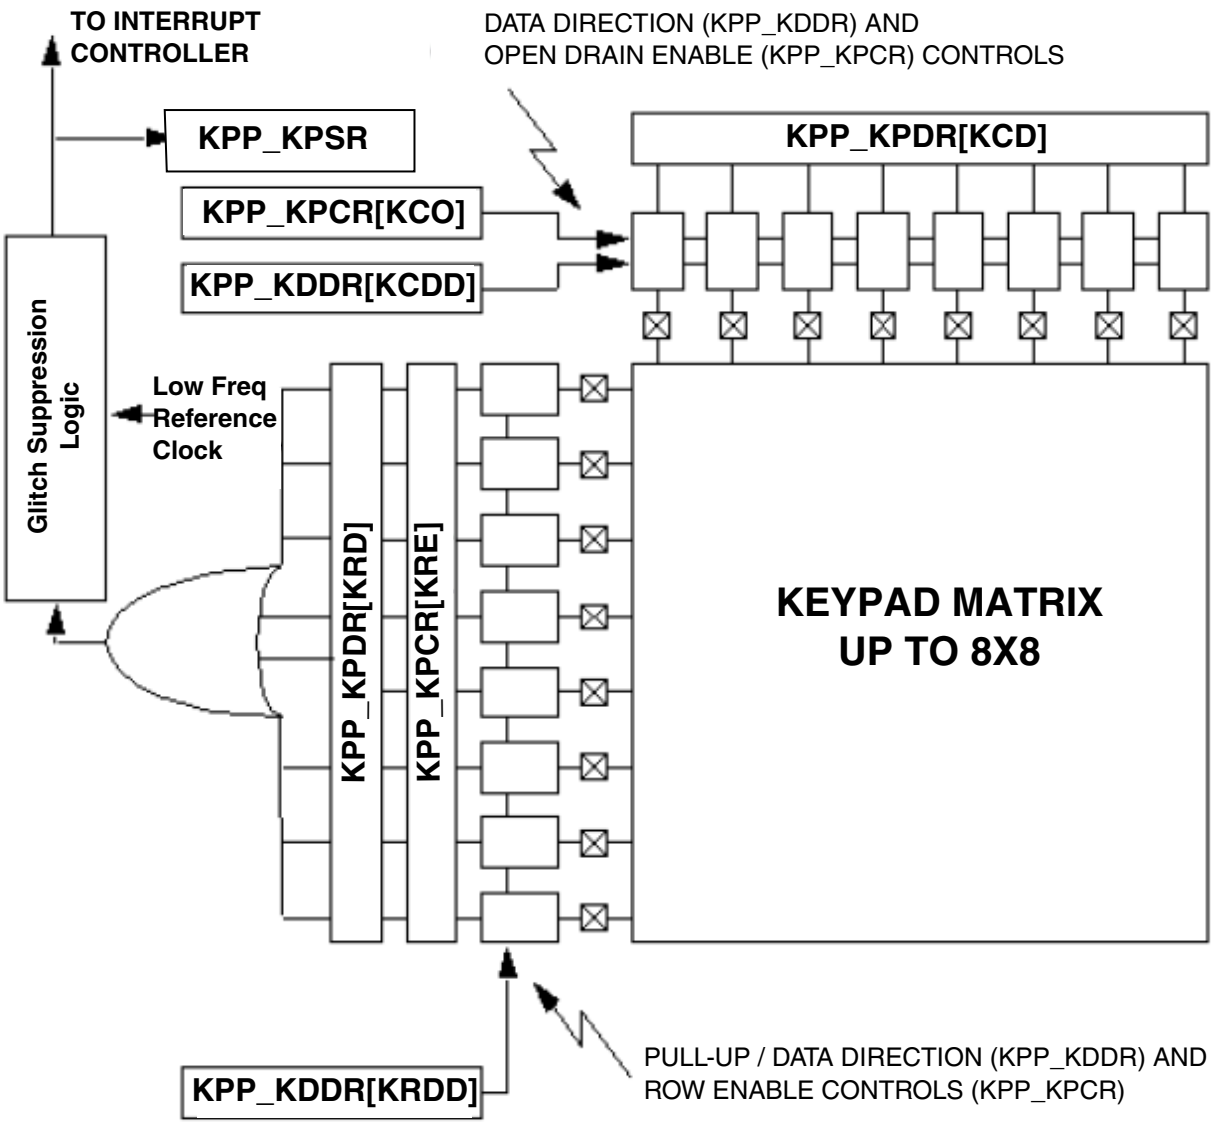


Figure 15-27. KPP Peripheral Block Diagram

15.4.1.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

15.4.1.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

15.4.2 Clocks

The table found here describes the clock sources for KPP.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-37. KPP Clocks

Clock name	Clock Root	Description
ipg_clk_32k	ckil_sync_clk_root	Low-frequency reference clock (32 kHz)
ipg_clk_s	ipg_clk_root	Peripheral access clock

15.4.3 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

Table 15-38. KPP External Signals

Signal	Description	Pad	Mode	Direction

Table continues on the next page...

Table 15-38. KPP External Signals (continued)

Signal	Description	Pad	Mode	Direction
		GPIO1_IO11	ALT6	
KEY_ROW7	Row input or output pin, from chip	EPDC1_GDOE	ALT3	IO
		SAI2_TXD	ALT6	

15.4.3.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

15.4.3.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

Table 15-39. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

15.4.3.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

15.4.4 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

15.4.4.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

15.4.4.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

15.4.4.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

15.4.4.4 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

15.4.4.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock source.

This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

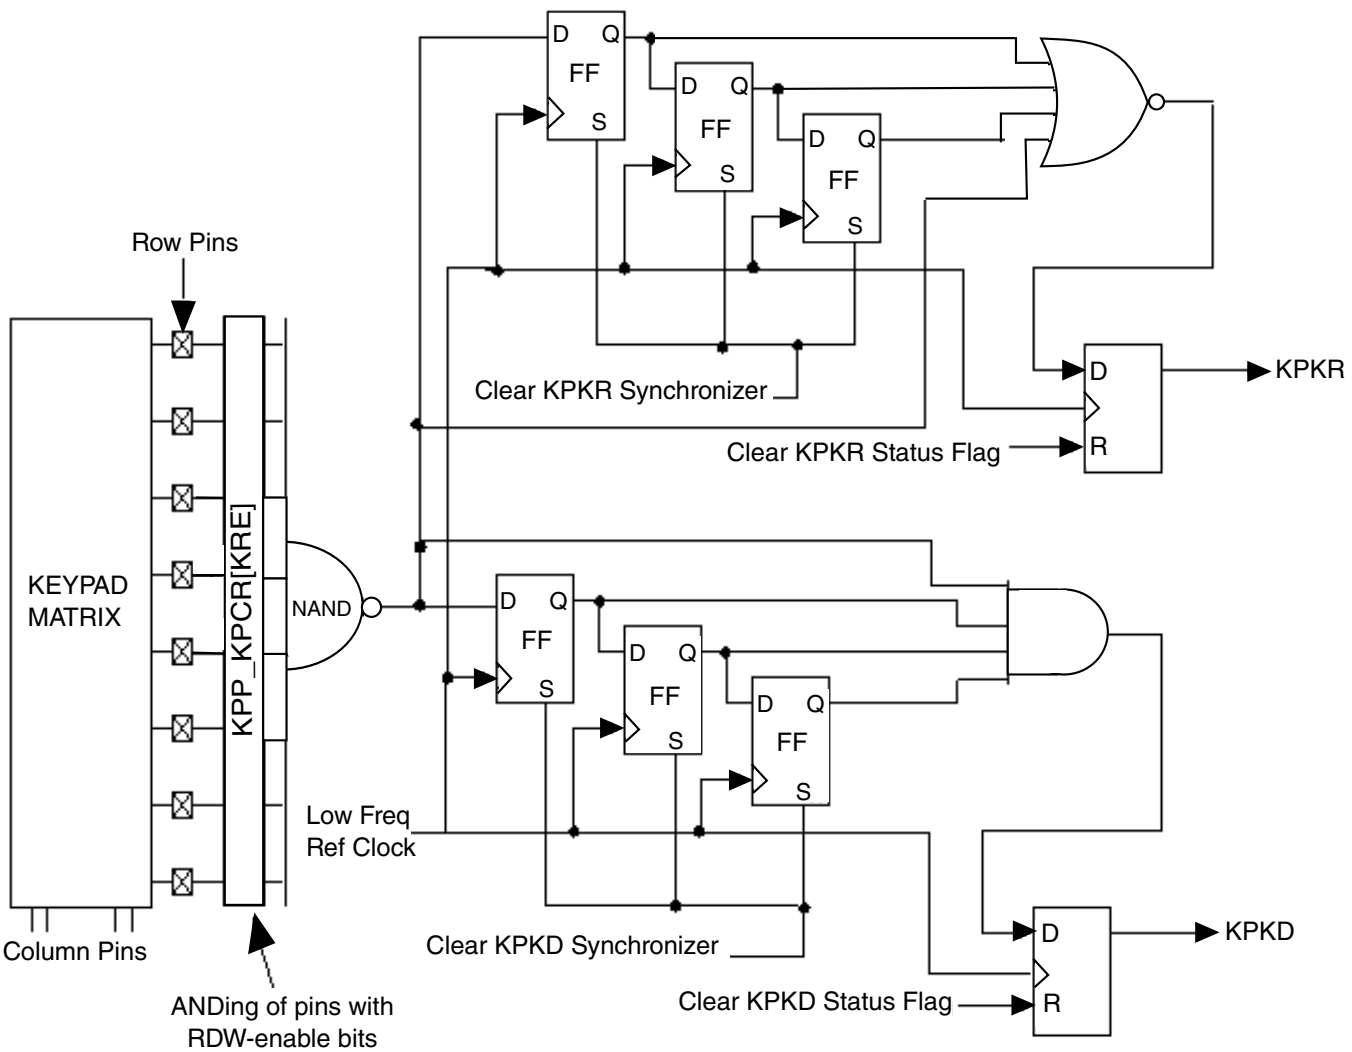

Figure 15-28. Keypad Synchronizer Functional Diagram

15.4.4.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly.

See the following figures for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

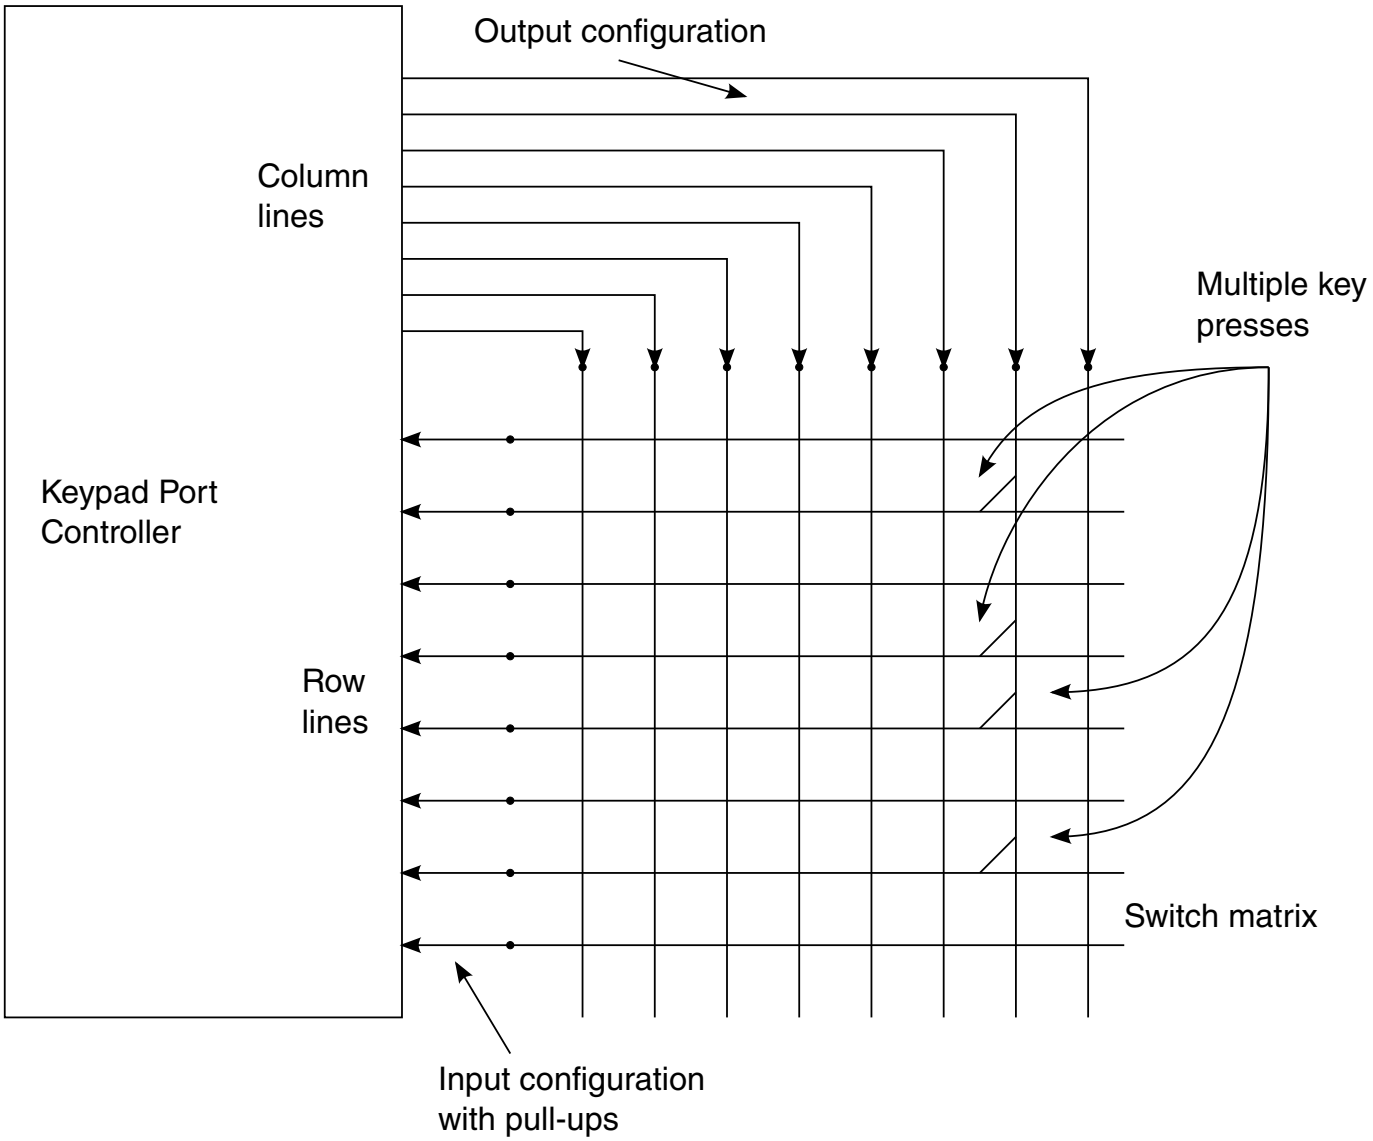

Figure 15-29. Multiple Key Presses on Same Column Line (Simplified View)

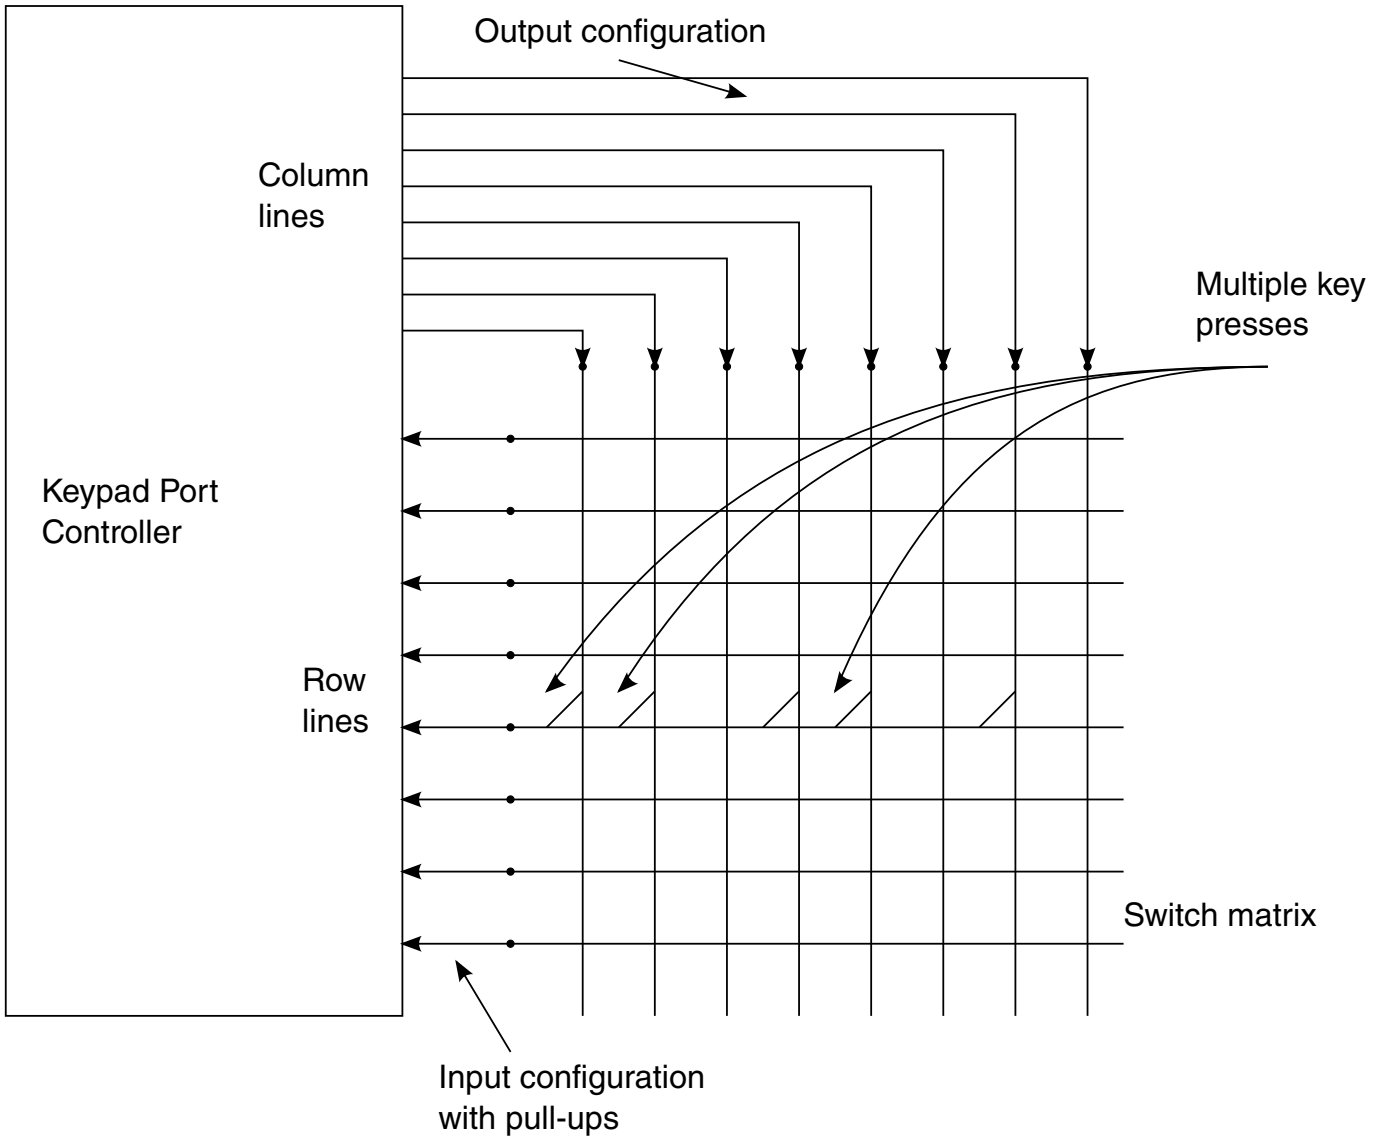

Figure 15-30. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

15.4.4.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As can be seen in Figure 15-31, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 15-32).

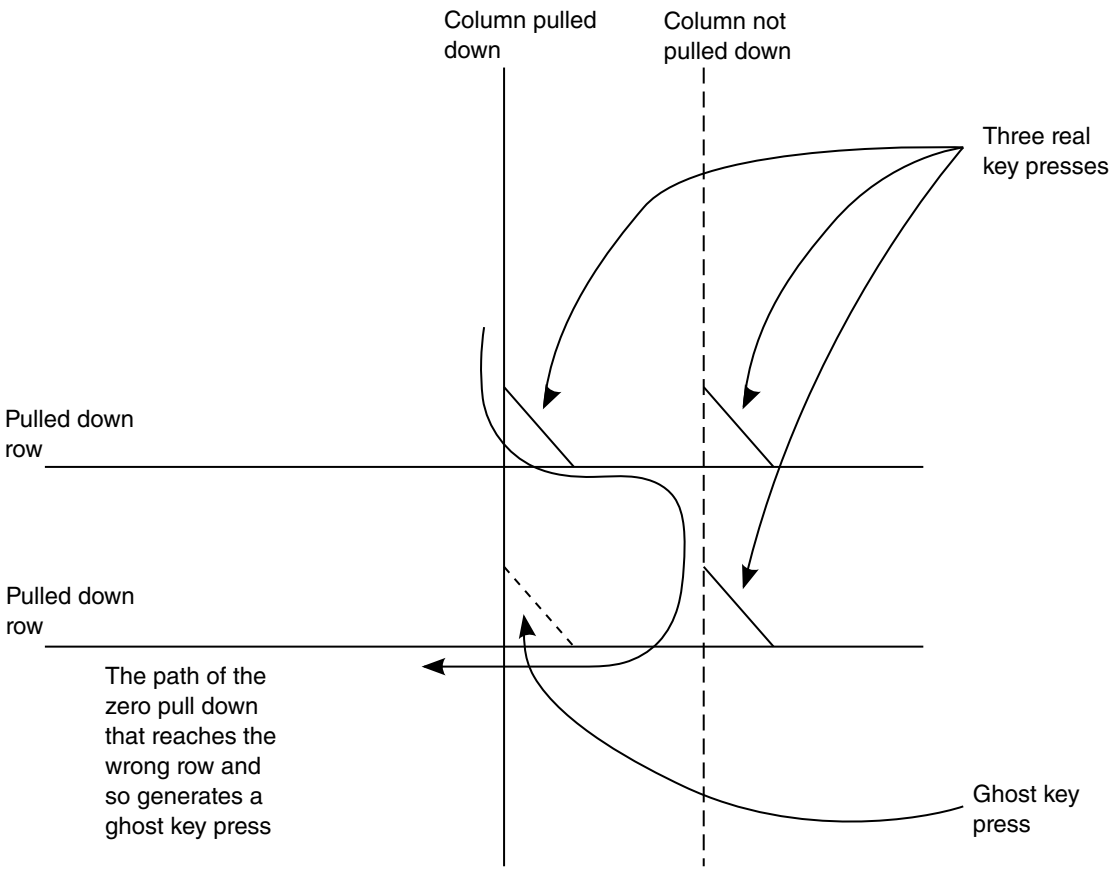

Figure 15-31. Decoding Wrong Three- Key-Presses

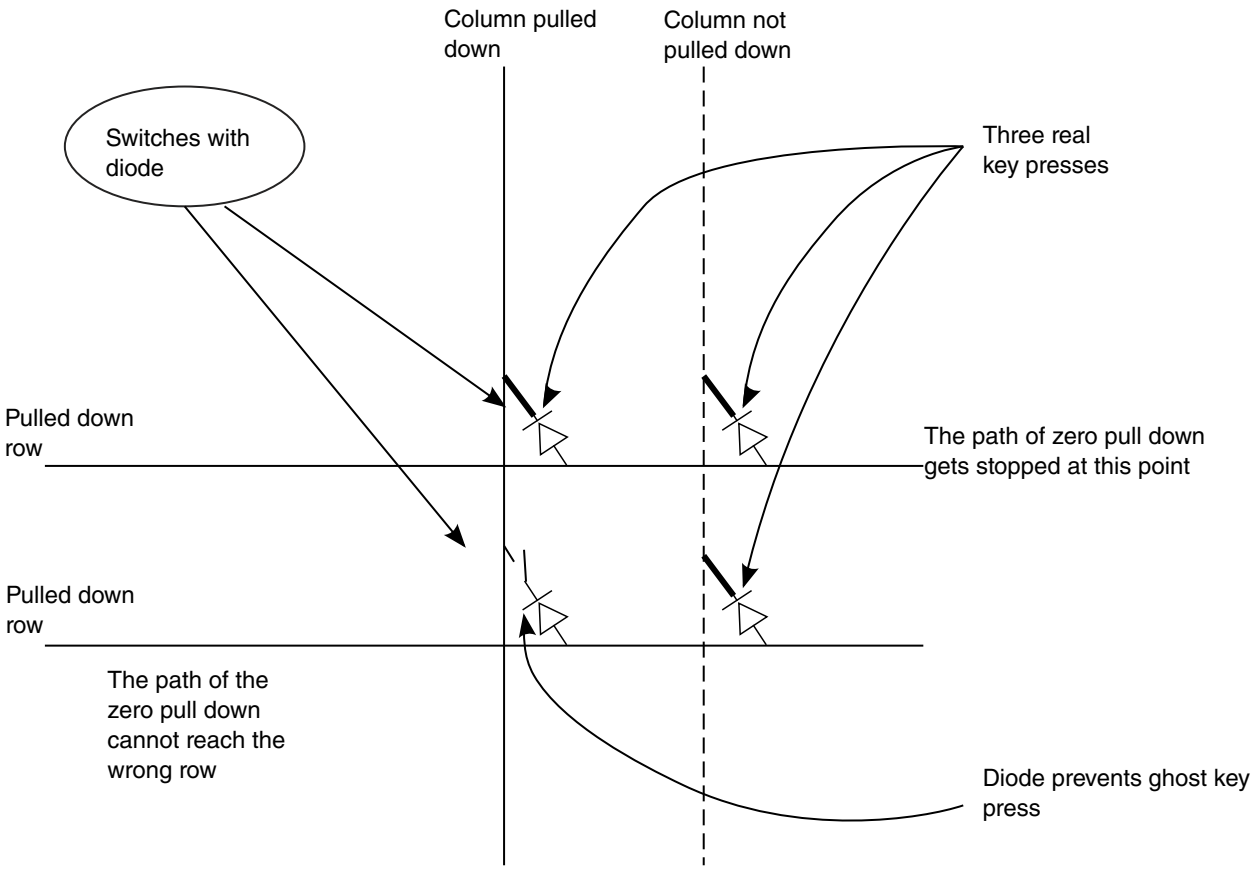

Figure 15-32. Matrix with "Ghost" Key Protections

15.4.4.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 15-33, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

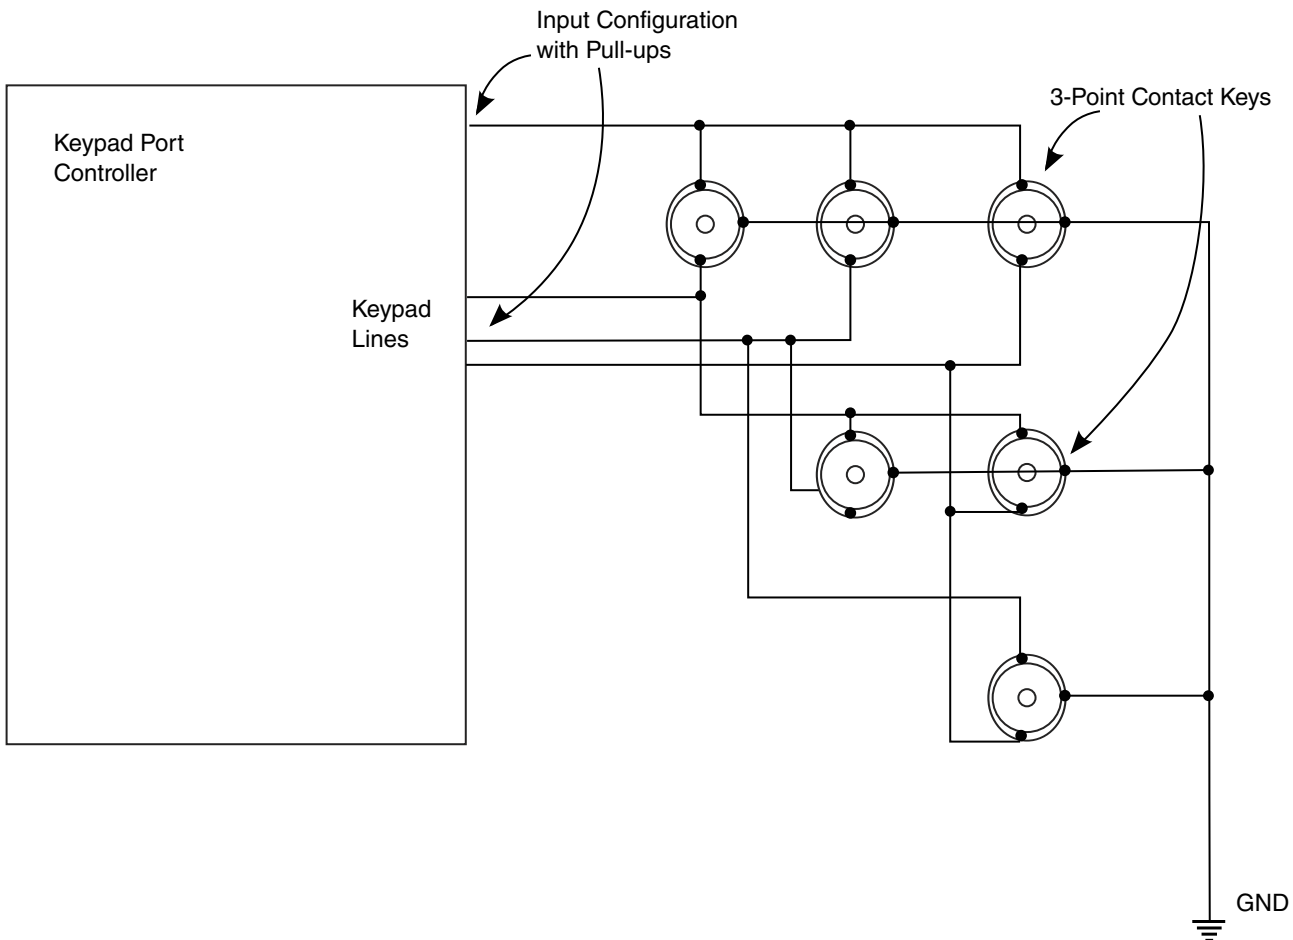

Figure 15-33. KPP Interface with 3-point Contact Key Matrix (Simplified View)

15.4.5 Initialization/Application Information

15.4.5.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

15.4.5.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

15.4.5.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

15.4.6 KPP Memory Map/Register Definition

The KPP contains four registers.

KPP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3032_0000	Keypad Control Register (KPP_KPCR)	16	R/W	0000h	15.4.6.1/ 4367
3032_0002	Keypad Status Register (KPP_KPSR)	16	R/W	0400h	15.4.6.2/ 4368
3032_0004	Keypad Data Direction Register (KPP_KDDR)	16	R/W	0000h	15.4.6.3/ 4370
3032_0006	Keypad Data Register (KPP_KPDR)	16	R/W	0000h	15.4.6.4/ 4370

15.4.6.1 Keypad Control Register (KPP_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

Address: 3032_0000h base + 0h offset = 3032_0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCO								KRE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPCR field descriptions

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input. **NOTE:** Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin.

Table continues on the next page...

KPP_KPCR field descriptions (continued)

Field	Description
	0 **TOTEM_POLE** — Column strobe output is totem pole drive. 1 **OPEN_DRAIN** — Column strobe output is open drain.
KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

15.4.6.2 Keypad Status Register (KPP_KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

Address: 3032_0000h base + 2h offset = 3032_0002h

Bit	15	14	13	12	11	10	9	8
Read	0						KRIE	KDIE
Write								
Reset	0	0	0	0	0	1	0	0

Bit	7	6	5	4	3	2	1	0
Read	0				0	0	KPKR	KPKD
Write					KRSS	KDSC	w1c	w1c
Reset	0	0	0	0	0	0	0	0

KPP_KPSR field descriptions

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value 0.
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of

KPP_KPSR field descriptions (continued)

Field	Description
	being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 KRSS	Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0 No key release detected 1 All keys have been released
0 KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

15.4.6.3 Keypad Data Direction Register (KPP_KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.

Address: 3032_0000h base + 4h offset = 3032_0004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCDD								KRDD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KDDR field descriptions

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 0 **INPUT** — COLn pin is configured as an input. 1 **OUTPUT** — COLn pin is configured as an output.
KRDD	Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0). 0 **INPUT** — ROWn pin configured as an input. 1 **OUTPUT** — ROWn pin configured as an output.

15.4.6.4 Keypad Data Register (KPP_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Address: 3032_0000h base + 6h offset = 3032_0006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCD								KRD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPDR field descriptions

Field	Description
15–8 KCD	Keypad Column Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to column ports 1 Read/Write "1" from/to column ports
KRD	Keypad Row Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to row ports 1 Read/Write "1" from/to row ports
